Roszkowska-Menkes (2017) identifies two major streams of CSR criticism. The representatives of the first group undermine that businesspeople may have social responsibilities (p.76). The most famous opponent of CSR was Milton Friedman (2007), who argued that "In a free-enterprise, private-property system, a corporate executive is an employee of the owners of the business. He has direct responsibility to his employers. That responsibility is to conduct the business in accordance with their desires, which generally will be to make as much money as possible while conforming to their basic rules of the society, both those embodied in law and those embodied in ethical custom" (pp. 173-174). In the light of this quotation, it can be stated that social responsibility is not the primary purpose of a business. The relation between CSR and financial performance was often examined in literature (e.g. Fauzi and Idris, 2009; Nelling and Webb, 2009; Maqbool and Zameer, 2018; Cho, Chung and Young, 2019; Awaysheh, Heron, Perry and Wilson, 2020), but the results are not consistent with each other. Roszkowska-Menkes (2017) states that "it is unclear whether companies "are doing well by doing good" or "are doing good, because they're doing well" and have sufficient resources to invest in CSR and improve reputation of top managers" (p. 78). The second problem concerns the use of CSR as a marketing and PR tool, some opponents also accuse CSR to be an empty promise.

The doubts also refer to CSR reporting as well. Based on analysis of CSR reports published by companies listed on the Warsaw Stock Exchange we have the following conclusions:

- Companies use different guidelines or do not use any of them at all,
- Reports differ in content, volume and structure, which makes it harder to compare one report to another,
- Reports are not subject to external verification or external auditor only check if a given indicator/information has been included in the report, auditors do not check whether the information provided is true.

These doubts came back with the time of COVID-19 pandemic. According to Kramer (2020) coronavirus is a test for CSR. He stated that "A great many large companies talk about their values, or about how much they care for their employees and other stakeholders. The coronavirus crisis is the time for them to make good on that commitment".

In this context, we conducted a preliminary analysis of the activities of companies in the time of the COVID-19 pandemic. In the light of the results, we have observed that:

- In the case of companies, which previously reported on CSR: CSR activities are undertaken by companies, which have strong position; among them are companies from sectors, which were highly affected by a pandemic of COVID-19 (e.g. LPP from Clothes & Cosmetics sector) and affected to a lesser extent by pandemic (e.g. Lotos Group and Orlen Group from Oil&Gas sector); while CCC Group (company from Clothes & Cosmetics sector) announced the reduction of costs related to the i. a. supporting sport activity;
- On the other hand, we can observe that companies' from IT engaged in a lot of CSR actions (e. g. Asseco Poland or Atende Software); it is worth to mention that it is rare if ever companies from the IT sector publish the CSR reports.

Conclusions and Future Research

In the context of the above considerations, it is reasonable to ask the following questions:

1) Is CSR only for companies with financial stability?
2) Do the "extensive" CSR reports result from the mission and goals of the company, or are they just a marketing tool? Perhaps a piece of brief information on the activities related to CSR would be sufficient?
3) Will the COVID-19 pandemic affect CSR and its reporting?

According to the authors, the following scenarios are possible:

- Scenario 1: the idea of CSR will survive, but companies that are socially responsible will focus less on reporting and more on actual activity.
- Scenario 2: The idea of CSR will lose its significance because in times of crisis companies will focus on survival and CSR activities will be too expensive.

The above issues will be the subject of our future research.

Exploring the Role of Entrepreneurship and Innovation in the Privatization Process

Adriana DIMA

Bucharest University of Economic Studies, Bucharest, Romania
adriana.dima@man.ase.ro

Abstract

Privatization is a global phenomenon encountered in both developed western countries as well as developing countries. Privatization is not a spontaneous phenomenon, which can be achieved by a simple decree or law. This is a complex process that requires time and especially an adequate strategy in which to analyze the situation of each public enterprise and to decide its future in relation to the objectives of the economic policy correlated with the requirements of the market and the economic-social realities of the country. In the case of former communist countries, privatization represented a decisive element of the economic-social reforms in order to create an economy based on market demands. This research analyses the role of entrepreneurs and innovation in the privatization process by performing an in-depth literature review based on the articles, books and reports that tackle the concepts proposed and presenting Romania as a valid case study to illustrate the struggles encountered by a nation in the privatization process of the national companies. The main contributions of this paper are the presentation of entrepreneurship concept in Romania in the first years after the fall of communism and the proposal of a diagram that incorporates suggested actions that constitutes the basis of a privatization strategy for any public enterprise.

Keywords: Entrepreneurship, Innovation, Privatization, Economic Success, Entrepreneurial Initiative.

Introduction

Understanding the entrepreneurial activity and institutional premises is paramount for those interested in the problems of civilization progress and economic prosperity (Herbener, 1992). In this sense, the first step is the analysis of entrepreneurial activity on a free market and its comparison with that of a socialist system. Only after this analysis a privatization program can be designed, one that can generate, in the social exchange and in production, the maximization of the quality and quantity of entrepreneurship.

In the vast majority of activities, people prefer greater efficiency in organizing production, followed by obtaining voluntary exchange goods. Entrepreneurial activity becomes part of the division of labor as some people demonstrate that they have greater ability to cope with the uncertainties inherent in the process of social production (Brunsson & Olsen, 2018).

The economic calculation of losses or profit is the process by which people decide what and how to produce in the complex structure of social production (Rahdari et al., 2016). In the absence of economic calculation, no social system could record the real preferences for consumer goods nor produce them rationally, appreciating the opportunity costs. Monetary prices set by the liberal exchange of private property rights reflect the social rarity of goods, highlighting the preferences of individuals to buy some goods by giving up the value of others, or refusing to buy, keeping the value of consumer goods that should be sold otherwise (Hefeker, 2018). Price provides the information needed to make entrepreneurial anticipations about the future scarcity of consumer goods. Under these conditions, entrepreneurs can coordinate current productive activities, in order to create those consumer goods with the highest social value.

Entrepreneurs turn their attention to obtaining the most desirable consumer goods, by assuming the function of coordinators of those who cooperate within the division of labor system. This is done by voluntary exchange, to the extent that each entrepreneur creates a business firm for contracting different owners of production factors within it and subsequently contracting abroad, with the firms of other entrepreneurs.

As long as the production and exchange process is governed by entrepreneurs, its purpose represents obtaining profit and ensuring the sustainability of the business. This is a basis for continuous testing in the selection of entrepreneurs capable of contributing to this goal. Those who do not systematically make a profit and cannot avoid losses will be eliminated by specialized entrepreneurs.

Research Question and Methodology

The current ongoing research established as main objective to explore the role of entrepreneur and innovation in the privatization process. In order to achieve this objective, the following set of secondary objectives are proposed:

- a thorough literature review on the concept of entrepreneur, innovation and the stages of a privatization process;
- presenting a real case study to describe the privatization process and the emergence of entrepreneurship initiatives after the fall of communism;
- proposing a set of actions as the basis of a privatization strategy for any public enterprise.

In the interest of investigating the mentioned aspects, the methodology of the current paper includes literature review on the publications regarding the concept of entrepreneurship, innovation and privatization process for states that are in the process of transition after the fall of communism. Also, the research includes a case study, respectively the way in which action was taken in Romania after the fall of communism, which should serve as an example for the privatization processes of state companies.

Literature Review

After the fall of communism, the most urgent challenge for the former communist countries was to draft a privatization process for state-owned companies (Papadopoulos, 2018). The privatization of socialist production centers should have been carried out on the basis of the division of private property into shares and their distribution to the workers in each center. The alternative modalities of privatization of these centers suffer from either economic or ethical vices, or both (Szarzec & Nowara, 2017). For example, organizing a national auction, in which the state sells all the properties it owns is an injustice, as the state is an illegitimate confiscator of property, it has no justifiable right to sell or use the property it has expatriated.

The fairness and economic success of such a privatization is essential with regard to the free exchange of these actions. The newly born stock exchange would expand rapidly as specialized entrepreneurs create new firms and begin, with the emergence of free capital markets in general, to properly direct savings to the production structure and to various processes, for the creation of capital goods, without government interventions injecting irrationality in this process (Del Bo et al., 2017). Through legislation, money should be handed over to the market so that monetary inflation can stop immediately, the official currency becoming convertible into gold allowing entrepreneurs to produce money freely, within the framework of private property rights. The return of money to the market is a necessity for a coherent economic calculation without which a rational social production cannot take place. By allowing the state to maintain control over money, even if only partially, it certainly distorts entrepreneurial activity, because the state uses this power to control spending and capital flows.

Privatization should not be instituted at the same time as the complete abolition of forms of government intervention, in a new configuration of the division of labor and voluntary exchanges.

This is a necessary condition for allowing the existence of private property rights and for opening up directions for the expression of entrepreneurial activity and social production. State intervention should be stopped in terms of the contractual conditions of private individuals by stopping price controls or compulsory occupational licenses, the government apparatus would still be reduced, releasing more and more bureaucrats to the private productive sector (Klapp, 2019).

Entrepreneurial activity does not play a direct role in the design of the privatization program, but it indirectly plays a crucial role in undermining the centralized planning system, illustrating the benefits of freedom. Entrepreneurship is first and foremost a regional event, the individual decisions of the entrepreneur and the success or failure of start-ups are influenced, among others, by the variables of the regions where their activities are located (Wang & Tan, 2019). This influence has a much greater impact than the national or continental context. However, the region cannot be compared with the city, metropolitan area or urban area as in many countries, most regions tend to be rural. Closely related to the urban climate are cultural wealth, economic diversity, international connections and infrastructure.

Perceptions about entrepreneurship can affect the supply and demand side of the field. Regarding the offer, for potential entrepreneurs, perceptions include the availability and ability to become a perceived entrepreneur (Crecente-Romero et al., 2016). The level of education and the availability of entrepreneurship training programs are possible determinants of perceived skills. The quality and quantity of perceived opportunities can be improved by conditions such as population growth, economic growth, culture and national entrepreneurial policy. The fact that agents are seeing more and more successful entrepreneurs in the direct environment, especially the local one, can strengthen their perception of their own capabilities, without developing the real capabilities. This effect can be enhanced when the economic climate is favorable.

Moreover, there are demographic differences between entrepreneurial capabilities for socioeconomic or historical cultural reasons. Policy programs can explicitly target groups that have low levels of perceived capabilities, but also those of current capabilities. Thus, several distinct regional and national conditions may affect the perceived capabilities directly and indirectly. At an early stage, entrepreneurial activity should be higher in the main cities of a country, and it is expected that the same can be applied to perceived opportunities for entrepreneurship. In other words, the perception of opportunity should be higher in large agglomerations.

However, previous research indicates that the cities of the world have an entrepreneurial advantage in the direction of growth of jobs and business activities related to the creative class (Audretsch & Belitski, 2017; Audretsch et al., 2019). The results also indicate that entrepreneurship in global cities is not necessarily remarkable, in terms of innovation and technology, when the regional context is appreciated. Non-urban areas can thus achieve competitiveness. A strong link with the latest developments in a global city would then be important.

Innovation is a complex organizational process, with a socio-economic role, and entrepreneurs are economic agents that put innovation in a corporate context (van de Wetering et al., 2017). In the contemporary global economy, businesses and companies do not compete in the quantity of products offered, not even for their quality. Geographically, unlimited access to the world's resources allows for large-scale production. In addition, the development of technology and science makes possible the efficient production of quality goods and services. As a result, market competition is won by innovative economic agents and innovative companies, whose products bring more novelty and significance to consumers (Yun et al., 2016). Entrepreneurs stimulate existing companies to improve their products and innovate, ensuring their profile and increasing the level of satisfaction, and thus the standard of living of consumers.

The generation of knowledge through innovation is better done in certain environments, specific to large cities or industrial clusters, characterized by diversity and high levels of qualification. Generating new ideas is about the flow of people and the information between the company and the

environment. Technological innovations are made to meet market conditions (Tidd & Bessant, 2018). Experts and consultants are an important source of information for managers, because they know the new products, processes and developments in their field. Newly hired staff are likely to know alternative ways to use the technologies used by competitors or suppliers.

Entrepreneurs can meet the high costs of production factors by introducing innovations and adopting innovative technologies that require low cost factors. They can also discover new sources of high quality factors, increase supply and reduce their prices. These can have an impact on the growth rate, increasing the causal importance of entrepreneurship.

Conventionally, entrepreneurs can negatively influence economic growth and development, if they do not benefit from favorable opportunities supported by cheap production factors or, they do not expand their activity with possibilities for this (Urbano et al., 2019). In such cases, one can anticipate when the rate of economic growth and development will be lower than economic opportunities. The quality of the factors of production is an important factor of productivity, which in turn influences the cost of a unit of production manufactured by entrepreneurs. The higher the quality of the production factors, the higher the productivity and the lower the cost of a production unit (Bergeaud et al., 2017). The productivity of technology, raw materials and labor is of particular importance to the entrepreneur. Capital-intensive technologies are more productive than those that need more work. Working with modern technologies and skilled labor will be much more productive than unskilled labor.

If the productivity of the factors of production is low and the opportunities are unfavorable, then any measures taken by entrepreneurs will attract more productive factors and in larger quantities, leading to increased growth and economic development in relation to opportunities making entrepreneurship important (Henrekson, 2020). Its structure and volume are the main determinants of the reward that the entrepreneur will receive in this situation. As a rule, the higher the market volume, the higher the potential reward. The actual market demand for manufacturing products may correspond to the products that the contractor is capable of producing. As for the supply of production factors here the number of competitors fighting for this market will be an important factor. In the case of a market with a given volume, the higher the number of entrepreneurs fighting for it, the more favorable the opportunities will be. Therefore, we can say that the market opportunities will be more favorable for a small market, since it has a smaller population with limited incomes and purchasing capacities. If the demand and competition from products other than those that the entrepreneur proposes in the market is higher, the reaction of entrepreneurs to this situation may be different.

First, entrepreneurs can try to increase the existing market volume for their products by reducing costs and improving quality by diversifying products according to market tastes, or they can manipulate consumer tastes.

Secondly, entrepreneurs can seek to find new markets in the segments of potential consumers in their country or in other countries. If entrepreneurs react differently, entrepreneurship is likely to have a positive causal influence on economic growth and development. Of course, entrepreneurs can take advantage of market opportunities. They can be satisfied with the quantity of products offered in the market and will not look for other larger markets; they can keep prices high for their products and produce goods for a limited number of consumers. In this situation, entrepreneurship will be an important cause but with a negative influence.

One of the most important factors influencing the emergence of entrepreneurship is the government system (Estrin et al., 2019). The state can protect the entrepreneurs, within a country, from the competition of other entrepreneurs, directly or indirectly, promotes the behavior of the entrepreneurs, corrects the difficulties under the opportune conditions that they face. At the same time, instead of promoting entrepreneurship, it can create barriers and, instead of avoiding difficulties in the economic system, it can increase them. There are several possibilities to influence the conditions

suitable for entrepreneurship, the following are the most important ones (Hanohov & Baldacchino, 2018; Porfírio et al., 2018):

- *capital* - the state can increase the supply of capital investments through several levers including direct subsidies for entrepreneurs;

- *labor* - the state can also increase or reduce the productivity of the labor force. Increasing labor supply can be achieved through industry and immigration in cases where labor is limited, by assisting entrepreneurs in training workers, or encouraging entrepreneurs to provide training programs to raise the level of skills of workers. On the contrary, the government can use the labor force available for its own purposes, to introduce restrictions on labor mobility, and force entrepreneurs to employ excessive labor through increasing its costs and reducing labor productivity;

- *the raw material* - the positive influence of the state on the opportune conditions can take place by encouraging the discovery of new deposits or the discovery of substitutable sources. The state can also facilitate the import of resources not found in the given country. Conversely, the state may not practice all of the above methods, but may maintain the high tariff system for important raw materials and increase the costs of entrepreneurs' products;

- *the market* - the state can also play the main role in determining and regulating the composition of the market. The tariff policy adopted by the state is very important. This can increase for domestic entrepreneurs by promoting the import of substitutable products. The state can expand the foreign market through the policy of export expansion. The structure and volume of the internal market may be influenced by the taxation policy. The state can be an important point of the market by presenting the offer on some products.

The state not only influences the economic but also the non-economic factors, which are quite important in the emergence of entrepreneurship. It can reduce the legality of entrepreneurship through supportive policy; can ensure a high level of security for entrepreneurs based on property and investment protection laws, or can allow chaos or confiscation; can manipulate the access of groups of individuals to mobility channels through legal restrictions and can play an important role in promoting the ideology of supporting entrepreneurship. The most important way in which the state can negatively influence the entrepreneur is to directly assume the entrepreneurial role. A distinction regarding entrepreneurial identity is that between public and private entrepreneurship. The causal importance of public entrepreneurship is a more important issue than the factors that contribute to its emergence. The emergence of public entrepreneurship is explained by the issuance of decrees and orders. Also, the analysis of the combination of economic and non-economic factors that contribute to the emergence of public entrepreneurship is very interesting, because it has a very small share in the countries analyzed, which has not been given much attention. The state can influence the role of entrepreneurs and the way they obtain the factors of production. State policy can also affect the range of products that entrepreneurs produce.

Case Study for the Privatization Process – Romania

The privatization process requires both skill, professional capacity and a series of legal guarantees to allow: the exclusion of the risks of fraud and corruption; protecting the population; avoiding the replacement of the state monopoly with a private, national or foreign monopoly; the use of privatization techniques to adapt to the specific situations of the country and of each enterprise, etc. The quantification of the effects of privatization, especially on the economic level, must include increasing productivity, reducing production costs, tariffs and prices, improving the quality of products and services, etc. If it cannot be demonstrated that the privatization of the enterprise has advantages over its maintenance in the public sector, it is preferable to postpone the privatization of that unit.

There are several limits on "de facto monopolies" or "natural monopolies", which may represent enterprises that through their activity actually have a monopoly over the entire internal market - water, gas, transport by rail, etc. In general, these companies remained in public ownership, but a system of control of the costs they incur and, implicitly, of the prices charged, was set up in such a way as to limit the possibility of taking advantage of their monopoly situation. A limitation of privatization is also imposed by the existence of non-profit activities, social assistance services, some units with a low profitability - for example, the activity of the post office for the transmission of correspondence to isolated places. In these cases, if the emphasis were on profitability through their privatization, the social purpose of the respective units would disappear.

Adopting the strategy for each public enterprise should have been based on a concrete analysis, as shown in the below figure:

Figure 1: The strategy regarding the perspectives of a state company

Source: Created by author, based on literature review

Findings

Management Employee Buyouts (MEBO method) were the main method of privatization relevant for the first five years after the fall of communism in 1989 in Romania. Afterwards, as mass privatization began and case-by-case sales became increasingly used, MEBOs continued to be applied to an important number of companies. The situation consisted of two main aspects: there was a high number of employee-owned companies and there was a high percentage of employees who owned the majority of the shares of the companies. These companies were part of a vast category of industrial branches with varying sizes in terms of number of employees, from a few people up to 10,000 employees. Thus, the employers' patronage constitutes a relevant factor of the performance of

the Romanian companies, and the understanding of this aspect is important both from the theoretical point of view and from the point of view of the elaboration of the economic policies (Earle & Telegdy, 2002).

The first entrepreneurs to appear on the Romanian market were those who targeted primarily the factory buildings and the existing infrastructure within them. Unfortunately, many have shown interest in capitalizing on assets in companies and have not invested in their further development and long-term sustainability. The result was the bankruptcy of some companies considered empathetic during communism and many buildings in ruins. Following this fact, around 2008, an emblematic year for the very high prices of buildings and lands in Romania, the ruined buildings were sold for the capitalization of the lands on which later office buildings or malls appeared. The new constructions did not target the production sector, so this area no longer positively influenced the export sector.

Another part of the foreign investors sought to obtain financial incentives from the government offered for the purchase of former state-owned companies with large debts or in bankruptcy. These incentives were either to cancel part or all of the debt if investors undertook to hire a number of employees or to retain existing employees, or to grant them preferential contracts for certain public works, or to eliminate the obligation to make payments such as wage contributions to state for the company's employees for a certain period of time. Unfortunately, this policy also proved to be wrong, because most of the companies that were taken over in such conditions went bankrupt and were subsequently closed, the employees being laid off. It was found that investors used the incentives offered, and when they considered that the Romanian market is no longer attractive enough for them or the state stopped the tax exemption with the passage of the contract period, they moved production in other countries that have offered them superior advantages.

A third category of investors were those who subcontracted Romanian companies using the labor force for their Western factories. Basically, in Romania were processed in lohn system various components for cars, parts for agricultural equipment, clothing, etc. according to the contractor's specifications, with the materials provided by the contractor and under the brand of the foreign company (Gîrneaţă & Mascu, 2014). Unfortunately, the Romanian market was attractive in the short term, as long as the labor force was cheap. Foreign investments were minimal, mostly Romanian companies manufactured the orders received from abroad with the equipment already existing in companies, and the requested products did not represent innovations on the market, so the national research and development sector did not have to gain from this action.

The only medium-term benefit was the contribution of know-how with which foreign investors came, which generated the development of the local entrepreneurial spirit and further the initiation of new businesses. Because the models did not aim at innovation, few Romanian companies founded after the fall of communism or the state ones that were taken over by Romanian investors sought to create innovative products, with a very high added value, that are sustainable in the long run and that to lay the foundations of their own brand. Unfortunately, with Romania's accession to the EU in 2007, common measures were implemented at European level, such as guaranteeing a minimum wage. This aspect meant an increase in labor costs and a decrease in the attractiveness of Romanian workers for foreign investors who relocated to countries that offered lower hourly wage rates, such as Moldavia or Asian countries (Dima, 2018).

Conclusion

Entrepreneurship illustrates the benefits of freedom and undermines the centralized planning system of a former communist country. Entrepreneurs can be perceived as economic agents that put innovation in a corporate context. Market competition is gained by innovative economic agents and innovative companies that offer new and significant products to consumers. Entrepreneurs stimulate existing companies to improve their products and innovate, ensuring their profile and increasing the level of satisfaction, and thus the standard of living of consumers.

In the early 1990s, in Romania, with the fall of communism, the privatization process of state-owned companies was initiated. The main foreign entrepreneurs who came to invest in Romania mainly followed the benefits offered by a country in transition to capitalism. The small entrepreneurs in the years after the revolution were traders who seized the opportunity of a less regulated, little or no taxed market and began trade with Turkey or other neighboring countries. By taking advantage of state-owned enterprises or common resources, the entrepreneurship and innovation system has not even grown organically in Romania.

However, Romania is currently the country with the highest percentage in terms of entrepreneurial intentions in the European Union, 27% of Romanians say they want to start their own business. The percentage is more than double compared to the average registered in the European Union. The trends on the Romanian market largely coincide with those on the global market. Although there is uncertainty in the economic environment, entrepreneurial initiatives are open to innovation and global markets, using the advantages of technology.

Abstract

Contemplation of the world's disappearing supplies of minerals, forests, and other exhaustible assets has led to demands for regulation of their exploitation. The feeling that these products are now too cheap for the good of future generations, that they are being selfishly exploited at too rapid a rate, and that in consequence of their excessive cheapness they are being produced and consumed wastefully has given rise to the conservation movement. As such, natural resources are an important part of sustainability considerations of any country, thus being essential for a sustainable future, as well. Using these resources is fundamental to human well-being, because they are essential, practically, for all sectors of the economy, underpinning the environment people have built and provides them with the desired services. For these reasons, and for the sustainable management of natural resources, appropriate policies are needed to enable their economic and efficient use. Therefore, this paper identifies and presents European natural resource management policies (for crude oil, natural gas, coal and mineral ores) applicable in Romania.

Keywords: Crude Oil, Natural Gas, Coal, Non-Ferrous Ores, Environmental Protection

Introduction

The foundations for the sustainable management of mineral resources have been laid through a review of the concepts of sustainable development, their links with mineral resources, natural resources mineral national policies and management programs. The likelihood of improved choices among possible development options is increased when these decisions are based on knowledge and science. Scientific and technical experience can be applied to the monitoring of socio-economic and biophysical processes and, in this regard, to provide information and data for each stage of the political cycle, including for sustainability policies.

Economic, environmental and social issues need to be integrated into decision-making and the long-term effects on resources and capital must be taken into account, as well as the capacity to create future benefits. The decision itself must be comprehensive, participatory and also interdisciplinary.

Natural resources are an important part of any country's sustainability considerations. Discussions on the role of natural resources in sustainability tend to focus on the need to support ecosystems and maintain biodiversity. The fundamental purpose is to support the ecosystem.

Mineral resources are also essential for a sustainable future. The use of these resources is fundamental for human well-being, because they are essential, practically, for all sectors of the economy, they are at the basis of the environment built by people and provide the desired services [1]. However, these resources also have intrinsic characteristics that make them not only useful, but also

problematic. Sustainable development has emerged as a framework in which an appropriate combination of consumption and conservation can be sought.

It is counter-productive to talk about mineral resources as being sustainable as well as ecosystems, given that individual deposits have finite size and volume. However, there are several ways of approaching how minerals are related to sustainable development. One perspective focuses on the development of minerals as a source of creating the wellbeing of local communities and, by extension, as a tool for poverty eradication. This is an example of weak sustainability (Neagu *et al.,* 2018) because of natural capital's inevitable transformations resulting from the extraction and use of mineral resources [2]. The transition from the natural capital (mineral) to the human capital, and further, to human and social capital, can be described as the transition from the primary means at the final goods, i.e. the well-being [3].

Therefore, for the sustainable management of natural resources, adequate policies are needed to allow their economic and efficient use (Seymour, 1998). Thus, in the following paragraphs, various European natural resource management policies (for crude oil, natural gas, coal and mineral ores) applicable in Romania [4] will be identified and presented.

Management policies for hydrocarbon resources from Romania

Due to its geological and geographical peculiarities, Romania can be considered as a case study, with universal significance (Constantinescu and Anastasiu, 2019), because is one of the few small and medium countries in the world that has a diversity and complexity of geological resources similar to those of large countries such as the USA, Russia and China.

Romania is recognized in the specialty literature as the first country in the world with officially registered crude oil production (275 tonnes extracted in 1857) and the first refinery in the world, built by Marin and Teodor Mehedinteanu brothers, in 1857, in Rafov, near Ploiesti (The Science of Petroleum, 1938). If in 1900, 0.250 million tons were extracted (3rd place in the world after Russia and USA), then 1.1 million tons in 1920 (4th place in the world), in 1937 the maximum interwar production was 7.147 million tonnes, in order to reach a maximum production of 14.65 million tonnes in 1976 (20th place in the world); after this year, however, the decline in oil production began to become visible, a trend recorded even today. This decrease is the effect, mainly, of the natural decline of reserves, but also the reduced efforts of exploration and investment.

The oil extraction industry represents a strategic sector in the Romanian economy, as well as a pillar in the development of the other industrial sectors of the country.

Despite the decline, Romania remains the fourth largest oil producer in the EU (including the United Kingdom before Brexit) and the fifth largest oil producer in Europe (including Norway). Domestic production accounts for 5.5% of the EU production and 2.5% of the European production [5].

In turn, ***the gas extraction industry*** is a strategic sector both in itself and as a major contributor to the development of other sectors. Romania has a century of experience in natural gas production. In 2018, a quantity of 9.5 billion cubic meters (bcm) of natural gas [6] was extracted and an amount of 1.4 bcm was imported to cover the domestic consumption (SNGN Romgaz, 2017, 2018, 2019).

Apart from the economic role, domestic natural gas production also plays a geopolitical role, given that Romania has traditionally been much less dependent on imports than its neighbours. Given the economic slowdown in recent years, which has also attenuated domestic demand for natural gas, Romania has recorded several months in the last few years, when it has been able to fully cover the demand for gas from domestic production. Natural gas accounts for about one third of the domestic primary energy mix (Government of Romania, 2018).

Even though domestic natural gas production is declining, Romania is still the largest producer of natural gas in Central and Eastern Europe [9].

As such, in the next paragraphs, we shall present examples of policies that can be adopted in Romania in the field of hydrocarbon resources management.

✓ ***Policies to redevelop geological research activity in order to discover new reserves.***

There are major concerns both at European and global level in the redevelopment of the geological research activity in order to discover and develop new economically efficient reserves. Romania, in the conditions of the drastic decrease of this activity in the last 30 years, needs more and more the resumption and intensification of the geological research activity, by making 2D and 3D seismic profiles and making geological drilling, to attenuate the natural decline of the deposits in operation.

Harnessing the potential *of the existing oilfield portfolio* aims to maximize the recovery rates, in terms of economic performance, on one hand, and to rationalize this portfolio, on the other hand.

Thus, in order to discover new oil reserves, leading to the assurance of an annual reserve consumption coefficient of max. 4% and a reserve replacement ratio of 60-100%, are estimated total costs of about 300 million euros by 2021. Finally, in order to discover new natural gas reserves, are estimated total costs of about 500 million euros by 2025 (SNGN Romgaz, 2014).

✓ ***Policies to discover new oil and gas structures, both onshore and offshore.***

European countries with significant oil and gas reserves (Norway, the United Kingdom, the Netherlands, Denmark or Ukraine) are making great financial efforts to discover new deposits to replace the current reserve base, which is in a natural process of depletion (such as the case of the huge deposits in the North Sea, Ekofisk fields in Norway, and Groningen in the Netherlands). Romania, where the level of reserve replacement will not exceed 15-20% for oil and condensate, and respectively 15-30% for natural gas, must intensify, in turn, jointly efforts for discovering and geological survey with foreign companies of new gas structures, and to attract investments for pilot projects with foreign high profile companies for increasing the reserves in oil and gas fields (for research and rehabilitation purposes).

Therefore, three options may be identified in this respect: the discovery of new onshore oil and gas reserves, the development of extraction by hydraulic fracturing, and the exploitation of oil and gas proved reserves from the Black Sea Basin; among them, the exploitation of the Black Sea Basin reserves shows the greatest potential to reposition Romania in the regional energy hierarchy.

Hence, in order to increase the oil and gas safe reserves, in the short and medium term, Romania must assume as a priority investments in technologies that will lead to increasing the recovery degree from existing deposits; also, in the long term, investments must be driven in the development projects for the exploration of deep areas (under 3,000 m), of onshore deposits with complicated geology and of offshore deposits in the Black Sea Basin.

✓ ***Policies to increase (or at least stabilize) current levels of onshore oil and gas production.***

All European oil and gas producing-countries are interested in increasing domestic oil and gas production to meet the needs of domestic energy sector and other branches of their economies, and for the efficient and sustainable use of oil and gas internal resources, so these resources to be useful for the following generations. In Romania, where the hydrocarbon production decline is permanent and quite significant (a decline of 5% for oil and a decline of 1.5% for gas), the most feasible goal is to stabilize oil and gas production at levels as nearest to the current ones, including increasing the final recovery factor for oil and associated gas, or by drilling operations and commissioning of new wells.

Thus, in order to stabilize the oil production around 3.6-3.7 million tonnes annually, are estimated total costs of about 1 billion euros per year by 2021 (OMV Petrom, 2017).

Although natural gas is the most "green" fossil fuel, its production growth is closely linked to availability, competitiveness and the ability to compete in traditional sectors and expand into new

ones. Thus, in order to stabilize gas production around 9-9.5 billion cubic meters annually, are estimated total costs of about 500 million euros by 2025 (SNGN Romgaz, 2014) .

- ✓ ***Policies for the exploration, development and production of oil and gas offshore fields on the continental shelf of the Black Sea.***

The Romanian offshore area covers 22,000 square kilometres and reaches depths of over 1,000 m (ANRM, 2017, 2018, 2019). The entire area is divided into perimeters of different dimensions, some of them being granted by the holders for exploration, development and exploitation activities. The application of exploitation policies for the oil and gas proven reserves in the Black Sea Basin, such as those applied in the North Sea by countries such as Norway, the United Kingdom, the Netherlands, Denmark or Germany (the latter to a lesser extent), gives Romania the potential to become one of the most important natural gas producing areas in EU.

Moreover, these additional natural gas resources, becoming commercially viable, would help ensure Romania's sustainable energy supply, achieve long-term decarbonisation targets, as well as the development of the national infrastructure, or of other high value-added industries, such as chemistry and petro-chemistry.

Thus, the cumulative value of investments in offshore gas exploration, development and production was estimated at $ 22.2 billion [10]. Moreover, this economic growth will generate revenues to the state budget of about $ 26 billion, of which over $ 5.5 billion in royalties.

- ✓ ***Policies to develop the underground natural gas storage capacity.***

Development of natural gas storage capacities (similar to that of Germany or the Netherlands) for covering the peaks of consumption during the cold season, for increasing the security degree of gas supply of the consumers in crisis situations, as well as for increasing the energy security degree of the country is one of the important points of the energy strategy in Romania in the medium term (Government of Romania, 2018).

All these measures and actions aim to increase the safety coefficient in gas delivery, to values as close as those practiced by the countries of the European community, in order to avoid major disruptions in the national transport system and, respectively, in the gas supply of the consumers in crisis situations, at almost constant flows and prices throughout the year [11].

These actions also involve a significant volume of investments, with total estimated costs of about 500 million euros by 2021 (SNGN Romgaz, 2014).

- ✓ ***Policies for investing in infrastructure related to alternative transit and interconnection projects for the diversification of oil and gas sources.***

Romania's gas imports come entirely from the Russian Federation, which is an element of strategic vulnerability. From this perspective, it is extremely important to integrate the Romanian natural gas market into the European market. Security of gas supply is at the heart of any energy policy, as any disruption of gas supplies has important consequences for the economies of EU Member States.

In the context of geo-politics and geo-strategy of European energy routes, Romania benefits from the advantages of geographical location on important transport corridors and access to potential major natural gas resources recently discovered in the Black Sea, which leads to the need to efficiently exploit these opportunities.

As such, for the implementation of these policies, the total investment effort depending on the deadlines is estimated at 1.62 billion euros by 2026 (SNTGN Transgaz, 2018).

In the context of the materialization of the BRUA [12] project, starting with 2020, Romania will have the necessary conditions for profiling as a regional *natural gas hub*. It is essential to realize the interconnection projects and the modernization of the natural gas national transport system (SNTGN), in order to have an efficient internal market for natural gas. Regarding the price of natural gas from

Romania on the regional market, it will be established on a trading platform within the *regional hub* (probably CEGH [13] in Austria).

- ✓ ***Policies for ecological reconstruction in order to comply with European environmental norms.***

In the evolution of hydrocarbon extraction sector, Romania will follow the best practices for environmental protection, while respecting the national targets assumed as an EU Member State. Climate and environmental policies, focused on reducing greenhouse gas emissions (GHG) and changing social attitudes in favour of "clean energy", are another determining factor that shapes investment behaviour and consumption patterns in this sector.

Thus, for the purpose of ecological reconstruction in the extraction of crude oil in order to comply with the norms provided by the environmental legislation for this field of activity, total costs of about 500 million euros per year are estimated by 2021 (OMV Petrom, 2017). Finally, for the purpose of ecological reconstruction in the extraction of natural gas in order to comply with the norms provided by the environmental legislation for this field of activity, total costs of about 150 million euros per year are estimated until 2025.

- ✓ ***Policies for the development of a regional oil and gas hub, from the perspective of new discoveries included.***

The insularity of the Romanian gas market is no longer justified, as long as all EU Member States have obligations to implement and monitor in order to achieve the objectives set out in EU legislation (regulations and directives).

In the horizon of 2025-2035, with the prospect of discovering new indigenous sources of oil and gas, and new regional sources of imports, as well as an increased interconnection with adjacent markets, ***Romania can become a regional hub*** (like the Netherlands, whose positioning is known as a "roundabout" of North-western Europe, i.e. a hub for gas infrastructure that provides transportation, transit and storage for the North-western region of the European gases). This would stimulate industrial competitiveness through optimal energy prices, generate economic growth and job opportunities. Romania's interest and sustainable development must be promoted concurrently with the creation of an attractive business environment, in which the Government, regulatory agencies and legislators must be competent and steady partners of the investors.

Management policies for coal resources from Romania

The Romanian political regime prior to 1990 was characterized by the promotion of a self-sustaining economic development strategy in the provision of coal resources, through an explicitly mentioned policy of ensuring energy security, which led to the exploitation of technically and economically unfeasible deposits, regardless of costs and consequences on the environment, thus resulting in a sector of coal mining artificially developed, with numerically oversized workforce. Access to new technologies and know-how has been reduced in the sense that coal mining has become increasingly inefficient.

After mining worker strikes in the early 1990s, in the context of industrial decline and declining energy consumption, successive Governments artificially maintained coal production by providing *significant subsidies* in coal mining to maintain production and save jobs.

The role of coal as a fuel resource in the Romanian economy has been in a continuous decline over the last two decades. The significant restructuring and reforms that have taken place and will continue in the coal sector are aimed at improving the operational efficiency of the entities in the sector, promoting private investments, together with judiciously solving the social and ecological problems of the sector.

However, the future of coal in Europe, and therefore also in Romania, depends on the success of the EU 20/20/20 Program, as well as on its rivalry with natural gas, within the energy mix (Coria and Sterner, 2011).

The extraction of mineral resources is under the strong influence of the environment, technological changes and capital investments necessary both to maintain current production capacities, and to open new mines. Given Romania's coal and lignite reserves, long-term mining experience and tradition, energy consumption will be ensured through a mix of fuels in which coal will continue to represent 34-38% (Government of Romania, 2016, 2018).

As such, in the next paragraphs, we shall present examples of policies that can be adopted in Romania in the field of coal resources management.

- ✓ ***Policies to maintain subsidies in coal mining.***

The subsidy was applied in most countries (including Romania) in order to maintain the level of production (for example, in Ukraine: cross-subsidization of state-owned mines, which produce losses, by profitable mines), to reduce the economic and social pressure, with deadlines set by EU regulations. It involves considerable financial efforts, slowing down the processes of technical innovation and economic development.

We believe that the EU should not impose time and value limits on Member States in granting state aid to the coal industry. If the State falls within the framework of climate and energy policies in the period 2020–2030, in particular with regard to the reduction of greenhouse gas emissions, it must be allowed to support its mining industry.

Such an approach can lead to the continued exploitation of coal, even on a smaller scale, so that the energy security of each EU Member State can be achieved at any time.

The European Commission should authorize Member States to grant state aid in the area of coal mining (and not for closure programs), based on a strategy put forward by each state concerned to establish a clear and stable framework to enable industry to invest in modern and clean coal mining and combustion technologies.

- ✓ ***Policies to allow transfer of lignite-based energy production capacity to a security reserve*** (applied in Germany) ***to ensure supply-demand balance***.

We consider that, based on the strategy of national energy security and efficiency, it will be necessary to maintain a balanced energy mix that will ensure Romania the capacity to absorb some shocks in the supply and limit the dependence on external energy resources, in the perspective of 2035.

In the long run, maintaining the role of lignite as a primary energy carrier will be conditioned by the endowment of new capacities with CO_2 capture, transport and storage technologies.

Considering the pit-coal and lignite reserves Romania has, the long-term experience and tradition of mining, energy consumption will be ensured by a mix of fuels in which coal will represent 34-38%.

Due to the role of domestic coal resources in meeting the country's energy requirements, the policies to be applied in the mining sector will have to ensure the competitiveness and successful operation of economic units in the market economy.

- ✓ ***Policies to application of restructuring and governmental agreements*** (applicable in Germany) ***in order to achieve economic development and diversification in the mining areas.***

The zoning of coal reserves by economic criteria, the restructuring of the coal extraction activity, and its placement on a commercial basis determines the restriction, sometimes until the total cessation of the productive activity, to mines with costs that exceed the current average in the sector and without chances of rehabilitation. The result of such actions materializes in the redundancy of the labour force, with a direct consequence of the decrease of incomes of the population from mining regions, with restrictive consequences on local economy and the decrease of incomes for local budgets.

Although the restructuring programs and agreements with governmental actors agreed that they should be accompanied by measures necessary for job creation, they did not materialize, so that in the mining

areas a level of unemployment well above the national average was reached, respectively a standard of living located at the threshold of poverty or subsistence.

- ✓ ***Policies to favouring "energy transit" to renewable energy and to honouring commitments assumed by decarbonisation climate agreement in Paris and strict EU climate policy.***

Most countries with plans to phase out coal need to make additional efforts added to the least costly current measures to implement the mines closure programs. However, countries that rely heavily on coal need additional measures at regional and national levels to achieve the sharp decline in coal production needed over the next decades.

In the context of the sustainable use of coal resources, the achievement of profitability of mining units must be accompanied by a high degree of job security, modernity and innovative production processes, and a low level of negative impact on the environment.

The implementation of these policies is supported by the presence of an opportunity starting with the phase of exploitation of coal deposits, namely the possibility of implementing modern technologies for the capture of coal methane and the emissions of methane from the deposits in operation, and the degassing of coal.

In the future, EU legislation provides for the reduction of certificates available for CO_2 emissions and offers two new funds to support innovation and the transition to reducing carbon emissions, a step forward in regulating commitments under the Paris Agreement. The new law will speed up the withdrawal of emissions certificates on the "carbon market" from the EU Emissions Trading Scheme (ETS), which covers about 40% of EU greenhouse gas emissions.

- ✓ ***Policies to increase stakeholder involvement.***

Stakeholders, namely administrations, politicians, large companies, research institutions, civil society and citizens can be increasingly involved by establishing regional economic, social and restructuring Councils made up of representatives of the main stakeholders (as applied in Germany and Czech Republic).

The social partners were permanently connected to the realities and problems that mining sector faced or is facing, so that, depending on their nature, they were analysed by Government representatives and materialized in several protocols.

- ✓ ***Policies to attract local and foreign investment in exploration, extraction and processing worldwide by creating a favourable investment climate for mine privatization***.

The result of applying these policies (similar to Bulgaria, Ukraine, Serbia) is the realization of environmental commitment and standards, as well as the compliance of extraction and combustion operations with the provisions of the EU acquis.

- ✓ ***Policy for privatising and listing on the Stock Exchange*** (similar to Poland and Czech Republic) ***of the largest producers of coal in order to allow profitability of extraction activity.***

The Romanian government has such a coal mine under construction with a Chinese investor, but has not yet made significant progress on the project.

- ✓ ***Creating a clean coal technology centre, co-financed with EU funds*** (as in Poland)**.**

The aim is to improve the combustion and gasification of coal and create the conditions for reducing carbon emissions.

- ✓ ***Applying a unitary policy at national level to provide a perspective on strategic geological reserves,*** by creating the centralized institutional potential for the development of strategies on mineral resources.

Management Policies for Mineral Resources from Romania

Romania has a great diversity of non-ferrous ore deposits, but with a reduced content of useful substance, with specific mineralogical features and cantoned at a relatively high depth, which implies technological extraction and preparation difficulties.

Polymetallic ores deposits, in terms of quality, have reservoirs which are characterized by low content of useful substances (1.94% Zinc, 1.01% Lead), and from the economic point of view, lies at the lower point of their exploitability compared to those in other countries. Moreover, some deposits also have difficult exploitation conditions which, together with the low useful content, determine the inefficiency of the exploitation activity. Due to this, the exploitation of these resources has been stopped (Government of Romania, 2016).

Speaking of ***gold reserves,*** Romania has resources amounting to 760 million tons of ore, existing since the period when these deposits were exploited through a processing infrastructure based on cyanidation process (Government of Romania, 2016). Unfortunately, because of the economic difficulties in ore mining, the two autonomous companies that subordinated the mining units stopped the gold ores exploitation. The environmental catastrophe that took place at the tailings pond in Baia Mare, resulted in pollution with cyanide of river Tisa and showed the deficiencies of mining waste disposal system. This highlighted the danger of processing gold ores with cyanide.

As such, in the next paragraphs, we shall present examples of policies that can be adopted in Romania in the field of mineral resources management.

- ✓ ***Policies for revising the legislative framework in the field.***

For this purpose, it is necessary to establish a coherent legislation and an adequate information framework in accordance with the requirements of the European Union in the field of ore exploitation.

- ✓ ***Policies for reviewing the institutional framework in the field.***

For that it is necessary to establish a new framework institutional referring to: the creation of a National Authority (perhaps within the current National Agency for Mineral Resources - ANRM) ; setting up of the National Geological Service that, independently, to ensure updating, management and public use of the national geological data fund, to elaborate the geological atlas of Romania, etc.; the creation of the Geological Survey Department, which will have to recover and store the entire mining database lost after 1989.

- ✓ ***Policies to attract investments in the non-ferrous ore mining industry in Romania.***

The creation of a stable legislative system, adapted to the European legislation, will increase the interest of the investors for the Romanian mining industry. This interest is intended both in the concession of mining perimeters for the beginning of production operations, and in the endowment with modern mining technologies. Application of new and modern technologies will significantly influence the work safety improvement, while, due to the implementation of environmental solutions, emissions of harmful substances to the environment will decrease considerably.

The regulation of small-scale and artisanal mining operations, on the other hand, will encourage investments in the exploitation of non-ferrous ores, especially of gold and silver. Anyhow, there is a model applied in the interwar period, when the National Bank was implicated in precious metal extraction, by purchasing gold from gold-seekers to whom financial incentives were granted, and encouraging them to capitalize on the gold they extracted. We appreciate that this initiative, redesigned and supported by modern legislation, can develop.

- ✓ ***Policies to develop education and research in the field.***

Higher education in mining still exists. Therefore, in order to have well-trained staff, the cooperation between mining sector and universities needs to be improved. Emphasis will also be placed on the development of vocational education, improving cooperation with secondary and occupational education.

✓ ***Policies to reduce the impact of mining industry on the environment.***

Technological processes meant for the extraction of non-ferrous ores have a strong negative impact on the environment, both because of the extraction itself, and the substances used in production processes. It is well known that gold is extracted by cyanidation, a process that produced, not only once, devastating environmental accidents. Therefore, rigorous monitoring of all environmental factors must be carried out during mine closure operations.

In this respect, the entire legislation in the field, applied at EU level, has also been adopted by Romania. Such measures are capable of guaranteeing, at present and in the future, basic principles of ethics, responsibility and transparency, such as to provide the citizen with the necessary peace and security, to discourage illegal, immoral or dangerous practices in the extractive industry and to promote the safe, efficient and profitable exploitation of Romania's natural resources.

Conclusions

Romania is an exporter of electricity and petroleum products (Government of Romania, 2018), but at the same time imports approx. 69% of crude oil consumption, 10.6% of natural gas consumption, small amounts of coal (about 3%) and uranium ore. Given the exports of petroleum products, the degree of dependence on crude oil imports to cover domestic consumption is about 50%. In 2017, the import of primary energy resources represented 37.8% of the total primary energy resources.

In the medium term, Romania will continue to be the main producer in the region among the countries that already have a national production of this kind, with 46% of the region's production followed closely by Italy with 41%.

Indigenous EU production will continue to decline significantly over the next 20 years. This decrease could be easily mitigated by the development of oil and gas production fields in the Romanian offshore sector of the Black Sea and in Cyprus. The total production could fall by more than 60% by 2040 or even more, if finally the non-FDI developments are not put into operation.

In such a market environment, Romania has, through the opportunities offered and its geographical position, the possibility to become ***a regional balancing/trading hub*** that would significantly contribute both to ensuring/streamlining cross-border trade in natural gas, and energy security of Europe.

Moreover, EU policies for the use and promotion of the use to the greatest extent possible of alternative fuels will mitigate the impact of the dependence on imports of crude oil and petroleum products market in Romania. This process will be possible to the extent that the development of infrastructure related to the production and use of alternative fuels will be carried out in direct relation to their competitiveness in the fuel market.

Globally, ***coal*** has been and remains one of the main energy resources, a cheap, expanding base for economic and social development. Accounted on the vast and well-distributed resource base, coal will make a significant contribution to eradicating energy poverty.

At the same time, the environmental problems generated by the exploitation of coal resources can find their solution in the improvement of new clean technologies.

In Romania, ***the energy produced based on pit-coal or lignite***, with all the inconveniences presented, gives security to the national energy system; therefore, coal will continue to be a major energy pawn, with major importance in ensuring energy security, even if is desired that its share in the energy mix be diminished.

At the foundation of the national energy efficiency and security strategy, it will be necessary to maintain a balanced energy mix that will ensure Romania the absorption capacity of some shocks in supply, on

one hand, and limit the dependence on external energy resources, in the perspective of 2035 and beyond, on the other hand.

To cope with globalization and climate change, ***the EU's energy policy and integrated mining policy*** are vital strategic elements. Behaviour change, energy efficiency and renewable energy sources have led to the modernization of technologies and research and development (R&D) activities. It is known that technological equipment incorporates large quantities of metals, of which a significant proportion is represented by rare and precious metals, which can be find in small quantities in Europe.

The security of supply of European industries can be improved by substantial investments in the mining sector of the new Member States with geological potential, by using and improving already existing EU support mechanisms. Major mineral resources are available in the countries of Eastern Europe, where the geological structure has always allowed mining activities. However, in the new EU countries this sector has been underfunded by the State, so the current situation does not reflect the real potential of the non-energy mining industry. From this perspective, it is essential to invest also private capital in these enterprises, in order to provide the financial resources that have so far been provided mostly by the State.

At this point, ***the mining industry*** has greatly restricted its activity and is waiting for important decisions to be made. Many mines and quarries that had as their activity the extraction of non-ferrous metals, are in conservation but can be reopened using other technologies and complying with the legislation in force. Therefore, the decision-making bodies must align with the European policies in the field, to finalize the harmonization of the European legislation with the Romanian one.

Various Forms of Basic Income as a Remedy in Times of Crisis

Milena KOWALSKA

Wroclaw University of Economics and Business, Wroclaw, Poland,
e-mail address: milena.kowalska@ue.wroc.pl

Abstract

Basic income is a social policy tool that raises as many positive as negative emotions. It is a controversial instrument but still discussed. This idea is raised especially in times of danger, when the social, health, or economic crisis may deprive citizens of their livelihood and wellbeing. The following article provides the definition and assumptions for basic income. Various modifications of guaranteed income occurring in the literature are indicated. The ideas of negative income tax, fixed grant, and then universal basic pension were presented. Differences in particular models were indicated and their advantages and disadvantages were discussed.

Keywords: Guaranteed income, Crisis management, Unemployment

Introduction

Equalizing of social and economic inequalities is still a current and important topic in a scientific debate. The environment around us is constantly changing (Kulhanek and Sulich, 2018). The challenges that society must meet also are changing. Nowadays, two very important aspects give socio-economic inequalities a new context.

The first is an aspect that was hard to predict and whose consequences will be felt by every citizen - the first pandemic on such a large scale. It has exposed the failure of health care in crises in many countries, and its economic effects will be felt for a long time. It was during the pandemic, when many people were deprived of the opportunity to perform their work due to sanitary and epidemiological safety, in the public discussion various options for additional social transfers that would allow reducing significantly income inequalities of people and even all employees of enterprises from industries particularly affected by the crisis.

This situation has shown that the unpredictability of the environment can even leave the day-to-day well-paid and well-educated citizens without financial resources. Even if their existence was not threatened, their subjective quality of life significantly decreased, which is largely based on the material situation (Christoph, 2010).

The second aspect affecting the equalization of socio-economic inequalities are issues related to the environment and the use of natural resources. It is believed that satisfying basic human needs while respecting life support systems on earth, is the essence of sustainable development, which in turn is also an idea describing the relationship between nature and society (Kates et al., 2001)

The concept of sustainable development, of course, does not only concern the environmental aspect but also provides for civilization changes in the ecological, social, and economic aspects (Pawłowski, 2009; Sulich et al., 2020). In the era of an increasingly conscious society, the goal should be to equalize socio-economic inequalities while respecting the environment, natural resources, and technology that supports the ecology.

In the current reality, taking into account the progressing globalization, and at the same time with the emerging serious crises that all countries of the world have to face, the question is more and more often asked about what characteristics should be implemented by individual countries social policy, on what values should resist and what tools she should use. The thesis on the ideal features is made by the

authors of one article, indicating that new instruments of social policy should meet the following assumptions (Leff et al., 2019):

- they should be more cost-effective,
- they should be paid to individuals, not for example households or the head of the family,
- the administrative procedure should be simple and as cheap as possible,
- they should be transparent and secure,
- they should mobilize benefit applicants for risk-taking and planning
- they should not discourage anyone from working,
- they should maximize personal freedom and enable decisions that do not violate social norms.

Universality and equality with individuals, simplification of the procedure by limiting the procedure necessary to examine administrative decisions in each case, social security that maximizes personal freedom and motivation to take up work without the risk of losing benefits are advantages attributed to basic income.

The use of the term 'basic' in the name is intended to underline its safe nature. A basic income is one that citizen can regularly count on, it is a foundation that ensures a secure existence, but at the same time it should be emphasized that its size is not dependent on the size of basic existential needs - the benefit can be both smaller and larger than the minimum required amount to survive. (Parijs, 2000). However, it can be a particularly difficult benefit, crises would allow citizens to survive and then motivate them to take up further professional activities. During a pandemic, both employers and employees, regardless of the possibility of running their business, would also receive funding then.

Besides, there is a positive relationship between basic income and the environmental effect achieved. It is believed that basic income would give individuals a chance to experiment and live outside the productivism and growth-based paradigm, would allow the transfer of activity to a more autonomous ground, which would probably be less harmful to the environment, citizens could focus more attention on the ecological and emotional sphere, choose more free time, and thus less use of materials and natural resources (Howard et al., 2019). Other benefits of basic income are considered (Fitzpatrick, 1999):

- elimination of fear of an uncertain tomorrow - in the context of losing or quitting job
- increasing interest in one's own business and at the same time decreasing the role of paid employment
- simplification of the redistribution system,
- reduction of administrative costs
- recognition of social rights as human rights
- strengthening the employee's negotiating position (financial security possessed)

The article aims to analyze the features of the social policy instrument which is the basic income and to review the instruments that are a modification of the common definition of the basic income.

Basic Income - Different Variants

Universal Basic Income

The idea of unconditional income that citizens receive - also known as "territorial dividend" and "state bonus," "demogrant" and "citizen's wage," "universal benefit", or simply "basic income" - is the subject of public discussion not only from decades but also for hundreds of years (Parijs, 2004).

The definitions of guaranteed income include: "an income paid by a political community to all its members on an individual basis, without means test or work requirement" (Parijs, 2004).
In the definition of basic income, D. Raventós emphasizes his unconditional income - it is income that is paid to citizens or residents regardless of whether they want to take up paid work or not, whether they are rich or poor, and have any other sources of income. Benefits individuals, not groups, not families, but individuals (Raventós, 2009). This is a solution that can motivate to take up a job, because taking up a job by a beneficiary does not entail a loss of benefit. In times of crisis it allows to survive.

Narrower definitions require all benefits to be replaced by guaranteed income, and wider ones allow tax credits to be treated as a type of guaranteed income. However, the vast majority of definitions focus on the cash payment of basic income as a citizen's benefit.

The authors do not prejudge the amount that guaranteed income would amount to, although they emphasize that it should be sufficient for a modest life and at the same time participation in the cultural, economic, and political life of a given society (Dowding et al., 2003; Sulich, 2016). G. Standing, in turn, indicates that it should be a sum that will cover basic material needs, and at the same time will facilitate the pursuit of other life goals (Standing, 2015).

Scientists point out that if basic income cannot be implemented for political reasons, then other instruments that are its modification may be an alternative way to achieve the same goal (Jaquet et al., 2000; Suplicy, 2000).

Negative Income Tax - NIT

A negative income tax idea may be close to the idea of guaranteed income. This is the concept proposed by Milton Friedman. It consists of deducting from the tax liabilities of each household the amount of guaranteed income that its residents are entitled to. In the case of a positive difference, the household must pay tax. In the case of a negative difference, a household - negative tax is paid.

Friedman indicates that NIT should be below the subsistence minimum amount to activate and encourage citizens to work. This is the opposite assumption than for basic income. He also emphasizes that the amount of NIT should depend on the capabilities of the society concerned. It does not exclude tax progression for incomes that exceed the threshold (Friedman, 1962).

The advantage of such a solution may be greater efficiency in terms of costs compared to guaranteed income, as there is no need to pay guaranteed income to those citizens who earn high incomes and then take them away from them in collected taxes.

NIT also has several disadvantages - to operate efficiently, it would have to be supplemented with an advance payment system so that citizens can use it not only after settling the tax year, but on an ongoing basis, income is guaranteed by a solution supporting units, not households as a whole thus, it supports households with lower incomes, usually less well-off women, and does not transfer the part of their tax credit due to higher-earning households.

Also, UBI, unlike NIT, supports people who want to take up a job, does not deter them from administrative procedures and loss of benefits for a time that coincides with the time they are already working, but when they have not yet received their remuneration for work (Parijs, 2000).

D. Tondani, in turn, indicates that there are fundamentally economic and ethical differences between the basic income and the negative income tax that is its modification. NIT is financed by high and middle-income taxes for the benefit of the poor. In the case of guaranteed income, the wealth tax is redistributed to those on a middle and low income. He also believes that low-income labor supply is being more intensively reduced by NIT than by UBI (Tondani, 2009). During a crisis - also pandemic - it can be one of the tax solutions giving economic impulses and protecting citizens against losing their livelihood.

Stakeholder Society

Another alternative is the idea of a "fixed-height grant" or "participation". Bruce Ackerman and Anne Alstott are considered originators of this idea (Ackerman and Alstott, 1999). It is a proposal assuming a universal and cumulated (in four quarterly installments) payment for a person reaching the age of majority, which he can spend for any purpose.

A well-known proposal that implements this idea is to donate 80,000 dollars to persons 21 years of age. The funds can be used for any purpose - purchase of an apartment, opening an enterprise, or consumption. Funds for this program would come from a 2% wealth tax, which could then be replaced by an amount tax of the amount previously transferred. Such a payment is treated as a cumulative guaranteed income that is paid once in a lifetime in exchange for regular money transfers (Parijs, 2000).

However, this is not an unconditional income. To receive the benefit, a citizen must finish high school and not be punished. The foundation of this idea is the universalization of ownership. Its authors promote the assumption that "everyone should own property." Besides, they want to promote the activity of young people who can translate their energy and creativity into entrepreneurship (Sulich, 2017). In their opinion, this is state support that equalizes the chances of starting into adulthood (Guczalska, 2017). This solution can be a natural economic impulse in uncertain times when citizens' risk appetite is falling. On the other hand, the assumption of stimulating entrepreneurship among young people can be replaced by the conservative accumulation of funds or their allocation to consumption.

Wright points out that stakeholder grants can probably have a real impact on capitalist class structures because they allow a citizen to change the proportion - a larger number of citizens will "be their bosses". Also, it indicates that even though some people will allocate such a grant for consumption, and when opening more enterprises by young people is likely to increase the number of those that turn out to be unsuccessful, it will still affect the class structure, increase entrepreneurship among young people and it will be a chance for many citizens to take responsibility for their future (Wright, 2004).

The disadvantages of such a solution are indicated by C. Pateman - in her opinion, the transferred capital may be lost by the citizen and does not constitute material security. The originators, however, believe that the possibility of losing capital is something natural, every decision made by citizens, especially the one regarding capital, is and should be at risk (Sulich and Zema, 2017). Also, the author believes that core capital can support women in the labor market, but it is basic income, paid out regularly, that gives a chance to change culture-based stereotypes about the role of women and makes employment cease to be the only valued form of work (Dowding et al., 2003).

Universal Basic Pension

B. Ackerman and A. Alstott indicate that in compensating for inequalities it is necessary to introduce an unconditional pension, which would be collateral in a situation in which citizens would not use the opportunity - received capital (Ackerman and Alstott, 1999). Universal Basic Pension is a benefit that all citizens would be entitled to, regardless of whether they had paid pension contributions in their life.

Basic Pension is defined as: "the benefit is either a flat rate (the same amount is paid to every retiree) or it depends only on years of work, but not on past earnings, nor does additional income in retirement change the value of basic pensions " (OECD, 2009). It happens that this benefit is also called civic retirement. This means that, by definition, old-age pensions from citizenship, or possibly from the place

of residence. The entitlement to receive this benefit is obtained after exceeding a certain age and being a citizen or resident of a given country for a long time (Czepulis-Rutkowska, 2014).

The main advantages of the civic pensions system are (Sołtys and Jagodziński, 2011):

- a simple and uniform system for all citizens
- permits administrative savings - does not require the collection of personalized contributions
- implements family policy
- does not discriminate against women
- can motivate citizens to undertake investment activities

In some countries, solutions are being introduced that modify the civic pension. An example would be a concept that has been implemented in Great Britain. The pension paid out there is divided into two parts - Basic State Pension and Additional State Pension. Basic State Pension is paid to anyone who reaches the required retirement age and demonstrates adequate seniority, while Additional State Pension is paid in the amount depending on the income of the person and the number of social security contributions. Basic State Pension is paid regardless of the number of funds accumulated but remains a contributory and not universal benefit. If the contributions paid to social security are insufficient, the citizen is entitled to an incomplete or supplementary pension to his spouse (Johnson and Stears, 1996).

Another modification of the Basic Pension is the "Mama 4+" program introduced in Poland, which is a program addressed to people who gave birth and raised or raised at least four children and did not acquire the right to an old-age pension, or their pension is lower than the lowest old-age pension. This is a non-contributory benefit. Persons aged 60 and over for women and 65 years for men can apply. However, this is not unconditional income because it indicates the requirements that the recipient must meet ("Serwis Rzeczypospolitej Polskiej", 2020).

One thing is certain - most European countries are on the verge of serious demographic problems. Negative population growth and an aging society are the main motivation to look for new solutions for pension systems. To introduce a basic pension, European decision-makers must answer several questions - which social groups and on what terms entitlement to a basic pension could apply, what would be the level of the benefit, how and from what sources the benefit would be financed, including those regarding administration, organization and management issues the program and in the case of Europe - what should the role of the European Union be in introducing such a guaranteed service (Goedemé and Lancker, 2009). Universal Basic Pension is an instrument that secures seniors, and at the same time, allows them to participate in sustainable development - meeting the needs of retirees would not reduce the satisfaction of the needs of future generations. Moreover, it would enable reform of the pension system burdening the state budget.

Conclusion

The idea of guaranteed income is still valid, also due to the possibility of its modification. Everything indicates that the world, and especially its socio-economic order as we know it will be transformed in the near future.

Automation and robotization of work, increasing unemployment, the economic crisis caused by the stoppage of work of many enterprises due to pandemics, climate change, and increasing use of natural resources are just some of the challenges that modern economics has to deal with.

Money transfers that would retain their unconditional character could undoubtedly be an antidote to the uncertain future for most of society. The article presents the idea of unconditional income but also indicates various types of its modification.
Negative Income Tax appears to be the least controversial variant among those presented.

Unfortunately, the amount of differentiation of this benefit does not diminish administrative costs in making decisions, and can even overstate them.

The fixed grant awarded is an idea that could increase entrepreneurship among citizens and have a positive impact on the economy - including the one recovering from the economic crisis.

The last of the presented options is the citizens' pension being considered more and more often by various countries. It would not only be a security benefit for people who had not paid their contributions in their entire life but would also motivate to invest. Its construction, however, would have to be determined depending on the individual capabilities of countries, and in the case of Europe perhaps even the European Union.

All of the forms of guaranteed income presented above have one aspect in common - they are instruments in every option that secures the means necessary to support citizens and can have a positive impact on citizens' entrepreneurship. Thus, they support two aspects at risk in times of crisis - economic security and economic development.

The article does not indicate the sources of funding for any of the programs, but it is believed that the increased administrative efficiency in terms of cost and general social consent to increase taxes, which would be dictated by increasing economic and environmental awareness, may be reflected in reality.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme “Regional Initiative of Excellence” 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

The purpose of this study is to identify, through a Systematic Literature Review (SLR), the marketing strategies used to promote tourist attractions and make them more competitive. Marketing strategies are important elements for the economic development of a tourist destination and to keep it competitive in the market. However, it is important for managers to be cautious when choosing strategies to promote their tourism offerings, as wrong strategies can compromise many factors, including economic ones. The methodology used in this research is the survey of articles using the keywords competitiveness, marketing and tourist attraction that guided the searches in databases of international relevance. In RSL, 649 articles were identified, which after three inclusion and exclusion processes reached the 07 articles that answered the guiding question of the research. The results show that the main marketing strategies used to promote tourist attractions are: organization and participation of regional and international fairs, participation in regional tourism events, conferences and festivals, use of social media, use of slogans in advertising material and websites. promotion, brochures with city slogans, sports and photo competitions, billboards, mass media (film and TV), promotional videos, photo CD provided to visitors, signage in historic centers and city slogans. However, the most used strategy, according to the studies, is digital media, especially social networks, where supply and demand can interact, creating a relationship and strengthening CRM (Customer Relationship Management). The results show that there are many marketing efforts used by managers, both in the public and private sector, to enhance tourist destinations and thereby increase visitor numbers. The use of the literature review methodology, through the RSL technique that makes an exhaustive review of empiric research published in relevant journals, allow a synthesis of the marketing strategies used in the promotion of tourist attractions. Although the study provides useful results it is not possible to generalize, since the number of articles that answered the guiding question was researched.

Keywords: Marketing Strategy; Commercial Competitiveness; Tourist Attraction; Systematic Literature Review

Introduction

The changes that occur in the competitive environment in the tourism sector are very fast (Martínez, Galván & Lafuente, 2014), even though the service is considered a perishable product because it is not stored. In fact, it has to be consumed at the same time as it is sold, making tourist destinations offer higher quality services with added value to their consumers. Therefore, it is important to understand how to adapt to these changes and to use them as a competitive advantage (Boes, Buhalis & Inversini, 2016; Acar, 2018).

The competitiveness of tourism destinations is the ability of a destination to add value through the integrated management of benefits and processes to the economic and social model, and thus preserve the position in the market in relation to the competitors (Crouch & Ritchie, 2000; Hassan, 2000). And in order to become more competitive and attract more tourists, destinations should not focus their efforts solely on public policies, cultural and natural resources, infrastructure and the qualification of the workforce, but also on marketing to prospect potential tourists and innovation that leads to the long-term economic performance of individual firms, cities, regions and nations (Booyens, 2016; Crouch & Ritchie, 2000).

Marketing is a management strategy that uses a variety of tools with the objective of stimulating the consumption needs of products and services on potential clients. In the tourism sector, marketing should act as a facilitator of regional development, promoting the tourism activities of a region (Martínez, Galván & Lafuente, 2014). According to Kotler (2010), tourism marketing is responsible not only for attracting more tourists to the destination, but mainly for developing quality goods and services to meet the needs and desires of these visitors. It goes beyond the promotion of attractions, it is the management of the brand as a whole, it is the definition of the identity of the tourist destination, and its strengthening through strategies that can develop a strong image of the destination (Beni, 2012; Vignati, 2012; Kotler, 2010).

Marketing strategies are important elements for the economic growth of the tourist destination and to keep it competitive in the market, since its development depends mainly on the flow of tourists. However, it is important that managers are cautious when choosing strategies to promote their tourist attractions, since indicators with negative results due to the wrong choice of strategy can bring damage to several factors, not just the economic ones.

The objective of this study is to identify, through a Systematic Review of Literature (RSL), the marketing strategies used to promote the tourist destination to make them more competitive.

Methodology

The present paper was elaborated from the methodology of the Systematic Review of Literature (SRL). A SRL is one of the methodologies used in bibliographic reviews, being a form of research that uses scientific literature studies on a specific topic, enabling the researcher to have a broad view of what is being studied in a given period, or country or year. It is a complete and "indispensable" research to discover studies already carried out on a certain area of knowledge (Saur-Amaral, Ferreira & Conde, 2013; Santos, Firme & Barros 2008; Sampaio & Mancini, 2007).

For this study, three keywords were chosen: Competitiveness, Tourist Attraction and Marketing (Competitiveness, Tourist Attraction and Marketing), which were submitted to the search process in the national and international scientific-scientific journals: Science Direct, Scielo, Social & Behavioral, MEDLINE / PubMed, LILACS, Bireme and ISI Current Contents. However, only two, Science Direct and Scielo, obtained positive results in the searches. During the search, an AND was used, with the purpose of giving more amplitude to the search and restricting the keywords.

For the better reliability of the searches and the results of this study, three exclusion processes were carried out: In the first, papers that did not contain any of the keywords in the title of the work, the chapters of books and bibliographic studies were excluded, and included for analysis that contained at least one of the keywords in the title. The second process was through the reading and analysis of the summaries of the articles, where the methodology and results were analyzed, excluding those that did not respond to the initial questioning; In the third one, the papers were analyzed in a more thorough way: only those that responded to the initial questioning were included.

The papers selected in the third triage were once again analyzed in more depth and the data extracted from variables to compose a table with the results of the study, namely:

- Title: The title in the original and translated language;

- Author / year: Identifies which authors are studying tourism marketing;
- Journal: Which scientific journal publish on tourism marketing;
- Methodology: Which methodology did these authors use to study tourism marketing;
- Location: Which sites have already been studied;
- Sample: Number of subjects searched;
- Subject: Who are these subjects;
- Keyword repetition: Displays the relevance of each keyword within each paper;
- Marketing strategies used: They present which marketing strategies are being used in tourism marketing;
- Conclusion: Where relevant parts of the completed study are scored.

In Figure 1 it is possible to observe all steps performed in RSL to answer the guiding question of the study.

Fig. 1: Research design

Source: Prepared by the authors.

Results

The results are summarized in Tables 1 and 2, where Table 1 presents the related variables, plus the characterization of the papers and Table 2 the variables related to the results.

As can be seen in Table 1, 649 papers were identified with the RSL in the databases Science Direct (645) and Scielo (04), of which 601 were rejected in the first stage, leaving 48 papers for the analysis of the abstracts, that, after this analysis, 20 were rejected and 28 papers were for the reading stage of

the paper, of which 21 were rejected and only 7 were included as they answered the guiding question about what is being done in the promotion of the tourist attractions to make them competitive.

All rejected papers were unrelated to the keywords and / or did not answer the guiding question of the search. From the analysis of the collected material it was possible to verify that the studies related to marketing strategies in the promotion of the tourism are relatively recent, published in their majority of them in the years of 2015 and 2016.

In relation to the keywords, it can be observed that there are no papers that relate the keywords tourist attractive with competitiveness and marketing. Besides the word tourist attraction does not relate to the other keywords in the research, it is not mentioned once individually in the papers, while the word competitiveness was cited 15 times and the word marketing 360 times. This result shows the importance of studies that relate the word tourist attraction with the other two, in addition to showing that tourism marketing is a topic that has been discussed and widely discussed. Of the magazines, the Journal of Destination Marketing & Management was the one that most presented papers with the keywords were published. Of the seven papers that answered the guiding question of the research, only one was done by Brazilian researchers. Regarding the methodology addressed in the studies, the qualitative, through a case study with in-depth interviews is preferred by the researchers.

Table 1: Characteristics of Selected Articles in RSL

Item	Original Title	Author/Year	Journal	Methodology	Local	Sample	Subjects
11	Joint destination marketing in the South Central Coast region of Vietnam	Lan Thi Phuong Nguyen and Douglas Pearce (2015)	Journal of Destination Marketing & Management	Qualitative/ interview/website analysis	Central Coast of South Vietnam	8 provinces	Target marketing Organizations
22	Traditional cultural manifestation marketing and service quality- The case of Dubrovnik Summer Festival	Marija Dragicevic and Ana Tevsic (2015)	Procedia Economics and Finance	Quantitative/ interview	Dubrownik (Croatia)	200 interviewed	Festival participants
33	Innovación en la promoción turística en medios y redes sociales: Un Estudio Comparativo entre Destinos Turísticos	Guilherme Mendes Thomaz, Alexandre Augusto Biz and José Manoel G. Gândara (2013)	Estudios y Perspectivas en Turismo	Qualitative/ exploratory	Paraná (Brazil)	5 countries	California (USA) Valencian community (Spain), Emilia Romagna (Italy), French riviera (France) e Paraná (Brazil)
44	Dynamic destination image formation and change under the effect of various agents: The case of Lijiang, 'The Capital of Yanyu'	Honggang Xu and Tian Ye (2016)	Journal of Destination Marketing & Management	Qualitative/ observation and interviews	Lijiang (China)	41 interviewed	32 tourists/ 7 public workers / 2 bar staff
55	The image of the creative city: Some reflections on urban branding in Turin	Alberto Vanolo (2008)	Cities	Qualitative/case study	Turim/Italy	1 country	Promotional materials and political documents
66	Destination branding and reconstructing symbolic capital of urban heritage: A spatially informed observational analysis in medieval towns	Aleksandr Michelson and Katrin Paadam (2016)	Journal of Destination Marketing & Management	Qualitative/ multicases/ analysis of promotional material and official websites	Germany	7 cities	Bruges (Belgium), Lübeck (Germany), Stral-sund (Germany), Tallinn (Estonia), Toruń (Poland), Visby (Sweden) e Wismar (Germany)
77	La imagen del Camino de Santiago: Análisis de su representación promocional como producto turístico	María José Andrade Suárez and Iria Camaño Franco (2016)	Tourism & Management Studies	Quali/quantitative/ questionnaires	Santiago de Compostela	2.131 interviewed	Pilgrims

Source: Prepared by the authors.

Following the results (Table 2), it is possible to identify that the marketing strategy most used in promoting tourism attractions is digital marketing through social networks and official sites of tourist destinations. The other used strategies that also contribute to the promotion of tourist attractions are: organization and participation of regional and international fairs, participation in events, conferences and festivals of regional tourism, use of social media, use of slogans in publicity material and official websites, promotional posters with slogans of the city, holding of competitions of photos and sports, publicity panels, mass media (cinema and TV), promotional videos, photographic CD provided to the visitor, signage in the historical centers with UNESCO logo and city slogan.

Table 2: Characteristics of Selected Item Results in RSL

IItem	Repetition of keywords			Tourism Marketing Strategies			Conclusion
	Competitiveness	Tourism attractive	Marketing	Fairs and events	Media Digital	Other Strategies	
11	22	0	144	Participation of regional and international fairs / Organization of fairs / events and conferences / regional tourism festivals	Social Media	Printed Folders / Photo & Sports Competitions	The DMOs of the eight provinces studied carry out marketing activities individually and others together.
12	11	0	25		Internet in general	Advertising Panels / Mass Media Vehicles / Promotional Folder	Modern marketing practice requires the segmentation and direct evaluation of the segment market.
33	0	0	75		Social Media (Facebook / Twitter / Youtube / Flickr)		Well-planned and used social media and media together can increase the number of users, achieve greater visibility and create a great competitive advantage for the business or tourist destination.
44	11	0	37		Internet	Mass Media / Film / TV / Promotional Videos	The findings reveal that this anomalous image has been formed under the forces of the market with the combined effect of various agents and nowadays become well known.
55	2	0	25	Host sports events	The use of the slogan "increasingly beautiful" in advertising material on the official website	Advertising brokers, Promotional DVD of passion lives here, the photographic CD provided to foreigners to help them compile articles in the city.	Tourism seems to persist in the Fordist heritage that is still challenging to deal with, persisted in a deeply Fordist culture in promoting a cultural brand for the city.
66	5	0	41		Official website	Signage in historic centers with UNESCO logo and city slogan / Folders with slogan / In touristic promotional materials	The construction of symbolic capital over built heritage, with socioeconomic and cultural practices as significant contributors to the creation of unique selling propositions, can result in a successful destination brand.
77	4	0	13		Social Media	Advertising campaigns on TV / posters with slogan and promotional video "Now is when, Galicia is where" / "Galicia, thinking back to you" / can you keep a secret? / "People who want to recommend you Galicia"	The results show that in general, tourists visiting Santiago de Compostela are not driven because of the publicity but because of the experience they expect to find and that the projected image in advertising is precisely to provide information.

Source: Prepared by the authors.

According to the study carried out by Nguyen and Pearce (2015), the most developed destinations are the most active in terms of marketing, and the least developed have their most modest marketing actions. For the destinations that wish to receive ISO 9001 certification, the study did by Dragicevic and Tevsic (2015) shows that certification is directly related to the improvement of product quality and the creation of new marketing strategies; and that sponsorship and financial support are a tool to strengthen the image of fate and not an expense.

Public and private tourism organizations should interact with users on their social networks, allowing interactivity between supply and demand, and should also create innovative marketing strategies. For Thomaz, Biz and Gandara (2013), for marketing strategy in media and social networks to be efficient, they need to work in an integrated way with others and with the main site.

In the study carried out by Vanolo (2008), the use of video technology for mobile phones, and in the subway system driven by a computer, although not as innovative, is a very used strategy with an excellent return; Vanolo also pointed out that more economical heterogeneous actions such as supporting local artists in public spaces create a public consensus, in addition to zero risk.

Tourist destinations with historic centers offer tourist experience in various ways, according to the study of Michelson and Paadam (2016). These unique experiences intensify the reproduction of the symbolic value that can be used in the destination brand strengthening the heritage of local culture. The offerings of products anchored in this cultural inheritance integrated in the brand creates a differential, which guarantees its competitive position in the international market of cultural tourism.

Creating an identity of the destination is one of the first, and perhaps the main marketing strategy that fate management should worry about, because the image becomes a key issue in the analysis of the behavior of tourists before, during and after living the tourist experience, besides guiding the choices of the other strategies to be used in the marketing planning of the destination (Suárez & Franco, 2016).

The marketing strategies used to promote the tourist attractions found in the study are represented in Figure 2. The most used is digital media, especially social networks, where supply and demand can interact, creating a relationship and strengthening CRM (Customer Relationship Management).

Figure 2: Marketing Strategies Used to Promote Tourist Attraction

Source: Prepared by the authors.

What may be contributing to managers investing in digital media as a marketing strategy is the use of the Internet in the world. According to research conducted by the Internet Word Stats (2017) are 3,366,261,156 users worldwide, about 51% of the world population, and 139,111,185 users in Brazil, 65% of the Brazilian population, and of these Brazilian Internet users, 80% access social networks, and besides the most accessed social networks in the country, Facebook is in first place with 70%. This data corroborates with the most used social media, according to the results of the study, they are Facebook, Official sites, Instagram, WhatsApp, Twitter and Blogs.

Besides the interaction of supply with demand, social media has a low cost. Some marketing strategies that could be used as well as outdoor advertising, radio and catalogs with tourist attractions did not appear in any of the papers studied, so the reasons for their exclusions.

The important thing before selecting the marketing strategies to be used in the promotion of the destination is to make a plan, identifying the profile of the tourists, and with this data in hand select the strategies according to the ratings, so the return will be greater.

Conclusions

The use of the methodology of bibliographic review, through the technical RSL allowed a synthesis of the marketing strategies used in the promotion of tourist attractions. The results show that there are many marketing efforts used by managers, both in the public and private sectors, to boost tourism destinations and consequently increase the number of visitors.

In addition to identifying the strategies being used, the study provided information that can strengthen the development of the local site with other strategies such as the use of CRM, the creation and use of slogans in advertising material, joint marketing actions with other destinations, as well as develop products anchored in the unique identities of integrated cities.

It was also possible to identify that there are many studies that mention tourism marketing with a focus on brand management, but few are exploring strategies used to promote the destination or its tourist attractions.

It is expected that new studies that relate marketing to competitiveness and tourist attractions will be made, since their results can be used to guide tourism managers and future researchers.

Abstract

This paper is devoted to the process of implementing omnichannel concept in companies. Omnichannel's main idea is to integrate all channels between customers and companies. Omnichannel state of the art has been just scratched, that is why, there are close to none guides, that can help companies to implement the omnichannel concept. Creating the sequence of integrating channels in implementation the omnichannel concept is a natural next step for authors' current research. It is an extension to recent authors' studies of factors in implementation the omnichannel concept. However, the sequences of integrating channels can lead to different results. Recommendations regarding the integration process and its sequence provides guidelines for senior management to take a decision, on how the implementation process should be performed correctly. The sequence of integrating channels shows not only the implementation process itself, but it corresponds with the level of omnichannel concept company can acquire. Having knowledge about these aspects can lead to better understanding on, how to coordinate company's divisions, which take part in customer service process, during implementation. This article mainly focuses on potential customers' knowledge. Data about shopping experience was acquired from survey and from in-depth interviews with potential customers. The primary objective, of this research, is to answer the question: „combination of which customers service channels can give synergy effect in customers' shopping experience?". Inference on the results from the survey and the synergy effect from combination of customers service channels let authors create recommendations for managers in terms of what pairs of channels can create synergy effect in customers' experience.

Keywords: omnichannel, multichannel, synergy, customer service channels, e-commerce

Introduction

The term omnichannel comes from Latin word "Omnis" which can be defined as "all, universal, whole, every". Based on Latin definition Omnichannel means "all channels together" (Juaneda-Ayensa *et al.*, 2016).
In omnichannel concept during the process of purchasing there are many touchpoints between customers and shops. Those touchpoints are placed across multiple channels. The idea behind omnichannel is to integrate those channels (Neslin and Shankar 2009).
Nowadays, customers are willing to use different channels as they want, not as they are forced to use (Bell *et al.*, 2014). Development of communication technologies gave more free will to customers in terms of choosing channels (Rangaswamy and van Bruggen, 2005).

The main idea behind integrating omnichannel concept is to unify the brand experience of customers during the process of purchasing (Hansen and Sia, 2015, Gupta *et al.*, 2004; Shah *et al.*, 2006). The

purchasing experience for customers is a critical knowledge for companies (Barwitz, N., & Maas, P. 2018, (Homburg, Jozić, and Kuehnl 2017) and it can affect companies' sales growth (Cao and Li 2015). The technological development led customers to freely use multiple channels to interact with retail companies Chheda et al., 2017, Leeflang et al., 2014. Companies are more and more aware that their value can benefit from interaction options in different channels (Baxendale et al., 2015, Kumar and Reinartz, 2016)

Omnichannel has developed from multichannel approach. Multichannel idea was to give as many as possible channels to customers, but there was close to none integration between those channels (Cummins *et al.*, 2016, Verhoef, 2012). However companies start to engage customers in multi and omnichannel strategies during purchase process for better customers' experience (Bianchi et al., 2016, Brynjolfsson et al., 2013, Homburg et al., 2017, Verhoef et al., 2007). Channels and touchpoints in multichannel and omnichannel may include:

- printed catalogues and leaflets delivered to mailbox or hand to hand on streets,
- phone contact by telemarketers,
- direct traditional mailing,
- e-mailing,
- retails stores,
- e-commerce,
- mobile and TV apps,
- TV adverts,
- tradeshows,
- social media.

The list of channels was created based on (Kushwaha and Shankar, 2013, Baxendale *et al.*, 2015; Broussard, 2016; Li and Kannan, 2014; Peltier *et al.*, 2003; Wind and Hays, 2016a, 2016b; Zahay *et al.*, 2004), authors' experience and Internet search on shops websites.

Each channel has its own attributes, that the customer takes into consideration. Each of the attributes has its own value for different customers (Balasubramanian et al., 2005, Lee and Ariely, 2006). The aspect of ranking up was described in Wojciechowski & Hadas 2020. Those attributes can be: price and quality of the product, risk, availability of channels, outside influence of channel choice and convenience (e.g., Ganesh et al., 2010, Gupta et al., 2004, Inman et al., 2004, Verhoef et al., 2007, Yu et al., 2011). Attributes mentioned before are similar to 7 Right rules of logistics, which refers to right product, customer, quantity, condition, place time and cost. The risk aspect in implementation the omnichannel concept was described in (Wieczerniak & Milczarek, 2019), (Wojciechowski & Hadas, 2018).
Authors decided to conduct research on, how does integrating channels influence the customers' experience. The reason for this was, that touchpoints, it's variety and numbers are not always taken into account in the decision-making process (Li and Kannan, 2014).

Methodology of research

The primary objective, of this research, is to answer the question: „combination of which customers service channels can give synergy effect in customers' shopping experience?". The methodology of this research consists of several steps, which are presented in (fig.1). Steps that are far to the left are milestones and determine each chapter.

Fig. 1 : Algorithm of methodology of this research

The first step of this research methodology was the scope of literature in the aspect of customer service channels. The next step was to figure out touchpoints in every customer service channel. It was followed by grouping channels and creating recommendations in combing customers' service channels. All mentioned before tasks led to creating survey. After the survey was published, it took around 1 month to acquire enough data. Statistical calculations were made. The last step was the interpretation of data.

Preparation of the study

In this chapter there are presented grounds that led to designing the questionnaire and criteria to assess level of synergy. In table 1 there are presented all researched channels. There is also a list of pros and cons in each channel. This list was created based on authors' experience.

Table 1: Pros and cons in each channel

Parameters:	Printed catalogues and leaflets	Telephone contact	Newsagents	Stationary retail stores	Direct mail	Digital media, including e-commerce	Mobile platforms	Social media
Pros:	Delivers information of the offer to many potential customers, low cost	Delivers information of the offer to many targeted customers, low-medium cost, can place an order right away, standalone channel	Pickup point, low-medium cost	Delivers information of the offer to many targeted customers, can place an order right away, standalone channel, pickup point	Delivers information of the offer to many targeted customers, low-medium cost, can place an order right away, standalone channel	Delivers information of the offer to many targeted customers, low-medium cost, can place an order right away, fast response to customers' questions	Delivers information of the offer to many targeted customers, low-medium cost, can place an order right away, fast response to customers' questions	Low-medium cost, can place an order right away, fast response to customers' questions
Cons:	Needs customers to make contact to order, it's not standalone channel, most people get rid of leaflets right away, not even reading them	Customers can be disrupted when called and can hang up (called calling), customers need to deliver all information and place an order in one call	Needs customers to make contact to order, it's not standalone channel, customers need to visit newsagent personally	High cost, customers need to visit store personally and not all products may be available on hand	Needs customers to make contact to order	Needs any type of delivery to customers and customers to make contact to order	Needs any type of delivery to customers and customers to make contact to order	Needs any type of delivery to customers and customers to make contact to order

Definition of synergy in this article is as follows – significant growth of customers' experience, as a result of combining two channels. Combining channels is a step to acquire full omnichannel in a company. Combination of each pair of customers' service channels (Table 2.)

Table 2: Combination of each pair of customers' service channels

Current channels: / Combined channels:	Printed catalogues and leaflets	Telephone contact	Newsagents	Stationary retail stores	Direct mail	Digital media, including e-commerce	Mobile platforms	Social media
Printed catalogues and leaflets	X							
Telephone contact	Faster opportunity to place an order	X						
Newsagents	Additional pickup points	Presentation of the offer to customers and encouragement to see the offer	X					
Stationary retail stores	Presentation of the offer to customers and encouragement to see the offer, additional pickup points	Presentation of the offer to customers and encouragement to visit	Additional pickup points	X				
Direct mail	Distribution of catalogues and leaflets	Transfer of package / letter status	Additional pickup points	Additional pickup points	X			
Digital media, including e-commerce	Presentation of the offer to customers and encouragement to see the offer	Presentation of the offer to customers and encouragement to see the offer	Additional pickup points	Additional pickup points	Distribution of orders	X		
Mobile platforms	Presentation of the offer to customers and encouragement to see the offer	Presentation of the offer to customers and encouragement to see the offer	Additional pickup points	Additional pickup points	Distribution of orders	Additional places where you can make an offer	X	
Social media	Presentation of the offer to customers	Presentation of the offer to customers and encouragement to see the offer	Additional pickup points	Additional pickup points	Distribution of orders	Additional places where you can make an offer	Additional places where you can make an offer	X

Based on table 1 channels were grouped by similarities in pros and cons they represent. That is the reason why in questions 1 – 10 there are 5 different channels considered. Result of grouping are as follows:

- printed catalogues and leaflets – no grouping
- telephone contact – no grouping
- direct mail – no grouping
- newsagents and stationary retail stores – grouped together as stationary stores
- digital media, including e-commerce, mobile platforms, social media – grouped together as e-commerce platform

Respondents answered the following questions:

Question 1 - The first channel of customer service are printed catalogues and leaflets, they are to be combined to a telephone contact (orders placed by telephone). Will this have a positive effect on your experience in the purchasing process?

Question 2 - The first channel of customer service are printed catalogues and leaflets, they are to be combined with stationary stores (orders placed personally at the counter). Will this have a positive effect on your experience in the purchasing process?

Question 3 - The first channel of customer service are printed catalogues and leaflets, they are to be combined with direct mail (orders placed by sending the order form by traditional mail). Will this have a positive effect on your experience in the purchasing process?

Question 4 - The first channel of customer service are printed catalogues and leaflets, they are to be combined to the e-commerce platform (orders placed on the store's website). Will this have a positive effect on your experience in the purchasing process?

Question 5 - The first channel of customer service is telephone contact (telemarketing), it is to be combined to stationary stores (orders placed personally at the counter). Will this have a positive effect on your experience in the purchasing process?

Question 6 - The first channel of customer service is telephone contact (telemarketing), it is to be combined to direct mail (orders placed by sending the order form by traditional mail). Will this have a positive effect on your experience in the purchasing process?

Question 7 - The first channel of customer service is telephone contact (telemarketing), it is to be combined to the e-commerce platform (orders placed on the store's website). Will this have a positive effect on your experience in the purchasing process?

Question 8 - The first channel of customer service is stationary stores (showroom) they are to be combined to direct mail (orders placed by sending the order form by traditional mail). Will this have a positive effect on your experience in the purchasing process?

Question 9 - The first channel of customer service are stationary stores (orders placed personally at the counter), they are to be combined to the e-commerce platform (orders placed on the store's website). Will this have a positive effect on your experience in the purchasing process?

Question 10 - The first channel of customer service is direct mail (orders placed by sending the order form by traditional mail), they are to be combined to the e-commerce platform (orders placed on the store's website). Will this have a positive effect on your experience in the purchasing process?

Question 11 - Which shopping model do you prefer? First, looking at offers online, then buying in a stationary store (webrooming), or looking at offers in a stationary store, and making purchases online (showrooming)?

Each pair of channels was compared in question 1 – 10. 7-point Likert's scale was used to measure the level of synergy/dysergy presented in table 3. Synergy is defined to yield more than the sum of the individuals. Dysergy is defined as antonym to synergy, that is conflicting desires (Cooper 2017), which leads to yield less than the sum of the single elements. Elements in this article are customer service channels.

Table 3 : Scale of level of synergy/dysergy as a result of combining two channels

Answer: (Likert's scale)	Level of synergy:
Strongly agree	3 perfect synergy
Agree	2 significant synergy
Somewhat agree	1 weak to none synergy
Neither agree nor disagree	0 neutral combination
Somewhat disagree	-1 weak to none dysergy
Disagree	-2 significant dysergy

Answer: (Likert's scale)	Level of synergy:
Strongly disagree	-3 pointless combining

Conduct and results of the study – recommendations in combining customer service channels

The research was carried out on a sample of 105 respondents who make purchases and returns using various customer service channels. The research was directed to clients who are active users of information technologies in purchasing processes.

The obtained results provide a lot of important information on customer service combinations desired by customers (potential impact of the analysed solutions on the shopping experience).

Fig.2 : Impact of channels combination: printed catalogues and leaflets with telephone contact on the shopping experience

Channel combination: printed catalogues and leaflets with telephone contact divides respondents into 2 groups (fig.2). The first group (slightly larger) indicates positive effect on experience in the purchasing process. The second group of respondents did not notice the positive impact. The distribution of answers allows us to conclude that the channel combination is justified, but its impact will be significant only for some clients.

Fig.3 : Impact of channels combination: printed catalogues and leaflets with stationary stores on the shopping experience

The results for the combination of channels: printed catalogues and leaflets with stationary stores clearly show positive effect on experience in the purchasing process (fig.3) This traditional combination of customer service channels in the opinion of customers gives significant effects, so it should be recommended whenever it is compatible with a trading company strategy or vision statement.

Fig.4 : Impact of channels combination: printed catalogues and leaflets with direct mail on the shopping experience

Channel combination: printed catalogues and leaflets with direct mail in the opinion of most customers does not have a positive impact on experience in the purchasing process (fig.4). The result can be interpreted in such a way that it is a traditional and old-fashioned solution and because of this it lacks features that are important for a client looking for high service standards in every possible aspect. The combination of these channels should probably not be regarded as unfounded or incorrect. Rather, it is the basic solution that should be extended, i.e. it should not function on its own.

Fig.5: Impact of channels combination: printed catalogues and leaflets with the e-commerce platform on the shopping experience

The results for the channel combination: printed catalogues and leaflets with the e-commerce platform show unequivocally positive effect on experience in the purchasing process (fig.5). This is a very preferred combination of customer service channels, which should be clearly recommended to commercial enterprises.

Fig.6 :Impact of channels combination: telephone contact (telemarketing) with stationary stores on the shopping experience

Customer feedback on channel combination: telephone contact (telemarketing) with stationary stores is ambiguous (fig.6). In the respondents' opinion, slightly negative opinions prevail. Generally, however, the results are distributed in a way that makes it difficult to formulate business recommendations. The possible combination of these channels requires in-depth research to determine their legitimacy for the target customer group.

Fig.7 : Impact of channels combination: telephone contact (telemarketing) with direct mail on the shopping experience

Customer feedback on channel combination: telephone contact (telemarketing) with direct mail (orders placed by sending the order form by traditional mail) clearly indicates that this solution is unreasonable (fig.7). This is an undesirable combination of customer service channels. In the authors' opinion, this solution is also doubtful as to its legitimacy because the purpose of telemarketing is to conclude a transaction during a single contact and it does not require expansion with an additional channel.

Fig.8 : Impact of channels combination: telephone contact (telemarketing) with the e-commerce platform on the shopping experience

Customer feedback on channel combinations: telephone contact (telemarketing) with the e-commerce platform (customer service on the store's website) allow us to conclude that this is a good solution (fig.8).

Fig.9: Impact of channels combination: stationary stores with direct mail on the shopping experience

Another considered solution is to combine channels: stationary stores (showroom) with direct mail (orders placed by sending the order form by traditional mail). The results obtained (fig.9) clearly indicate that for most customers this is a solution that will not ensure an increase in their satisfaction. For this reason, it cannot be recommended as valuable.

Fig.10 : Impact of channels combination: stationary stores with the e-commerce platform on the shopping experience

Channel combinations: stationary stores (orders placed personally at the counter) with the e-commerce platform (customer service on the store's website) is the most preferred solution in the opinion of customers. The results clearly indicate the legitimacy of implementing such a solution (fig.10), because it gives the greatest potential for creating a positive experience in the purchasing process. In this case, it can be assumed that synergy effect is achieved for combining customer service channels understood as significant growth of customers 'experience. By comparing the obtained result with the question

about the preferred shopping practice of showrooming and webrooming, you can get a wider picture. After years of change in customer preferences, consisting in the popularization of e-commerce, currently there is a lack of a clear advantage between preferred practice (showrooming or webrooming) (fig.11).

Fig.11: Preferred practice of showrooming and webrooming

Currently, customers are equally eager to use both practices, and thus the combination of channels: stationary stores with the e-commerce platform is fully justified for commercial entities. This will limit the migration of customers who visit a stationary store in one company and make purchases through the Internet in another company.

Fig. 12 : Impact of channels combination: direct mail with the e-commerce platform on the shopping experience

The last considered solution is to combine channels: direct mail (orders placed by sending the order form by traditional mail), they are to be combined to the e-commerce platform (customer service on

the store's website). The obtained results indicate the validity of this solution for a significant number of clients (fig.12).

Table 4: Descriptive statistics from survey

	Descriptive Statistics								
Nvalid = 105	**Mean**	**Median**	**Mode**	**Min**	**Max**	**Lower quartile**	**Upper quartile**	**Variation**	**Standard deviation**
Q1	0,02	0,00	1,00	-3,00	3,00	-1,00	1,00	2,54	1,59
Q2	0,90	1,00	1,00	-3,00	3,00	0,00	2,00	2,19	1,48
Q3	-0,88	-1,00	-2,00	-3,00	3,00	-2,00	1,00	2,97	1,72
Q4	1,79	2,00	2,00	-2,00	3,00	1,00	3,00	1,47	1,21
Q5	-0,28	0,00	-2,00	-3,00	3,00	-2,00	1,00	3,32	1,82
Q6	-1,25	-2,00	-3,00	-3,00	3,00	-3,00	0,00	2,44	1,56
Q7	0,30	1,00	1,00	-3,00	3,00	-1,00	2,00	3,14	1,77
Q8	-0,68	-1,00	-2,00	-3,00	3,00	-2,00	1,00	2,72	1,65
Q9	1,73	2,00	3,00	-3,00	3,00	1,00	3,00	2,01	1,42
Q10	0,34	1,00	1,00	-3,00	3,00	-1,00	2,00	3,48	1,86

Detailed results for the analysed combinations of customer service channels can be found in the table 4. The analysis of mean and median as well as distribution measures allows determining the strength of the impact of a given combination of customer service channels on shopping experience and differentiation of customer opinions. In most cases it is clearly mentioned, that customers prefer to have a choice as to what channels to use in shopping process.

Table 5 : Correlation matrix based on effects from combining customer service channels

	Q1	**Q2**	**Q3**	**Q4**	**Q5**	**Q6**	**Q7**	**Q8**	**Q9**	**Q10**
Q1	1,00	0,16	0,29	-0,04	0,05	0,25	0,10	0,09	-0,24	-0,10
Q2	0,16	1,00	0,26	0,27	0,51	0,20	0,32	0,17	0,17	0,28
Q3	0,29	0,26	1,00	-0,04	0,39	0,59	0,23	0,47	-0,25	0,15
Q4	-0,04	0,27	-0,04	1,00	0,14	-0,13	0,25	-0,16	0,31	0,21
Q5	0,05	0,51	0,39	0,14	1,00	0,53	0,63	0,30	0,05	0,47
Q6	0,25	0,20	0,59	-0,13	0,53	1,00	0,44	0,59	-0,19	0,25
Q7	0,10	0,32	0,23	0,25	0,63	0,44	1,00	0,22	0,07	0,49
Q8	0,09	0,17	0,47	-0,16	0,30	0,59	0,22	1,00	0,03	0,20
Q9	-0,24	0,17	-0,25	0,31	0,05	-0,19	0,07	0,03	1,00	0,32
Q10	-0,10	0,28	0,15	0,21	0,47	0,25	0,49	0,20	0,32	1,00

Correlation analysis for the answers given, in table 5, allows to identify the compliance of customer assessments regarding the impact of individual channel combinations on the shopping experience. In the context of searching for the synergy effect or lack thereof, the following relationships pay attention:

- compatibility between Q3 combination ratings (printed catalogues and leaflets with direct mail) Q6 (telephone contact (telemarketing) with direct mail) and Q8 (stationary stores with direct mail) by clients and their generally negative rating. Here, the common channel

is direct mail, which has been explicitly rejected as a valuable enrichment of the customer service channel.

- compatibility between Q4 (printed catalogues and leaflets with the e-commerce platform), Q7 (telephone contact (telemarketing) with the e-commerce platform), Q9 (stationary stores with the e-commerce platform) shows positive relation based on e-commerce.
- compatibility between Q5 (telephone contact (telemarketing) with stationary stores) and Q8 (stationary stores with direct mail) show a little negative rating based on stationary stores. This situation may suggest, that there is a trend of leaving traditional stores in favour of e-commerce and showrooms.

Conclusion

In current market conditions, conducting business activity requires having many service channels, tailored to the clients' expectations. Research results show that arbitrary combination does not necessarily mean increased customer value. Instead of the expected synergy effect in the purchasing experience, which is supposed to constitute a competitive advantage, it may even deteriorate current state of customers' experience. The authors of the article analysed the selected connections of customer service channels in pairs and created a conceptual model between those channels. The date for analysis was acquired from over 100 respondents, who make purchases and returns using various customer service channels. The limitation of this research study is the point of view – customers and analysing channels only in pair, not in groups. Then based on the results of the research, obtained the answer, how does the impact of these connections affect the shopping experience. Combining customer service channels can result in different results:

- achieving a significant synergy effect of shopping experience (in the opinion of a wide group of customers),
- a perceptible benefit only for a limited group of clients, while disapproving another group of clients,
- no noticeable results, because the connection is neutral in the opinion of customers, while disapproving another group of clients,
- negative reception among clients (connection pointlessness).

As a consequence of the obtained results, managers are provided with the information, which service channels should be integrated in order to rationally implement the omnichannel concepts. The process of implementing effective customer service requires IT support in the form of CRM systems. Knowledge of service channels desired by customers is also important for the development of their functionality. The authors' research on the opportunities and threats of implementing the omnichannel concept also prove that IT systems are a key source of information about retained shopping customers in existing channels. Nevertheless, at the stage of designing a comprehensive solution, which is a modern customer service system, it is necessary to decide which channels will be available.

The pairing of customer service channels has allowed the identification of common parts for connections that are positively determined by customers, and for ones that are negatively determined by customers. The next natural stage of research is to exclude negatively defined service channels and to examine relationships not only in pairs, as was the case in this article, but also round-robin, creating more complex solutions. Based on this article research conceptual contribution, a connection matrix can be created that can be used as a template to determine the required modules when implementing CRM or ERP II systems in enterprises.

The Practice of Strategic Management of Polish Enterprises: Concern For CSR, Image or Greenwashing?

Katarzyna ZADROS

Czestochowa University of Technology, Poland
Katarzyna.zadros@pcz.pl

Abstract

Research background: Modern companies are looking for a competitive advantage, not only in new technologies and innovative products offered to clients, but also in the introduction of modern tools to management. This type of activities includes the implementation of the concept of sustainable development, eco-development and CSR into management practice. Research shows that some companies with a strong market position try to shift organizational and financial burdens associated with the implementation of selected socially responsible practices to their subcontractors, while usurping at the same time the effects of their application. Also they often introduce solutions that the market forces to apply as CSR initiatives, although in practice they are PR activities only. Therefore, it is interesting to conduct research aimed at diagnosing the real intentions of introducing this kind of solutions into practice. Purpose of the article: The analysis of literature and company information on CSR practices and sustainable development, including eco-solutions, allows us to diagnose research areas that require deeper analysis and allow us to determine the purpose of the proposed article. It is to examine how individual pillars of CSR and sustainable development are used in creating and implementing the organization's strategy and shaping its image, and in what situations it should be assessed as a "greenwashing". Methods: Implementation of this objective will be served by the study of international literary sources, as well as case studies conducted on the basis of source materials of selected companies and institutions involved in reporting good practices.

Keywords CSR; environment, development; organizations culture

Introduction

Corporate Social Responsibility, in accordance with the assumptions of the Lisbon Strategy, is the most effective tool for building the European economy as most dynamic, competitive and capable of long-term sustainable development. Implementation of Corporate Social Responsibility in contemporary organizations is based on the undertaking of prospective initiatives covering business, society and the environment, giving the opportunity to accomplish sustainable development principles, in order to ensure the future generations a quality of life not lower than that of the current generations (Stappen, 2006; Ingaldi, 2015).

In Albinger and Freeman's view, CSR is the most appropriate configuration of social responsibility principles, processes of reaction to social problems, policies, programs and possible to follow-up results, referring to company social relations for each business organization (Albinger, Freeman, 2000, p. 243.). Therefore, companies striving for long-term market success and a strong market position generally implement CSR principles and promote initiatives in this area, in this way sending a message about their responsibility to the business partners, thereby increasing own attractiveness as business partners. However, there is no hard evidence that being a responsible company is a guarantee of good economic condition. There are no hard indicators to measure the economic effects of socially responsible activities. R.N. Farmer and W. Dickerson-Hogue (1973, p. 11) already recognized this problem in the 1970s, stating that there is no recognized method for measuring the effectiveness of socially responsible activities, other than by measuring the degree of implementation of adopted economic goals.

Perhaps because of this, it is not uncommon to hear, that under the guise of CSR activities, companies

use fraudulent practices or even commit misdemeanors and crimes which allow them to achieve a better market position, sometimes even without generating additional costs. That is why one should agree with the statement of Sachs, that societies indiscriminately recognized the implementation of the sustainable development and CSR as a salvation for the Earth, which is environmentally endangered (Sachs, 2010, pp. 1-5).

That is why various questions arise: First of all, is it an acquiescence for unfair practices and is it possible that the concealment of those is the true reason behind the appearances of irregularities in the implementation of CSR, and it likely being the cause for tendency of using cheap substitutes instead of real activities? Second, is it the desire to generate profit with the lowest possible cost that is the source of such behavior, or are there other factors responsible for such a state of affairs, like for example cultural conditions?

The consequence of asking these questions is a study aimed at assessing whether the largest Polish companies reach PR practices and greenwashing, implemented under the name of CSR, and what ramifications may arise due to determining such companies as socially responsible.

The selection of Polish companies that belong to the group of the largest market players is not accidental. It is the result of the authoress conscious decision, resulting from the fact that for many years she has been able to track changes taking place in these companies. She could also observe the changes that have been taking place in recent years in the policies and strategies of the largest state-owned companies, while not seeing the reflection of these changes in CSR reports. Therefore, these problems will become the subject of analysis later in the study.

Literature Review

In contemporary studies on corporate social responsibility, many researchers notice the existence of a relationship between the possibilities of introduction and implementing CSR, and the dominant culture within the organization (Fukuyama, 1997). This culture is also an element of social capital deciding about interpersonal cooperation skills, giving way to the possibility of real implementation of social responsibility (Trompenaars & Hampden-Turner, 2012).

Activities from the area of CSR serve to build credibility, contribute to strengthening the market position while shaping the social image in internal branding and external relations employer branding through competition based on non-material assets, specifically the brand and human resources (Wojtaszczyk, 2010, p. 20). As a result of this, CSR becomes a management strategy based on multidimensional relations, (Kazojć 2014, p. 36), and not just a attractive public relations tool used for the promotion of the company. In modern times, the concept of CSR has been precisely defined, and simultaneously methods, techniques and tools for its measurement have been developed. Said tools make it possible to build reports, which subsequently can be verified by independent institutions.

The most important means of reporting is an indicator called GRI - Global Reporting Initiative (Szejnwald-Brown et al., 2009, pp. 182-200; Toppinen et al., 2011, pp. 191-205; http://www.global reporting.org.pl/ing.org.pl). In 2007, GRI developed the Integrated Reporting Framework for economic, environmental and social aspects of business operations and disseminated the idea of creating integrated reports that combine the entire reporting of an organization. The GRI Integrated Reporting Framework defines the Standard Information that should be included in the report and performance indicators from the key areas (Global Reporting Initiative, 2013).

They also indicate 10 principles to ensure the quality of reports and comparability in the scale of individual companies within member countries and on a global scale. The rules were divided into two categories: rules for defining quality and rules for defining content. These standards also provide two levels of reporting: basic (core), meaning reporting of at least one indicator for each of the main areas, and extended (comprehensive), obliging to report all indicators (Koskela, 2014, pp. 294-308; Kudełko et. al., 2016, p. 83).

Supporting the implementation of CSR is also possible due to the AccountAbility AA1000 series standards (Pflugrath et al., 2010, pp. 239-254). Thanks to them, the company is equipped with methods allowing to manage engagement in relations and dialogue with stakeholders in order to build company value, stimulate its innovation, risk management as well as create corporate governance and apply modern management methods.

ISO 26,000:2010 standard (Guidance on social responsibility…) has a crucial meaning in the analyses and elaborations concerning good practices in Europe. It aims to assist organizations in:

- contributing to the implementation of sustainable development rules and extending the responsibility by society‘s health and welfare issues,
- taking into account the stakeholders expectations,
- checking the compliance of company’s actions to the binding laws and international standards of behavior;

Despite so many methods and tools recommended by international institutions for reporting good practices, or preparing non-financial reports (Directive 2014/95/EU…), even the largest companies still have a large room for maneuvers in reporting.

The criticism of activities that are traditionally considered as socially responsible began with a debate between two American lawyers: Dodd and Berly, for a long time before the formalization of the concept. "The discussion concerned whether the sole obligation of entrepreneurs is, or is not, to create profit for shareholders. (...) Dodd, in opposition to Berly, postulated in 1932, that the entrepreneur's goal should be not only to bring profit, but also to act in the social interest "(Kopeć, 2016, p. 130). Friedman (1962; 1970, pp. 32-33), a supporter of Berly's view from the turn of the 1960s and 1970s was one of the greatest CSR critics.

Tracking dishonest practices used by companies leads to the generation of reports, rankings and other elaborations describing socially irresponsible practices e.g. *Corporate Irresponsibility America Newest Report* elaborated by Mitchell (2002).

Term CSI was first used by Armstrong in 1977. In his opinion social irresponsibility consists in permanent disregarding and ignoring of regular research in this field which leads to negative results (Armstrong 1977, pp. 185-213). Kotchen and Moon (2011, p. 2) believe that CSI is a set of company behaviors that cause an extreme increase of costs and/or promote distribution of conflicts.

Other critics issued a concern as to whether it is the duty of companies to act for the benefit of society and if they have the appropriate prerogatives and skills (Kaman, 2015). Many authors also allege that behind the façade of CSR activities there is a number of pathologies and a pursuit for profit and power as described in Bakan, (2004; Chatterji and Listokin 2007, pp. 52-63).

Numerous socially irresponsible practices are widely described by supporters of the post-development concepts (Anyanwu & Nweake, 2014, pp. 105-109; Encarnation-Tadem, 2007, pp. 92-97; Sachs, 2010, pp. 1-5). These practices can even be called "black CSR" (Lulewicz-Sas, 2013, p. 9).

Highlighting and making certain activities of companies public makes it possible to have doubts as to whether they are indeed an element of CSR or are they simply PR campaigns, promoting the company. So what is PR, and what is CSR? Both efficiently serve for supporting strategic management, something essential for building the culture and identity of the organization. Actions taken in both fields also serve similar purposes: building the company's image and thus gaining a competitive advantage as a consequence.

According to Gohil and Gohil (2016, pp. 384-387) PR activities allow modulating the level of satisfaction of stakeholders and are a broad process of communication for the organization in order to build social responsibility and realize the interests of said stakeholders while maintaining mutual respect. While PR actions are for building its image. In other words, they "overtake" the introduction

of CSR and prepare the organization and its employees for its implementation (Tomic et. al., 2006, p. 26).

Increasingly used greenwashing is another dangerous activity for stakeholders and the environment. It is beneficial and serves for the intention of company act of spreading disinformation, in order to convince stakeholders - especially consumers - that the company acts responsibly and ethically towards society and the environment (Rowell, 2002, p. 19). This concept also includes selective disclosure of positive information along with the simultaneous concealment of negative data, in order to create a false image, excessively beneficial for the company (Bowen & Aragon-Correa, 2014, pp. 107-112). Common greenwashing practices include (Bowen, 2014, pp. 17-23):

- providing incorrect information about product features,
- suggesting pro-ecological or pro-social character of the subject based on tendentiously selected product features,
- not presenting evidence on CSR activities,
- using general and imprecise expressions in the product information,
- using facts that are not related to the real condition,
- use of false labels, signs and certificates concerning CSR,
- deliberately omitting unfavorable information about the product or its manufacturing process.

Along with how greenwashing methods and techniques become more and more sophisticated and take the form of "symbolic corporate ecologism" (Short & Toffel, 2010, pp. 369-396), they become more and more difficult to grasp and prove. Research conducted in North America and Europe indicates that for over 90% of products that were advertised as ecological, at least one of greenwashing practices was applied (Lane, 2012, pp. 582-587; TerraChoice, 2010, p. 11).

A brief literature review presented here and the issues raised by it prompted the authoress to make an attempt of investigating whether the largest companies in Poland seen as socially responsible implement genuine CSR strategies in building market position and image, or if they use unethical, immoral and illegal ways in order to minimize costs while achieving the greatest benefits.

Methods

The primary sources of information on the basis of which the research was conducted are: scientific publications on the issues, opinions of experts and reports published by the surveyed companies and independent national and international institutions dealing with researches on this issue. The presented analysis was also carried out based on data and information provided in the latest CSR reports by companies belonging to the WIG 20 group, as well as reports by journalists specializing in the so-called "Investigative journalism", who gather and verify information regarding various types of practices that are contrary to the principles of CSR and sustainable development.

For the purpose of research, concerning the presented article, mainly qualitative methods have been used, and the starting point for the aforementioned analysis was to look for an answer to the key, from the researcher's point of view, question: Are the largest Polish companies dominated by the approach to CSR as an area of activities determined by their strategy and national assumptions for sustainable development, or are they rather image-based activities?

The examined companies were divided into three categories, based on information on the basic business profile: industrial and commercial entities, service providers and third, insurance and financial companies. In the group of industrial and commercial companies listed on WIG 20 are nine companies: CCC, DINOPL (from 2019) JSW, KGHM, LOTOS, LPP, PGNiG, PKN Orlen, SANPLAST. Second, six companies conducting commercial and service activities: Eurocash (until 2018), CDProjekt, Cyfrowy Polsat, Orange Polska, ENERGA (until 2018), PLAY (from 2019) PGE and TAURON. Lastly, five insurance and financial entities: Alior, PKO BP, PKAO SA, mBank and PZU SA.

The study includes the analysis of reports developed after the entry into force of EU rules on the

obligation of non-financial reporting. For most companies, these are reports for 2018. At the time when study was conducted, only one company published the report for 2019, so it was assessed by the authoress.

Results

Most of the surveyed entities issued integrated reports, adapted to EU requirements and containing a very large amount of non-financial information in 2018 already. Table 1 shows how fast growing the number of companies developing such reports in Poland and worldwide are.

Table 1: Changes in the number of reports reported to GRI

Fiscal year	Number of reports (approximate values)			
	Sustainable development (CSR)		Integrated reports (GRI)	
	World (±)	Poland (±)	World (±)	Poland (±)
2004	2000	0	10	0
2005	2300	1	10	0
2006	2900	4	60	0
2007	3400	3	110	1
2008	4100	15	190	1
2009	4900	13	240	4
2010	5800	29	275	12
2011	5900	37	360	18
2012	6200	41	375	28
2013	6900	49	410	22
2014	12700	40	1450	20
2015	41600	55	27300	28
2016	50500	551	31000	31
2017	53400	631	32600	36
2018	55700	601	34500	51

finan.	0	0	5	0	2	3	5	2	5

Source: own study based on company reports

Only one of those companies does not publish commonly available reports, nor does it place information about the rules and reporting standards on its website. A fee must be paid first to access its reports. The rest not only create CSR reports, but more and more often develop comprehensive integrated reports, consistent with the guidelines of not one, but several standards at the same time.

Most often it is the GRI standard, 14 companies reports are based on its older version, while 6 of them use the newest version. Nowadays it gets more often for 15 of those companies CSR strategy, and thus its reporting, to include ISO 26 000, some of the surveyed organizations also include UN guidelines included in the Global Compact (GC) and Agenda 2030 for sustainable development (http://ungc.org.pl/sdg/sustainable-development-goals).

Upon examination of the company reports, we see great care taken in their preparation and very

meticulous registration of all activities which allow us to state that the company meets the requirement of a standard, which is used as a basis.
However, it should be kept in mind that reporting and boasting about achievements and good practices in the area of CSR does not mean that at the same time companies do not conduct activities, that could be considered ethically questionable or even contrary to the CSR and sustainable development principles. The best examples for this are companies from the energy and mining industries. In their reports, they pride themselves in actions taken for the environment and social well-being, however in practice they invest more and more in acquiring and developing conventional energy sources, while the amount of "green" energy they produce is symbolic. In 2018 it was 21 210 GWh at the total production of 179 335GWh, or 12.45% of the total energy generated (https://www.are.waw.pl/).

In the cases of energy and mining companies there are visible elements of PR manipulations. Photographs presented in folders and reports are shown in a way that makes elements of the natural environment, like forests, green fields and blue water, appear in the background (https://raportzintegrowany 2018.gkpge.pl/en/; file:///C:/Users/KATATR~1/AppData/Local/Temp/ raport-csr-2019.pdf; et all.). Fuming chimneys are rarely seen however, there are no mine heaps, waste dumps or landscapes with visible mining damage. Even though in the immediate surroundings of those facilities, changes can be encountered at every step, indicating the degradative nature of their activities. Even when for years past they have been one of the largest polluters in Europe.

The charts included in the reports show a decreasing emission of gases harmful to human health and the natural environment, including SO_2, however there is no such data on changes in CO_2 emissions (European Green Deal…).

A different matter related to these issues is the excessive exploitation of hard coal deposits, extraction of which becomes more and more dangerous and increasingly expensive, while at the same time causing more and more mining damage. In 2016 the mining company spent almost 55 million PLN on its extraction, and in 2018 it was already over 92 million (no data for 2019) (https://www.jsw.pl /media/wydarzenia/artykul).

In authoress opinion this problem is shown in the reports, however it is presented in such a way, that the reader may get the impression that it is of no significance, and that it does not contribute to the deterioration of the conditions and quality of life of the inhabitants of city Jastrzębie and its surroundings.

There are also ambiguities and doubts in the assessment of the actual activity and purposes of CSR reports prepared by other groups of companies. Particular doubts concern the LPP report, which is the first document so comprehensively developed by this company (https://www.lppsa.com/en/ sustainable-development). The question arises whether the company was forced by EU regulations to develop a CSR strategy and undertake reporting, or perhaps its aim was to strengthen the image which was heavily damaged after the collapse of a building that was LPP's production facility that took the lives of about 1,100 people working there. However looking at the amount of space in the report devoted to efforts made for improving safety at work in Asian companies producing for LPP, the second option was probably dominant. Especially because in LPP report there was no mention, that activities aiming to improve occupational health and safety appeared only after this incident, additionally there is no information regarding the issue of compensation. It seems that between the years of 2013-2018, in business practices implemented in Asian countries, LPP switched from greenwashing activities to a carefully developed and implemented PR campaign (Rozwadowska, 2016; Guzik, Zapart, 2017). But is it already a social responsibility? It is probably still too early for such statement.

In addition to data analysis for individual groups and individual companies, we can also indicate that the information appearing in the reports of almost all enterprises raise doubts as to their assessment as socially responsible companies. These issues concern corporate governance, and more specifically diversity policy. Each of the surveyed companies states that they do adopt such policy and undertake extensive actions to combat all forms of discrimination, while at the same time it is enough to familiarize oneself with the composition of management and supervisory boards in order to gain certain

doubts. In each of these groups there are only, or almost only men, managerial positions are also more often occupied by representatives of the aforementioned sex (https://www.lppsa.com/en/about-us/management; https://www.gkpge.pl/Investor-Relations/PGE -Group/Management; https://kghm.com/en/about-us/leadership et all.).

Additionally most of these reports show data indicating that female employees working on the same positions as men receive lower salaries. One can speak about such information as suggesting the existence of the "glass ceiling" phenomenon in the higher structures, however there is no information indicating that the company notices this problem. On the other hand, the report emphasized information on equal participation of women and men in training sessions, identical assessment systems, etc.

For service and financial-insurance companies it is a distinguishing characteristic that they employ mainly young people, aged no more then 30-40 years, and as such, the number of employees in older age groups is significantly lower (https://raportroczny2018.pzu.pl/en/business/employee/human-capital-management; https://www.mbank.pl/en/annual-report/ 2017/; http://www.raportroczny2018.pkobp.pl/en/otoczenie-banku/nasi-pracownicy/; et all.). Opposite problem can be seen in industrial companies, especially JSW, where a significant percentage of the crew are people over 40, or even 50 years old, so here, in turn, a generational gap may occur, and as a result an inability to obtain an inflow of new employees in the future is possible (https://www.jsw.pl/raportroczny-2017/pl/CSR/ZatrudnienieIWynagrodzenie/ZatrudnienieIWynagrodzenie/). Of course, these phenomena cannot be identified with the negative phenomena that accompany improper implementation of CSR, although in the future they may pose threats to the functioning of the organization and foster unethical practices in the area of employment.

Summing up the assessment of content in presented reports about the CSR and sustainable development, according to the authoress, there is a visible interlacing of CSR and PR messages, but misleading or clearly false information weren't noticed. Typical CSI or greenwashing practices cannot be indicated. High ratings of the reports of the surveyed companies issued by independent auditors and expert institutions, with the Responsible Business Forum at the forefront, seem to confirm this claim.

Conclusions

The analysis of issues of interest to the researcher made in this study, based on integrated reports, as also reports on sustainable development, CSR and scientific and journalistic studies as well, made it possible to conclude, that in the surveyed companies and their reporting, socially responsible practices and their proper presentation prevail.

However, in many cases, there will also be attempts to bypass or downplay unfavorable information, and to take initiatives included in good practices in order to weaken public dissatisfaction from the negative impact of the organization on social development and the environment, instead of forming conditions for long-term progress for both company and communities that companies can influence.
It also seems that the analyzed reports are dominated by information on good practices, while there is no notice of greenwashing practices. However, it cannot be excluded that these practices are mixed with PR activities meant to build a positive image of these companies in society.

At the end of the discussion, one more afterthought arises, coming not from the analysis of company documents and reports contained in various types of publications, but from observation of social and health reality related to the development of the COVID-19 pandemic. According to the published reports, companies particularly focused on their activities related to the environment and ecology, seeing them as a source for shaping the image and their market position. It seems that in the near future this approach will change and much more attention will be devoted to human health and threats to it, which can also in a completely new way, now difficult to predict, affect the functioning and economic condition of companies.

Evaluation of Threats to The Internal Safety and Internal Security of The State

Jacek BIL

Military University of Technology in Warsaw, Poland
e-mail: jacek.bil@wat.edu.pl

Abstract

The assessment of a state of an internal safety and security is based on reports of the decision-making centres responsible for ensuring the functioning of the State safety and security system and is estimated on the basis of studies carried out by public opinion research institutions. The problem of assessing a state of an internal safety and security of the State is embedded in the perception of the phenomenon being assessed. A failure to correctly identify threats to the internal safety and security environment is related to the ability to disclose them and prioritise the degree of individual threats. The purpose of this Article is to pay attention to the proper identification and response to actual threats to safety and security of the State and to related needs.

Keywords: Internal Safety, Internal Security, Threats, Public Safety, Public Security, National Safety, National Security, Constitutional Safety, Constitutional Security,

Introduction

In many cases, scientific studies on the internal safety and security of the State are geared to referencing definitions of safety and security or to creating new terms for the problem. Extensive scientific discourse raises subjective and objective issues of internal safety and security and their relations with other types of safety and security, e.g. international security. Without, of course, reduction of the importance of scientific theories in the field of safety and security sciences, many of the publications devoted to this issue remain in the current of theoretical discussion. Another challenge for the proper assessment of the State's internal safety and security is to succumb to a kind of fashion for particular phenomena, in the case of internal security in recent years these are the terrorism threats. An additional problematic issue in this area is that representatives with a poor range of theoretical knowledge, not to mention practical knowledge, are engaged in discourse. A separate problem of presenting the State's internal security threat is the studies prepared by the analysis and information departments of individual state administration entities responsible for public communication. In this editorial, using the qualitative research method, scientific studies on internal safety and security issues have been analysed. The result of the study indicates that the vast majority of the analyzed articles include the issue of terrorist attacks, including the construction of local and national systems aimed at counteracting such threats, as well as the issue of theoretical consideration of internal safety and security and its institutionalization. Among the analysed items were, among others, studies and compact items: Susan E. Clarke, Erica Chenoweth *„The Politics of Vulnerability: Constructing Local Performance Regimes for Homeland Security”,* Susan Page Hocevar *„Building Collaborative Capacity: An Innovative Strategy for Homeland Security Preparedness”,* Linda Kiltz *„ Perceptual Framing of Homeland Security”,* Charles R. Wise *„Organizing for Homeland Security*”, Robert R. Friedmann, William J. Cannon *„ Homeland Security and Community Policing: Competing or Complementing Public Safety Policies”,* Shawn Reese *„ Defining Homeland Security: Analysis and Congressional Considerations”,* Christopher Bellavita *„Changing Homeland Security: A Strategic Logic of Special Event Security”*, Katarzyna Grosicka, Leszek Grosicki, Przemysław Grosicki *„Organizacja i Kierowanie Instytucjami Bezpieczeństwa Wewnętrznego Państwa”,* Marian Kopczewski *„Bezpieczeństwo wewnętrzne państwa – wybrane elementy”, „Bezpieczeństwo wewnętrzne państwa. Wybrane zagadnienia”,* red. Stanisław Sulowski, Michał Brzeziński, oraz Zbigniew Ścibiorek, Bernard Wiśniewski, Rafał Kuc, Andrzej Dawidczyk „Bezpieczeństwo

Wewnętrzne. Podręcznik Akademicki". In addition to scientific studies, the analysis also included a document prepared by Eurostat called *"Crime statistics"*.

Threats to internal safety and security

The above mentioned studies (representatives of American centres) refer to the tragic event in 2001 related to the terrorist attack on public and strategic facilities in the United States of America and to the natural disaster state caused by Hurricane Katrina in 2005. Terrorist attacks continue to have a high probability to be carried out in Europe, the United States of America and other places which are linked to counter-terrorism activities against major terrorist organisations. Equally high risk is posed by events related to the occurrence of natural forces, which recently affected Australia - bushfires, (Karnaszewski, 2020), USA - forest fires (Gersz, 2017), Bahamas - Hurricane Dorian (Rogacin, 2019), Mozambique, Zimbabwe, Malawi - Cyclone Idai (Goldin, 2019), storm in the Tatra Mountains - Poland (Krzywda, Mateusiak, 2019), and also forest fires in Greece (Krzymińska, 2019). Both terrorist attacks and disaster response and recovery events are activities that fit into a crisis management scheme that falls within the area of a common safety and security. Crisis actions are also taken as a result of erroneous or intentional human activity. Examples of such events include the failure of the BP oil rig in 2010 in the Gulf of Mexico (Przybylski, 2017) or the crack of the sewer collector under the Vistula River in 2019 (Chełmiński, 2019).

As already mentioned above, the threat of terrorist attacks is still a current challenge for the state administration obliged to ensure safety and security, but in addition to this phenomenon (the central phenomenon, in the opinion of many researchers), many other activities undermining the internal safety and security of the State are spreading. Reacting to terrorist threats and disasters is part of the crisis response, qualified as undertakings for general safety and security. Internal safety and security, in addition to the indicated general safety and security, includes the areas of public and constitutional safety and security. At present, it seems that these two issues do not give rise to a comprehensive discourse on threats to the internal safety and security of the State. When building a responsible internal safety and security strategy, one should not succumb to stereotypes and imposed leading trends; on the contrary, reliable analyses should be carried out to show the actual threats that result in:

- ✓ the economic situation of the Country,
- ✓ unemployment,
- ✓ social sentiments and tensions,
- ✓ he hostile influence of other states and countries,
- ✓ frequent staff changes in the institutions responsible for safety and security,
- ✓ enacting legal acts that are unclear and contrary to the Constitution,
- ✓ failing to react to reported social problems,
- ✓ the lack of public support for initiatives by executive authorities,
- ✓ the distortion of democratic values expressed by the power triangle,
- ✓ malfunctioning system for disclosing and prosecuting perpetrators of criminal, drug-related crimes and organised crime, including cross-border crime.

These points do not constitute a closed catalogue of causes which may directly or indirectly affect the emergence of threats, but are only an indication of the need for constant monitoring of areas where behaviours directed against the health, life and property of citizens may occur, as well as against the economic interests of the State and the credibility of the legislative, judicial and executive powers. By analysing the information on the Europol website, it is possible to identify the main areas of criminal activity that affect the state of internal safety and security of the State, such as, among others:

- ✓ trafficking in people and trading in human slaves,
- ✓ illegal immigration,
- ✓ terrorism,
- ✓ trading and trafficking in narcotics,
- ✓ cyber-crime,
- ✓ sexual abuse of children,
- ✓ the counterfeiting of money and means of payment,

- ✓ economic crime,
- ✓ trading and trafficking in arms,
- ✓ crimes against the environment,
- ✓ organised crime - criminal/narcotics/economic crime
- ✓ corruption, bribery,
- ✓ illegal trade in works of the arts,
- ✓ xenophobia and racism (Europol, 2020).

Ensuring internal safety and security resulting from the need to respond to the threats identified in the above points is confirmed by Interpol's areas of interest. The official website of this institution highlights risks related to: corruption, counterfeiting of means of payment, crime against children, crimes against national heritage, cybercrime, drug trafficking, environmental crime, financial crime, trafficking in firearms, trafficking in people, trafficking in counterfeit goods, organised crime, terrorism, car theft and also crimes against the population and war crimes (Interpol, 2020). Another institution that illustrates the sources of threats to the State's internal safety and security is the Federal Bureau of Investigation (FBI), which lists terrorism, espionage, cybercrime, corruption, crimes against civil liberties and rights, organised crime, economic crime (white collar crime), violent crimes against health and life, and crimes related to the production and trafficking of weapons of mass destruction (FBI, 2020) in its catalogue of behaviours that have a negative impact on safety and security. The areas of threat to the internal safety and security of the State, as identified by the three major organisations involved in identifying and combating crime, seem to coincide. In addition to terrorism, there are crimes directed against both citizens and the economic interests of the state. Crimes (corruption, espionage) are also indicated, which affect the shaking of democratic foundations of nation states.

In an attempt to identify the sources of threats to the State safety and security as accurately as possible, the author referred to the analysis of the Eurostat report entitled “Crime statistics”, which provides a quantitative summary of criminal acts committed in European countries in the years 2008-2017. Between 2012 and 2017 according to information provided by the police the robberies committed in the EU fell by 30.3% to around 317,000 in 2017. A significant increase in this type of offences occurred in the years 2008-2012. In 2016–2017, on the other hand, the total number of robberies in the EU decreased by 22,000, only Ireland, Cyprus, Romania, Slovenia and Sweden recorded some increase (a total increase of 266 assaults). An analysis of assaults registered by the police in relation to the population (number of crimes per 100,000 inhabitants) shows that in 2017 the highest indexes were recorded in Belgium (167), France (150), Spain (144) and Portugal (115). The lowest results were diagnosed in Romania (16), Estonia and the Czech Republic (15), Cyprus (14), Slovenia (12), Slovakia and Hungary (9). In the United Kingdom this index was the highest in England and Wales (132). Of the EFTA countries, Switzerland had the highest index - 21 assaults. The report also indicates data on the homicide crime. In 2017, the police in the European Union recorded around 4,300 homicides (excluding data for the Netherlands), which is the 22% decrease compared to 2008. Statistics indicating the number of homicides per 100,000 inhabitants show that in 2017 the highest values were recorded in Latvia (5.6), Lithuania (4.0), Estonia (2.2) and Malta (2.0), and the lowest in the Czech Republic and Italy (0.6) and Luxembourg (0.3). In the EU, the number of assaults in 2017 recorded by the Police was around 589,000. The number of assaults recorded by the police varies considerably across the EU. Different rules, frequency of reporting and recording practices affect the quality of the comparison, e.g. in the same list, i.e. the categories of robbery and extortion (assaults), some countries have shown criminal acts related to intimidation, or have included completely different categories, e.g. homicides. Another category of criminal acts is theft of vehicles. In 2017, police units registered about 573,000 vehicle thefts in the European Union countries, which is 35% less than in 2008. Between 2008 and 2017 a downward trend in vehicle thefts was recorded in the European Union. However, Ireland, Greece, Spain, Latvia, Malta and Romania saw an increase in car thefts between 2016 and 2017. Belgium, France, Luxembourg and Hungary have not reported outcomes (Eurostat, 2020).

With reference to this study, it must be assumed that criminal offences continue to constitute a serious threat to internal security of the Country. The impact of external threats that directly affect the internal safety and security of the Country, which include, in particular, espionage and soft power measures, must be added to the above-presented information. Initiating by the external aggressor the tools of information combat in the form of disinformation or reflexive management leads to destabilization of the political system of the State. An important element of the information combat is the targeted transmission of information, by using the instrumentation chosen according to conditions (society, political elite). The lack of a proper reaction of the State to the undertakings undertaken by the aggressor may lead to destabilisation of the adopted model of the State functioning, both in the political, economic and social sphere.

Forecasting threats affecting safety and security of the State

The development of a model of actions aimed at combating crime and responding to events with a terrorist dimension, or actions being a result of natural disasters and technical failures, is a necessary measure to ensure the internal safety and security of the State. However, just as important as not more important are the actions preceding events that affect a state of safety and security of citizens and administrative structures of the State. To this end, it is necessary to refer to an issue somewhat overlooked in the common discourse on safety and security, which is forecasting. As Brunon Hołyst points out, forecasting is an integral part of crime prevention, but it is underestimated and unpracticed knowledge. The key objective of conducting forecasts is to obtain information on the dynamics and structure of phenomena (crimes). Three basic functions are assigned to forecasting: preparatory, activating and informative function. With regard to the time criterion, forecasting can take the form of short-term (up to 2 years), medium-term (up to 5 years) and long-term (over 10 years). Assuming that crime is an important phenomenon affecting threats to internal security, the organisation of the fight against criminal acts should be regarded as the integral part of controlling all fundamental social processes. For a proper model for fighting crime it is necessary to forecast social phenomena, including pathological ones. Criminological prognosis is understood as any statement made about the future characteristics of criminal phenomena, built on the basis of the conducted observation, description of the phenomena and laws that specify the relationship between successive phenomena (Holyst, 2017).

When using the instruments used for criminological forecasting, it is also necessary (when choosing the right methodology, e.g. in the form of expert opinions, reflections or analogies) to strive for comprehensive forecasting of threats relevant to the internal safety and security of the State. By maintaining the division of the State's internal safety and security into public, general and constitutional safety and security, it is possible to develop the research frameworks for each of these categories to accurately predict future events. For understandable reasons, future criminal behaviour will be examined differently from spying behaviours or behaviours targeting the decision-making structures of the State.

Conclusions

A key aspect for building a strategy to ensure the retention of the internal safety and security of the State is to identify threats in this area. Stereotypic understanding of threats narrows cognitive horizons that become incomplete and do not provide decision-makers with accurate information about threats. Currently, terrorist threats are presented as the most serious source of social unrest. Other criminal activities, such as the financing of terrorism, money laundering, immigrants, cross-border crime and organised crime, are therefore attributed to this phenomenon. Many European countries have not been affected by a direct terrorist attack, or have been affected only once, and yet it is this type of threat that is given priority. The author of this article understands the seriousness of the events resulting from the terrorist attack and appreciates the initiatives to build and strengthen the already existing anti-terrorist system, but would like to draw attention to the need to rebuild the perception of today's threats. The proposed approach does not reject the issue of terrorism, on the contrary, it focuses on the further approach to monitor (forecast) the risks associated with it. This system must apply equally to criminal and economic crime and to crimes that harm the vital interests of the State. Actions directed against the State Treasury or corruption-like actions are certainly not as expressive as terrorism, but they certainly have a equal if not bigger destructive impact on the

condition of society and state structures. Citizens of the States do not want to be victims of thefts, robberies, or do not want to see one of their loved ones become victims of trafficking in people and want to have freedom of development. However, these objectives will not be achieved if the threats of this type of crime are marginalised. An additional problem in responding properly to a security threat is that decision-making centres suspend, do not publish or do not produce reports containing the actual scale of the problem. None of the political elites in power will be in favour of the full and timely reporting of data that could affect, for example, the election or support for the government. Threats to the State's internal safety and security continue to change and take on new, hitherto unknown forms, such as pandemics, and therefore ongoing monitoring and forecasting of future events in an objective light seems to be a necessary measure to ensure the State's internal safety and security.

Abstract

The present study through the analysis of the telecommunications field in Portugal, aims to demystify the strategies that are being used, in a technological era, to achieve organizational goals regarding employee satisfaction and, by other side, employee turnover. Human Resources Management covering its origin, its dominant perspectives, the evolution of the concept and its dimensions and emphasis is given to the actions and activities of Internal Marketing suggested by the literature, as well as the tools used for an effective practical implementation of this, within the organizations and also how this area of studies is so related with HRM. In terms of methodology, the manuscript presents a qualitative approach using direct observation, a focus froup and structured and semi-structured interviews within Portuguese companies and focus group. Three semi-structured and 2 structured interviews were conducted in February 2019, individually, to the Human Resources Administration and focus group with employees. For the analysis of both the interviews and the focus group, it was used the technique of content analysis of Bardin. Job satisfaction is the answer for the decreasing of turnover, increasing of retention and the management of IM which, not only translates into higher sales and loyal consumers, but also means less costs with workers by boosted performance. As key persons in organizations who are responsible for a capable workforce, HR managers must have full and real-time information to measure, predict, and manage workforce change and development. The adoption of IT by HRM is important for growth as organizations face quick changing environments. More specifically, the systems of IT adopted by HRM contain HR Information System, HRM System, e-HRM, and so on.

Keywords: Electronic Human Resources Management, Internal Marketing, New Technologies, Retention, Turnover

Introduction

The business world itself demands constant adaptation to changes in our society, specially in the current global context characterized by a dynamic, competitive, innovative and volatile environment. For this reason, it is necessary for the concept of change to be sharp within organizations. Organizations should respond proactively to being able to keep up with the fast changes today's society is under. Organizations are becoming more aware of this reality, are looking for new ways to offer competitive advantages to their stakeholders (Guimaraes e Borges, 2009a). As such, consolidated capital and organizational structures are no longer enough elements for the success and maintenance of the business and, in order to cope with these growing environmental demands, it is urgent for organizations

to develop strategies. In this way we can point out that a business strategy can be defined as the direction or scope of a company in the long term, aiming to achieve some kind of competitive advantage, through the configuration of its resources and activities, in a changing environmental context, meeting the needs of the large stakeholders (Grant, 2010). The present study aims to verify, through the analysis of the telecommunications field, to demystify the strategies that are being used, in a technological era, to achieve organizational goals. Given the quick changes in technology in the past decades, technology proven to have a significative impact on Human Resources Management, and it is likely to move the field in some new directions in the future. The world has experienced cultural, societal and economic changes based on the increasing domination of digital technologies (Ferreira & Sousa, 2020), which have led to the current period called the digital age or digital era (Malheiro et al., 2019; Sousa et al. 2020). Digital technologies play an increasingly flagrant role in both the lives of employees and Human Resources Management, which seems to be affected in multiple ways (Prensky, 2001). This special issue focuses on the impact of these changes on Human Resources Management, in relation to changes to the workforce, to Human Resources Management in general and more specifically to the use of technology in delivering HRM activities. Along with the technological transformations and advancement of the Internet has emerged a concept that is called e-HRM (electronic Human Resources Management) which uses information technology in two ways: Firstly, technology is necessary to connect people who are usually segregated in different spaces and it allows interactions between them, in this way technology is serving as a medium with the aim of connection and integration; Secondly, technology supports all people involved completely, replacing them in the execution of HR activities.

Sales field is undeniably challenging for the Human Resources Management. Adjacent to the persistent hiring of people by these companies, it is a reality where the search for a job and the difficulty in getting it, has caused several people to look for alternatives, most of the times to choose a job they do not desired. In this field, companies have several places with immediate entry, however companies are willing to invest in the new employees but, by the opposite, employees do not believe in the organization, resulting in a huge challenge for the Human Resources Management and Internal Marketing. The retention of employees in this area is something that companies are struggling with, so it is necessary to plan and implement a successful and sustainable strategy in the short and long term. In fact, without a good and well-functioning internal relationship, external customer relationships will not develop successfully. It is necessary to manage employees - on all levels - internal relationship (Gummesson, 2011). Further on this study, it would be possible to establish the determinants of job turnover, the strategies developed for employee retention, and the Internal Marketing practices such as communication, empowerment and Job embeddedness which highly influences whether an employee intends to continue with the current job or not (Holtom et al., 2006). This study appears to be extremely important because, despite of the fact that more than thirty years of literature on the subject, in the current context, the application of Internal Marketing in companies remains scarce and little in complexity (Conceição, 2012; Van Maanen & Schein, 1977). However, the growing concern of organizations to engage their employees in business is notorious, even being understood as key elements for organizational success. Human beings are seen as the DNA of companies, they are unique resources and difficult to replicate, and may even constitute an aspect of competitive advantage (Grant, 2010). Given this view, it is currently verified that the employees are encouraged to participate in the direction of the companies, giving suggestions for the improvement of the work processes. Thus, the presented study is to analyse an average size company, whose main activity is the provision of services in the area of telecommunications, where everyone is asked to know the company and to "sell" their service. The manuscript structure is divided into Human Resources Management, Internal Marketing, Methodology, Context, Analysis/Discussions of the Results and General Reflections/Conclusion.

Human Resources Management

The term Human Resources (HRM) has developed over time among other terms and meanings such as: human capital, workers, personnel, staff, etc. In this ontext, Padoveze (2000) describes human capital as the set of skills, knowledge and individual experiences of an organization's employees to perform certain tasks. Therefore, Human Resources Management Capability (HRMC) is a very important business' capability. Skills and knowledge of human resources can be hard for competitors to imitate, these are unique and exclusive, not like machines and other assets that can be acquired in

the market by any competitor. In fact, this is one of the assumptions of the VRIN framework (valuable, rare, inimitable and non-replaceable) a set of resources capable to support achievement of sustainable competitive advantage (Barney, 1991) . Later on, the author adapted the VRIN framework into the VRINO framework with the 'O' (organisation) denoting if a firm is "organized to exploit the full competitive potential of its resources and capabilities" (Barney, 1991, p. 56). This new paradigm of competition, management acknowledged the importance of people and gradually take the conscience that the competitive advantage depends, in the most part, of the qualified people, the capacity of developing them inside the company and making them th key for competitive advantage. Like Ulrich (1998) observed, the main traditional competitive aspects can be sooner or latter copied – cost, technology, distribution, production, etc – however, it remains people, the key-factors. The literature reveals that, although it was not well received, the designation of Human Resource Management quickly established itself in contrast to traditional personnel management practices (Cunha et al., 2010). That is, the function of HR detached itself from its traditional connotation to fit strategically in the business strategy, which is recurrent to use nowadays different terms to define the HRM activity in an organization, such as: Human Resource Management, Personnel Management. The HR function are often confused as being synonymous with each other, without any distinction being made at the level of their content, however the following definition indicates the essence of what HRM really is: "HRM is a distinctive approach to employment management which seeks to achieve competitive advantage through the strategic deployment and a highly committed and capable workforce using an array of cultural, structural and personnel techniques" (Storey, 2007, p. 4).

As management area, the Human Resources function arises as a response to organizational needs. Being an activity, it is transversal to the whole organization, that is, everyone practices it, and requires professionals specialized in HRM as a specialized activity (Fernandes, 2012). Thus, HRM is a set of knowledge, and at the same time, an activity too, while knowledge is something heterogeneous that intents to achieve results, influencing people's behaviour and attitudes through a defined management system. In order to do this, it has a management system tailored to the needs of the organization that will influence employees' behaviours and attitudes (Neves & Gonçalves, 2009; Ribeiro & Gomes, 2016; Bloom & Van Reenen, 2011). Regardless Guest, Paauwe and Wright (2012) states that it is not possible to assert that a good HRM has an impact on organization performance. Therefore, one of the purposes of HRM is to recruit people who are capable, flexible and committed to the organization, and for this it is necessary to reward the performance and development of key competences. Today, HRM's role is far more comprehensive than simply looking after its employees. Thus, HRM has a strategic area for the organization, in that it does not limit its intervention only when problems arise, thus assuming management functions such as planning, monitoring and control. Given this, it is perceived that the effectiveness of HR functions has a significant impact not only on top managers but also on all workers in the organization (Chimoga, 2014). In the concept of HRM, people are no longer seen as a cost to be considered as an investment, that is, one of the most competitive assets. Thus, knowledge and skills must be expanded so that the organization produces value in individual, organizational and social terms (Neves & Gonçalves, 2009). Soft and Hard Models of HRM are the two of the most widely adopted models of HRM are the hard and soft versions. McGregor (1960), created and developed in the 1960s models about the Motivational theories X, Y and these are based on opposing views of human nature and managerial control strategies. The hard model – theory X - is based on notions of tight strategic control, saying that the average workforce is more efficient under strict supervision and authoritarian approach. In here managers believe their employees are less intelligent than the managers are, lazier than the managers are, or work only the necessary; While, for other side, there is the soft model is based on control through commitment and according to this model - Theory Y – work is as natural as play or rest, people are not inherently lazy, they have become that way as a result of experience. People will exercise self-direction and self-control in the service of the objectives to which they are committed. People have potential and under proper condition they learn to accept and seek responsibility (Barrick et al., 2015).

Therefore, it is possible to sustain that Human Resources Management is constantly evolving, thus posing a challenge for Human Resources managers in the way they plan their strategies for the management of their workers (Chimoga, 2014), in general. Thus, the organizational approaches of the last decades have emphasized that the effective management of the human resources of an organization

can be a fundamental determinant for the improvement of organizational performance and to achieve a sustainable competitive advantage (Caetano & Tavares, 2000; Lo et al., 2015). The world has experienced a cultural, societal and economical changes based on the increasing dominance of digital technologies. In sum, these changes have led to the current period called the "digital age" or "digital era". Digital technologies play an increasingly flagrant role in both the lives of employees and HRM, which seems to be affected in multiple ways. This special issue focuses on the impact of these changes on HRM, in relation to changes to the workforce, to HRM in general and more specifically to the use of technology in delivering HRM activities.

New technologies have created a new generation of employees and the organizational structure has changed. The changes are organized in a way that today the absence of organization on the www (World Wide Web), means the loss of huge capital resources. Nowadays the business faces many challenges such as globalization, the value chain for competitiveness and technological changes, specially, three focal areas labelled as digital employees, digital work and digital employee management. The concept of "digital employees", a first major area, has various terms such as "digital natives" Prensky (2001), "millennials" (Deal, Altman, & Rogelberg, 2010) or "net generation" (Tapscott & Barry, 2009), it is assumed that the early interaction with digital technologies has shaped a new generation of people with distinctively different attitudes, qualifications, behaviours, multitasking capabilities, expectations and learning by doing and preference of instant gratifications and frequent rewards (Prensky 2001).

Internal Marketing

The origins of Internal Marketing started in the seventies, when it was recognized the importance to attend the needs of the employees so that they could be able to offer quality services, in order to satisfy their clients. (Berry, Hensel, & Burke, 1976) argued that Internal Marketing could be applied to change organizational capacity and not only service delivery, at the same time that the internal communication to be promoted would allow understanding the difficulties in customer service, developing the potential of employees in the execution of a superior service (Vilas-Boas & Sousa, 2019). In this way, Internal Marketing was a solution for companies to offer an exception service. According to these authors, activities such as disseminating the decisions made, obtaining frequent feedback, training and rewarding employees who serve clients with excellence, fulfil the objective of Internal Marketing. Sharing the same view, (Sasser & Arbeit, 1976) argued that organizations should understand their employees as their first market. In this relational perspective, Internal Marketing meant that managers and the other members of the organization were essentially partners, treating the organization as their employees' clients and, therefore, they could perceive their clients more clearly in the service' delivery. In this sense, it is definitively important to mention the value of the Nordic School, which made a very important contribution in the study of Internal Marketing. The origins of this School go back to the early seventies, through the investigations of Christian Grönroos and Evert Gummesson (2000). It is a School of Marketing, where a way of thinking has developed through service marketing research in Scandinavia and Finland, thus gaining international knowledge. In the 1990s, was developed within a framework of a relational marketing thinking school (Grönroos, 2000). It should be noted that it was the Nordic School researchers who emphasized the nature of the relationship and the long-term in-service marketing, creating terms such as "buyer-seller interactions"; "Customer relationship lifecycle" (Gummesson, 2000); "Internal marketing" and "part-time marketers" (Gummesson, 2000). This author emphasizes the importance that these employees have in relation with the clients, since these influences the relations with the clients without belonging to the department of marketing or sales. Given the complexity of the concept, several definitions have been developed, and so far there is no consensual definition (Ahmed & Rafiq, 2003). In fact, this area still needs studies to consolidate its importance as an academic discipline and organizational management philosophy, which is why its practical application is not yet spread in all companies. The definitions found in the bibliography are varied and can be grouped into four dominant perspectives: 1) As a synonym of Human Resource Management; 2) As a use of marketing techniques in the internal market; 3) As a precondition for satisfied external customers; 4) As a way to achieve competitive advantages.

Some academics understand Internal Marketing as synonymous with Human Resource Management (Lewis & Varey, 2012). In this context, (Kotler & Armstrong, 2003) considered Internal Marketing to be "the task of hiring, training and motivating competent employees who want to serve customers well". This author emphasized the importance of Human Resources and reinforced this idea when he suggested that “employees are the company itself. Can build or destroy marketing plans" (Kotler & Armstrong, 2003). Another author who shares this view is (Varey & Lewis, 2000), who emphasizes that "Internal Marketing is the permanent training of service providers in order to improve the knowledge of their services and their capacities, making them aware of the opportunities and the marketing skills" (Varey & Lewis, 2000). The author justifies his opinion, arguing that there is a need to establish a close integration between different functional areas. It considers that the application of Internal Marketing can achieve this interdepartmental integration, which can align efforts around common goals. However, this approach is somewhat limited, as it does not reflect customer orientation, nor does it contemplate strategic marketing management. Furthermore, all successful management programs require commitment from top management and employees (Cascio, Mariadoss, & Mouri, 2010; Heskett, Jones, Loveman, Sasser, & Schlesinger, 2008; Kilburn, 2009; Kim, Tavitiyaman, & Kim, 2009; Robert & Cheung, 2010), and internal marketing is no exception. Kilburn (2009) argued that top management commitment is the most important factor that affects the effectiveness of internal marketing in the manufacturing environment.

In studying the implementation of internal marketing, service environment and supportive management affect the attitudes and behaviours of service employees (Sousa & Rocha, 2019). Shanock and Eisenberger (2006) showed that supervisors would influence employee perceptions and performance significantly due to their proximity to employees. Cascio et al. (2010), on the other hand, reported that frontline employees perceive top management commitment as having a greater effect on employee work behaviours than the influence of their direct supervisors. Cascio et al. (2010) also suggested that organizations should employ internal marketing to convince employees that top management is committed to enhancing employee satisfaction, empowerment, and service quality. In the social-exchange theory, Cropanzano and Mitchell (2005) reported that employees who recognize top management commitment to their staff, will give a positive return with better work attitude as expected.

Methodology and contextualization

The choice of a methodological research depends on the assumptions underlying the problem, and aims to achieve the objectives set for the study (Yin, 2005). In this way it is presented as a general objective, to verify the role of the New Technologies in the Human Resources Management, through the analysis of the telecommunications field, demystify the strategies that are being used, in a technological era, to achieve organizational goals. As specific objectives, the study intends to achieve the following: Present the advantages and disadvantages for organizations in the use of new technologies in HRM practices; Identify the influence of new technologies on HRM practices; Understand how new technologies strengthen the human resources management system; Realizing the consistency of HRM practices influences retention of employees; Understanding consistency in evaluations of human resource practices influences job satisfaction; Identify whether new technologies reduce turnover; Detect if the perception of relational justice influences the intentions of turnover; Understand the linkage of internal marketing theories simultaneously with HRM practices in the context of telecommunications.

Currently, in the Portuguese Telecommunication market exists several different operators. It makes sense to say that the market is diverse and reaches the needs of the different targets. There are two types of telecommunications operators operating in Portugal: mobile operators with their own network and virtual mobile operators. The difference between them is that Mobile operators with their own network have their own telecommunications network; and Virtual mobile operators use the network of one of the Mobile operators with their own network. The liberalization of fixed and mobile networks and the entry into the Portuguese market of new telecommunications operators increased competition, improved quality and reduced prices. The innovative spirit in national telecommunications was affirmed during the second half of the 1990s, through mobile phones, with the development of unique products (such as prepaid service), or the launch of new operators through various marketing initiatives times awarded internationally. According to Sampaio (2004), the mobile telecommunications market

in Portugal had an unusual history, since it began in the year of 1992 with the launch of two GSM technology operators: TMN (PT) and Telecel (now named Vodafone). For some years, through high investments in marketing, these two companies, in addition to competing with each other, stimulated market growth, striving to acquire new customers to always increase their consumption base, and in this way, the market grew day after day. In 1997, Portugal ranked 4th in the mobile penetration ranking and one year later, in 1998, Optimus entered the market, which already had 6 years of activity, with 15% of the population using its services. In 2014, two big events happen in the Portuguese telecommunication market. With the acquisition of Portugal Telecom by Grupo Altice and the new brand NOS launched by ZON Optimus, after combining the biggest fix broad band players and the major mobile telecommunication operator in Portuguese telecommunication market, NOS became the major player to provide integrated telecommunication services to customers. During the recent years, the telecommunications sector in Portugal has undergone deep changes, particularly with the emergence of new capabilities and innovative services by telecom operators, as the case of double-play, triple-play or quadruple-play bundles. These offers try to position themselves as distinctive and competitive, especially in the constant creation of new applications and features associated with each service. To summarise, Portuguese Telecommunications Companies use outsourcing in order to spread and wise their market across the country so, outsourcing companies can work for/with their brand (company). The next chapter will be focused on the data analysis of the data collection from an anonymous Telecommunication's Outsourcing Company.

Preliminary conclusions and future research

Given the results presented, it is possible to respond to the problem of this work, because it is perceived that companies are striving to modify their HR areas on most issues that indicate changes in a strategic role. In the literature review, it was reported the phases of management and the evolution attributed to HRM over time. Along with the phases of the management, it was observed that HR policies and operational area also progressing, which continue providing adaptations to the best strategic decisions in front of the organizational challenges. On the Internal Marketing side, it was explained how much IM is linked to HRM and what strategies have been used in his favour. In order to meet the general goal of this work, the information and results obtained from the research were used to identify and describe the fact that, commercial companies appear to have strategic initiatives for employee involvement, human capital as obtaining for competitive advantage and intellectual's management, indicating a concern from this companies to continuously improve their HRMP, given the prominence that this area has for the competitive advantage and position in the market for the companies. With all this, the main goal is to increase employee's retention. However, the researcher treated data that still applies until now. The researcher interviewed former colleagues knowing already the business, due to previous work experience, that sometimes may affect the transparency and clearness. It was interesting to listen the answers to the different subjects, and surprisingly match or disrupt the ideas pre-made. It is suggested that future research should seek to not only understand employee characteristics in relation to organisational change efforts in further detail, for example the extrinsic and intrinsic motivators, but also seek to place these in terms of organisational and geographic cultural context sector in other fields besides Telecommunications. The researcher emphasis the extreme importance of this study complemented with: Internet of Things and Human Resources Management; 4.0 Industry; 5.0 Industry.

Abstract

Currently, farms face the challenges of contemporary agriculture, natural environment, and agribusiness. Conducting activities as part of the common sectoral policy which cater for diverse needs requires policy makers to develop advanced tools aimed at monitoring the implementation of scheduled results. In addition, farmers should apply effective management based on advanced decision-making tools and with the sectoral policy priorities factored in. The unfolding advancement of the digital economy creates an opportunity of using the so far unavailable data resources and cutting-edge data processing technologies to increase the analysis and assessment of the effectiveness of existing policies in the field of agriculture, environmental protection and mitigation of climate. The purpose of this article is to analyze and evaluate the usefulness of national and regional databases in agricultural and environmental management against the objectives and priorities of the CAP.

Keywords: Agriculture, Environment, Policies, Data Bases, Management

Introduction

What we are currently observing is the emergence of a new type of economy – digital economy, conditioned by the growing use of digital technologies. These processes are now becoming universal and global in nature. Societies, economy, and politics are now subject to digital transformation. The increasingly common processes of forming digital representations of each and every area of the real world and of deriving value from the information thus obtained (datafication) mean that governments are gaining access to more and more data on citizens as well as on political, economic, and social conditions and phenomena (Śledziewska, Włoch 2020). Such data make it possible for politicians to influence decisions made by entrepreneurs and to plan and implement their political priorities in terms of public policies such as environmental protection, mitigation of climate change, and the provision of healthy and safe food. The creation and use of data resources used by governments is a crucial driver behind the development of innovation and science. Owing to these phenomena, it has become possible to introduce new solutions associated with e.g. planning, measuring the effectiveness of, and monitoring laws and policies based on the so far unavailable data coming from numerous sources and on new technologies and advanced data processing methods.

Development goals specified in strategic documents are usually determined by identifying measurable and verifiable key factors analyzed in the economic, social, environmental, institutional and spatial domains.

Therefore, the purpose of this article is to analyze and evaluate the usefulness of national and regional databases in agricultural and environmental management against the objectives and priorities of the Common Agricultural Policy (CAP).

Evaluation of the effectiveness of the CAP in the light of environmental protection and socio-economic factors

Development, intensification, and industrialization of agriculture are key forces of biodiversity and ecosystem services loss (Diaz et al., 2019) as well as climate change (IPCC, 2019). Historically, some agricultural practices have supported biodiversity and multiple ecosystem services. Yet such practices have been increasingly abandoned or replaced by intensive farming systems which maximize yields through the unsustainable use of natural resources and at the expense of biodiversity and ecosystem services (Stoate et al., 2009). Such processes are determined by socioeconomic and technological factors but also supported by public policies. The European Union's (EU) Common Agricultural Policy shapes the EU's agricultural sector (Hodge, Hauck, and Bonn, 2015) and supports a variety of practices contributing to wide-scale biodiversity loss (Pe'er et al., 2014; Gregory et al., 2019; Pe'er et al., 2019; Van Swaay et al., 2019), climate change (Alliance Environment, 2019), soil erosion (Orgiazzi et al., 2016; Hamidov A et al., 2018; IPBES, 2018). CAP programs which could oppose these developments are not enough and/or underfunded (Alliance Environment, 2019; Pe'er et al., 2019). Furthermore, the current CAP is ineffective and inefficient in addressing the social and economic challenges (ECA, 38 2016; Pe'er et al., 2017a). The CAP has undergone several reforms, partly aiming to enhance its environmental and social performance. Some positive outcomes have been described (Batáry et al., 40 2015; Walker et al., 2018), yet effective measures are still required to reverse negative trends (e.g. Pe'er et al., 2017b) – indicating the need for a much more fundamental change to the CAP in order to deliver on prevailing environmental and socioeconomic challenges (Bojar, Sikora, Dzieża, 2017). The CAP post-2020, as proposed by the European Commission in June 2018 (EC, 2018), acknowledges the need to address environmental and sustainability challenges and introduces a new Green Architecture and a delivery model that offers Member States (MSs) higher flexibility as to how they implement the CAP. It seems that donators of CAP funds should pay closer attention to the role of effective use of knowledge centers, enabling synergic effects to be obtained from cooperation between multiple research centers in the EU and across the world through merging the findings from different projects (Bojar, 2018). It is also worth noting, however, that there are often contradictions between the ecologic and production goals of agriculture, and they often determine the inefficiency of funds allocated to supporting sustainable development. Moreover, it seems that cultural, mental, and economic differences between farms in different EU member states require a differentiated approach to the tools used to shape farmers' attitudes and decisions. It requires more decentralized policies distributing funds directly to agent-based models of farms that allow consideration of all the specific conditions of a given entity.

One such key solution within the new concept for CAP can be relevant models and software applications based on the newest achievements of IT, (cloud computing, machine learning, etc.), to set, verify, gather, process, and retrieve frittered away and heterogenic data arising from different domestic and regional data bases.

Criteria of Analysis of The Data Bases Useful for Environmental Protection Management of Rural Areas from A Perspective of The Concept of a Systemic Model of Contemporary Sustainable Agriculture

Currently, farms face the challenges of contemporary agriculture, natural environment, and agribusiness. Sustaining market agriculture alongside agribusiness and eco-services in a model of balanced growth requires integrating such objectives as requirements of food consumers (cheap food goods, enough quantity, quality, healthy, safety), profitability of market farming guaranteeing the welfare of farm families and societies from surrounding agriculture (efficiency of production factors usage), appropriate natural environment protection, and revitalization of rural areas. The concept of a model farm for inducing growth (fig. 1) shows crucial determinants of contemporary challenges in agriculture-integrated economic, social, and environmental goals guaranteeing sustainable development.

Fig. 1: Determinants of contemporary challenges of agriculture within model of inducing growth

Source: own study

In this context, the Common Agricultural Policy (CAP) seems to be an especially important tool for shaping the behavior and decision-making of farmers in the most sound way to better enable them to face the contemporary challenges of agriculture.

The theory of the evolutionary changes of a farm can also help to explain the mechanisms shaping this adjustment process running in agricultural enterprises (fig. 2).

Fig. 2: Mechanisms shaping evolutionary changes in farms

Source: own study

Public data sources and datasets classification and characterization

The impact assessment of CAP policies is mainly reliant on the Farm Accountancy Data Network (FADN) and the Farm Structure Survey (FSS) databases. FADN is an annual farm survey that gathers detailed EU-wide accounting data from a sample of agricultural holdings. FSS provides harmonized data on the structure of agricultural holdings regarding land use and livestock, farm laborers, machinery and equipment as well as participation in rural development programs.

The basic unit of the FSS is the agricultural holding and a complete agricultural census is updated over long periods (with intermediate sample surveys). Despite the fact that information present in the FADN and FSS has allowed the impact analysis of previous CAP versions, in the digital era, it seems appropriate to use larger data sets, especially for the assessment of recent and more targeted policies.
At the national level, many public institutions collect and provide datasets that could complete the information provided by the FADN and FSS for policymakers and researchers. Selected public institutions and examples of data sources useful in this area are presented in Figure 3

Fig. 3: Polish public institutions and examples of data sources

Source: own study

Table 1 presents the results of the classification of publicly available data sources in terms of socio-economic and environmental areas (table 1).

Table 1: Classification of domestic data sources in terms of socio-economic and environmental areas

Producer	Name of data source	Type of data source / category
Agency for Restructuring and Modernisation of Agriculture (ARiMR)	RDP 2014-20 (PL) Implementation reports	Database / Socioeconomic (Policy)
Statistics Poland	Agricultural and horticultural crops	Database / Socioeconomic
Statistics Poland	Local Data Bank	Database / Socioeconomic and environmental

Table 2 presents the content and classification of datasets available in the agriculture category in the Polish database – Strateg.

Table 2: Agriculture category datasets classification of the Strategy database

Strateg database (producer: Statistics Poland), agriculture category content:	**Type of datasets**
Agricultural land area in good agricultural condition	Environmental
Agricultural land area per 1 tractor (in ha)	Socioeconomic
Area of forest burned	Socioeconomic
Average area of agricultural land in agricultural holding	Socioeconomic
Consumption of mineral fertilizers in terms of pure ingredient per 1 ha of agricultural land	Environmental
Ecological areas in thous. ha	Socioeconomic
Exports of agricultural-foodstuff goods per capita	Socioeconomic
Forest cover	Environmental
Forest renewals and afforestation	Environmental
Gross agricultural output per 1 ha of agricultural land	Socioeconomic
Households in rural areas with access to connection with a download speed of at least 100 Mbps	Socioeconomic
Index of implementation of National Program of Forested Areas Increase	Environmental
Index of prices relations ("price gap") of sold agricultural products to goods and services purchased	Socioeconomic
Indices of agricultural output prices (previous year=100)	Socioeconomic
Indices of gross crop output (previous year = 100)	Socioeconomic
Number of agricultural holdings	Socioeconomic
Number of agricultural holdings engaged in activities other than farming directly related to the farm	Socioeconomic
Number of certified organic farms	Socioeconomic
Number of full-time employees in individual farming per 100 ha of agricultural land	Socioeconomic
Number of organic farms (Poland=100)	Socioeconomic
Organic agricultural area under conversion in organic holdings.	Socioeconomic
Percentage of agricultural products samples of inadequate marketable quality	Socioeconomic
Share of (active) registered non-profit organisations with headquarters in rural areas in the total number of those organisations	Socioeconomic

Strateg database (producer: Statistics Poland), agriculture category content:	**Type of datasets**
Share of agricultural holdings of an agricultural land area of 100 ha and more in total number of agricultural holdings	Socioeconomic
Share of expenditure on agriculture and hunting in the state budget	Socioeconomic
Share of farms with agricultural land area from 1 to 5 ha in the total number of farms	Socioeconomic
Share of individual agricultural holdings with the land area above 1 ha managed by a person up to 40 years of age in the total number of individual agricultural holdings	Socioeconomic
Share of processed products in export of agri-food industry products	Socioeconomic
The area of certified organic agricultural land and agricultural land under conversion in organic holdings	Socioeconomic
The area of certified organic agricultural land in organic farms	Environmental

Table 3 contains an exhaustive description of the selected national database on agriculture. The metadata on data collection, database updates and database content are presented in detail. This in-depth characterization of data sources can be used in the process of improving the tools for assessing the effectiveness of the existing agri-environment-climate policy to better adjust them to the various priorities of individual policy submeasures. This is particularly important in terms of the dynamic development of the digital economy and how it is used to, for instance, shape agricultural producers' attitudes and decisions that are conducive to the implementation of current social priorities.

Table 3: Detailed characterization of the selected domestic data sources (Agricultural and horticultural crops)

Name	**Agricultural and horticultural crops**
Type of dataset	Results of the sample surveys and final estimates of agricultural and horticultural crops and statistical reports coming from farms of legal persons and organizational entities without legal personality.
Content	87 datasets, It contains detailed results of estimated output of basic agricultural crops, i.e. cereals by species, including spring and winter crops, oilseeds, potatoes, sugar beets, edible pulses, fodder crops: permanent meadows and pastures, pulses and legumes with grasses, both for fodder and for seeds, root plants and maize for green fodder and production of horticultural
Structure details	The data is structured according to different parameters: 1) by region (Voivodeship), 2) by area of crops, yields and production, 3) by forms of ownership. Crops structure: 1) Main agricultural crops production 2) Fodder crops production 3) Horticultural crops output
Format	Tables in XLSX format and publication in PDF format
Data source access	Datasets are available free of charge for downloading in the Statistics Poland website – Agriculture, Forestry Section. This data can be downloaded in: https://stat.gov.pl/en/topics/agriculture-forestry/
Anonymous	Yes

Name	Agricultural and horticultural crops
Access to specific farms	No
Producer	Statistics Poland
Last actualization	The last one was published on 30.05.2019 (2018 annual edition), archive: 2017 and 2011.
Update frequency	Annually (archive: 2017 and 2011)
Periods covered	2018, 2017, 2011
Geographic scope	Poland, regions, voivodships
Geo-referenced dataset	NUTS 2 divisions - Voivodeships

Summary

As a sector of the economy, agriculture operates in a diverse economic and socio-cultural environment. The complicated nature of agricultural sector research is emphasized by many authors, and the level of agricultural development in a given area is shaped by not only vital climatic and soil circumstances but very often by complex economic, social and cultural interrelations. Under such conditions, conducting activities as part of the common sectoral policy which cater for diverse needs requires policy makers to develop advanced tools aimed at monitoring the implementation of scheduled results. In addition, farmers should apply effective management based on advanced decision-making tools and with the CAP priorities factored in. The unfolding advancement of the digital economy creates an opportunity of using the so far unavailable data resources and cutting-edge data processing technologies to increase the analysis and assessment of the effectiveness of existing policies in the field of agriculture, environmental protection and mitigation of climate change.

Abstract

In the article there are presented and discussed theoretical concepts and contemporary theories developed in social sciences – as a methodological basis for improving the acquisition and leadership competences development in the army. A methodological platform (leadership navigator) was developed to focus the processes of shaping and developing leadership competencies.

Keywords: Social Sciences, Leadership Theory, Leadership Practice

Introduction

The practice of organizing business activity, the practice of commanding in the Army, facing the contemporary conditions shaped by technological and technological progress, but first of all the progress of the universal recognition of civilization values and human rights (as members of contemporary organizations, as members of modern communities citizens) defines completely new competences for people who play leading roles and functions in organizations, communities and in the Army. Former traditional functions and roles of managers and commanders, as well as their traditional roles and functions of leaders underwent and are still undergoing dramatic transformations. A contemporary manager (a member of a large corporation management or a new, innovative start-up), each member of a public organization management (self-government administration of the contemporary region); each commander (at every level of command), apart from very complex professional competences, must have very highly evaluated, perceived, understood and appreciated by subordinates, co-workers, leadership competences. Competences need to be based on a very high level of moral values of modern leaders, a very high level of emotional intelligence and a very high level of moral credibility. Hence the common process of discovering and creating leaders by subordinates, co-workers, leaders who, having high professional competences, have special abilities to build trust in teams of co-workers and subordinates, and to positively influence their behavior. The phenomena of striving for the members of organizations, societies, task teams to lead the leaders in situations of implementation of complex ventures despite seemingly unlimited possibilities of obtaining information and knowledge provided by modern information and cognitive technologies can be considered as the phenomena of cognition. We are entangled in many networks of various influences, in many sources of a huge amount of information, which modern people are "bombarded" with, which are huge information resources, it is difficult for us to process due to the limited abilities of organs and human functions. Hence the search for and creation by modern members of organizations of such individuals who are willing to take responsibility for the behavior of other members of the organization (teams), for their actions and decisions. Hence, not only searching for, but conscious education and development of leadership competences in all areas of human activity, including the Army.

Not only large global corporations have been created and developed as ventures invented and developed by their leaders, but above all, basically all modern innovative enterprises, build their business models and development strategies on innovations created by employee teams, led by

leaders. In this respect, it is impossible not to emphasize the special role of creators and start-up enterprises in creating and implementing successful strategies for those innovative organizations for the progress and development of modern technologies. Civilization progress, which, unfortunately, is caused significantly by technological progress, changes the roles and functions of leaders in organizations and societies. Namely, the role and organizational function of leaders go down in the hierarchy, and the functions performed by leaders in organizations are mainly resulting from the duties of leaders – projects, ventures, task group leaders and innovation teams, that are organized as part of e.g. an innovation management system in enterprises. And, what needs to be emphasized, these new leadership roles in organizations are created by the interaction, mutual impact of members of organizations discovering and creating leaders – especially talented managers and commanders. These leaders have leadership competencies, mainly the high level of emotional intelligence and integration of the declared moral values advantages actually undertaken and attitudes presented. Another challenge facing the practice of leadership today is the need for commanders – leaders of high qualifications in the area of knowledge about the use of information and cognitive technologies, including technologies based on artificial intelligence (AI). The use of these technologies for integrated real-time command in the five-dimensional military operations theater space (land, air, space, maritime and cyberspace) requires not only modern commanders of very high professional competences, but also the ability to use security systems against various forms of cyberattacks, as well as ability to verify the information received in excess is not always true and not always conveyed in just and positive intentions.

Towards Creating A New Type of Leadership, Leading in The Army

Traditionally, leadership was defined as a particular type of people management by leaders with specific attributes of professionalism, a high level of emotional intelligence, whose role in the organization is mainly limited to directing and commanding in accordance with praxeological criteria (effectiveness, efficiency, planning, control). In contrast, commanding today, in the future, is understood as a type of task teams management, organizations and communities, the essence of which is a targeted impact on the attitudes, actions of members of these teams and organizations, as well as entire societies through managers, very high competences commanders, professionalism in leadership, commanding in the conditions that are imposed by the implemented modern information and cognitive technologies, as well as through endowed with special abilities and competencies, recognized by other members of teams and organizations in the processes of mutual interactions, which interactions are created in the course of undertaken and implemented activities. The targeted influence of the leader on co-workers, subordinates is based on the unique psycho-mental abilities of mutual interaction of people in cooperating networks during the implementation of team members tasks, organizations etc. (J. Stachowicz, M. Nowicka-Skowron, 2019; J. Ledzianowski, 2020).

The functions of conduction, hereinafter, were described in the form of the required conduction style model, which was called the Wise Leader model. Leadership wisdom is built by the highest level of utilization of knowledge, creativity, but in accordance with moral values and norms, as well as with the highest possible level of emotional intelligence of the leader. Smart Commander is an outstanding professional in fulfilling his command functions, but above all a manager, project-manager, a leader who uses his professional knowledge, uses and develops it in a credible and socially responsible manner. The commander's wisdom, formed on the basis of his credibility, is manifested in building an ever higher level of trust among subordinates – which, as has been said, provides a platform for undertaking and implementing complex, risky ventures in a creative way. In the literature other models are known to describe different types of conduction styles, methods, and required competencies to perform that function. The essence of J. Adair's model is exercising leadership functions in such a way as to harmonize the three main needs that are met during leadership processes (J. Adair 2000):

- G. Yukla's model, in which there are contrasted the styles of behavior and preferred values of a transforming leader as a leader referring to positive moral values to styles of performing the function of the leader, the so-called transformative who increase the involvement of

partners regardless of whether the effects of their behavior are beneficial to them by manipulating their behavior.

- The model of sensual leadership based on less organized innovation teams and on full agreement to experiment during innovation processes (K. Krzakiewicz 2008).

Models – patterns of ways, dominant attitudes and values of shaping competences in undertaking behaviors, functions and decisions making up the success of leadership in teams, subunits and organizations characterized by the limited concept, but above all they do not answer the question of how a modern leader should behave in order for his functioning to be assessed by the subordinates and superiors as socially responsible.

Theoretical grounds for building the modern commanders leadership competences

Assumptions for building a modern leadership theory:

a) At each level of command, a high, constantly improved and developed share of leadership competences in the overall, i.e. integrated, potential of the commander's competence fulfilling the role of management, motivation of selection and shaping task teams for the implementation of specific ventures, tasks, strategic planning (formulation of departments' mission and strategy, strategic ventures) is justified.

b) The process of integrating professional competences in the application and use of modern information and cognitive technologies, strategic competences, competences, skills in organizing tasks, undertakings and leadership competences occurs during undertaking and implementing specific tasks, undertakings for a specific level of command.

c) The driving force of the integration of these different types of competencies, and above all their shaping and development for the efficient and socially responsible implementation of these tasks are the leadership competences of modern commanders. Competences shaped according to pattern of the Wise Leader (J. Ledzianowski 2020, J. Stachowicz, M. Nowicka-Skowron 2019). The higher the potential of leadership competences of commanders during command, leadership during the processes of performing specific tasks, enterprises, the higher the level of effectiveness and innovation of implemented tasks.

d) The modern leader competences potential is determined, modeled and shaped on personality attributes, knowledge, but above all on the preferred moral values (credibility) that make up the Wise Leader model. Moral values and related moral norms, as taught by R. Ingarden, define various varieties of good such as: honesty, justice, truthfulness, faithfulness to vows and evil: injustice, unfaithfulness.

e) The key features of the leadership competence shaping pattern are: a high level of command credibility integrated with large professional competences, the dynamic nature of shaping these competences during the implementation of these tasks – projects, recognition of the important role and importance of the commander's influence (impact) – leader on the behavior of subordinates – team members carrying out tasks. At the core of the leadership competency potential of leaders there are their specific abilities that are not common, but possible for shaping and developing, and the ability to shape attitudes and behaviors of subordinates. The psychology sciences provide a lot of evidence to explain the phenomena of empathy and value transfer. At this point, one should recall the work of F. Crick and J. Watson (creators of the theory of so-called mirror neurons), as well as the work of Ch. Keysers 2017 (creator of the theory of shared circuits trying to explain the phenomenon of the interaction of living entities on each other, including the transfer of value). Through shared circuits surrounding people in the structure of influences and interactions transfer emotions, values to the area of the human brain. Emotions and values, as many say and

experience teaches, are "contagious." The invisible bonds of shared circuits entwine our minds together forming the organizational structure of the system beyond the individual. In this process, mirror neutrons are mechanisms that materialize functioning, thinking, and action in an integrated, global, constantly evolving social system. Human emotions and intuition are phenomena that probably will never allow artificial intelligence to take on human abilities.

f) Leadership competences are developed in a network of mutual relations – interactions – influences of subordinates and the leader. These mutual relations constitute the role of a leader in subdivisions by building mutual relations of interpersonal trust.

g) Built relationships of trust between the commander with a high potential of leadership competences and subordinates – the implementers of specific tasks and undertakings are the driving forces in shaping and developing the innovative potential of task teams and subunits; potential capable of undertaking and using subsequent tasks – projects at an ever higher level of innovation and an ever higher level of social responsibility. P. Sztompka formulated a very wise principle of shaping and developing trust in task teams in departments, organizations and communities. In his opinion, as those teams, organizations, and various activities undertaken and implemented by them, the potential of trust in those teams, organizations, communities increases in line with the phenomena that characterize self-accelerating growth spirals (P. Sztompka 2007). Interactions and mutual influences of the commander - leader and members of the task forces, subunits, divisions shape the self-potential of these teams and subunits. Self-potential, i.e. recreation and development of the organizational culture, including the culture of innovation. Explanation of those phenomena of self-potential can be found in the works of F.J. Varel (1992), J. Stachowicz (2017), J. Tischner (1998) and N. Luchamann (1995). The works of Alber-Laszlo Barabasi (2018) known for developing a theory explaining the phenomenon of individual success as a phenomenon shaped by positive thinking, praises of the environment, community, individual, man taking specific actions, also well explain the processes of mutual interaction of team members and the positive influence of a leader on attitudes and the behavior of team members and the community. I emphasize here the impact and influence of a leader with a high level of credibility. Practice, observation of phenomena occurring in communities and organizations gives many examples of impact "toxic" leaders – unreliable leaders taking various actions to manipulate members of organizations and teams for various not always positive actions on team members, communities. Shaping and developing higher and higher levels of interpersonal trust in a group of cooperating subordinates, employees, members of local communities, e.g. the local ones, builds and develops those teams, organizations and communities as communities more and more innovative, open and capable of cooperation for the common good.

h) High leadership competences at all levels of command is the potential of more and more innovative problem solving, which is shaped by command practice in the face of challenges and threats that contemporary commanders with increasingly higher competences in using modern information and cognitive technologies, including technologies based on AI, must deal with.

i) The higher the level of leadership competence measured by the level of "distance" from the MDL pattern (distance measured by the level of emotional intelligence, credibility, level of confidence potential, efficiency and innovation of task performance), the higher the authority of the commander. The authority of the commander moves with it to the other positions held in the service and it makes easier building of trust relationships during the undertaking and implementation of various tasks, and thus consolidates this authority.

Recommendations for modern leadership practicing (navigator of modern leadership)

Shaping and developing leadership competences are processes that take place during the implementation of tasks, command projects in the network of cooperating implementers of these tasks. During the implementation of tasks and leadership projects, there are cooperation processes whose causative potential depends on the nature of social relations – mainly interpersonal trust occurring in those teams. The driving forces of this process of increasing leadership competence in the commander towards ever higher perfection measured by the MDL pattern are:

- high level of leader credibility,
- high level of professional competence (in the area of knowledge and skills in the rational use and the use of information and cognitive technologies, including AI) as well as in the area of ability to use organizational techniques and methods (innovation management, risk management, project management).

The higher the level of moral credibility of the commander, the higher the level of his professional competences, the higher the level of integrating these competences for the purposes of efficient, effective and socially responsible task performance, undertakings, the higher the level of mutual trust in the group, branch, task implementers, the higher the potential of the implementation teams tasks, the higher the level of leadership competence of the commander.

Fig .1: Shaping and development of leadership competences (leadership navigator)
Source: own elaboration

Assumptions of modern leadership theory

- Conscious, professional "discovery" of rare leadership skills, taking into account in particular the important role of axiological, emotional factors in shaping and developing leadership competences.
- Professional organization of the program for shaping and developing leadership competences in the programs of training and improving for managers, leaders and politicians.
- Including in the programs discovering and developing leadership competences the fact of mutual relations and the interaction of leaders, subordinates and colleagues.
- Recognition of the special importance of standards – authorities of people with a high level of emotional intelligence and credibility in the processes of shaping leadership skills.

- Professional consideration of the impact on the processes of leadership of modern information and cognitive technologies.

The basis of the modern leadership theory assumptions is the contemporary network theory of organization. The assumptions of that network theory of organization are:

1. Social reality is understood as a dynamic social being that happens as a network of activities of people – members of the organization – as the creators of this social being.

2. Every action, intention, idea of people affects all other actions, intentions, ideas in networks of mutual influences of influences.

3. Social reality has the features of a self-organizing system in which harmony is mainly provided by an axiological factor.

4. Changes in social reality are the effects of intentional creative processes of people, members of the organization, in particular those members of the organization who take the role and function of initiators and strategists of those changes – i.e. among others entrepreneurs, managers and leaders.

Works in that area have been undertaken for several years, among others by J. Stachowicz (2017), K. Perechuda (2007), N. Luchmann (1995) and others.

Conclusions

1. In the author's intention the constructed model of shaping and developing leadership competences should constitute a methodological platform for improving the processes of commanders training, for improving the processes of their development and competences.

2. Studies undertaken to formulate a model for shaping and developing the competences of a modern commander are a positive confirmation of the legitimacy of the work undertaken to create and develop contemporary organization theory (network theory of organization), and within it – modern leadership theory.

Abstract

The paper presents the Wise Commander - Leader model (in Polish: Mądry Dowódca - Lider – MDL) justified by modern command conditions: i.e. the pattern of preferred command systems, conduction systems, necessary competences, as well as functions and behaviors of a modern commander. The model should be a pattern for shaping and developing leadership competences in the army. The pattern of this process was also developed as a model for shaping and developing leadership competences – as a practical recommendation to reach the pattern of Wise Commander - Leader (MDL). The paper also presents, discussing the experience and achievements of a military academy in this field, shaping and developing leadership competences for the needs of the contemporary army.

Keywords: leadership, command and leadership styles, moral value systems, emotional intelligence, trust

Introduction

The last dozen of years has been a period of radical transformation of the mission and vision of the contemporary army. More about the review of the literature on military leadership and research opportunities for scientists in the field of leadership can be found in the article: 'Military leadership: A context specific review' (L. Wong, P. Bliese, D. McGurk, 2003). This is not only ensuring security against contemporary, new threats, generated by dynamically developed new information and cognitive technologies, but, what is important, contemporary mission the army fulfills in the conditions of necessary, continuous cooperation and trust based on cooperation. The cooperation is based on collaboration of institutions and organizations with the local, as well as the regional community, etc. Challenges defining the special role of high competence and leadership skills commanders in contemporary armies are:

1. The dynamic development of complex military ventures in a qualitatively new reality, which is cyberspace, in which new information and cognitive technologies dominate.

2. The complexity of tasks undertaken at all levels of command requiring an innovative high level of command independence.

3. Independence, innovation of command characterized by a particularly high share of commanders' moral competences – their integrity.

A specific distinguishing feature of the leader's intentional actions for successfully fulfilled and morally and responsibly carried out tasks is: exerting a special impact – influence – a leader on subordinates – partners – on the performers of those tasks. This contemporary command of the army is, in fact, about new commanding competences and skills, but first of all it shapes the absolute

necessity to develop (at all levels of command) the necessary leadership competences. This necessity is very well understood in organizing and preparing commanders training processes in allied armies. In our Army this necessity is also well understood; programmed projects and training and other programs are undertaken and continued at all levels of command, training, and new programs for the preparation of command staff are developed and implemented – as indicated and clearly emphasized by the Chief of General Staff, General Rajmund Andrzejczak (R. Andrzejczak 2018).

The legitimacy and directions of changes and improvement of command in a contemporary army

Practicing command in contemporary conditions creates the need to establish and implement a new command model. The model – pattern consists of the preferred command style, including the dominant leadership style, the required professional skills, etc. A contemporary commander with his competences, command and leadership skills and a high potential to influence the attitudes and behavior of subordinates, i.e. the Wise Commander takes command of task teams in the conditions of the growing share of information and cognitive technologies (including AI technology). He is a professional in the application and use of those technologies; he is also a specialist with high skills in using organizational techniques and methods such as project management, risk management and innovation management. The contemporary commander manages teams composed of specialists in the use of those technologies, who by undertaking specific tasks have knowledge, skills, as well as a high level of their own creative ability to undertake these tasks at a high level of innovation. The level of innovation in the implementation of those complex tasks by subordinates is significantly dependent on the credibility of the commander. The credibility is based on the very high potential of moral and organizational values. Credibility means meeting expectations, fulfilling our obligations towards those whom we have trusted. It is an agreement and harmony between professed moral values systems and behavior. It is compliance with the declared motives of activities and their implementation. The necessary, high level of innovation of subordinates, the implementers of tasks that are undertaken at all levels of command, require a high potential for mutual trust (J. Stachowicz, M. Nowicka-Skowron 2019).

The requirements of efficient and socially responsible as well as moral command constitute the pattern of command styles and leadership styles preferred by a contemporary commander. That pattern was called the Model of the Wise Commander, Leader (MMDL). Traditionally, leadership was defined as a type of people management by leaders with specific attributes of professionalism, a high level of emotional intelligence, whose role in the organization is mainly limited to leadership and command in accordance with praxeological criteria (effectiveness, efficiency, planning, control). In contrast, leadership – contemporary preferred leadership according to the MDL model is a type of task teams, organizations and communities management, the essence of which is the targeted impact on the attitudes, actions of members of those teams and organizations, as well as entire societies through managers, commanders with very high professional competence in management; command in the conditions imposed by the implemented contemporary information and cognitive technologies. It is commanding by commanders endowed with special abilities and competences recognized by other team members, organizations in the processes of mutual interactions, which interactions are created during undertaken and implemented activities. The targeted influence of the leader on co-workers – subordinates is based on the unique psycho-mental abilities of mutual interaction of people in cooperating networks, during the implementation of tasks, team members, subunits.

The specifics of practicing contemporary command according to the model of the Wise Commander - Leader (MDL) in activities – military undertakings

a) The necessity and legitimacy of a high proportion of leadership competences at all levels of command. Indeed, at the lowest levels of command, the tasks undertaken by the subunit commanders are complex projects that require a lot of innovative involvement of subordinates. Hence, at each command level commanders should have a high potential for leadership competence.

b) Bonds of trust between commanders and subordinates that shape and develop during the implementation of subsequent tasks and ventures, they shape and develop subunits, divisions etc. as innovative teams and organizations.

c) Pragmatics of promotion requires that commanders who change their official positions are followed by their authority achieved by professionalism in command, and first of all by moral credibility, which determines the potential of the ability to influence subordinates and colleagues. The results of research in the sciences: psychology (positive psychology), sociology (field theory, as well as the theory of spiral confidence development in teams with a high level of interpersonal confidence potential P. Sztompka 2012), modern organization theories (positive organization theory), network theory organizations justify the thesis that: The Smart Commander MMDL interact and positively affects other partners, and the partners, subordinates, trusting commanders also build positive relationships of trust and cooperation with him. These processes are described by J. Stachowicz (2014), P. Sztompka (2012), K. Perechuda, A. Stachowicz-Stanusch (2011), M. Heller (2015), N. Luchmann (1995) r.), HR Maturana, F.J. Farela (1992).

d) High level of moral credibility of the modern commander (MDL) determines the resolution of conflicts between the freedom associated with the individuality of people, subordinates and the rigors arising from and institutional hierarchy in military communities and the associated rigors of the need to observe military discipline and command-based command.

e) High leadership competences practiced at all levels of command are the potential for innovative solutions to many problems shaped by command practice in cyberspace reality and, which is undoubtedly related to the need for high skills of modern commanders, the use of modern information and cognitive technologies – including AI-based technologies.

Model of shaping and developing leadership competences in the contemporary army

Analyzes and studies undertaken in the course of research, as well as observations and analyzes undertaken in the course of organized teaching processes and specialist leadership workshops, are a methodological platform for constructing a model of the process of leadership competence development in military organizations. The model is presented in Figure 1.

Fig. 1: Shaping and development of leadership competences

Source: own elaboration

During the process of developing command competence and the process of military promotion, commanders acquire knowledge and experience, reinforce and develop their "moral - ethical competence", they confirm and develop their emotional intelligence. The integration processes should be emphasized at an increasingly higher level during the development process of command and professional competences. The driving force of this integration is the moral credibility of the modern commander (MDL). The role and value of ethics in the process of shaping leadership competencies is extremely important. It is worth to look at this problem in more detail in the article: *"Ethical leadership: A review and future directions"* (M.E. Brown, L.K. Treviño, 2006). The process of leadership competence development is, of course, associated with the increasing level of commander responsibility, but also with increasingly complex and risky tasks that he receives to undertake and perform at subsequent levels of command. In the initial phase (phase 1) of this process, "discovering" leadership predispositions appears, revealed and developed already during the participation of future officers in the activities of pro-defense organizations and participation in uniform classes – this level of shaping command and leadership competences is described as: Candidate. Pro-defense organizations and teaching innovations in the form of so-called uniformed classes should be a potential source of recruitment for military service candidates, as well as candidates for schools and military academies. These functions are already well fulfilled by those organizations, but, like all activities, they require further improvement. Pro-defense organizations are concentrated in the Federation of Pro-Defense Organizations (in Polish: Federacje Organizacji Pro-obronnych), consisting of five shooting associations, the Academic Legion and the FIA, which has 250 members and its field departments in large cities. The FIA's task is also to train youth in uniformed classes. Last year (as of February 9, 2019) there were 576 schools in Poland implementing pedagogical innovations in the field of defense education. It was 57 thousand of students who received education in about 2,000 uniformed, military, penitentiary, police, Border Guard classes (M. Schwarzgruber, 2019). The next period (phase II) – the period of study in military schools and academies – is the phase of shaping, teaching professional command competences, but also raising awareness and developing leadership competences with the use of direct impact methods (professional knowledge and credibility) by commanders, lecturers to subordinates – cadets. For example, an officer graduating from the General Tadeusz Kosciuszko Military University of Land Forces has also a master's degree in management and quality sciences, or a master's degree in security sciences. This stage is described as: Potential - Contemporary Commander.

The next stages are the adaptation of graduates of Military Universities to take command duties and the stages of subsequent promotions, and as a consequence the development of leadership competences. It is not without significance for the fate and quality of officer life after the end of the military service. Contemporary enterprises and contemporary public organizations are even waiting for managers and leaders who have acquired many experiences of leadership in the army. We describe these stages as: Professional and Wise Commander - Leader. Cadets – future officers – after the period of adaptation, undertake further five-year university level education in their basic military specialties, but also in academic fields. This period is mainly studying for the acquisition of command competences, but also in the characteristic orientation of the study weave on military specialties and specialties of management and security, acquisition and development of leadership competences. The key potential for the development and constitution of contemporary commanders (at all stages of education, improving those competences both during studies and service) is the personal example and experience of reliable, with a high level of emotional intelligence, and a high level of moral credibility of officers - commanders, educators. As it has been many times emphasized, the key issue for the development and constitution of modern commanders is the personal example and experience of credible, with a high level of emotional intelligence and high credibility potential of officers - commanders, tutors and lecturers of the Military University of Land Forces. Indeed, the practice of command in contemporary conditions forces such shaping and development of leadership competences. They are realized through the influence of the commander on subordinates in the processes of carrying out increasingly complex tasks that require cooperation and creativity.

Professional commander can and must, today, be efficient, effective, but above all socially responsible. He should accept and rationally fulfill leadership functions. The impact of the Professional Commander on subordinates - participants and implementers is determined by the level of competence and responsibility at each level of command; the company level is probably the first and main level of testing and development of developed leadership predispositions, it launches a special process of building interpersonal trust. The trust is built between the commander - leader and executors of complex and creativity demanding tasks undertaken in conditions of particular risk. The processes of mutual interaction of the commander and his subordinates (while undertaking complex, innovative and risky tasks) shape and build teams of implementers as special communities in which the process of self-propelling spiral of confidence growth occurs (P. Sztompka, 2012). The commander - leader in led by him sub-units and departments wins - shapes - special groups of subordinates in which mutual trust and trust in a competent commander take place. These groups gain specific competences for creative and innovative problem solving during the implementation of complex and risky ventures. The network of these subordinate groups is further the structure and mechanism of constitution of all subunits commanded and led by the Leader Commander, in which the culture of trust and cooperation is built. These organizations are able to solve complex and innovative problems and undertake tasks, enterprises in a creative and socially responsible way – obviously under the leadership of the Commander - Leader.

The next stage in the development of leadership competencies is the phase in which the Leader Professional achieves an ever higher level of leadership competencies, called the achievement of the level of competence of the Wise Commander (MDL). Leadership wisdom builds the highest level of utilization of knowledge, creativity, but in accordance with and legitimately with moral values and norms, as well as with the highest possible level of emotional intelligence of the leader. The high level of emotional intelligence of the Wise Commander is shaped by social trust relationships in performer groups and communities in which the leader is leading. Intelligence is more than the ability to use knowledge for practical purposes, it is the ability to use all human skills: knowledge, emotions, moral values for practical purposes. Emotional intelligence is a high human skill in managing own emotions and the emotions of partners, that is, subordinates.

The next phase of the development of leadership competencies, which are achieved by outstanding personalities, are commanders of the authority of great strategists, leaders, great social, political and military undertakings. These Leaders - Personalities are role models for all of us in constituting and developing command and leadership competences. A lot has happened in the scientific field over the

past 20 years, especially regarding service leadership, but many critics still have this problem. It is worth referring to the article from 2019: *"Servant Leadership: A systematic review and call for future research"*, which thoroughly reviews the literature in this field and presents interesting research conclusions (N. Eva, M. Robin, S Sendjayac, D. van Dierendonck, R.C. Liden, 2019).

Conclusions

1. There is a widespread awareness that the education and development of modern commanders as outstanding Professional - Wise leaders is a condition for the armed forces to fulfill their mission. In the Polish Army, comprehensive actions have been taken to prepare a comprehensive tooling of the budget used, using the experience of the Allied army's program to shape the development of these leadership competences. The Gen. T. Kosciuszko Military University of Land Forces has a special role and place in that work; which results from its experience and the achieved effects in this area. Due to their function, pro-defense organizations as well as uniformed schools are also important for shaping and developing the competences of contemporary commanders. It is time to really develop their functions and use them also in the practical process of shaping and improving these leadership competences among commanders.

2. The developed Wise Commander – Leader and developing leadership competencies models can be successfully used as a methodological platform for the necessary, continuous improvement of processes for shaping and developing leadership competencies in the Army.

The Radial Cycle of Resilience. Adaptation of The Concept in Economic Recession on Selected Examples

Magdalena MAJCHRZAK

WSB University in Poznan, Poznan, Poland
magdalena.majchrzak@wsb.poznan.pl

Abstract

The direct inspiration to write the article were signs of the economic crisis that appeared along with the COVID-19 coronavirus pandemic. Many economic recessions in the modern world are predictable. The repeatability of threats and the real likelihood of subsequent ones justify the need for proper preparation of enterprises. Therefore, research was undertaken to develop a methodical basis for formulating a model of resilience, which can be used in the sector of small and medium-sized enterprises in Poland in economic recession. The research hypothesis was formulated as follows: The level of preparation of small and medium-sized enterprises in Poland for functioning in economic recession is insufficient and requires adjustment. The following research methods and techniques will be used to verify the hypothesis and achieve the purpose of the research: induction and deduction method, criticism of the studied problem in the aspect of previous scientific achievements by analysing the literature on the subject and the multiple case study method based on in-depth interview technique (IDI). The result of the research is a contribution to the development of resilience theory and the creation of a proprietary concept based on the radial cycle of resilience. The proposed reference model of the enterprise is based on three elements: resistance, flexibility, strategic revitalization. It gives the opportunity to apply in economic practice in economic recession.

Keywords: radial cycle of resilience, economic recession, enterprises, multiple case studies

Introduction

Economic recessions recur with varying frequency and their duration varies (usually several years). Their effects are severe for the economy and for enterprises. It is therefore important to be well prepared for any subsequent economic recessions. One solution is the adaptation of the resilience concept by enterprises. This concept has been described by many researchers using multidimensional and relative concepts. However, there is no universal concept that can be used in any sector of the economy and in any size enterprise (most concepts only include large enterprises).

Using quality analysis, a broad, universal and new approach to the concept of resilience was presented. Factors that enable the application of this concept in business practice are also indicated. The research hypothesis was formulated as follows: The level of preparation of small and medium-sized enterprises in Poland for functioning in conditions of economic recession is insufficient and needs to be corrected. The verification of the hypothesis has been subordinated to the goal, which is to develop a methodical basis for the formulation of a resilience model that can be used in the sector of small and medium enterprises in Poland in conditions of economic recession. The application of the proposed concept by enterprises does not necessarily mean an absolute return to previous conditions, but it may indicate the ability to respond to challenges resulting from negative effects and changes. The application of the resilience concept will also affect the rate of economic growth, macroeconomic stability and macroeconomic market efficiency. This is confirmed by researchers pointing out that the use of resilience by enterprises has an indirect impact on growth, private investment and employment (Tierney 2003).

Theoretical Basics

Many economics theorists and practitioners use the terms recession, depression and crisis interchangeably and synonymously. They refer to the decline in economic activity with economic, social and political consequences.

Recession is an ambiguous concept in the literature on the subject. According to J. Shiskin, re-assignment is a state in which the real gross domestic product decreases over the next two quarters in the economy [Shiskin 1974, p. 222]. This interpretation has been accepted in all European Union countries. In the United States, the National Bureau of Economic Research (NBER) has a special committee on determining the time of the American economy entering recession (Business Cycle Dating Committee). NBER defines economic recession as: "a significant decline in economic activity, scattered throughout the economy, lasting more than a few months, usually visible in a decline in real GDP, real income, employment, industrial production and wholesale and retail sales" [The National Bureau from Economic Research 2020].The terms recession and crisis are treated in the literature equally [M. Drozdowicz-Bieć 2012, p. 29]. In turn, depression is understood as a deep and prolonged recession. Both recession and depression are often preceded by rising oil prices, slumps in government debt and currency markets. This is related to the direct indebtedness of the economies and the inability to meet their obligations towards creditors. Earlier, "speculative bubbles" have risen on the currency, commodity and securities markets. Examples of recent years include: The Mexican Peso Crisis of 1994, the Financial Crisis in East Asia from 1994, the Russian Financial Crisis of 1998, the Argentine Economic Crisis of 1999 or the Financial Crisis 2007-2009 [Buckley 2011, p. 243 -246].

A. Mitroff and M.C. Alpaslan [Mitroff, Alpaslan 2003, p. 10] distinguished three types of crises due to their sources (Figure 1):

1. Natural accidents: earthquakes, floods, fires.
2. Normal accidents [Perrow 1999, pp. 464]:
   a) Economic crises: recession stock market crashes, hostile takeovers.
   b) Physical crises: industrial accidents, supply breakdowns, product failures.
   c) Personnel crises: strikes, exodus of key employees, workplace violence or vandalism.
3. Abnormal accidents:
   a) Criminal crises: product tampering, kidnappings or hostage situations, acts of terrorism.
   b) Information crises: theft of proprietary information, tampering with company records, cyberattacks.
   c) Reputation crises: rumour mongering or slander, logo tampering.

Fig. 1: The Wheel of Crises

Source: Mitroff. I.I., Alpaslan, M.C. (2003), "Preparing for Evil", Harvarde Business Review, April 2003, 10.

There are many indications that before the global economy, another economic crisis that started the 2019/2020 pandemic. Despite many questions and uncertainties, it seems that the effects of a pandemic will be much more economically severe than previous threats of this type. In times of extraordinary and recurring threats, it is necessary to prepare market players for subsequent recessions. Entities should be resilient (proactive) and not vulnerable to crisis (reactive).

Research Material and Methodology

Research to date has confirmed the great importance of preparing enterprises for economic recessions and their consequences. At the level of research on the application of the concept of resilience in enterprises, there are many theories, but often they have little practical utility and the possibilities of application limited to large enterprises. This gap, in part, is complemented by pilot studies, the results of which are presented in this article. The research hypothesis was formulated as follows: The level of preparation of small and medium enterprises in Poland to operate in economic recession is insufficient and needs to be corrected. The verification of the hypothesis has been subordinated to the goal of developing a methodical basis for formulating a resilience model that can be used in the sector of small and medium enterprises in Poland in economic recession. This goal will be achieved through:

1. A literature review of the concept of resilience and presentation of the author's concept.
2. Theoretical identification of factors shaping the resilience model of a small and medium enterprise (components of the resilience concept).
3. Empirical verification of factors shaping the resilience model of a small and medium enterprise (pilot studies).
4. Presentation of the possibility of applying the concept of resilience in small and medium-sized enterprises and the possibility of conducting wider research in this field.

Realization of research goals will be possible thanks to the following research methods and techniques:

a) the induction and deduction method, which will include checking the correctness and verification of all elements of scientific and research work that will be performed to verify the hypothesis.
b) criticism of the studied problem in the aspect of previous scientific achievements by analysing literature on the subject (and other online sources), in the field of economic recession theory and the concept of resilience;
c) analysis of secondary data obtained from publicly available sources such as European Centre for Disease Prevention and Control (ECDC) databases,
d) multiple case study method, which in addition to the general heuristic method, will be used to carry out primary research. The choice of method was determined by the research goal and the variety of real situations [Meredith 1998]. Additional arguments in favour of using this research method was the fact that the practical application of the concept of resilience is still unknown, and the phenomenon itself is not fully discovered [Yin 2003]. The in-depth interview technique (IDI) will be used. Interviews were carried out in eight polish service enterprises belonging to the SME sector. The literature presents various views on the number of cases that should be analysed in order for the conclusions of the study to be scientific. The dominant view suggests four to ten case studies [Glaser, Barney 2001]. The goal is not statistical replication but theoretical. This number also has practical reasons, i.e. due to financial and time constraints. Contact details came from its own database (the author conducts research focused on the service sector since 1999). The selection of samples was carried out using the expert method, based on the knowledge and experience of specialists in the field of the phenomenon under study. Only enterprises that undertake any actions aimed at preparing for the situation of economic recession were invited to the interviews. Interviews were conducted in the first quarter of 2020, based on a structured scenario consisting of three parts: a metric and record part containing information about the audited entity (company size, headquarters location, length of market existence), the main part containing information on implementation the concept of resilience in the enterprise and the summary part. Interviews have been supplemented with the process of examining enterprise documents and their content.

Extensive documentation has made it possible to characterize enterprises including parameters that cannot be identified in quantitative research. Among others, thanks to this research it was possible to examine the process of preparation for the economic recession and planned changes in this respect. The reference model of the enterprise applying the resilience concept and prepared for economic recession emerged from the research.

Research is the first step in the process of verifying the theory and its falsification (in the understanding of K. Popper's critical rationalism). The conclusions drawn on the basis of the case study method, consistent with the assumptions of the phenomenological paradigm, allow for the explanation of exceptional phenomena. These phenomena may be valuable in another environment and organization as an interpretation of phenomena, but they cannot be completely predictable in the future. G. Walsham lists four situations in which the generalization of conclusions adopting an interpretative perspective is justified: concept development, theory creation, drawing specific implications and contribution to knowledge in the form of a rich description of the phenomenon [Walsham 1995]. In this study, the multiple case study method will be used to describe, test and create a new theory that will find application in business practice [Eisenhardt, Graebner 2007].

The Concept of Resilience - New Approach

Resilience in direct translation means resistance, flexibility, strength, revitalization. There is one word missing in Polish that would convey the meaning of the English term "resilience". The term "resilience" was most likely used for the first time in 1973 [Holling, 1973] to refer to ecology. Ch. Perring also attempted to adapt the concept in economic sciences in 2006. Perrings referring to sustainable development. According to him, resilience is the ability of the system to deal with disorders without losing its functionality. It is the ability to withstand market or environmental shocks without losing the ability to effectively allocate resources (market and supporting institutions functionality) or to provide the necessary basic services (production system functionality) [Perrings 2006, pp. 417-427]. Enterprise resilience can also be defined as the company's ability to cope with and adapt to change (Gallopin 2006). Resilience is also the ability of an enterprise to assess the degree of threat, realize mutual

relations and interrelationships between business activities, information and technologies in an enterprise (Gomes, 2015). Regarding regional and local policy, P. Regibeau and K. Rockett define resilience as the ability of the economy, society, organization or individual to successfully return to the state from before the unexpected shock [Regibeau, Rockett, 2013, pp. 107-147]. On the other hand, World Bank experts assume that resilience is the ability of the economy or society to minimize losses in living standards in the event of extraordinary threats [Hallegatte, 2014, pp. 2-3]. The resilience concept is therefore present in interdisciplinary fields dealing with complex systems such as enterprises, infrastructure systems and ecosystems [Carpenter et al., 2001].

Taking into account the sources of the concept of resilience and previous economic interpretations, it is proposed (and this definition will be adopted in this article) to interpret resilience as resistance, flexibility and the ability to strategic revitalization in the conditions of extraordinary threats.

Resilience is not only one concept, but a broader conception of the functioning of enterprises. The most important component of resilience is resistance, which T. Bishop and F. Hydoski defined as "the company's ability to recover before the stress factor" [Bishop, Hydoski 2010, p. 23]. The organization's resistance can be assured by four interactions:

1. Risk assessment - identify, categorize and estimate risk factors and indicate which strategy should be used to reduce them.
2. Risk prevention - you need to implement appropriate prevention strategies that will aim to anticipate and counteract specific risks.
3. Detection of irregularities in accordance with previously accepted risk areas - etc. through periodic audit, constant monitoring.
4. Responding to irregularities - scenarios should be prepared in the event of irregularities in order to minimize their negative impact on the enterprise.

The second component of the resilience concept is flexibility. R. Krupski presented a broad interpretation of the proposals of various authors [Krupski 2008, pp. 15-17]. When looking for the result of different concepts, it can be assumed that flexibility is the ability to adaptify an organization to the conditions in the environment. The term adaptation was used deliberately as a synonym for adaptation, due to the widespread use of the term adaptation in the English-language literature [Gibson, Ivancevich, Donnelly 1998, p. 38]. Adaptation can be external - consisting of the organization's ability to influence the environment or internal - boiling down to adaptive changes in the organization. Flexibility is also often considered in the arrangement of organizational subsystems: financial, manufacturing, market and strategic management. [Krupski 2008, p. 22]. The information subsystem will be analysed within each of the four subsystems.

The third element contributing to the concept of resilience is the strategic revitalization of the enterprise. The revitalization process is identified with strategic change [Floyd, Lane, 2000, p. 155]. This change requires a new look at human resources management and company organization (renewing) [Nogalski, Marcinkiewicz, 2004, p. 49]. Efficient strategic revitalization of an enterprise should potentially bring it not only to improve efficiency, but also to improve its competitive position in the market, establish better relations with customers, changes in the organizational structure conducive to its flexibility of response, increase the range of deletions assigning rights, adapting activities (processes) to customer requirements, developing new skills and key competences, optimizing the value chain, etc. [Walas-Trębacz, 2008, p. 97]. Therefore, there are close relations between resistance, flexibility and strategic revitalization.

Results and Discussion

The research was conducted in connection with extraordinary events initiated in China at the turn of 2019 and 2020. According to the logic of theoretical analytical replication, enterprises differing in size, location of the seat and time of existence were selected for multiple case studies. Among the eight enterprises were three enterprises belonging to the group of micro-enterprises, three small and two medium enterprises (according to the criterion of the number of employees and net turnover from the

sale of goods, services and financial operations). Each of them was located in a different province (with a different level of development). Two of the analyzed enterprises exist less than 5 years (exactly 4 years), three from 5 to 10 years (two existed 8 years, one 9 years) and three over 10 years (two existed 20 years, one 24 years). Thus, all enterprises operated at least 4 years before the COVID-19 corovirus pandemic.

The study was carried out by the method of multiple case studies. Three components of the full resilience concept were taken into account: resistance, flexibility, and the ability to strategic revitalization. The research is supplemented by the fourth part, which is a summary and at the same time gives guidance as to the prospective expectations of enterprises.

As part of the resistance test, entrepreneurs were asked the following questions:

• Which of the company's subsystems is the most vulnerable?
• Please assess the significance of individual elements of enterprise resilience building.
• Please assess the individual components of the company's resilience against competition.
• How, how often is the risk assessment carried out?
• Is risk prevention carried out and how?
• whether and how is risk prevention carried out?
• What is the reaction to irregularities?

When testing flexibility, the following questions were asked:

• How do you assess the significance of the flexibility of individual subsystems compared to competition?
• Please assess the flexibility of individual enterprise subsystems.
• Please assess the external flexibility of the organization (ability to influence the environment) compared to the competition.
• Please assess the internal flexibility of the organization (ability to introduce adaptive changes in the organization) compared to the competition.

The study of the company's strategic revitalization capacity was based on the following questions:

• Please assess the significance of the individual effects of the company's strategic revitalization.
• Please evaluate the effects of the company's strategic revitalization
• In which of the areas is the strategic regeneration process more important?

The following questions were asked in the supplementary part:

• Is there a need for external support in a recession situation:
• Who should provide such support?
• Any actions are necessary to maintain the competitiveness of the government's side?
• When should such support occur?

In the field of enterprise resistance testing, managers were asked a question about the vulnerability of individual enterprise subsystems to the risk of economic recession. Six of them said that the financial subsystem was the most vulnerable, and two indicated a high vulnerability of the strategic management system. Answers to in-depth questions have shown that enterprises do not have sufficient financial security for the most part. There were statements: "I don't have money set aside for the time of recession" or "What should I put aside? There are salaries, leasing". Managers also have concerns about their own management skills in times of crisis. They are also concerned about the market and production subsystem. When assessing the significance of individual elements of resistance building (risk assessment, risk prevention, detection of irregularities, responding to irregularities), in the majority (7 people), they attach the main importance to the final stage - responding to irregularities. They even think that this element is definitely better organized than their competitors.

Depth questions about earlier stages of building resistance lead to the conclusion that managers assume that their enterprises cannot afford creating permanent risk management systems. There is a lack of risk assessment and no strategies to mitigate them. Similar is the case with preventive strategies - they do not exist or are poorly developed. Detection of irregularities is usually carried out through a periodic audit (6 enterprises), less often by constant monitoring (2 medium-sized enterprises). The reaction to the detection of irregularities is to prepare scenarios of proceedings in the event of similar irregularities in the future (6 companies). However, they do not include other types of threats. Two of the surveyed enterprises operate on an ad hoc basis, without preparing any scenarios for the future. Therefore, there is a lack of long-term policy in enterprises in this respect. Strategies, even if they exist in the form of a document, rarely contain instructions on how to deal with an economic recession (only 1 in 8 cases).

In the field of testing the flexibility of enterprises, managers were asked a question about the importance of flexibility of individual subsystems in the enterprise. Everyone considered the flexibility of the financial subsystem to be the most important. By this flexibility they mean, for example, shifts in tax payment dates, credit instalments and leasing instalments. Market flexibility and strategic management are equally important. Comparing themselves to the competition, managers (6 people) decided that the financial subsystem of their enterprise is less flexible than the competition subsystem. At the same time, most assess low their external flexibility and high internal flexibility. Seven managers believe that their enterprise has a high capacity to introduce adaptation changes. Their views are largely based on properly selected and loyal employees and well-established market position (in the studied group there are only two enterprises existing for less than 5 years). There are such statements: "I know the market well, I know how to survive on it", "I have a permanent team of employees, everyone knows what to do."

In the scope of testing the strategic revitalization capacity of enterprises, managers were asked a question about the significance of individual effects of the company's strategic revitalization. Six of them believe that the most important effect of revitalization will be the improvement of the company's efficiency. Managers also count on improving their competitive position. Next to this there are statements such as: "I would decide on strategic revitalization of the enterprise if I knew that it would improve my relationships with clients" or "for me revitalization is to increase flexibility of response". Managers also believe that strategic revitalization will create the opportunity to tailor activities (processes) to customer requirements and optimize the value chain. Additional effects may be: development of new skills and key competences, and increasing the scope of delegation of powers. Generally, most of them (5 people) recognized that the process of strategic revitalization is more important in human resource management than in the organization of the enterprise. In a depth interview, they add: "going through the crisis is easier thanks to the employees involved", "when the crisis came, I realized that I can only count on myself and my employees."

In the summary part, managers were asked a question regarding the assessment of the implementation of the resilience concept through three components: resistance, flexibility and strategic revitalization. Everyone decided that they implement it to some extent. Medium-sized enterprises on a scale of 1 to 5 rated the implementation of the concept at 4, the others on a scale of 1 to 3. Everyone is convinced that this concept should be implemented in a broader dimension (perhaps the answers arise from the time of the survey - rampant pandemic). There is a certain relationship here: the location of the headquarters in a richer provinces (GDP per capita) affects the willingness to take action to correct the adopted strategies in a shorter time (up to 1 year). It is interesting that despite the fact that there was no such question from the interviewer, the managers themselves add that they need help to get through the current crisis and prepare for the next one. They await government support in the form of, inter alia, low-interest loans and credits that can be redeemed, as well as shifting tax payments, credit instalments and leases over time.

Summing up, it can be stated that managers are aware of economic crises occurring at different frequencies and the need to prepare for them. They see their chances in building resistance, flexibility and strategic revitalization of the enterprise.

Theoretical research and multiple case studies allow to create a reference model of the enterprise applying the concept of resilience in economic recession (Figure 2).

Fig. 2: Radial cycle of resilience

Source: own study.

The conducted research, which requires continuation, allowed to identify the initial boundary conditions necessary to meet the introduction of the resilience concept:

1. The model is introduced based on the radial cycle of resilience.
2. The introduction of the model is preceded by a thorough analysis of three areas of the enterprise: resistance, flexibility and strategic revitalization at all levels.
3. The model must be adapted to the enterprise life cycle. Failure to do so may result in the enterprise losing competitiveness.

Multiple case studies have shown that, in addition to the existence of boundary factors for the introduction of the proposed reference model, there are success factors, i.e. those elements that justify the success of the project. Belong to them:

- having a financial reserve during the economic recession,
- management skills in times of crisis,
- loyal employees and employees prepared for work in crisis conditions,
- good market position,
- organizational structure with the ability to quickly adapt to changes,
- openness of managers and employees to strategic revitalization.

Quick implementation of the proposed solutions may contribute to minimizing the economic effects of economic recessions. The expected effects of the ongoing pandemic, as well as subsequent economic crises indicate the need for proper preparation of enterprises and moving beyond traditional operating patterns.

Conclusion

A large part of the economic recession in the modern world is predictable. The repeatability of threats and the real likelihood of subsequent ones justify the need to build an enterprise model that would be able to function in changing economic conditions, including times of extraordinary threats. Many managers realize that it is impossible for a company to go through a crisis without prior preparation. Qualitative research has shown that a good solution is to use a concept based on the radial cycle of resilience. The proposed enterprise reference model is based on three elements: resistance, flexibility, strategic revitalization. In the literature on the subject, they are often analysed separately. This is not appropriate, among others, due to the large relationship between the enterprise's resilience and its competitiveness (Stephenson 2010, pp. 27-32). Building a thriving company should be a strategic initiative that changes the way the company operates and increases its competitiveness (Sheffi and Rice, 2005). These authors point out that the company's resilience can be achieved by reducing vulnerability and increasing flexibility, which indicates the company's ability to return to the "right path" in the event of disruption.

In relation to the recession, which began with the events in China 2019/2020, additional tips are given to entrepreneurs by Philipp Carlsson-Szlezak, Martin Reeves and Paul Swartz [Carlsson-Szlezak, Reeves, Swartz 2020]:

1. You should be very cautious about forecasts that may be currently characterized by high uncertainty. Many scenarios remain feasible and companies should examine them.
2. Turmoil in financial markets must not be allowed to affect judgments about business operations.
3. Focus on signals of consumer confidence, trust your instincts and learn how to use information about our company to calibrate such information. The impact will not be identical for everyone, and the conclusions will be specific to your industry.
4. The company should be prepared for both positive and negative scenarios.
5. In a pandemic, it's worth thinking about the period of the company's operations after it expires. The following questions should be answered: What micro- and macroeconomic effects will the current threat bring? What opportunities or challenges will arise?
6. It is worth considering the possibility of better preparation for the next crisis. It may be worth implementing new technologies or new processes faster, which would allow you to gain a competitive advantage in the event of another crisis.

As a result of scientific research, the hypothesis has been positively verified and the research goal has been achieved. As a result, a reference model of the enterprise was proposed, based on the radial cycle resilience: resistance, flexibility, strategic revitalization, possible to apply in economic recession.

Blockchain - A Crypto-Intensive Technology - A Review

Muhammad Imran SARWAR [1], Kashif NISAR [2], Shama ANDLEEB [3]and Muhammad NOMAN [4]

Faculty of Computer Science & IT, The Superior College Lahore, Pakistan
[1]info@imranchishty.com, {[2]qashef, [3]andleeb.it, [4]noman.chaudhry979}@gmail.com

Abstract

Researchers, critics and industry gurus are agreed that Blockchain is the next big thing. Blockchain is the technology that has shifted the entire paradigm of computer applications in the last decade. The key concept behind the development of Blockchain was to create a chain of data which is immutable, confidential, open-source and located on a de-centralized peer-to-peer (P2P) network. The ownership of Blockchain doesn't belong to a single person or a group but each node on the network therefore, it works without the involvement of any centralized authority. Blockchain was originally designed for cryptocurrency but this technology has been using in many other fields and application like Health, Finance, Banking and IOT etc. Big things come with big challenges so is the case with Blockchain and beside technical challenges, advancement in technology and hardware, Blockchain technology still claims flawless because of cryptographic primitives. This study contributes to review on different cryptographic techniques like ECDSA, SHA-256 and RIPEMD160 used in Blockchain technology and to exemplify its implementation, we choose Bitcoin.

Keywords: Blockchain, Bitcoin, Cryptography, ECDSA, SHA-256, RIPEMD160.

Introduction

Blockchain a is type of distributed de-centralized database which uses blocks to store data and each block is coupled with other blocks using strong cryptographic hash functions and then forms a chain of blocks, that's why it is called Blockchain. Information in these blocks is immutable therefore this technology stands high among other top technologies. Vertical industries are also revamping themselves by implementing Blockchain (Sarwar M. Imran, Nisar and Khan, 2019). Blockchain has some indispensable characteristics like data is distributed among all nodes over a de-centralized network, data in blocks is infeasible to delete or alter and all is transparent.

The World Economic Forum states that, "58 percent of all survey respondents said, they expect that by the year 2025, 10 percent of the global GDP will be stored using the Blockchain technology" ('World Economic Forum - Survey Report, September 2015 - The Global Agenda Council on the Future of Software and Society - Technology Tipping Points and Societal Impact', 2015). From the facts, it can surly be stated that Blockchain based applications would be high in demand and expecting huge investment inflow. Blockchain Vertical Opportunities Report released in 2018 states that "The business value of Blockchain is projected to reach US$ 2.0 trillion by 2030" (Tait *et al.*, 2018).

Blockchain, like any other technology, should be clearly differentiated as technology and its implementation. Blockchain is a technology and Bitcoin, Ethereum and such other cryptocurrency applications use Blockchain to work with. Blockchain is a sort of database which stores records or data and Bitcoin uses Blockchain as data storage. Blockchain technology is a combination of cryptography and an economic model which works on P2P de-centralized network (Lin and Liao, 2017) as illustrated in Figure 1.

Blockchain was allegedly developed by Satoshi Nakamoto for the cryptocurrency Bitcoin and the only purpose for developing such technology was to ensure a reliable and secure transaction mechanism between two users on a P2P de-centralized network. Nakamoto addresses the challenge of ownership of the digital currency and suggests a solution that is based on Public Ledger (Nakamoto, 2008) .

Fig. 1: P2P De-Centralized Network

ROADMAP: Our study purely focuses on the Blockchain as a Crypto-Intensive technology and, Bitcoin is the case to exemplify its implementation. However, cryptocurrency is out of scope of this study. The remaining of this paper is organized as follows: Characteristics and architecture of Blockchain are introduced in section 2. Section 3 discusses about the Cryptographic primitives of Blockchain. Literature review is presented in section 4 and the paper is concluded in the last section.

Characteristics and Architecture

A. Characteristics of Blockchain Technology

- *De-centralized*. Blockchain stores data on every single node on a P2P de-centralized network. Unlike conventional centralized and distributed data storage schemes, every node becomes the data owner so there is no need for any centralized authority to record, keep or maintain the data.

- *Persistency.* Stored data in the chain is persistent and traceable since the formation of a chain is designed in a way that any transaction or block can be validated. In case of Bitcoin, a complete trail is available for every single coin and there is only single ledger uses to record all transactions and this ledger is available on all nodes. This feature is also important to deal with double-spending problem.

- *Open-source.* Records in a public Blockchain is open to view by anyone and can be checked publically.

- *Consensus.* Every block that is to be added in the chain must be approved by all the participants involved in the transaction. As the consensus mechanism is predefined through an algorithm, it ensures a complete trustable environment between the participants and all rules must be followed for a block to become the part of the chain. A transaction becomes invalid if it violates any rules or violated by any participant.

- *Anonymity.* Parties involved in a transaction remain anonymous because there is only one thing needs to know before initiating any transaction and that is receiver's ID and any further details is not available in the chain.

- *Immutable.* The maximum time allowed for adding a block of transaction(s) into the chain is 10 minutes and it also requires 51 percent nodes to validate the block. Every precursor block becomes more and more immutable as new blocks are added into the chain and 51 percent nodes are required to endorse any alteration in any block or transaction and then further altering all successor blocks to update the chain. It nearly becomes impossible for

the miners and attackers to alter a group of blocks which have already become the part of chain.

B. Architecture of Blockchain Technology

Blockchain is a sequence of blocks which are tightly coupled using a cryptographic Hash function SHA (Secure Hash Algorithm). Every block contains the Hash value of the previous block. The chain starts from the block which is called genesis block which doesn't contain the hash value because it is the starting block in the chain. Block is the fundamental part of Blockchain and it has two parts; the block header and the block body as illustrates in Figure 2.

A typical header part of a block contains the following information:

(i) Block ID: Every block in the chain is assigned a unique ID to get recognized.
(ii) Timestamp: current time is stamped every-time a new block is created. This time is taken from UNIX times server in seconds as universal time since 1970 (Zheng *et al.*, 2017).
(iii) Hash – Current Block: Hash value of current block which is to be mined.
(iv) Hash – Previous Block: Hash value of previous block.
(v) Merkel Root: A merkel root is the hash value of all transactions' hashes in a block.
(vi) nBits: A difficulty level to determines how difficult it would be for a miner to mine the block.
(vii) Nonce: It is a 32 bit random number to be searched by the miners to produce a correct hash value. This number ensures that any computation that has already been done for a block during the mining process, never used again in any other block.
(viii) Other Information: Any other information as per the requirements of the application.

Fig. 2: Block Structure (Nakamoto, 2008)

The body part of the block contains data, record or transaction(s) and is digitally signed by the participants as illustrated in Figure 3.

Fig. 3: Bitcoin Transaction (Nakamoto, 2008)

Cryptographic Primitives in Blockchain

Blockchain was introduced in 2008 and it was the first application that doesn't need any rusted third-party. Eliminate the third party from the system was a new and a revolutionary idea which was never attempted before. Strong cryptographic functions were used which changed the entire scenario and now we are available with a technology that can be trusted without any third-party. All have done with help of robust cryptographic primitives. Blockchain has some other features like de-cartelized, double spending resistance and scalability, now it has become a trusted underlying technology or framework for cryptocurrencies. There are two important cryptographic primitives use in Bitcoin (to practically understand, we will exemplify Bitcoin as a case study), hashing algorithms and digital signing algorithms as illustrates in Figure 4.

Fig. 4 : Hash Functions Implementation in Bitcoin (Wang *et al.*, 2019)

Since the innovation of Bitcoin, more or less all cryptocurrencies have adopted this technology and there is no single evidence available which suspects or challenges the security mechanism of Blockchain. For the purpose of hashing, SHA and RIPEMD-160 (RACE Integrity Primitives Evaluation Message Digest) are used and ECDSA (Elliptic Curve Digital Signature Algorithm) uses as Digital Signature Algorithm for signing a transaction digitally.

A. Hashing Algorithms

Bitcoin uses SHA-256 and RIPEMD-160 algorithms for hashing. These algorithms are used in combination and due to the reason they not only increase the security but also maintain the highest level of privacy in Bitcoin transactions. The purpose of using the combination is to ensure two main requirements namely one-wayness and collision-resistance (Wang *et al.*, 2019). The purpose of one-wayness is to ensure that the hash is not invertible or at-least infeasible and collision-resistance which means to avoid having the same output of two different inputs. For a hash value with 256 bits output length, the possibility of breaking one-wayness will take 2^{256} times a brute force attack and similarly to avoid having same output from two different inputs will take $2^{256/2}$ times birthday attack.

SHA is a popular cryptographic hashing algorithm which has different variants SHA-0, SHA-1, SHA-2 and SHA-3. It was designed by National Security Agency (NSA). Bitcoin uses SHA-2 family variant and in particular SHA-256 which has 256 bits output with a block size of 512 bits and complete in 64 rounds. This cryptographic hash function creates and output of fixed length from an indefinite length of input.

Here it is important to highlight that the output of SHA-256 cryptographic algorithm will always remain the same for a particular input and this algorithm also satisfies preimage-resistance, second-preimage-resistance and collision-resistance properties as well. This cryptography technique is altogether different from encryption and decryption algorithms. The second cryptographic function that uses in Bitcoin is RIPEMD160 which is a cryptographic hash function based upon the Merkle-Damgard construction. Bitcoin uses SHA-256 and RIPEMD160 in combination and collectively called HASH160 when it uses in Bitcoin. Moreover it is also used to hash the transactions in the block to create a merkle tree and this algorithm is also uses to hash the transaction that is singed by the sender using his / her private key (Giechaskiel, 2015).

B. Digital Signing Algorithms

A public key cryptography is a high-level frame work that uses in many different applications. Bitcoin uses ECDSA to digitally sign the transaction and to ensure the rightful owner of the funds. The ECDSA is consisted of the following three key elements:

Private Key: A private key is only known to the person who generates it and it is a positive integer value. A user having a valid private key can unlock the funds for further using or sending.

Public Key: Public Key is based on the private key and in Bitcoin it is uses as an address of the party. It acts like an ID of the holder and doesn't need to keep it secret. This key is publicly available and uses to authenticate if the information is been sent by the right person.

Signature: A signature is mathematically calculated value generated with the combination the transaction and the private key of the sender.

When a user creates a wallet and becomes the part of Bitcoin, a pair of public key and private key is generated. The public key derives from the private key and further uses in the verification process. A Public key is a user ID for identification and becomes the address of user's wallet and is publically visible on the network. The public-key cryptography is the underlying technology for wallets and transactions. Whereas, the private key is only knows to the user which is the only proof of ownership of a wallet. If private-key is lost, then everything associated with it lost forever.

There are two steps involve in the signing process: *signing* and *verification*. For example: Alice wants to send a message to Bob, by using her private key she would do:

Signature = Sign (Message, Private-Key)

Where *Sign* is a function to encrypt message using original *Message* and Alice's *Private Key*. Signature and original message then send to Bob for verification. Bob verifies the value received from Alice by using Alice's public key as:

Result (T / F) = Verify (Message, Signature, Public-Key)

Where *Verify* is a function which decrypts the received message using *Message*, *Signature* and Alice's *Public Key* and gives results in True or False. An important element of crypto-system security is based on ECDSA which derive its security from the computational infeasibility of the Elliptic Curve Discrete Logarithm Problem (ECDLP) which is hard to break. Authenticity and security in Bitcoin are ensured by ECSDA (Kikwai, 2017).

Literature Review

This review covers the articles published in recent years. We have tried different combinations through different conditions, to search appropriate material to support our study which included journals publication, conference proceedings and different online articles.

To support our study and to ensure comprehensive and systematic methodology for searching the material, we started from Google and Google Scholar. The search option was only limited to the titles. The keywords: Cryptography Primitives on Blockchain, Securities issues in Bitcoin, How safe Bitcoin is, and their combinations were used. We further explore IEEE and ACM digital libraries to find out related material. The articles' abstracts were carefully read to check their relevance for the review. Only articles closely addressing Blockchain, Bitcoin and Cryptographic primitives were selected.

Conclusion

We have systematically studied the cryptographic primitives used in Blockchain technology and particularly in Bitcoin. It is found that the combination of SHA-256, RIPEMD160 and ECDSA ensures that the security barriers of Bitcoin are still strong and reliable. There is no such evidence in past that any hacker broke the security and tried to enter into the system. Bitcoin data is safe and protected by the hash algorithms and is still strong enough to resist any known method by the hackers. We analyzed that there are possibilities that if 51percent of miners pool them to control the mining process. Further there are chances of Man-In-The-Middle attack and has been reported many times but again, this is the network security related issues. Overall, we are convinced that Blockchain and Bitcoin are quite safe as they have adopted the combination of best security algorithms which are unbreakable and irrevertible.

Future Study: Quantum Computing is a new theory which is expected faster and accurate manifold. We propose to revisit the security levels of Blockchain by keeping in view its processing speed as it could be a threat or an opportunity for the future of so-far so-safe Blockchain technology.

E-Financial Reporting as A New Challenge for Accountants

Joanna KOGUT

Wroclaw University of Economics and Business, Poland
joanna.kogut@ue.wroc.pl

Abstract

The purpose of the article is to present e-financial reporting, analyse the opinions of accountants from the perspective of its application in accounting as well as identify and discuss the biggest challenges for companies resulting from its implementation. The article starts with a brief introduction addressing the development of information and communication technologies affecting every area of life, including accounting. E-financial reporting is one of the examples confirming an ongoing revolution in this area. Next the essence and scope of financial reporting as the final product of accounting are discussed. A new technological solution is also identified, i.e. e-reporting. The core part of the article presents the source of introducing e-statements, the method of their preparation and forwarding. Owing to the synthetic analysis of the conducted survey results, it was shown that this solution poses a new challenge for accountants which, however, they are capable of meeting, whereas the benefits of its implementation are measurable.

Keywords: Accountant, Financial Statement, E-Financial Reporting, Accounting

Introduction

The development of information and communication technologies introduced numerous changes in economic and social life and also the way of entities' functioning in the 21st century (Scapens, Ezzamel, Burns, Baldvinsdottir, 2003). It resulted in both business entities and stakeholders operating in a virtual space (Siegel, Sorensen, 1999) (cyberspace), in which communication is carried out between computers connected in a network. The application of modern technologies has become an indispensable component of entities' functioning on the market, which requires quick access and acquisition of information (Umble, Haft, Umble, 2003) and imposes costs related to the implementation of technology and the respective security.

The development of information technology exerts impact on almost every area of contemporary life worldwide. This phenomenon also refers to accounting and creates new challenges for business entities. On the one hand, it improves the functioning of many of them, and on the other – adds new responsibilities. The emergence of technological solutions, such as financial and accounting programmes, transaction systems, IT systems supporting management in companies and many others, have changed the way of accounting functioning.

Digitization of many aspects of public life is continuously progressing, which also results in the need for ongoing changes related to legislation in terms of adapting the standards followed by the functioning institutions and their legal structures to the advancing computerization.

Standard Audit File (SAF), e-statements or abandoning VAT declaration represent just a few examples of the ongoing revolution in the area of accounting.
One of the most difficult technological solutions takes the form of e-financial reporting, which imposes new obligations on entrepreneurs, accountants, auditors and a number of other entities.

Therefore, the purpose of this article is to discuss e-financial reporting and analyse the opinions presented by accountants from the perspective of its application in accounting based on the survey

results (Report, 2019) conducted by the Accountants Association in Poland and also to identify and discuss the biggest challenges for companies resulting from its implementation.

The applied research methods include the analysis of legal acts, the analysis of survey results, the subject literature overview and conclusions.

The essence and scope of financial reporting

Financial reporting represents one of the most important forms of communication between enterprises and other entities with their environment. It is often referred to as the language of business. The primary role of financial reporting is to provide both reliable and transparent presentation of the entity's financial standing and the generated financial result, as well as characterize the key areas of its functioning, mainly through the prism of monetary values. From the perspective of the reported information addressees, its reliability, credibility and timeliness are of fundamental importance. These problems are particularly important in terms of ensuring business transactions security and the efficiency of capital allocation processes performed on capital markets. The information exchange system, both between the business entities themselves and their institutional environment should be used to support the decision-making processes carried out by the stakeholders. Therefore, the information presented in financial statements should not only be characterised by high quality, resulting from the need to reflect the actual situation in a true and fair manner, but also reach the interested parties quickly enough to allow making rational and effective economic decisions.

In the conditions of an increasing complexity of business processes, efficient and effective reporting on the current situation requires using adequate solutions in the area of accounting organization and reporting.

The focus on providing due credibility and reliability of the reported information is particularly important, especially in the case of public companies and such financial institutions as banks, insurance companies, investment and pension funds or brokerage houses. Access to reliable and updated information, reflecting the economic situation is of key importance not only for the immediate stakeholders, but also for the stability of the entire financial system. Hence, these entities have to follow specific financial reporting obligations (Żukowska, Zuba-Ciszewska, Bolibok, 2016).

The information resulting from a financial statement is crucial not only for the entity which prepares it, but also, and perhaps primarily, by the external entities, such as, e.g.: investors, banks, insurance companies, leasing companies and the entity's contractors. The key decisions taken in every enterprise and in relation to each of them should be preceded by an in-depth analysis of the data disclosed in a financial statement.

Accounting, including reporting, is highly formalized, thus both national and international law are important in their functioning. The basic legal act referring to accounting and reporting in Poland is the Accounting Act (Act, 1994). This Act sets out the accounting principles, the procedure for auditing financial statements by statutory auditors and the principles for performing activities in the field of bookkeeping services.

Article 2 of the Act specifies which business entities are obliged to apply its provisions, and thus issue financial reporting (to a different extent). These provisions outline the diverse scope and form of the prepared statements. This diversity applies to many entities – enterprises (manufacturing and providing services, banks, insurers, other financial institutions, micro and small entities). The templates of financial statements are included in the annexes to the Accounting Act: Annex No. 1 – template of a financial statement for companies other than banks and insurers, Annex 2 – template of a financial statement for banks, Annex 3 – template of a financial statement for insurers and reinsurers, Annex No. 4 – template of a financial statement for micro-entities, Annex No. 5 – template of a financial statement for small entities and Annex No. 6 – template of a financial statement for NGOs.

The diversity of financial reporting also applies to the entities included in the sector of public finance, foreign entities, entities which do not perform business activities and other entities covered by the regulations of the Accounting Act, which has been specified in the implementing provisions to the Act.

The provisions of balance sheet law and the implementing legislation provide the sufficient legal basis, covering all issues referring to accounting (reporting) for the majority of business entities and other entities obliged to do so.

The scope of national and international accounting regulations in force is different in various countries. Many of them have adopted the International Accounting Standards (IAS) and/or the International Financial Reporting Standards (IFRS) as the national accounting standard. In Polish legislation the following hierarchy has been adopted: the Accounting Act applies as first, however, in the case of absence of the respective regulations provided by the Act, a given entity should follow the National Accounting Standards (NAS) first, and in the absence of an appropriate national standard should be guided by IAS and/or IFRS. Since 2005, the EU has introduced IFRS as outlining the applicable principles to be adopted while preparing financial statements for the listed companies. Thus, the EU directives and the international accounting and financial reporting standards (IAS and IFRS) have a significant impact on the Polish Accounting Act.

Financial statements should present a number of structured information. However, the ability to read and interpret them remains the condition of their usefulness. The IAS Conceptual Framework (Conceptual Framework, 2004) assumes that the addressees of financial statements have the indispensable economic knowledge, including accounting, the particular industry sector and the respective economic activities, and also are capable of reviewing and analysing the presented information in detail.

As the above discussion shows, financial reporting plays the key role in contemporary economic reality. However, the increasing complexity level of the carried out business operations and the need to provide the interested parties with the fastest possible access to high-quality, reliable information to be used in the decision-making process is becoming a growing challenge for all entities required to prepare financial statements.

E – financial reporting – a new stage of accounting digitization

In Poland, the digitization in accounting has reached a new level starting from 1st October 2018. Another amendment to the Accounting Act (Act, 1994) introduced the obligation of preparing electronic financial statements in the form of XML standard file (so-called e-statements) and signing them with an electronic signature, which are later forwarded electronically to one of the below repositories, appropriate for the given business entity type:

- National Court Register (NCR), which collects financial statements prepared by the entities entered in the Business Register and provides them to the interested parties, and also forwards them to the National Revenue Administration (NRA),
- National Revenue Administration (NRA), which collects financial statements from the Corporate Income Tax (CIT) payers, who are not listed in the Business Register held by the National Court Register and also natural persons, as well as provides them for the relevant Revenue Offices.

The introduced amendments are in accordance with Community law, in particular Directive 2013/34/EU (Directive 2013/34/EU) and Directive 2017/1132 (EU) (Directive 2017/1132). The provisions of the aforementioned Directives impose the requirement on Member States to provide the duly approved annual financial statements and activity reports along with the audit report, and ensure that the above documents can be submitted in an electronic version.

The submitted set of electronically signed documents consists of: the annual financial statement prepared in accordance with Art. 45(1f) of the Accounting Act, including balance sheet, profit and loss account, additional information, and for the entities whose financial statement is subject to an

annual audit by a certified auditor also a statement of changes in equity (fund), cash flow statement, report on business operations if required by the provisions of the Act, the auditor's report on the statutory audit of the financial statements, if it was carried out, as well as the resolutions on the statement approval and the distribution of profit or coverage of loss, which are prepared as hard copies and submitted to the repository in the form of a scan certified by the person responsible.
Therefore, currently it is possible to use two types of e-financial statements: a structured format – saved in XML standard and an unstructured one – saved in any format.

The Ministry of Finance published, on the Public Information Bulletin website, the logical structures of financial statements to be used in preparing statements since 01/09/2019 by:

- entities other than banks and insurance companies (Annex No. 1 to the Act),
- small entities (Annex No. 5 to the Act),
- micro entities (Annex No. 4 to the Act),
- NGOs (Annex No. 6 to the Act),
- alternative investment companies,
- banks (Annex No. 2 to the Act),
- brokerage houses,
- insurance and reinsurance undertakings (Annex no. 3 to the Act),
- cooperative savings and credit unions,
- small cooperative savings and credit unions,

as well as the consolidated statement structures of:

- entities other than banks and insurance companies,
- brokerage houses
- insurance and reinsurance undertakings.

A financial statement, in a structured form, is prepared using an online application which creates files in XML format, but the responsibility for the correct data transfer to this format, including its technical aspects, lies with the person preparing the statement. An unstructured file can be attached to the XML file that includes additional information and explanations. This file is saved in an encoded form and due to its subsequent presentation in the National Court Register, it is recommended to save it in PDF format.

Next the annual financial statement, both in a structured and unstructured form, is signed by the person entrusted with keeping the books of account and the head of the business entity, where, if the entity is managed by a collective board, the statement is signed by all members of the board. This signature is an electronic one: advanced, qualified or personal.

The method of submitting financial statements depends on the status (category of the business entity), however, the generally accepted principle is their submission to one place only. Table 1 presents the statement components which have to be forwarded and the repositories they are submitted to.

Table 1: Components of the financial statement and its forwarding method

No.	Status (category) of the entity keeping the accounts	Place of forwarding	Form		
			annual financial statement	activity report	other documents
1	Entities entered in the Business Register of the National Court Register preparing financial statements in accordance with the Accounting Act	repository of financial documents held by the National Court Register	prepared in XML format, signed by the person responsible for keeping the accounts and by the entity manager – electronic signature	prepared electronically in an unstructured form signed by the entity manager – electronic signature	a) certified auditor's report on the statutory audit (if performed) – prepared in an electronic version and submitted with a qualified electronic signature b) resolution on the approval of the financial statements by the approving authority – prepared and signed in paper form; a scan certified by a management board member with an e-signature is submitted to the National Court Register repository (in a partnership – by a partner or a general partner) c) resolution on the distribution of profit or loss coverage – prepared and signed in paper form; a scan certified by a management board member with an e-signature is submitted to the National Court Register repository
2	Entities entered in the Business Register of the National Court Register preparing financial statements in accordance with IAS	repository of financial documents held by the National Court Register	electronically signed in any form by the person responsible for keeping the accounts and by the entity manager (the entire management board)	as in point 1	as in point 1
3	Entities – corporate income tax (CIT) payers – not entered in the Business Register of the National Court Register (preparing financial	National Revenue Administration (NRA)	as in point 1	not applicable	as in point 1, but excluding point c (if these are companies not entered in the Business Register of the National Court Register, point c applies)

	statements in accordance with the Act)				
4	Civil law partnerships preparing financial statements in accordance with the Act and their business partners (taxpayers of both personal income tax (PIT) and legal corporate income tax (CIT)	they do not forward financial statements to NRA or NCR; if the financial statement was audited – it is forwarded for publication in the Court and Economic Monitor (C&EM)	prepared in any electronic form, signed electronically by the person responsible for keeping the accounts and by all the partners conducting the company affairs	not applicable	in the case of forwarding for publication in C&EM – as in point 1, but excluding point c
5	natural persons preparing a financial statement in accordance with the Act	NCR; if the financial statement was audited, it is also forwarded for publication in C&EM	as in point 1	not applicable	in the case of forwarding for publication in C&EM – as in point 1, but excluding point c and instead of the resolution on approval – the decision on approval; these documents are not forwarded to NCR

Source: author's compilation based on: (the Act of 29 September 1999, Bakalarz, 2019).

A financial statement, along with the required documents, has to be sent to either NCR or its bodies within the deadlines specified by the legislator. The entities entered in NCR, which do not prepare financial statements in accordance with IAS are obliged to send e-statements within 15 days from the approval date of the annual financial statements (in accordance with Article 69 of the Accounting Act), i.e. usually not later than by July 15 of the following year. In turn, the personal income tax (PIT) payers, who keep the accounts and are required to prepare financial statements, should submit e-statements to NCR by the end of April (in accordance with Article 45(5) of the Personal Income Tax Act). Preparing and submitting e-statements is subject to electronic time-stamping, which allows the respective authorities to monitor them more accurately.

The importance of the obligation to prepare financial statements in relation to the entities' financial standing and, thus, the implementation of the transparency principle means that their violation may result in criminal liability for the violations specified in the Accounting Act. Failure to prepare a financial statement, despite the existing obligations, or failure to prepare it in accordance with the provisions of the Act or presenting unreliable data in its content, as well as failure to submit a financial statement or an activity report in a relevant court register is subject to specific sanctions.

Pursuant to the provisions of Art. 77(2) of the Accounting Act, the first of the above mentioned violations is punishable with a fine or imprisonment for up to two years, or both. However, in accordance with Art. 79(4) of the Act, a person who, contrary to the regulations in force, refrains from submitting financial statements to the relevant registers is subject to a fine or the penalty of restricted liberty.

The responsibilities related to financial reporting rest with the manager of the business entity, who is a member of the management board. He/she bears full responsibility for keeping the deadlines and the mode of submitting financial statements as well as their proper construction. If an entity is

managed collectively, where no single person responsible in this matter has been indicated, all management board members are subject to criminal liability.

E - financial reporting in the opinion of accountants

Within the framework of the adopted purpose of the article, i.e. presenting e-financial reporting and analysing the opinions of accountants from the perspective of its application in accounting, the results of the survey, carried out by the Poznań Branch of the Accountants Association in Poland (Report, 2019), were verified . The conducted analysis is focused on identifying and presenting the biggest challenges for companies resulting from the implementation of e-financial reporting, as assessed by the accounting-related environments.

914 representatives of accounting professions, working both in the internal financial departments of companies (47%) and in accounting offices (49%), as well as other entities involved in the financial reporting process, participated in the survey requesting to provide answers about the entity level of preparation, being either the respondent's employer or a client. The vast majority (98%) took an active part in this process, however, for the majority of them it was a new challenge.

In terms of the respondents' positions at work, their vast majority occupied the decision-making functions. The largest group covered people employed at the chief accountant position or the accounting department manager. The second, most numerous group were the owners of service entities keeping the accounts. Among the representatives of internal accounting departments in the entities – most people worked in medium-sized and small companies. The survey also covered over 30 tax advisory offices and entities performing audits of financial statements.

At first, the respondents assessed, in general, the entity's preparation level for the process of preparing and submitting e-statements using the scale of 1-10. The responses provided to this question were assigned to five categories, where 17% of the respondents rated the preparation level as very poor, 24% as poor, 25% as moderate, 21% as good and 13% as very good. It shows that the answers were relatively evenly spread, which indicates the cross-sectional nature of the study constituting the basis for the report. The cross-sectional nature of the survey is also confirmed by the even division according to the authorization tools of financial statements, where 35% used a qualified electronic signature, 20% a trusted profile and 43% both of these forms.

In the vast majority of entities (65%), the accounting departments faced difficulties at every stage of the e-reporting process. Most problems (indicated by approx. 20% of the respondents) were encountered at the stage of signing and submitting e-statements to the National Court Register/National Revenue Administration. Approx. 9% admitted problems with preparing and providing e-statements to shareholders /owners. Only approx. 2% of the respondents came across problems with approving an electronic version of the statement.

A detailed analysis of the prepared report shows that the actual problems with e-reporting have their source outside accounting departments and do not result from the substantive preparation of the accounting personnel to the occurring changes. The biggest identified problems, associated with the discussed process, are presented in Table 2.

Table 2: Problems in the process of e-financial reporting

No.	Problem	Scale of the problem (%)
1	Insufficient time to prepare the organization of changes in the financial reporting process	39,5
2	Reducing the actual time for preparing financial statements	40,9
3	Absence of appropriate adjustments related to IT solutions – accounting program, Enterprise Resource Planning (ERP) system	35,7
4	Unclear provisions referring to e-financial statements	31,4
5	No trusted profile and/or qualified electronic signature of people signing the statements	35,2
6	No availability of e-NCR system, IT problems related to accessing e-NCR	35,1
7	Lack of knowledge/awareness among the individuals responsible for approving the statements	18,5
8	The need of programming knowledge and skills among the financial and accounting personnel	33,8
9	Absence of the professionally prepared explanations and instructions on completing the logical structures of e-statements	21,8
10	Absence of instructions about submitting e-statements to NCR/NRA (setting up a profile, submitting e-statements etc.)	15,4
11	Absence of appropriate IT support (external/internal)	20,3
12	Unavailability of persons approving the statements	18,5
13	Lack of knowledge/awareness among the management staff	19,8
14	Lack of knowledge/awareness among the financial and accounting personnel	10,7
15	Unclear notes in the logical structures of e-statements	17,7
16	Unavailability of the individuals responsible for signing the statements	9,3
17	Lack of knowledge/awareness among the individuals responsible for signing the statements	10,7
18	Errors in the logical structures of e-statements	12,0
19	Lack of knowledge/awareness among the certified auditors performing audits of e-statements	1,1
20	Unavailability of the certified auditors performing audits of e-statements at the time of signing them (along with the audit report)	0,4

Source: author's compilation based on (Report, 2019).

The comparison of answers provided by the responses and presented in the form of the above list, shows the actual, objective problems related to accountants' work or even, in general terms – the entire organization. The conducted analysis indicates that it was possible to prepare, in a proper way, for carrying out the process of both preparing and submitting e-financial statements. Every eighth respondent admitted that the organization being his/her employer or client was very well prepared for the e-financial reporting process. However, certain objective problems occurred, the source of which was outside the accounting departments or accounting offices, and predominantly took place during the stages of providing and submitting the statements. These difficulties were also associated with insufficient time needed to prepare financial statements and with IT solutions, both used in the company and provided on websites.

Interesting conclusions result from the analysis of the respondents' seniority in the accounting and finance departments, in the context of the identified obstacles. The fewest number of problems referred to the respondents presenting 11-15 years of professional experience, i.e. the ones who had already been dealing with digital technologies at an early stage of their careers. This group covered the largest percentage of employees and business owners, the best prepared for the e-financial reporting requirements.

Having analysed the research results, it can also be stated that the companies with the functioning internal accounting were better prepared for this task. It is especially true for large and medium-sized companies carrying out a broader scope of reporting obligations on a daily basis. The new solutions have often proved to pose a significant problem for micro and small organizations. In addition, the companies characterised by good infrastructure and IT support did not report major problems related to generating and sending e-statements.

Incorrect assessment of the companies' preparation, being the clients of accounting offices, could have been the result of the management boards' dismissive approach to the obligation of e-financial reporting, and thus – the absence of their active participation in the entire process. The companies commissioning the accounting services to external entities transferred the entire work to accounting offices and expected a comprehensive service with their own minimal participation. However, the external entities have limited possibilities of controlling the actual implementation stages of preparing e-financial reporting within the companies and exerting an effective pressure on management boards for greater involvement.

Conclusion

A financial statement is an important source of information about the entity's financial status. For a long time, the entire business trading reported the need for introducing electronic financial statements allowing an effective use of the data provided therein through, e.g., cross-sectional compilation of individual data. The respective legal provisions strengthened the implementation of EU legislation, as the submission of electronic financial statements in a specific format facilitated access to these statements, as well as using the data they provide by the interested entities from all EU and EEA Member States.

Changing the form of preparing and submitting financial statements resulted in new obligations related to transforming the traditional statement into XML format. Generating the appropriate e-financial statement structure also imposes covering additional expenses by companies related to the electronisation of financial statements. However, its implementation aims at improving the accounting processes and allowing more efficient use of the data provided in such statements. Obligatory reporting in an electronic form, along with the internal mechanisms of data correctness control will allow tax administration to obtain the information regarding the financial results of entities on an ongoing basis.

It is also a great opportunity for entrepreneurs because, on the one hand, they will have to organize their recording and reporting processes to obtain high quality data, and on the other – owing to the public records, they will have free access to verified and reliable information about the financial condition of their contractors.

In the author's opinion, the conducted analysis of the survey results allowed meeting the adopted goal of the article, i.e. identifying and discussing the biggest challenges faced by companies and related to the implementation of e-financial reporting. According to the author's assessment, accountants met the challenge of preparing the first e-financial statement and signing it with an electronic signature successfully. The difficulties appeared primarily outside the accounting departments, at the stage of signing the statement by the management board members and when submitting the statement to NCR/NRA.

The electronisation of financial statements is an example of the rapidly advancing digitization in relations between entrepreneurs and government institutions, which will definitely contribute to increased work efficiency in accounting departments and allow saving the time spent on preparing financial statements. This, in turn, will force entities to improve their work organization and regularity.

As a result of the digitization of financial statements and e-NRA service, employees, suppliers and competitors have access to financial data, whereas e-financial reporting has a chance of becoming a new tool for developing a positive company image, which the best entities, focusing on good cooperation and active communication between management and accounting will definitely be capable of using to their advantage.

Abstract

The retail sector as a result of transformational changes has undergone significant changes that influenced mostly buying behavior of consumers. The development of large-scale retail chains brings many positives as well as negatives, which directly affect the population. The main objective of the article is to focus on the retail network of large enterprises with 20+ employees in the Slovak Republic, namely retail sales in the context of GDP per region in the SR according to NUTS III classification. The number of observations for variable ranges from 72 to 80. When verifying the development (i.e., changes), the number of variables is from 64 to 72. Measurement has taken place in two basic phases for the purposes of achieving the goal and the presented hypotheses a). and b). The retail network is constantly growing. At the end of 2016, according to the Statistical office of the Slovak Republic in Slovakia is more than 14,000 retail units with more than 20 employees. The structure, size, location and innovation of retail operations are one of the tools to attract customers under their roof.

Keywords: Economic Development; Retail-Trade in Slovakia; Revenues; Retail Formats; Regional GDP

JEL Classification: M29, O11, L81

Introduction

The perception of retail is becoming increasingly important in all countries of the world, including Slovakia. Also in Slovakia, retail is part of GDP creation. After years of stagnation, the business sector experienced a positive turnover in mid-2016, reflecting growth in retail sales. The trend continued in the first quarter of 2017. The source of this development is the positive results of the Slovak economy, which posted a 2.9% GDP growth in 2016. Retail sales in 2016 amounted to EUR 19.3 billion and increased by 2.2% compared to the last year. The most dynamic growth was recorded in retail sales specialized in food, beverages and tobacco. Specifically, growth was 17.1%; in fuel retailing (mainly due to rising prices) - growth of 5.8%, for goods for culture and sport - growth of 3.8% and in non-specialized retail stores - growth of 2.2% (Ťapuš, 2017).

Issues of the retail development and its influence on the region is currently considered as particularly topical taking into account the economic attenuation in the world. Because of transformation changes, the retail-trade industry underwent through significant changes influencing mainly the shopping behavior of consumers. The development of large-scale retail-trade networks brings many positive but also negative matters directly affecting the population. This very specialized theme fills in a gap

in the field of research that was specific for the integration processes related with the accession of the Slovak Republic to the European Union.

The contribution of the article lies in the assessment and evaluation of the retail network (enterprises with 20 and more employees) in Slovakia during the integration processes into the structures of the European Union, in relation to revenues linked to gross domestic product (GDP) for individual regions of Slovakia (NUTS III level).

Literature Review

Retail can be characterized as an area of constant change, where it is very important for traders to react flexibly and adapt to customer needs and wishes. Changes in the market make it easy for new competitors to enter retail. However, it also brings frequent failures to sales units that do not adapt quickly to these changes. Therefore, there is a natural flexibility in the retail industry towards all the changes that occur. At the same time, retailers need to consider all parts of the so-called retail mix when creating a sales strategy (Soukalová, 2004).

Retail Activity

One of the most striking features of the current retail trade in Slovakia is at its first hand its concentration and the changing retail network structure, where small shops and supermarkets have been replaced by large-scale business formats such as supermarkets, hypermarkets and discounts. However, the construction of these large-scale facilities also brought restrictions. Localization models, analyses and various other theories are trying to explain these notions (Križan et al., 2017; Spilková, 2012).

According to the authors Tonysheva & Kuzmina (2018) represents of the balanced development of local food markets in the conditions of existing socio-economic differences and intermunicipal and is condition for ensuring the physical and economic accessibility of food products for the population of the region.

Retail activity in Slovakia is defined and delimited by the legal norms found in the Trades Licensing Act and the Commercial Code.

Legal provisions from the point of view of companies are dealt with in more detail by Horzinková (2010); (Chapčáková & Hečková, 2010). The Trades Licensing Act is a basic public law that sets the rules for businesses. Retail is defined as the purchase of goods for sale to the final consumer (retail) or for the purpose of their sale to other traders (wholesale). The law also states that retail is part of free trade that requires compliance with the general terms of this law. Neither professional nor other competences of subjects are required (Zákon č. 455/1991 Zb). The Commercial Code regulates business and other business related matters. Entrepreneurship is understood to be a continuous activity undertaken by an entrepreneur in their own name and on their own responsibility for profit. Retailers - Entrepreneurs are registered in the Trade and Business Register (Zákon č. 513/1991 Zb.).
The final consumer is very important, or most important, in this case. This type of business is operated in stores, outside of them and in retail organizations (Kotler & Keller 2013).

Levy, Weitz & Grewal (2012) state, that retailing is a key element of the distribution chain, linking production to consumption. The distribution chain is described as a summary of companies that make and distribute products and services directly to consumers. They also define it as a summary of activities that add value to products and services.

Important element for industry is the development of technology and the internet which brought great changes to the way consumers shop. The traditional way of visiting a store is considered no longer

relevant, replaced with online shopping through social media, websites, and ecommerce (Afriza et al., 2019).

Retail Transformation

The retail transformation processes in the 1990s in Central and Eastern Europe have resulted in increased interest in consumption culture and in the area of retail capital linked to the "re-emergence" of retail geography in terms of moving away from traditional localization to economic and cultural geography (Ducatel & Blomley, 1990; Križan, 2009). The transition of retail from central market management to a market economy was a complex transformation process that included qualitative changes and had to respond to the situation and conditions of the emerging domestic and foreign markets. This process was not simple and was essentially closely related to the transformation of the entire economy (Trembošová & Dubcová, 2013).

After 1989, the stage of concentration was fully manifested by the arrival of a larger number of multinational retail chains in regional cities in the Slovak Republic. This stage also affected rural municipalities with comparable signs of an increase in the number of stores (Trembošová & Dubcová, 2016). Naturally, the greatest emphasis is placed on food shops in the regions. The level of retailing in individual rural and urban municipalities is highly differentiated. Significant differences in retail equipment between western and eastern territories have been created, reflecting the size of municipalities and their economic base (Križan, Barlík & Bilková 2017; Križan et al., 2016; Danielová, 2011).

According to Pícha et al. (2012), retail is an important sector of the national economy in terms of its contribution to individual macroeconomic indicators. Retail sales are a significant indicator that reflects household consumption developments. Household expenditure is an important component of gross domestic product (GDP), affecting the behavior of other economic operators and consequently the development of other indicators.

Internationalization in the Slovak retail sector has become intense after the transition to a market economy. Many international companies have established themselves in the internal markets of post-communist countries, and this trend continued in the second half of the 1990s and continues today. Changes occurred after the entry of large retail chains into the Slovak market, which became apparent after 1996 and even more after 2000. Major chains operating in individual regions of Slovakia are mostly: Tesco, Billa, Kaufland, Coop Jednota, Lidl and others. They significantly increased competition in the regions, resulting in the disappearance of several small stores. The process of internationalization does not affect consumer behavior as much as the process of globalization does (Lauko et al., 2008). Since globalization can be characterized as an evolutionary trend in the development of society, at least a brief excursion into retail development within retail formats in Slovakia is necessary to define the globalization in retail (Križan, 2009).

Table 1: Retail Formats

Formats	Retail strategies	Store
Supermarkets	Price ranges are mostly low due to discounts and bonus benefits. These are self-service shops with a wide range of grocery and non-grocery goods.	Billa, Terno.
Hypermarkets	Price-aggressive policy with a discounted orientation, the advantage is a full range of grocery, non-grocery items such as: clothing, furniture, hairdressers, restaurant, or refreshment facilities.	Tesco, Hypernova, Kaufland.
Specialist wholesalers	The prices are similar to those in specialized department stores, with the exception of the range that differs in goods, namely, sports equipment, electrical goods, and furniture stores. They concentrate mainly on one product type. They feature hall construction solutions with lower operating costs.	Ikea, Kika, Nay, Elektroworld.

Specialized and highly specialized stores	Price ranges are mostly higher than in other sales units, high demands on staff expertise. They can focus on grocery or non-grocery assortment of goods.	DM.drogéria, Tauris, Zdravá výživa
Mixed stores (neighborhood stores)	Price ranges are largely high due to low demand for goods; retail outlets are mainly located in rural areas. It is characterized by proximity to the customer.	Gas stations.
Grocery store	Price ranges are on average, stores are located near the population (customers), especially in housing estates.	Fresh, CBA,
Full-range department stores	Price ranges are mostly at medium and higher prices, a wide range of products with individual departments managed by a specialized manager.	Baumax, Hornbach. OBI
Discount stores	The main criterion is the low price, the range of fast-moving and fast-selling, self-service type, limited range of goods.	CBA, Lidl

Source: Spilková, 2012

The current status and spatial distribution of services (retail) is the result of the long-term development. In this context, social trends and their impacts, such as industrialization and urbanization, can be taken into account, resulting in the concentration of this sector in cities (Bilková & Križan, 2013).

The scope and structure of the grocery retail area has been significantly influenced by the expansion of international retail chains to Slovakia. The emergence of retail chains can be seen as a logical phenomenon that results from the global trend of the global economy, the trend of using the "economy of sale" effects. Part of the philosophy of a typical retail chain is also the same or very similar way of selling, designing stores, as well as other elements confirming central management. The characteristics of individual retail formats are also interestingly developed in several scientific studies (Križan, 2009; Kotulič & Marchevská, 2013; Viestová, 1995; Spilková, 2012; Benda-Prokeinová et al., 2017).

Pikora (2007) points out that the development of retail sales has, in addition to unemployment, a significant impact on investor behavior, share price developments and thus stock indices, as investors link their expectations to the overall development of the national economy with these indicators.

Methods and Methodology

The aim of the paper is to evaluate the revenues for own performances and goods in the retail trade in relation to the regional GDP in Slovakia during the integration processes into the structures of the European Union.

The narrowly specialized topic fills the gap in the given area of research for the monitored period (2000 - 2010), which was a specific integration process related to the accession of the Slovak Republic to the European Union and the European Monetary Union. The analysis is based on the data base for the regions of the Slovak Republic according to the NUTS III classification and thus it is the so-called panel data, where the spatial dimension consists of regions and time - years. In total, the number of observations for individual variables is from 72 to 80. In case the development (i.e., changes) is verified, the number of variables is from 64 to 72.

Measurements take place in two basic phases for the purpose of achieving the stated goal and the hypotheses presented a). and b).

Phase one (I)

It is implemented using regression statistics to determine the most appropriate model from the selected options. Regression analysis according to Rimarčík (2006) is the starting point for inferring the results and expressing other analyses of measurements. Individual regression analyzes are recorded in Microsoft Excel. It is based on the linear, power, exponential and logarithmic model. Selection is based on maximum index of determination R2, quantile of Student distribution and Fischer distribution with degrees of freedom.

Phase two (II)
After evaluating phase one, presented hypotheses are verified using panel regression models. Individual analyses of the examined regression are recorded in statistical software - Stata. The properties of time series are discussed and then the panel test is applied. In order to find out how the variables are being examined, the panel test: Harris - Tzavalis (1999) test is used. This test is designed based on these reasons:

- verifies the null hypothesis, there is at least one nonstationary time series in one panel (e.g. GDP for all regions); as opposed to the alternative hypothesis and all-time series are stationary;
- the test counts with one, common auto regression coefficient for all-time series, which makes it more suitable than other tests for such smaller panels;
- for small samples, the strength of the tests is relatively low. Therefore, if, despite this disadvantage (small sample), the null hypothesis is rejected, it would be considered as a strong signal that the time series are stationary. First, this level-variable test will be used, taking into account the possible presence of a deterministic trend.

The key feature of the time series of (macro)economic indicators that needs to be explored in terms of their modeling is the stationarity. The time series is generally considered to be stationary if its stochastic properties are invariant to time, i.e. its diameter, variance, and covariance do not depend on time. Time series testing for stationarity is necessary for regression analysis. This is a common problem in time series analysis. If the time series are neither stationary nor cointegrated (for more details, e.g. Hatrák, 2007) and enter regression analysis, then deceptive results can occur. In fact, the non-stationarity of time series leads to the problem of so-called apparent or spurious regression, the results of which can be considered worthless (Haluška, 2011).

The principle is that if both variables have a trend at a given time interval, a strong relation between variables can be found in the analysis, even though there may be no relation between them. This phenomenon is often accompanied by the fact that in the regression analysis a high coefficient of determination are obtained and at the same time the residues from the regression model are significantly auto correlated.

Many economics and econometrics researchers are mainly focused on research of time series in individual fields. Among the Slovak economists is Benčík (1999), whose research is focused on consumer prices and nominal wages in Slovakia in terms of time series research. Also including, Ostrihoň and Ivaničová (2015), their research partly focuses on the production homogeneity of regions of Slovakia, municipalities and household consumption (Haluška, 2011; Adamišin & Tej, 2012; Buleca et al., 2017).

If they are stationary, there is a tendency to trust the regression model. If they are not stationary, the confidence in the results obtained is largely questionable.

The results are shown in the following Table 2, which shows the verification of (non)stationarity of level variables.

Table 2: Verification of (non)stationarity of level variables

	N	Trend?	Harris - Tzavalis (1999)	
			Z statistics	p – value
GDP per capita adjusted by price index	72	Yes	-1.186	0.118
Revenue in retail trade adjusted for price index	80	Yes	-2.221	0.013

Source: (authors), statistical software - Stata

This analysis shows that the following variable is stationary (taking into account or not taking into account the deterministic trend):

- revenues (adjusted for price index and trend taking).

If only this variable enters the regression analysis, the results (if trends are present) will not be considered misleading. If at least one non-stationary variable enters the analysis, the "confidence" of the results will be decided by verifying that residual autocorrelation is present in the regression models.

The Harris-Tzsavalis (1999) panel test is also used for changing variables. They can be used to analyze the presence of a dynamic relationship between variables. At the same time, as a rule, these variables are stationary and this test will only verify this property. Changes are expressed from original variables using the following relation:

((variable in time t) – (variable in time t – 1)) / (variable in time t – 1).

If these development variables are concerned, the symbol Δ is used. In the case of changes, the null-hypothesis of non-stationarity of variables was rejected by the Harris-Tzavalis (1999) test in each case. Therefore, if variables expressing changes are used in the next analysis, the result can be statistically trusted, results are apparently not deceptive.

Table 3: Verification of (non) stationarity of variable changes

	N	Trend?	Harris - Tzavalis (1999)	
			Z statistics	p – value
GDP per capita adjusted by price index	64	No	-5.725	0.00
Revenue in retail trade adjusted for price index	72	No	-10.653	0.00

Source: (authors), statistical software - Stata

Panel regression is used to verify all hypotheses, while fixed effects are considered (regions are not selected randomly - therefore, it is necessary to prefer models with so-called fixed effects as models with random effects). The following assumptions are made for each of the models:

- residual Heteroscedasticity (Wald test);
- panel Dependence of Residues (Pesaran Test);
- residue auto-correlation (LM test);

Survey Results

The essence of the problem solved is the determination of the research goal of the paper. The research objective of the paper is to evaluate the revenues from own performances and goods in retail trade in relation to regional GDP based on verification of (non) stationarity of level (changes) variables and panel regression. Two research topics and two hypotheses have been set on the basis of the stated goal.
Topic a). Is there a statistical correlation between revenues from own performances and goods in retail and regional GDP per capita within the regions of Slovakia?

Topic b). Is there a statistical link between the development of revenues change from own performances and goods in retail trade and regional GDP change per capita within the regions of Slovakia?

Price indices are adjusted in the case of regional GDP as well as revenues from own performances and goods in retail. This transformation does not affect the results in this case because it is applied to both variables. The following two hypotheses are verified.

Hypothesis a). We assume that there is no statistically significant linear relationship between revenues from own performances and goods in retail (adjusted for price index) and regional gross domestic product (adjusted for price index).

Hypothesis b). We assume that there is no statistically significant linear relationship between the development of revenues change in retail (adjusted for price index) and the development of regional gross domestic product change per capita (adjusted for price index).

The results from these tests are presented in the tables and refer to the standard fixed effect panel model. If some assumptions are violated, then panel regressions are estimated by a method in which the breach of these assumptions is taken into account. The exact procedure depends on the specific results of testing these assumptions and the data on which these regressions are performed. Therefore, a specific procedure for each of the tests is presented.

Table 4: Results of regression statistics and its statistical testing for hypothesis a).

	Linear	Exponential	Power	Logarithmic
Reliability Value R	0.88493	0.760279	0.70253	0.78363
Corrected coefficient of determination	0.883286	0.756855	0.698219	0.780494
t calculated	23.20186	14.89988	12.76543	15.80816
F calculated	538.3262	222.0065	162.9562	249.898
t table value (quantile of Student's distribution)	2.647905	2.647905	2.648977	2.648977

Tables 4 and 5 show the results of these measurements. Therefore, other correlation analyses are based on a linear model.

Table 5: Results of regression statistics and its statistical testing for hypothesis b).

	Linear	Quadratic
Reliability Value R	0.048883	0.057862
Corrected coefficient of determination	0.033542	0.026972
t calculated	1.785074	0.931491
F calculated	3.186488	1.873179
t table value (quantile of Student's distribution)	2.657479	2.658857
F table value (critical value)	7.062192	4.971015
Number of comparisons	64	64

Source: (authors), statistical software - Stata

Hypothesis a). is verified using panel regression models. The shape of the regression model in verifying the hypothesis a) is as follows:

$$gdpadj_{i,t} = \alpha_i + \beta_1 revenuesadj_{i,t} + \beta_2 year_t + u_{it}$$

The estimation of this model is based on the assumption that the variable [revenuesadj] (sales for own performances and goods in retail trade adjusted for the price index hicp) is considered stationary and variable [gdpadj] (GDP per capita adjusted by the price index hicp) for non-stationary. Therefore, similarly as explained in the previous text, the result of the residual autocorrelation test will also determine whether this hypothesis can be statistically solved at all.

The results suggest that auto-correlation is present in the residues. Therefore, this hypothesis cannot be solved meaningfully. For full disclosure, the panel regression results are shown in the table below.

Table 6: Results from hypothesis a) testing in panel regression

N	72		Groups	8
	Coefficient	**Std. Error**	**T- stat.**	**p-value**
Revenues in retail trade adjusted for HICP price index (revenuesadji,t)	1.79	0.29	6.19	0.00
Year (yeart)	345.99	56.26	6.15	0.00
Constant	-687057.60	112438.40	-6.11	0.00
R^2 modified (from the OLS assumption)	97.22%			
Wald test	0.000			
Pesaran test	0.407			
LM test	0.001			

Source: (authors), statistical software - Stata

Hypothesis b). with respect to the interrelationship of changes of both variables. Hypothesis b) was translated in panel regression:

$$\Delta gdpadj_{i,t} = \alpha_i + \beta_1 \Delta revenuesadj_{i,t} + u_{it}$$

Table 7: Results from hypothesis b) testing in panel regression

N	72		Groups	8
	Coefficient	**Std. Error**	**T- stat.**	**p-value**
Revenues in retail trade adjusted for HICP price index (Δrevenuesadji,t)	0.05	0.03	1.63	0.11
Constant	0.03	0.01	3.95	0.00
R^2 modified (from the OLS assumption)	-4.93%			
Wald test	0.526			
Pesaran test	0.620			
LM test	0.091			

Source: (authors), statistical software - Stata

Both variables are stationary, so the relationship that is (not) found in this regression is considered relevant to this analysis. All assumptions that are verified are considered to be met (p-values are all greater than 0.05). However, the relationship between sales variable and GDP (both adjusted for price indices) was not found (p-value is 0.11). For this reason, the hypothesis b) is not rejected; rather the following statement is presented.

There is no significant linear relation between the development of turnover change in retail trade (adjusted for price index) and the development of regional gross domestic product change per capita (adjusted for price index).

Discussion

The authors of Bento, P., Restuccia, D. (2020) documented in their study a comprehensive and comparable data set for the average size of enterprises in production within services. We welcome the positive impact on average business size and GDP per national and the remarkable similar income flexibility in manufacturing and services. It also compiles and documents data on correlated distortions in previous productions and industries, which have a negative impact on the distortion and GDP on the domestic market in both sectors. According to Carter, M. (2019), in terms of retailers of food and non-food products, net profit margins have decreased in recent years. The reason was a decrease in gross margins, which indicates a decrease in the number of company's price strength. The companies are trying to compensate for the decline in margins through such measures such as vertical supply chain integration and product mix modification. According to a recent study by Dujak, D. (2019), dealing with a distribution system that significantly affects not only the cost structure of

retailers and their suppliers, but also their cost structure. Results indicate high degree of retailers' satisfaction with centralized distribution mainly due to lower costs and increase in sell-out traffic. While suppliers also feel cost reduction, they are not satisfied with change of distribution system model mostly due to lost control over physical product flow. This study proposes a four-phase methodology - diagnostics, program design, assignment and design - that considers grouping suppliers by means of K and fuzzification according to several criteria. In addition, a case study analysis of 149 retail suppliers in Colombia grouped companies into high (8), medium (32) and low (109) risk groups, each of which was assigned tailor-made development programs. The results obtained support the use of the proposed methodology to improve supply chain performance for organizations with many suppliers in need of development programs Buriticá, NC, Matamoros, MY, et al., (2019). According to a recent study *"Sustainable Initiatives and Organizational Reshaping in Food Retailers"*, which examined how large food retailers adopt corporate social responsibility (CSR) programs for employees and their families. The findings point to the need to redefine organizational structures and implementation processes. Selected cases highlight the importance of closer coordination between organizational dimensions in the implementation of the CAP in the retail sector, with some cases showing delays in the implementation of organizational tools and employee involvement Risso, M., & Tavino, S. (2020).

Conclusion

Hypothesis (a) was based on regression models: Driscoll-Kraay (t-statistics, p-value), OLS (R2 modified), LM test, Wald test, Pesaran test. Significant links between own performances and goods and regional GDP were statistically insignificant from the results of the LM test, which confirmed the presence of auto-correlation in residues. Therefore, these results cannot be further interpreted. Hypothesis (a) cannot be verified.

Hypothesis (b) was expressed similarly to (hypothesis a), i.e. based on regression models: Driscoll-Kraay (t-statistics, p-value), OLS (R2 modified), LM test, Wald test, Pesaran test. However, the relationship between the development of revenues from own performances and goods and the development of regional GDP was not found (p-value is 0.11). Consequently, hypothesis (b) is not rejected. The hypothesis was confirmed.

The issue of retail development and its impact on the region is currently considered to be a topical issue in view of the ongoing economic downturn in the world. The development of sales in the Slovak retail sector depends largely on the structure and number of outlets, which according to statistical surveys are divided into department stores, shopping centers, hypermarkets, mixed stores, supermarkets, wide-range grocery and other specialized stores. The network of retail outlets with 20 or more employees is growing year by year in terms of reporting units. The number of hypermarkets and supermarkets is growing with the emergence of retail chains and the number of shopping centers, self-service stores and discount stores is declining. It is very likely that, in generalizing the relation between consumer buying behavior and commercial supply, the concentration in the retail services sector will increase, which will increase the competition for retailers, and the pursuit of meaningful innovation will be a matter of future direction and survival in the industry.

Abstract

The goal of the study was to compare the fairness assessment levels for various traditional and ICT-based forms of personnel selection tools. Basing on data from an e-questionnaire conducted on a sample of 405 employees in Poland, a comparison was made of 6 different forms of interviews (including long-distance), 4 forms of reference checking (including social and professional media screening), 4 active work-related methods (including playing computers games and internships), and 4 tests/questionnaires. Potential candidates were found to assess the various forms of selection conducted using tools from a given group in different ways. ICT-based selection tools are generally given lower assessments as compared with their traditional analogues, with the exception of screening of professional media. Respondents who have been previously evaluated by a given selection tool perceive process favorability of this tool higher than those who have no experience with this selection tool.

Keywords: Personnel Selection, ICT-Based Selection Tools, Organizational Justice, Process Favorability.

Introduction

Research into employee selection at first focused on the predictive value of data provided by a selection tool for success at work (Truxillo & Bauer 2011; Ployhart, Schmitt & Tippins 2017). With time, researchers started focusing on other measures of success (e.g. litigation intentions, withdrawal from the selection process, turnover) in their assessments of the quality of the selection process. However up until the 1990s, the employer's perspective dominated, and minimal attention was devoted in studies to candidates' interests (Truxillo & Bauer 2011; Ployhart, Schmitt & Tippins 2017).

S.W. Gilliland's (1993) fairness-based model introduces a new approach in the research on applicants' reactions to selection methods, by applying constructs from Greenberg's (1990) organizational justice theory. This model connects applicants' and employees' reactions to selection procedures with their perceptions of procedural and distributive justice of selection methods. Steiner & Gilliland (1996) proposed a methodology, until now followed by almost all studies into how candidates perceive selection tools (Nikolaou et al 2019: 103). However, although numerous studies have been conducted within this framework, reviews of the literature emphasize that we do not know whether the form in which a tool is implemented has significance for its acceptance level (Truxillo & Bauer 2011; Nikolaou & Oostrom 2015; Truxillo et al 2018). Specifically, there is no data on whether online equivalents of traditional tools are similarly accepted (McCarthy et al 2017).

The goal of the study was to compare the acceptance level of the different forms in which 4 types of selection tools are used. Data was collected from 405 respondents in Poland through an e-questionnaire on a panel devoted to market research. Comparisons of assessments were made for various forms of the following: interviews (4 typical interview methods, stressful interview and long-

distance interview); methods based on others' opinion (2 types of traditional reference checking and 2 types of social media screening); active work-related methods (2 types of traditional work samples and 2 types of simulated work samples); and 4 types of tests/questionnaires. It was found that potential candidates assess the various forms of a tool from the same group differently. It was also confirmed that respondents who have been previously evaluated by a specific selection tool perceive process favorability of this tool higher than those who have no experience with this selection tool.

The article is organized in the following way: part 1 describes the traditional methodology of research into the acceptance of selection tools, to outline its assumptions and limitations. Part 2 introduces the premises of the study and the research hypotheses. Part 3 presents the research methodology, and part 4 describes the research results. section should follow keywords.

Assumptions of the standard methodology for studies on the assessment of fairness of selection tools

The dominating methodology in studies on the assessment of fairness of selection tools (Truxillo & Bauer 2011; Nikolaou & Oostrom 2015; Truxillo et al 2018) bases on Steiner and Gulliland's classic study (1996). In it, acceptance of a tool is analysed by distinguishing distributive justice (process favorability, i.e. the fairness of the result of the selection decision) and procedural justice (fairness of selection procedures). These constructs are measured with the use of a questionnaire, with 2 questions indicative of the former, and 7 questions indicative of the latter. Each group of questions is preceded by a short description of the tool to be assessed. Each of the questions is assessed on a 5- or 7-point Likert scale. This research procedure has been followed multiple times (Anderson, Salgado & Hülsheger 2010; Bilgic & Acarlar 2010; Ispas et al 2010; Anderson, Ahmed & Costa 2012; Liu, Potočnik & Anderson 2016), despite its arduousness for respondents (Bilgic & Acarlar 2010), and the questionability of its underlying assumptions.

The most fundamental of these controversial assumptions is that respondents comprehend the tool they assess in a similar way. This is obviously incorrect, however, as some respondents know the tool from their own experience, others from everyday exchanges with colleagues, and yet others – from a description they read with greater or lesser attention. This observation finds confirmation in Snyder & Shahani-Denning's research results (2012), which have shown that subjects who know a given selection tool from their own experience give it a higher fairness assessment.

A second group of assumptions concerns the determinants of the opinions shown in a questionnaire. Standard methodology assumes that the main criterion followed when responding to questions in a questionnaire is fairness assessment. This in turn assumes that emotional attitude is evened out with respect to (at least) the selection tools, and (more broadly) with respect to ways of communicating with the employer. However, studies have shown that fear of being assessed by a given tool, such as a test (Arvey et al 1990), affects not only the result, but also the respondent's emotional attitude towards the fact of being assessed, and in effect – his/her assessment of the fairness of such a test (Nikolaou & Oostrom 2015).

Despite the broad use of ICT-based selection tools, attention is drawn in the literature to the scarcity of studies both on how they are accepted (McCarthy et al 2017; Woods et al 2019), as on how the fairness assessment of various forms of the same personnel selection tool is differentiated (Truxillo & Bauer 2011; Nikolaou & Oostrom 2015; Truxillo et al 2018). We may, however, expect that candidates' responses will differ in the case of face-to-face interviews concerning qualifications, or their reactions to a stressful situation provoked during the interview.

Assumptions of the Research

Four basic types of selection tools were chosen for the study (interview, reference checking, work sample and questionnaire), and each of these had several forms (variants of the tool type). In effect,

the study analyzed: 6 types of interviews, 4 types of methods based on others' opinions, 4 work sample related tools (simulated and specific work samples), and 4 types of written tests and questionnaires (Tab. 1).

In this article we use the term "form of implementing a selection tool" as a general term to describe the differentiation between ways in which a specific type of tool is implemented, the effect of (a) a specific method of creating stimuli for the candidate, and (b) communication channel through which the stimulus is delivered to the candidate. The first group of differences includes, e.g.: method of constructing interview questions, simulated or real work samples and references gathered from various types of people. The second group includes face to face and ICT-based communication. Such a multidimensional approach seems useful for an explorative study.

The aim of this study was to verify whether the different forms of implementing selection tools from a given group (e.g. using different interview methods) affects assessments of their process favorability. We based on a common sense expectation that assessments of recruitment interviews will differ depending on whether the interview used stress-inducing techniques, or was "traditional" and concerned candidates' educational and professional experiences. In addition, we wanted to verify whether the perception of fairness of ICT-based selection tools is lower than that of similar traditional tools. The belief that technology-mediated communication decreases fairness assessment level for a given selection procedure is based on media richness theory, according to which the acceptance level of media of a lower density (in their role of communication tool), is lower (Daft & Lengel 1986). According to some (McCarthy et al 2017), this should also be relevant for selection tools. Partial confirmation for this belief may be found in earlier empirical studies concerning technology-mediated interviews (Blacksmith, Willford & Behrend 2016; Langer, Kőnig & Krause 2017), however our research focuses on a broader range of selection tools. An indirect argument that this may be expected for social media searching may be the unwillingness of candidates concerning this type of recruiter activity (Aguado et al 2016). On the other hand, however, we may expect that present-day candidates, living in internet times, are not only familiar with this kind of communication, but treat it as naturally as traditional methods.

A second goal of the study was to verify if experience with a given tool affects perception of its fairness. Research conducted on a sample of 169 employees in Mumbai (Snyder & Shahani-Denning 2012) showed that fairness scores were significantly higher if participants indicated that they have previously been evaluated by the same tool. The study showed this to be true for personality tests, personal contacts, assessment centers, biographical information blanks, written ability tests, honesty tests, online information and graphology, but not for interviews, resumes, personnel references and work-samples. In the latter case, the differences were insignificant, which was explained by the fact that almost all subjects had had experience with the given method (Snyder & Shahani-Denning 2012: 306).

Table 1: Types of investigated methods, their descriptions and their abbreviations

No	Description of method type	Abbreviation
	Group: Interviews	
1	Interview concerning your experience and qualifications	Interview (qualifications)
2	Interview during which you have to describe in detail how you acted in the past in specific situations	Interview (episodic)
3	Interview during which you have to describe how you would act in a given (hypothetical) situation	Interview (situational)
4	Interview concerning your strong and weak points	Interview (strengths and weaknesses)
5	Interview during which interviewers try to frighten and stress you	Interview (stressful)

6	Long-distance interview (e.g. via Skype)	Long-distance interview
	Group: Based on others' opinions	
7	Checking your credentials (references) by interviewing people who know you	Personal references (acquaintances)
8	Checking your credentials through interviews with your former bosses	Personal references (former bosses)
9	Being assessed on the basis of information that can be found on "non-professional" social media (such as Facebook)	Social media screening
10	Being assessed on the basis of information to be found on "professional" social media (such as LinkedIn)	Professional network screening
	Group: Active work-related	
11	Work samples (you show how you would perform in a given task)	Work sample
12	Assessment center (exercises conducted in a group over 1-2 days, observed by several assessors)	Assessment center
13	Being accepted for an internship, and then those who show they possess the appropriate competencies for the job are proposed a normal work contract	Internship
14	Being asked to play a computer game, on the basis of which it is assessed whether the player is suitable (has the required competencies) for the job	Computer game
	Group: Written tests and questionnaires	
15	Written tests checking your professional knowledge (e.g. exam concerning legal knowledge, procedures, standard solutions)	Written knowledge test
16	Questionnaire describing situations and a set of solutions for each, with a forced choice of the solution that best describes your behaviour in the given situation	Situational questionnaire
17	Cognitive skills test with tasks and logical puzzles to solve	Cognitive skills test
18	Personality tests	Personality test

Source: Own elaboration based on (Woźniak 2013) and (Steiner & Gilliland 1996)

We thought it worth repeating this study with the use of several ICT-based tools, rather than just one. On the one hand, previous experience favours an increase in perceived ease of use – it is one of the determinants of attitude toward using technology in the Technology Acceptance Model (TAM) (Davis, Bagozzi & Warshaw 1989). Hence, we may expect that previous experience with being assessed with the use of a given selection tool will favour more positive assessment of the tool, through its perceived ease of use. On the other hand, however, the negative valence of this experience may lower its score (through a decrease in its perceived usefulness).

If we define the research goals in this manner, i.e. that a variety of different forms of the use of a given selection tool need to be assessed, the sheer length of the measurement tool (questionnaire) forces us to limit the study to an analysis only of process favorability. In this case, the measuring questionnaire consists of 2 questions for each of the recruitment tools, with assessments made on a 7-point Likert scale (Steiner & Gilliland, 1996).

The following hypotheses were posed:

H.1. The different types of methods, grouped into four categories;

a) interviews (qualifications, episodic, situational, strengths and weaknesses, stressful, long-distance),

b) methods based on others' opinions (personal references from acquaintances, personal references from former bosses, social media screening, professional network screening),

c) active work-related methods (work samples, assessment center, internship, computer games),

d) written tests and questionnaires

will be assessed in different ways, and (e) ICT-based methods will be rated less favorably than their traditional counterparts.

H2. Individual experience with a selection method affects perceived process favorability of this tool..

Method

Participants

The study was carried out using an e-questionnaire on the ankietowo.pl portal in January 2018. The portal has access to a panel of gamification-renumerated respondents, and declares that its composition corresponds (layer-wise) to the demographic structure of Polish society Our sample was not random – the responses of people who are not currently professionally active were rejected. It consisted of 405 currently employed subjects, and was dominated by female subjects (60.0%). The average age of participants was 33,31 years (SD = 12.44). 43.7% of respondents had university degrees, the remainder had at most high-school degrees. 34.6 % respondents declared that their job seniority was below 4 years, 36.5% – 5-15 years, 28.9 – 15 years or over.

Measures

A total of 18 types of selection methods were investigated. They were described to respondents as presented in Table 1, which also lists the abbreviations used for each type of method.

The first question concerns experience with a given method: “Recall the last recruitment you took part in, which gained you a job. What methods were used to assess whether you were suitable (mark all that you think were used)?”. In this question, respondents were not asked for their experience with the use of social media screening or professional network screening. Instead, they were asked to answer with a yes/no to the statement: “I think they searched for information about me on the Internet”.

The next two questions concerned process favorability measured on a 7-point scale, from 1 (“strongly disagree”) to 7 (“strongly agree”):

1. “[This type of method] is effective for identifying people qualified for the job.”

2. “If I did not get the job after [the use of this type of method], I would consider that selection based on [this type of method] is fair.“

The process favorability index was calculated as the mean score on those two items.

In the questionnaire, these two questions measuring process favorability were preceded by a description of the tool, which detailed facts and behaviours as they would be perceived and experienced by candidates (i.e., the description was phenomenological).

Lastly, respondents were asked about their gender, year of birth, job seniority, level of education and type of work.

IBM SPSS Statistic software (v.25) was used to conduct all statistical analyses. Statistical significance was set for a 0.05 level.

Results

In order to examine if the form of selection tool in each group affects perceived process favorability scores, four repeated-measures analyses of variance (ANOVA) followed by pairwise comparisons with Bonferroni's adjustment were conducted. Table 2 presents the results of these analyses. These analyses showed the large significant effects of method type in the "Interviews" group, moderate effects in the "Active work-related" group and low effects in the remaining groups.

In two of the three groups in which perception of ICT-based tools was tested, the lowest rated tool was the ICT-based one; in the "Interviews" group it took second last place. Contrary to our hypothesis that ICT-based methods will be rated less favorably than their traditional counterparts, in the "Tools that are based on others' opinions" group, one of the 2 ICT-based tools (being assessed on the basis of information to be found on "professional" (LinkedIN-type) social media) was not assessed lower than its traditional counterpart (checking candidate's references through interviews with his/her former bosses). This partly falsifies hypothesis 1, and indicates that not only communication channel, but also other factors (here: form of implementation of the method) affect how a tool's fairness is assessed.

To recapitulate, hypotheses 1.a-d were fully supported, while hypothesis 1.e was only partially supported, as not all the ICT-based tools investigated are rated lower than their traditional counterparts

Table 2: Process favorability ratings – means and standard deviations in groups

	Mean	Std. Deviation	F	p	partial η2
Group: Interviews					
Interview (qualifications)	5.16	1.13	163.72	<0.001	0.29 (large)
Interview (situational)	4.59 [A]	1.14			
Interview (episodic)	4.56 [A, B]	1.18			
Interview (strengths and weaknesses	4.45 [B]	1.12			
Long-distance interview	3.81	1.27			
Interview (stressful)	3.53	1.38			
Group: Based on others' opinions					
Personal references (former bosses)	4.11 [A]	1.26	16.97	<0.001	0.04 (small)
Professional network screening	3.98 [A, B]	1.41			
Personal references (acquaintances)	3.94 [B]	1.33			
Social media screening	3.68	1.44			
Group: Active work-related					
Work sample	4.51 [A]	1.10	50.69	<0.001	0.11 (moderate)
Internship	4.49 [A]	1.27			
Assessment center	4.21	1.21			
Computer game	3,79	1.40			
Group: Written tests and questionnaires					
Written knowledge test	4.49 [A]	1.14	6.43	0.001	0.02 (small)
Situational questionnaire	4.52 [A]	1.06			

Personality test	4.36 [B]	1.13			
Cognitive skills test	4.36 [B]	1.14			

Notes: Methods in the groups are listed in descending order of process favorability.
Means with the same superscripts in the groups are not significantly different at p<0.05

To determine if significant differences existed between perceived process favorability reported by respondents who have or do not have experience with given tool, 16 independent t-tests were performed for each selection method type. Apart from three tools – social media screening, professional network screening, and situational questionnaire, for which the differences between mean evaluations are insignificant – experienced respondents assessed the favorability process higher than the inexperienced (Table 3). Hypothesis 2 was thus supported.

Discussion and Conclusions

The goal of the study was to verify whether the form in which a specific type of selection tool is implemented affects how its fairness is assessed by candidates. Specifically, we attempted to verify whether the implementation of ICT-based methods during selection decreases acceptance level. Data collected with the use of an e-questionnaire from 405 employees in Poland showed that potential candidates assess various forms of interview, reference and opinion checking, (simulated) work samples, and tests/questionnaires in different ways, and ICT-based methods are usually – with one important exception – given lower evaluations than the corresponding traditional methods. Familiarity with a given tool (experience with it during a previous selection) was also found to increase acceptance for the given tool (measured by an assessment of its distributive justice) – again, with certain exceptions.

Table 3: Differences between perceived process favorability based on subjects' experience with a given method

Types of selection methods	Not experienced		Experienced		t-test		
	N	Mean (SD)	N	Mean (SD)	t	p	Cohen's d
Group: Interviews							
Interview (qualifications)	143	4.73 (1.04)	262	5.40 (1.12)	-5.83	<0.001	0.61
Interview (situational)	307	4.49 (1.09)	98	4.92 (1.25)	-3.08	0.003	0.36
Interview (episodic)	334	4.46 (1.12)	71	5.04 (1.34)	-3.41	0.001	0.45
Interview (strengths and weaknesses	284	4.33 (1.09)	121	4.73 (1.13)	-3.32	0.001	0.36
Long-distance interview	374	3.74 (1.28)	31	4.58 (0.98)	-3.57	<0.001	0.67
Interview (stressful)	383	3.50 (1.39)	22	4.16 (0.98)	-2.19	0.029	0.48
Group: Based on others' opinions							
Personal references (former bosses)	377	4.07 (1.25)	28	4.66 (1.31)	-2.41	0.016	0.47
Professional networks screening	386	3.96 (1.39)	19	4.45 (1.81)	-1.48	0.141	
Personal references (acquaintances)	351	3.87 (1.34)	54	4.34 (1.18)	-2.43	0.016	0.35
Social media	386	3.69	19	3.40	0.88	0.380	

screening		(1.44)		(1.50)			
Group: Active work-related							
Work sample	360	4.46 (1.08)	45	4.83 (1.27)	-2.13	0.034	0.34
Internship	361	4.42 (1.26)	44	4.99 (1.24)	-2.81	0.005	0.45
Assessment center	388	4.16 (1.20)	17	5.27 (1.15)	-3.73	<0.001	0.93
Computer game	393	3.76 (1.40)	12	4.79 (1.36)	-2.52	0.012	0.74
Group: Written tests and questionnaires							
Written knowledge test	340	4.40 (1.15)	65	4.96 (0.95)	-3.69	<0.001	0.50

Personality test	342	4.30 (1.16)	63	4.72 (0.92)	-2.76	0.006	0.38
Cognitive skills test	374	4.32 (1.15)	31	4.81 (1.00)	-2.29	0.022	0.43

Note: Standard deviations are given in parentheses

Apart from these general results, the study revealed some interesting details. Firstly, candidates assess professional media screening relatively well (i.e., not worse than checking references with former bosses), and differentiated it from social media screening, which is given a low rating. This result suggests that not only communication channel, but also the specific method of communicating within this channel are of significance for assessing the tool's fairness. This is consistent with the main assumption of the study, namely that the different forms in which tools from a given group are implemented will be evaluated in different ways, and supports the thesis that difference in implementation are not solely an issue of the density of the medium through which the activity takes place. This thesis, verified through an analysis of 5 types of interview, differing with respect to method of constructing questions, finds confirmation in the data in table 2. Similarly, evaluations of various forms of reference checking and active work-related selection methods were found to differ significantly.

Secondly, though having been assessed with the use of a given tool usually increases its acceptance, testing with both kinds of social media are an exception. The questionnaire used a single question to measure experience with being assessed through internet-based reference searches. Our data cannot therefore distinguish whether respondents who underwent social media screening during their last selection assess reference checking tools differently to respondents who had undergone professional network screening. The decision, made in the preparatory phase of the study, to have a single question was dictated by the assumption that questionnaire items should only include elements visible to the respondents – who were at the most able to guess that the recruiter had searched online for information about them. Hence verifying whether the experience of having references checked with the use of professional (LinkedIN type) social media screening favours later positive assessment of this tool, is an important future research direction, with significance for HR practice.

Two conclusions may be drawn from the fact that in selection practice, previous experience with a specific tool favours its later acceptance. If previous experience with a selection tool increases its acceptance, we may assume that this experience was a positive one. This means the work of previous recruiters (HR workers) is positively evaluated, and suggests that such positive experiences not only decrease fear (and so probably increase acceptance) of successive recruitments conducted with the use of the given tool – but also strengthen trust put in information provided by recruiters. This in turn increases the probability that giving candidates additional information before using the selection tool will decrease their fear of being evaluated by this tool. Earlier studies conducted in a laboratory

setting showed that fairness assessments may potentially be increased (e.g. McCarthy et al., 2017a), if before implementing the tool, candidates are informed about the reasons it is being used for. Applying these research conclusions to practice requires assuming that candidates will trust the information provided by recruiters at the beginning of the recruitment process. In effect this means that – with the significant exception of social media checking –acceptance of various forms of selection tools, including those based on ICT, will be increasing. This will happen both spontaneously (thanks to the positive experiences of being assessed by a given kind of tool), and in an accelerated way (when HR departments begin to include explaining why this selection tool is used as part of the procedure).

To summarize, our study suggests that with prospective candidates' current level of awareness, ICT-based selection tools should be used with the utmost care in Poland. Secondly, research into fairness should be broadened to include a greater variety of selection tools – both with respect to communication channels through which data about candidates is collected, as with respect to the method used to provoke behavior or collect data.

There are several limitations which need to be taken into account before drawing any categorical conclusions. Firstly, the study based its results on opinions declared by a specific group of respondents – relatively young people (average age of 33,3 years), currently not looking for work and not in the position of having to be subjected to selection by a given tool. The relatively low age of respondents suggests a relatively high level of internet literacy and hence an untypical attitude towards ICT-based tools – more positive, but also more aware of the risks associated with this medium. The fact that respondents are currently not undergoing selection is a limitation typical of most studies conducted in this field. In effect, the results are biased – but the direction of this bias cannot be a priori assessed.

Secondly, the study does not control whether all respondents similarly understand the recruiter's role in the given selection tool – specifically, how they imagine what the recruiter really does. Theory of organizational justice indicate that subjects' responses are not so much a reaction to the selection tool used, as to how they perceive and imagine the recruiter's behavior. From the HR perspective, it is not so much the fairness assessments, as their behavioural consequences (drawn attention to by organizational fairness theory) that are of significance. The perspective we adopted, with its phenomenological description of the recruiter's behaviour, constitutes just a first step towards limiting this phenomenon.

Abstract

Poor air quality is dangerous for health, the environment and many industrial activities; recently, it has been correlated to the pace of coronavirus outbreak in some areas. From an environmental regulatory perspective, it is a challenging problem, since regulators seem to be missing decision support systems to tackle the issue and come up with balanced policies. We advocate the use of integrated assessment modelling (IAM) as a tool of decision support system for regulators that are in charge of air quality control. Since pollutants in the atmosphere depend on multiple sources of emission and some of them have non-linear reactions when in contact with other substances, traditional models of response for air quality pollution do not perform well. IAMs allow for multi-objective optimization, also taking into account the costs and benefits of emission reduction in a Pareto-optimality framework of analysis. We use the RIAT+ software and methodology to show how IAMs is feasible and how it has been implemented at least in one case, providing useful insights to policy makers.

Keywords: Integrated Assessment Modelling – Air Quality Control – Decision Support System – Government Policy and Regulation

Introduction

Air quality is becoming an issue with serious consequences for human health and for economic systems worldwide. The Real-time Air Quality Index online provides an indication of how serious the situation is in some strongly industrialized areas around the globe (AQI 2020). As an example, in areas of high concentration of pollutants, initial correlations between air pollution and the diffusion of coronavirus have been observed, as particulate favors the spreading of airborne particles.

Current analytic models and holistic tools developed at academic level allow to harness data on the status of air and to identify measures that might be both effective and efficient for air quality control. Surprisingly, notwithstanding the wealth of such tools, regional governments very often fail to address the problem in practice, particularly in some countries and within more problematic areas. There seems to be a serious clash or a divergence between what the theory recommends and what the practice does, similar to those observed in other disciplines (Ungureanu and Bertolotti 2016).

In the United States, the Clear Air Act of 1963 was the first modern piece of legislation to require authorities to adopt plans for air quality control in so called non-attainment areas, where air quality standards are not met. The European Union followed the U.S. example and Directive 2008/50 now obliges Members states to implement air quality plans for regions or sub-regions where the quality of air deteriorates because of anthropic emissions. Notwithstanding the efforts at European level, the

situation does not improve in many areas and some Member States either failed to adopt plans or passed measures that eventually did not work. Our main research question relates to the motives decision makers fail to adopt in practice effective support decision systems. We believe the issue is both timely and useful to reconcile theory and practice and to make efforts of air quality control finally effective, as states are becoming more and more aware of the problem.

Theoretical background

In this paper, we advocate the use of integrated assessment models (IAMs) to introduce notions of efficiency in the adoption of policy measures to fight outdoor air pollution and enhance decision support systems (DSS) in the field of environmental control. Traditional and AI-powered models are instrumental to reduce discretionary powers and guide the decision-making process in regulating anthropic activities that have an impact on the environment and, more specifically, on air.

Contrary to the perception of policy makers, we aim to demonstrate that IAMs represent a solid scientific contribution to solve a widespread problem; science-driven approaches are hugely important for decision-makers and should become part of the environmental policies (Kørnøv and Thissen, 2000). Outdoor air pollution is caused by pollutants that float in the atmosphere and, more precisely, in its lower layer that is in contact with the planet surface (troposphere) (Sitaras and Siskos, 2008). Pollutants are caused by a number of natural and anthropic activities, that go from manufacturing to energy production, from mobility to heating households, to volcanic eruptions or fires. Emissions from human activities are more dangerous, as they increase the concentration of pollutants in urban areas and regions, where the population typically lives.

From a technical standpoint, the relationship between emissions and concentration is extremely complex and it is influenced by the meteorology and the chemistry at atmospheric level.

Meteorology will explain whether a pollutant, depending on the orography or the climate of a given area, remains more or less concentrated (for instance, because of mountains or hills that prevent transportation) or is dispersed (for instance, by the marine breeze of coastal areas). Chemistry of the atmosphere explains that some pollutants, when entering the troposphere, start combining with other substances and such reactions can be slow (as for SO_2) or more rapid (as for NO_x or VOC), thus determining different impacts on concentration and on the evolution of the air quality status.

With respect to the chemistry of atmosphere, pollutants are typically classified in primary and secondary. Primary pollutants are emitted in the air and preserve their condition, not being reactive and not combining with other substances. Secondary pollutants, instead, result from reactions among gas already present in the atmosphere, called “precursors”, and are the most dangerous and difficult to control, since concentration and impact on the air quality depends on several factors and conditions.
Secondary air pollutants include (EEA 2017):

- Carbon monoxide (CO), a compounded gas formed mainly by combustion of crude oil; its sources of emission are mostly related to transport, but also to industrial burning plants or household heating.
- Nitrogen Oxides (NOx), which includes NO and NO_2, are also related to combustion processes. Diesel engines and energy production and distribution systems are the main sources. Importantly, NOx are precursors of other secondary pollutants like ozone (O_3) and particulate matter (PM).
- Sulphur Oxide (SOx) is also mainly due to fuel combustion and the main sources are stationary power generation, industry, commercial, institutional and household (ISPRA 2015).
- Ozone (O_3) is a secondary pollutant, generated in the atmosphere by primary pollutants, that has transboundary effects and is activated through photochemical reaction. Consequently, its emergence is more significant when exposure to sunlight is higher (as during the day and in summer).

- Volatile Organic Compounds (VOCs) include a mix of different substances (like methane, benzene and hydrocarbons) that, according to their structure and nature, are organic and volatile enough to be considered vapor.
- "Black carbon is the sooty black material emitted from gas and diesel engines, coal-fired power plants, and other sources that burn fossil fuel", which is not otherwise classified (US EPA 2018).
- Particulate Matter (PM) is a class of substances very dangerous for human health. It is a combination of particles – solid and liquid – suspended in the air. It is composed both by primary PM and secondary elements. In practice, the chemical structure of PM is not identifiable ex ante, since it results from a variety of precursors, like sulphur dioxide (SO_2), nitrogen oxides (NOx), ammonia (NH_3), VOC, black carbon and primary PM. PM also has natural and/or human generated components. Among the natural constituents, there are sea salt, dust, volcanic ashes and pollen. Anthropic elements include, for instance, combustion and dust generated from road and tires wear, as well as fires from agriculture. Hence, sources of emission can be manifold. PM is further classified with respect to the diameter of the particles. If it is equal or less than 10 µm it is called PM10, and if it is equal or less than 2,5 µm it is called PM2,5.

Needless to say, the size of the particles is inversely proportional to the dangerousness of the particulate matter, since the smaller it is, the easier is the risk of absorption in the human body. PM is largely responsible for cardio-respiratory diseases and smaller particles can also penetrate cells and interact with DNA, causing alterations (WHO and OECD, 2015).

What is strikingly important to understand is that because of the many factors that interfere in the relationship between sources of emission and concentration of pollutants in the troposphere, as well as for the behavior of active pollutants and non-linear reactions, air quality control is not an easy problem to tackle. Therefore, it requires solid analytic models to direct any action aimed at improving the air quality status.

Methodology. the DPSIR paradigm for air quality control

In order to understand how analytical models can be developed to address the problem of pollutants to the purposes of air quality control, we refer to a conceptual framework of analysis originally developed by the European Environment Agency. Such framework is termed DPSIR, an acronym that stands for Determinants (Driving forces), Pressures, State, Impact, Responses, and it is an extension of the pressure-state-response (PSR) conceptual framework originally proposed by the OECD (OECD 2003). DSPIR is the first conceptual framework to come up with an integrated assessment model for air quality control, as it aims at providing a holistic approach to the problem, by describing the interactions between the environment and society (Guariso et al, 2016).

The DPSIR model becomes useful in modelling, since it allows a more accurate analysis of the relevant factors and their interactions, but it is also crucial in developing forecast models for ex ante and ex post regulatory assessment and in supporting decision-making processes in relation to actions that should be implemented. The following figure gives a graphical representation of DSPIR's elements, their reciprocal positions and interactions.

Fig. 1: DPSIR

The rationale behind DPSIR is the causal link among the elements. Individual and social needs, as well as the activities and the infrastructure aimed at their satisfaction (Determinants) exert pressures on the environment (Pressures). Such pressures cause changes in the condition of the environment and of natural resources (Status), whose effect is to produce consequences (Impacts) for human health, ecosystems, and the economy in general. Eventually, impacts require mitigation solutions, through responses, that can act – with various degree of effectiveness and various level of costs – on each of the previous elements.

To be sure, determinants refer both all socio-economic factors that satisfy individual and social needs (food, raw material, energy, or even culture, leisure and other human dimensions that entail individual choices) and infrastructure and activities aimed at producing goods and services. Hence, determinants include sources of emissions that have an impact on the quality of air. For clarity, we consider sources as belonging to four main categories: (1) industry and productive activities in general (2) agriculture and related activities (such as farming) (3) traffic and mobility in general and (4) heating and energy production.

Intuitively, only under extremely simplified models by influencing one of the sources there is a direct and positive consequence in terms of air quality, because anthropic activities cannot be shut down altogether and because of the behavior of pollutants deriving from the above-mentioned sources. More complex models of optimization are required and a vast body of research has been dealing with several proposals (for a review see Blond et al, 2017).

Pressures are represented by the set of human activities producing modifications on the environment, such as the release of pollutants in the air, or waste disposal or electromagnetic and acoustic pollution. Pressures cause changes in the state of the environment and, more specifically, on air. The development of models hinges on data on state, which can be monitored, measured and exposed to simulations that can predict its changes and evolutions. Authorities have developed air quality indexes and statistics reports based on data available within given geographic areas (US EPA 2018) and such data are typically available to download for uses also by the scientific community.

Impacts can be both negative and positive, and they depend on variations of the state of ecosystems, on health, on wealth and economy. Eventually, technical and regulatory responses are aimed at reducing or mitigating the consequences on the state, while trying not to cause side effects or impacts that can offset the advantages of regulation. Under this standpoint, IAMs become crucial to optimize the options available when facing a multi-level, multi-variable problem.

Integrated Assessment Modelling: RIAT+

The interactions of pollutants and the variety of sources of emissions and their nature trigger a reflection about the construction of a decision support system that integrates anthropic elements, economic considerations and natural phenomena in a holistic tool.

One such tool, that one of the authors of this paper contributed to develop is the RIAT+ (acronym of Regional Integrated Assessment Tool), that is able to handle non-linear phenomena (contrary to state-of-the-art solutions that follow a linear approach) and provides a multi-objective framework, that is supposed to overcome the traditional scenario analysis and the cost-benefit analysis. Improved versions of such systems are also available and improvements have been discussed and implemented in other research projects, also with a view to supporting policy makers in their attempt (Viaene et al, 2016).

To address the complexity posed by the economic and physical variables, the RIAT+ model resorts to neural networks and neuro-fuzzy models (Carnevale et al, 2009). The model relies on two objectives that must be optimized, that is the air quality (measured according to the standard AQI) and the costs of implementing actions that reduce emissions. The two dimensions of the model are relevant to the purposes of this paper, since the model itself allows for optimization by looking at both objectives from the perspective of efficacy and efficiency.

Importantly, RIAT+ proves a light model, that does not require significant computational power and extended runtimes, which makes it also suitable for timely applications when the decision-maker needs real-time tools to redress a situation where the air quality is worsening and multiple sources are responsible for concentration of primary and secondary pollutants.

Results on the application of RIAT+ to a real case

One of the tools based on the IAM approach is the RIAT+, a system developed by a consortium of European universities and research centers during the EU-funded OPERA project. After its development, RIAT+ was applied to assess the effectiveness of the local air quality plan of the Lombardy Region, in Italy (Carnevale et al, 2018; Turrini et al, 2018). By illustrating the results of the application, we aim to provide evidence of how IAM models can be used to assess and adopt measures that are not only effective, but also efficient, when considering the costs of their adoption.

Due to peculiar meteorologic conditions, Lombardy is one of the most problematic regions in Europe. Its intense industrial and agricultural activities also cause high level of atmospheric pollution and concentration of PM. Under the European regulation scheme, Member States and regions are required to adopt regional plans for air quality control where concrete measures are identified to limit the concentration of pollutants and to reduce the exposure of individuals to high levels of dangerous substances, particularly in urban areas.

The regional plan for air quality control (Regione Lombardia 2013) in Lombardy was approved in 2013 and then amended in 2018. It envisions a series of measures to reduce emissions and it is supposed to operate throughout 2020. Since 2018, it envisions a set of 66 measures for air quality control, that include:

- 26 measures related to road and off-road transportation (e.g., traffic ban in case of emergency or speed reduction on local roads).
- 27 measures for energy production and energy efficiency (e.g., introduction of maximum temperatures for household heating or limitation of daily operation for burning plants).
- 13 measures for agriculture and forestry (e.g., prohibition of fires to clean dry fields).

All measures can be classified in two main groups:

(1) End-of-pipe measures, that are instrumental to emission reduction of pollutants resulting from anthropic activities. They rely on technological systems of filtering that do not require a change in the productive process, even though they entail costs of adoption. End-of-pipe solutions are effective on emissions of traditional pollutants (NOx, SO2, PM10) but do not change the emissions of greenhouse gasses.
(2) Energy measures (including measure of energy efficiency) have an impact of emissions, as they alter the energy consumption. Such changes can correspond to a more efficient (and, as such, reduced) use of fuel or to a radical change of a human activity, such as the replacement of car transportation for individual uses with active mobility systems (e.g., biking). Energy measures do have also an effect of greenhouse gasses.

RIAT+ implements two different approaches of the decision-making modelling (Carnevale et al, 2012). On the one side, it assesses a scenario defined by a group of experts; on the other side, it allows to identify the emission-reducing measures that must be introduced or supported in order to decrease the level of concentration for secondary pollutants (particulate matter, NO2 and O3), while minimizing the costs of intervention. RIAT+ also allows for the evaluation of emissions of greenhouse gasses for any specific policy measure.

RIAT+ is boosted by a set of neural networks able to simulate the link between emissions of precursors and annual mean concentrations of pollutants and it is powered by a database that relates emissions with diffusion of specific technologies. The system performs a variety of activities: (i) calculates the costs of intervention, (ii) assesses the impact of given measures on the indicators introduced by local and national legislation for PM10, NO2 and ozone, (iii) generates maps of emissions and concentration (iv) measures the costs of the health system caused by exposure of the population to pollutants.

Importantly, as a decision support system, RIAT+ measures the distance between an actual policy measure with respect to the most efficient solution (that the system can identify, based on the combination of data available) or how effective is the policy on air quality control compared to the optimal value. Hence, RIAT+ can provide inputs on policies both in terms of cost-efficiency and of effectiveness.

The PRIA in Lombardy envisions a set of policy measures (classified both as end-of-pipe and energy-related). Their adoption produces a hypothetical future scenario. RIAT+ measures the impact of such measures ex ante by comparing the ideal scenario with a business-as-usual situation, where the current legislation as of 2020 is left untouched (CLE2020 scenario). Figure 1 below refers to the effectiveness of measures on PM10, NO2 and ozone indicators.

It can be easily seen that the effectiveness of the PRIA is more significant in the areas surrounding Milan (the capital city of the region) where urbanization and industry presence is stronger. The more intense reduction on the territory of mean annual concentration of PM10 equals 3.8 $\mu g/m^3$ (Figure 1)

Fig. 2: Map of annual mean concentrations of PM10 [µg/m3] for the reference scenario CLE2020 (left) and the PRIA-implemented scenario (right)

Figure 2 represents the expected distribution for the ozone indicator SOMO35. Because of the more intense reduction of NOx with respect to emissions of VOC envisioned in the PRIA, what can be observed is an increase of ozone concentration in large portions of the region and only in limited areas a decrease. The more significant reduction and the most significant increase of SOMO35 are 1836 $\mu g/m^3 \cdot d$ and 1803 $\mu g/m^3 \cdot d$ respectively, whereas the mean reduction is of 258 $\mu g/m^3 \cdot d$, corresponding to 1.7% of the average value of the domain.

Fig. 3: Map of the ozone indicator SOMO35 [µg/m3·d] for the reference scenario CLE2020 (left) and for the PRIA-implemented scenario (right).

Expected reductions for NO2 are similar to those for PM10. Most significant changes are visible in the metropolitan area of Milan, where it can be reached a mean decrease on the regional domain of 3.01 $\mu g/m^3$ (Fig. **4**).

Fig. 4: Map of annual mean concentration of NO2 [µg/m3] for the reference scenario CLE2020 (left) and the PRIA-implemented scenario (right)

Previous examples refer to the measurement of effectiveness for policy measures envisioned in the PRIA. As decision support system, RIAT+ allows a cost/benefit analysis of the PRIA policy measures compared with the reference scenario CLE2020. Policy measures are grouped in four main areas: (1) private transportation, (2) public transportation and other modes of so-called soft mobility (e.g., biking), (3) production of thermal energy (heating) or (4) generation of electric power. The analysis includes:

- Direct costs related to the adoption of each policy measure of the PRIA
- Direct benefits related to energy saving and reduced consumption of fuel
- Health benefits related to the reduced exposure of individuals to PM10
- Avoided costs deriving from reduced emissions of greenhouse gasses

The following table 1 illustrates for each policy measure the whole set of costs and benefits (expressed in million euro per year).

Table 1: costs and benefits (M€/year) of policy measures of PRIA divided by type

	2020 (M€/year)			
	Direct costs	Direct benefits	Health benefits (PM10)	GHG reductions (€20/t_{CO2})
Private transportation	208	966	57	~0
Public transportation	846	1454	~0	21
Power production	2590	2058	~0	122
Thermal energy	3781	8688	37	160
Total PRIA	7425	13166	80	303

RIAT+ can be also used to assess the trade-off between the (incremental) cost of end-of-pipe measure and some air quality indicators (AQI). For instance, as far as PM10 is concerned, there is a problem at decision-making level whenever the regulator (as it is for the PRIA in Lombardy) aims at multiple objectives. The trade-off analysis then becomes crucial to address all the goals envisioned in the plan. Figure 4 shows how RIAT+ tackles this issue. The Pareto curve is made of all combinations (within the range of all possible solutions of reduction of PM10 yearly mean concentration and restraint of intervention costs) for policy measures and corresponding costs of adoption. As an example, the P solution in the graph, requires total costs of 275M€ per year. It corresponds to a situation in which the most significant decrease of PM10 in a given point of the domain is 6.14 µg/m3, while the overall mean reduction is about 1.85 µg/m3, which is 9.7% of the mean value of the domain for the reference

scenario. The graph shows (quite strikingly) how with a limited cost (it is only 5% of the total cost of adopting the best available technologies), the mean concentration of PM10 can be reduced to 99% of the maximum reduction achievable by fully applying all the best available technologies (of course, with huge investments).

Fig. 5: Pareto Curve in the space of annual mean concentrations for PM10 and implementation costs for end-of-pipe measures.

A comparison among the reductions in emissions envisioned in the PRIA-implemented scenario and the solution P shows that the PRIA strategy is mostly focused on reduction of primary particulate (both PM10 and PM2.5 are reduced more than twice with respect to P), while the solution P is aimed mostly at other precursors (in particular NH3), whose emissions are reduced four times more than the PRIA strategy. Benefits for health are larger for the P solution because of the lower concentrations of PM10. The PRIA and the P solutions are not easily comparable for one reason, above all. For the solution P, the multi-objective problem only considers the application of end-of-pipe measures, while the PRIA includes also energy measures. Nonetheless, the multi-objective analysis is useful since it gives evidence of how important incremental actions for ammonia reduction are (being NH3 a precursor). This is just an indication for improvement of the PRIA, that comes from the use of the RIAT+ model as decision support system.

Discussions and Conclusions

Using evidence from the application of an integrated assessment tool developed from models of control systems applied to pollutants, we show how a data-driven assessment can be useful both in planning and in measuring effectiveness and costs of air quality control plans. Multi-objective decisions can be optimized and arbitrary solutions set aside when quality control is based on regulation of anthropic activities that relate to production, mobility, and leisure. Integrated assessment modelling can help develop different scenarios and dynamically adjust the solution, and chose according to current and local conditions of areas affected by concentration of primary and secondary pollutants.

Since regulatory solutions in some areas of the world prove ineffective, legislators should consider adopting more sophisticated approaches coming from the science of control systems and modelling. We do not contend to have found the ultimate model for air quality control and further research is needed to integrate multiple sources of data and improve the use of artificial intelligence techniques to further the analytical models. We believe continued research in the field might provide additional evidence that science can provide answers to the problem of managing air quality

Abstract

The article is devoted to the analysis of the effects of digital transformation of the countries of the Eurasian Economic Union. The classification of the main effects of integration of the economies of the countries of the Eurasian Economic Union (synergetic, macroeconomic, microeconomic, environmental, digital) is proposed. Based on a synthesis of the foreign experience and cooperation of the Eurasian Economic Commission with the World Bank, recommendations are given for the successful digital transformation of the economies of the EAEU countries. The characteristic of the effects of digital transformation of the economies of the EAEU countries is given and their influence on economic growth is determined. It is concluded that ensuring the accelerated development of innovative sectors of the economy, digitalization of the services sector, education, healthcare, public administration, information and economic security should be the main priorities in the implementation of the digital agenda for the transformation of the economies of the EAEU in the medium term.

Keywords: Eurasian Economic Union, digital transformation, integration, effects, risks, institutions

Introduction

In modern conditions, there is a transformation of the economies of Russia and the countries of the Eurasian continent, which is due to the transition from industrial-market to information-network economy. After the entry into force of the Treaty on the Eurasian Economic Union (The Treaty on the Eurasian Economic Union, 2014), a new stage of deepening Eurasian integration began, which is characterized by the formation of a digital economy in all countries participating in the Union. At present, the most important factor in economic growth, increasing competitiveness and the realization of the competitive advantages of the countries of the Eurasian Economic Union is the digitalization of all sectors and spheres of the economy and public administration. The legislative and regulatory basis for implementing the digital transformation strategy of the EAEU countries was the adoption of the "Guidelines for the implementation of the digital agenda of the Eurasian Economic Union until 2025", which were approved at a meeting of the EAEU Supreme Eurasian Economic Council in October 2017. The main directions of the EAEU digital agenda are: digital transformation sectors of the economy; cross-industry transformation; digital transformation of markets for goods, services, capital and labor; digital transformation of integration process management processes; development of digital infrastructure and ensuring the security of digital processes (The main directions for the implementation of the digital agenda of the EAEU until 2025, 2017).

Statement of the problem

The successful implementation of the digital agenda in the EAEU countries requires a comprehensive study of the conditions and mechanisms for creating a single digital space, digital platforms, network infrastructure, the introduction of incentive initiatives and the implementation of joint digital

transformation projects. The implementation of the tasks of the digital agenda, the creation of new digital sectors and industries, the formation of a single digital space of the EAEU will allow achieving a number of effects and an increase in the gross product of Eurasian countries.

Research Questions

- Development of a mechanism for implementing the concept of digital transformation of the economies of the EAEU.
- The impact of the digitalization of the EAEU economies on the emergence of innovative industries, new types of services, new jobs, increased productivity and the effectiveness of interaction between countries.
- Classification of the main effects of the integration of economies of the countries of the Eurasian Economic Union.
- Description of the main effects of the digital transformation of the economies of the EAEU countries.
- The impact of the digital transformation of the EAEU on economic growth.

The purpose of the study

In the all EAEU countries, national programs for digital transformation and development of the digital economy have been developed and adopted (Woodpeckers S.A., 2018). The main common elements are the creation of a single EAEU digital platform, the introduction of common digital standards, data exchange systems and electronic document management, as well as the development of digital EAEU infrastructure management systems. The creation of the EAEU digital space will allow achieving a number of effects from the implementation of the Eurasian digital agenda. Implementation of a joint digital agenda should lead to investment activity, achieving sustainable economic growth, employment growth and productivity growth in priority sectors of the economy. The implementation of the digital agenda also includes the use of new business processes, digital models of cooperation, the creation of digital assets and digital systems of government and information security.

Deepening integration is possible on the path to the formation and use of common digital networks, digital platforms and new digital technologies that allow us to break borders, create new jobs and develop new areas of economic activity and international cooperation.

Research Methods

Promotion of the EAEU digital agenda and development of a single digital market require taking into account positive foreign experience. The creation of the Common Economic Space of the EAEU should take into account, first of all, the experience of the European Union and other regional associations. In 2017, the EU adopted and implements the “Digital Agenda for Europe”, aimed at “achieving sustainable economic and social benefits through the creation of a single digital market based on high-speed Internet and compatible applications”. It is also important to generalize and analyze the experience of existing regional associations such as the Association of Southeast Asian Nations, the Gulf Cooperation Council, and others.

According to Western scholars, Eurasian integration has borrowed the experience of European integration within the EU, but there are differences in the approaches to the formation and functioning of these associations are significant. Thus, S. Roberts and A. Moshes believe that, unlike the countries of the European Union, the EAEU countries do not show much interest and willingness to delegate authority to the supranational level (Roberts S., Moshes A., 2016)

Western researcher D. Tarr emphasized that the Eurasian Economic Union includes a wide range of deep integration measures and support for lagging countries (Tarr D., 2016). The well-known Western European sociologist and one of the leaders of the sociological association of the European

Union, D. Lane, believes that the EAEU integration project fully fits into the logic of the ongoing process of regionalization of the world economy and international relations. In his opinion, the success of this project will depend on the rigidity of anti-Russian sanctions, as well as on how effectively the interaction of the EAEU with other regional unions BRICS, ASEAN, MERCOSUR and others (Lane D., 2016). The effects of the integration of the economies of the EAEU countries have various forms and are manifested in various fields. Among the effects of integration of the EAEU, the following effects should be highlighted:

- Synergetic effects of Eurasian integration that arise as a result of integrated integration in all EAEU countries;
- macroeconomic integration effects, consisting in the growth of GDP, the growth in the production of goods and services due to the expansion of sales and demand markets, savings in production, financial and administrative costs, the development of an economy based on new technologies and the expansion of cooperation ties;
- microeconomic effects of economic entities in the EAEU countries (enterprises), consisting in the growth of market share, expansion of sales, growth in revenue and profits of companies;
- integration effects of end consumers (population): increased prosperity (income) of the population of the EAEU countries due to lower food prices and increased employment, increased general educational and cultural level, increased security, improved environment, ensuring the comfort of life and business through the introduction of advanced international standards, institutional development;
- The environmental effects of Eurasian integration, including the effects of environmental activities, reducing carbon emissions, the use of energy and resource saving technologies, the joint implementation of environmental projects and the creation of environmentally friendly industries;
- digital effects of Eurasian integration, including macroeconomic, sectoral and microeconomic effects due to the transition to a digital economy in the EAEU countries, as well as special effects due to the convergence of national information and economic systems into a single EAEU geo-economic space (Dyatlov, SA, Lobanov, OS, Selischeva , TA, 2018)

Results of the study

For the successful implementation of the EAEU Digital Agenda until 2025, it is necessary to develop an organizational and economic mechanism that will ensure accelerated economic growth, create new jobs, improve public services and increase the competitiveness of the Union's economies. The following elements of this mechanism should be noted:

1. It is necessary to create the institutional and legal framework for the digital agenda, including ensuring the separation of roles, responsibilities and authorities between national and integration management organizations.
2. It is necessary to provide for the allocation of sufficient financial resources, taking into account the long-term and multilateral nature of the digital transformations of the EAEU.
3. To ensure the successful launch and maintenance of the dynamics of digital transformation, programs should be developed and launched to increase the level of digital skills and digital literacy of the general population.
4. For the successful development of reliable cross-border cross-industry digital platforms and digital solutions, distribution and broadband Internet access should be ensured.
5. It is necessary to create a single digital space, integrated digital platforms for coordination and interaction of national and integration management structures.
6. It is necessary to develop incentive measures to ensure the rapid development of innovative sectors of the economy, digitalization of the services, communications, education, healthcare and public administration of the EAEU.
7. Taking into account the digital and synergetic effects arising in the process of integration of the economies of the countries, it is necessary to develop and implement a system for operational and strategic management of the EAEU regional information and economic space (Dyatlov, S.A., Lobanov, O.S., Zhou, W.V., 2018).

8. It is necessary to ensure the preservation of information and economic security of the EAEU countries in the medium and long term.

The creation of such a mechanism must be carried out sequentially and in stages, taking into account available resources, priorities, complexity, the need to take into account the interests of all participants in the integration of national economic systems of the EAEU countries

According to World Bank estimates, the implementation of the joint digital agenda until 2025 will bring an additional increase in the EAEU's total GDP to 1% per year, and will also contribute to the creation of 8 million jobs and cost savings for businesses of $ 50 billion (Kostyleva T., 2018).

In 2016-2017 The Eurasian Economic Commission and the World Bank conducted a joint study to study international experience and develop recommendations on the maximum economic impact of the development of the digital space and the implementation of the digital agenda of the EAEU (Kheifets B.A., 2016). Digital technologies provide the EAEU countries with ample opportunity to transform their national economies. The emergence of new ways of interaction between people, communities and governments, access to information, doing business and interacting with public authorities contributes to increasing competitiveness in world markets. Due to the influence of digital technologies on all spheres of public life, the heads of the EAEU member states recognized the need to stimulate and manage technological transformation processes for the benefit of all members of society as new opportunities for regional cooperation and economic growth in the region (Vinokurov E., 2017).

A new quality of association arises on the basis of digital networks, common digital platforms and new digital solutions that reduce distances, remove boundaries, create new jobs and develop previously non-existent areas of business activity. In 2016, the Eurasian Economic Commission, together with World Bank experts, began work to study the current situation and develop recommendations for obtaining economic benefits from digital development. They studied the potential of creating a single digital space and implementing the EAEU Digital Agenda by 2025, aimed at creating a unified digital economy in the region and achieving related digital dividends.

The EAEU experts, together with the World Bank experts, developed a model for creating a single EAEU digital space, which should become an effective tool for identifying, approving, measuring, coordinating and monitoring actions aimed at achieving the goals of the EAEU Digital Agenda (The Treaty on the Eurasian Economic Union, 2014). The most important areas of joint digital initiatives within the framework of this model are: the creation of a common digital infrastructure; creation of integrated digital platforms; digitalization of leading industries and sectors of the economy; digitalization of national and regional markets. The main elements of the organizational and economic mechanism for implementing this model are: development of a general regulatory framework; creation of public-private partnerships for the implementation of priority digital initiatives and projects; development of partnerships between all participants in the created regional ecosystems; promoting the dissemination of best digital solutions and practices.

The successful transformation of the economies of the EAEU countries requires the implementation of innovative cross-cutting projects, the adoption of measures aimed at encouraging and stimulating the development of new industries and industry segments, the development of general rules for the use of information and communication technologies and the development of a favorable digital environment for the implementation of economic activities in the EAEU (Minasyan K., 2017). The most important task is to obtain synergistic effects and the accumulation of competitive digital assets using the advantages provided by Eurasian integration.

According to the European Commission, the creation of a single digital market in the EU can bring the EU economy an additional 400 billion euros per year, help create new jobs and increase productivity. Innovations such as cloud services and data analytics can add more than 2,000 billion euros to the EU's GDP by 2030 through increased industrial production. The implementation of the concept and programs of the EAEU member countries until 2025 involves the growth of the Gross

Product of the association due to the expansion of broadband Internet access, due to increased traffic bandwidth, due to the development and expansion of electronic commerce.

The most important area is the creation of cloud services and cloud computing in the EAEU member states for the research and educational community, as well as for state authorities in order to provide a new generation of cross-border services. Such cloud-based initiatives will provide Member States with the opportunity to consolidate existing data centers, increasing their resilience while reducing maintenance costs. Supporting the development of cloud technologies through the introduction of cloud services at Union level, the formation of a regional Eurasian network of data centers and regional operator companies, as well as the provision of Internet traffic caching services for European and Chinese providers will significantly accelerate economic development. According to World Bank estimates, the potential increase in the EAEU's GDP through this sector will be 0.95% by 2025. Savings resulting from the removal of legal barriers to the implementation of the EAEU Digital Agenda can potentially add 2.6% to GDP.

The development of the digital economy inevitably leads to a significant transformation of the labor market. This transformation is complex and takes place gradually, as more and more traditional sectors of the economy are engaged in the digital economy. This transformation affects job creation at several levels. Due to the introduction of ICT, process optimization, robotics, and overall efficiency gains, obsolete professions will disappear. However, according to experts, despite the release of a significant number of jobs under the influence of digitalization from the sphere of employment, the net effect of the creation of new jobs in new sectors of the digital economy will be positive.

For example, McKinsey estimates that one job in the ICT sector creates two to four jobs in other sectors of the national economy. PwC estimates that a 10% increase in digitalization reduces unemployment by 0.84%. Analysis of data on the French economy over the past 15 years showed that due to digitalization, an additional 1.2 million jobs were created and 500,000 jobs of outdated professions were eliminated. According to calculations, with an average penetration rate of fixed broadband in the EAEU at 30 percent, it can be expected that by 2025 about 3-4 million new jobs will be created, of which more than 1 million will be created in the digital economy. As a result of the implementation of the "Digital Agenda" of the EAEU member states, the achievement of target values of up to 3% of employment in the ICT sector for the EAEU member countries can provide an increase in employment by 2.4% by 2025 (Evaluation of the economic effects, 2018).

The growth of e-commerce platforms is creating a new group of micro-entrepreneurs who can access global markets and expand their business. Information, consulting, recruiting and job search services should be provided at the regional level together with an appropriate regulatory framework to ensure the free movement of citizens in the Union in search of work as new jobs are created throughout the EAEU. It is planned to create a new information system that accumulates data on employment and migration within the framework of the EAEU, which will allow providing cross-border services to employees and employers related to the employment and movement of workers between the EAEU countries. It is estimated that by 2025 up to 4 million new jobs can be created in the EAEU countries, including more than a million in the digital technology sector, and it is also planned to increase labor productivity by 1.73%. Optimization and robotization of production, as well as increased productivity, will certainly make some workers redundant, but the net effect of the development of a digital economy in the workplace will be positive (On approval of the Regulation, 2017).

The development of the services sector in 2018-2025, the removal of existing regulatory barriers in relations between the EAEU member states can increase the gross product of the Union by $ 42.3 billion. The possible effect of digitizing government procurement at the regional level is estimated at $ 1.6 billion. The provision of "open government" services can save $ 1.3 billion, the implementation of cross-border electronic services will save $ 0.5 billion.

Implementation of digitalization programs in the EAEU countries will provide additional dividends and effects in various fields and industries. According to available estimates, the greatest effect will be achieved in the manufacturing, fuel and energy, retail and services sectors. So, if the digitalization

level reaches 20% by 2025, an additional growth of EAEU GDP of 0.98% is expected in manufacturing, in retail trade - by 0.92%, in the service sector - by 2.2%. The share of digital services in the total export volume of the EAEU countries should grow from 28% in 2015 to 36% percent in 2025. Significant growth is expected in export-oriented digital services, which include outsourcing of information technology, outsourcing of business processes, cloud services, offshore programming and individual software tools and development.

It is important to note that the provision of electronic public services requires a sufficient amount of open data available to the public and business. The adoption of common digital standards for open data and ensuring synchronization and data quality are important for creating such a unified big data database in the EAEU. According to World Bank estimates, the potential impact of creating a regional open data warehouse could be a 1.34% increase in EAEU GDP by 2025. In general, according to World Bank estimates, an increase in the digitalization of the EAEU by 20% by 2025 could lead to an increase in the services market by 2.2% of the EAEU's GD (Knobel A., Lipin A. P., 2016).

The development of a system of electronic international transactions and electronic commerce, technologically compatible and compatible architectures, standards, data, processes, services, platforms, infrastructures and networks, which significantly expand the opportunities for cooperation between consumers and business structures in the EAEU member states, has great growth potential. Deeper Eurasian integration, subject to a 20% mutual reduction of non-tariff barriers between the EAEU countries, will lead to an increase in mutual trade by 12.4% or by $ 7.1 billion (Kofner Yu., 2020).

The Council of the Eurasian Economic Commission adopted a detailed plan for the implementation of the Guidelines for the development of a Single Window mechanism in the system of regulating foreign economic activity. This document serves as one of the project management tools for the development and implementation of the Single Window mechanism in the Member States of the Union (The Eurasian Economic Commission, 2020).

The increase in trade, the circulation of goods and services in the EAEU, as well as the more efficient use of the transit potential between Asia and Europe, requires the free movement of vehicles through digital interaction between the customs authorities of the EAEU member states. Since 2018, the customs services of the EAEU countries have begun work on the basis of the requirements of the new EAEU Customs Code, which introduces the mechanism of electronic tax returns and digital customs administration tools. Digitalization should significantly simplify the process of removing barriers in the internal markets of the Union. In the near future, the EAEU intends to form free trade zones and sign "Agreements on trade and economic cooperation" with Egypt, Israel, India, Iran, China, Singapore and Serbia (Sargsyan T., 2017).

The adoption and introduction of a single Customs Code of the EAEU countries leads to the transition to automated systems and electronic document management. Simplifying the procedures for making digital cross-border purchases can increase cross-border trade conducted by online businesses and increase consumer confidence in cross-border e-commerce in the EAEU. Digital solutions include finance, services, customs, procurement, taxation, logistics, and migration. Successful implementation of such solutions results in digital dividends. An example of such decisions is the basic registers of the public sector, which are official sources of basic information about citizens, the business sector, companies, licenses, land plots, etc. Basic registers are a key element in the development of new digital services in the EAEU.

A significant effect should be given to the development of Single Window systems and mechanisms in the system of foreign economic activity, electronic customs declaration in the EAEU countries. Measures aimed at simplifying cross-border procurement, including the elimination of customs and trade barriers, the introduction of electronic customs declarations and the transition to electronic trade document management should have a positive effect on increasing the EAEU GDP by 2025. Digital

trade and customs solutions include online processes related to export / import and expediting cross-border trade, including logistics, customs clearance, licensing and certification.

The implementation of the EAEU Digital Agenda will have a significant impact on the growth of cross-border electronic commerce, as online shoppers will be able to use duty-free online purchases in any member country based on common digital platforms, including identification and authentication platforms and digital cross-country.

The EAEU digital agenda includes the creation and implementation of a Trans-Eurasian logistic platform, which should become the basis for uniting all participants in trade and economic activity through integrated digital platforms and electronic data exchange. The creation of the EAEU digital logistics system should become a driving force for dynamic development in all sectors of the economy of the EAEU countries. The introduction of a digital cross-border logistics system should bring dividends and increase the efficiency of logistics companies in the EAEU economic space. According to the calculations of WEF experts, expanded digital cross-border logistics can increase the volume of international trade for the small and medium-sized business (Samokhin I.O., Abramova O.K., 2017).

To ensure the widespread use of new digital solutions, it will be necessary to solve the problems of widespread training of qualified personnel with professional digital abilities and skills, as well as the need to increase the overall digital literacy level of the population of the EAEU countries.

Based on the experience of the EU countries, it is necessary to create institutions of an interstate monitoring system, statistical collection and analysis of data on the digital transformation of the EAEU countries (country differentiation according to a number of indicators: the level of development of digitalization, networking, competitiveness, etc.). The cooperation of the EAEU countries and the EU in the collection, analysis and use of Big Data is of utmost importance. Big data includes a set of approaches, tools and methods for collecting, processing and analyzing large volumes of diverse structured and unstructured data. In the modern digital economy, Big data (network data) is becoming an important factor in economic growth, the main asset with market and social value, which lies in the possibility of using big data for innovation, development and creation of new ideas, technologies, products and services, as well as adoption flexible, operational and effective management decisions.

Conclusion

Summarizing and taking into account the positive foreign experience in creating integration structures for managing the digital transformation of the EAEU with a wide range of powers at the Union level is crucial for the success of digital transformation. It is important to determine the priorities of digital transformation and approve the list of basic digital services, the implementation of which will accelerate the processes of integration and digitalization in the EAEU. Given the scale and intersectoral nature of the digital agenda, it is important to create mechanisms for continuous monitoring of measures taken, monitoring and quantifying the progress and its results, as well as informing citizens about the ongoing changes in order to ensure the participation and commitment of all sectors of society (Sokov K., 2018).

It should be noted a number of risks arising in the process of digital transformation for the EAEU countries. Recently, the hypercompetitive pressure of global players-world leaders on the digital space of the EAEU countries has been intensifying. One of the risks is the significant dependence of the EAEU countries on the external market of digital technologies and digital services, in which the leading companies in the USA and China occupy leading positions. The digital inequality (digital lag) of the EAEU countries from the leading countries of the world is constantly increasing, which leads to an increase in threats to the digital sovereignty, information and economic security of the EAEU countries. Also a big risk is a brain drain, primarily of specialists in the field of digital, cloudy nano- and bio-neural technologies, from the EAEU countries to the developed countries of the world.

It should be noted that the widespread spread of the coronovirus pandemic in early 2020 became the main threat to the economies of the EAEU and other countries of the world. Therefore, one of the urgent tasks is to digitalize healthcare and create a flexible and effective e-Health system nationwide and the EAEU. Achieving the accelerated development of innovative sectors of the economy, digitalization of the services sector, education, healthcare and public administration, as well as ensuring digital independence, information and economic security should be the main priorities in the implementation of the digital agenda for the transformation of the economies of the EAEU in the medium term.

Taking into account the achievement of the main objectives of the digital agenda, the Eurasian Economic Commission has developed plans and identified the main trends in the implementation of the EAEU digital agenda in the main areas until 2025 (The digital agenda of the EAEU, 2019). Successful implementation of the strategy and programs of digital transformation and development of the digital economy of the EAEU member countries requires an integrated approach, coordination of efforts and coordinated actions of all national and integration departments, structures and regulatory institutions of the Eurasian Economic Union.

Abstract

Total Quality Management or TQM is an integrative organizational-wide management philosophy that is aimed at continuously improving the quality of processes, products and services by focusing on, meeting or exceeding customer expectations in order to enhance customer satisfaction and organizational performance. Thus, this paper aims to investigate the mediation role of the national culture between the TQM dimensions and performance. Therefore, a survey questionnaire was distributed to senior employee and managers at the Abu Dhabi Agriculture and Food Safety Authority. The results show that there is significant positive relationship between the TQM practice dimensions and performance. Pawer distance, uncertainty avoidance and Individualism mediate the relationship between the TQM and performance. Although dose not mediate the relationship between customer focus and performance. This study will contribute in the existing literature in the area.

Keywords*:* TQM practices, National culture, performance, UAE

Introduction

In the modern business landscape, both quality and innovation have become essential concepts that guide optimal performances for business organizations (Zehir *et al.*, 2012). As a result, organizations (whether for-profit, not-for-profit or regulatory ones) pay particular attention to optimizing and maximizing organizational resources to attain successes by employing strategic leadership and management techniques (Ahmad *et al.*, 2013; Aziz & Morita, 2016). One of such strategic management approaches which have stood out amongst contemporary management approaches and has gained widespread attention from industry and academia is Total Quality Management (TQM) (Haffar *et al.*, 2019; Jimoh *et al.*, 2019; Panuwatwanich & Nguyen, 2017). According to Eniola *et al.* (2019), TQM is an integrative organizational-wide management philosophy that is aimed at continuously improving the quality of processes, products and services by focusing on, meeting or exceeding customer expectations in order to enhance customer satisfaction and organizational performance (Baird, Jia Hu, & Reeve, 2011; García-Bernal & Ramírez-Alesón, 2015; Sadikoglu & Olcay, 2014). Thus, organizations that implement TQM improve their business performance by differentiating their products and gaining a competitive advantage in the market (Herzallah, Gutiérrez-Gutiérrez, & Munoz Rosas, 2014; Pérez & Gutiérrez Gutiérrez, 2013). Consequently, leading to positive results with increasingly higher profits, market share and superior performance (Eniola *et al.*, 2019; Kim, Kumar, & Kumar, 2012).

Several recent studies have found that the implementation of total quality management in an organization has a tremendous and significant association with organizational performance (Al-Dhaafri, Al-Swidi, & Yusoff, 2016; Kanapathy *et al.*, 2017; Sinha & Dhall, 2018). However, in contrast, some other researchers have found no association or in some cases negative associations between TQM and a firm's performance (Duarte *et al.*, 2011; Yeung & Chan, 1998). The mixed and

inconclusive nature of the relationship between TQM and organizational performance has been implied to be because of the level of TQM implementation within organizations. Arguably, organization with a higher level of implementation of total quality management principles have been shown to have higher levels of performance whereas firms with lower levels of TQM implementation have resulted in no association or sometimes negative associations with organizational performance (Aquilani *et al.*, 2017; Eniola *et al.*, 2019; Nawelwa, Sichinsambwe, & Mwanza, 2015).

Given that the Abu Dhabi Food and Control Authority (ADFCA) is responsible for ensuring that the Emirates' food and agricultural produce, as well as those from imports and exports, meets the acceptable standards required for consumption by the local populace, they face the challenge of maintaining a consistent and high degree of quality throughout their operational processes, as well as issues of food security, sustainable agricultural produce and maintaining a higher level of customer satisfaction. This has led to the implementation of strategic leadership approaches across the ADFCA (Aziz & Morita, 2016; Jabnoun & Sedrani, 2005). One of such strategic leadership approaches is the integration of Total Quality Management across the operational processes of the ADFCA. Implementing Total Quality Management is a necessary undertaking that is sure to bring about many benefits to an organization. For instance, TQM implementation has been reported to bring about improved productivity, customer satisfaction, improved quality, employee participation, teamwork, improved working relationships, employees' satisfaction as well as communication (Ahmad *et al.*, 2013; Besterfield, 2004). Hence, since the ADFCA's major priority is centred on food safety and security, which are also dependent on quality performance, the degree to which TQM is implemented at the ADFCA becomes of paramount importance.

One of the main concerns of the government of Abu Dhabi spearheaded by the Abu Dhabi Food and Control Authority is to ensure food safety, food security and sustainable agricultural produce (i.e. including those from imports and exports) and ensure that these produce meet the required standard for consumption by the local populace (ADFCA, 2016). Hence, the ADFCA was charged with fulfilling this responsibility. In 2015, it was reported in ADFCA (2016), that the ADFCA scored 99% in the food safety performance evaluation carried out by the United Arab Emirates' (UAE) Ministry of Environment & Water in conjunction with the Food and Agricultural Organization (FAO) of the United Nations (UN) (ADFCA, 2016). The evaluation came as part of the Ministry's effort to develop and enhance the food safety situation of the country and was executed with a team of experts from the FAO (ADFCA, 2016).

Given that the ADFCA is a regulatory authority, its organizational culture may be rooted in the national culture since the authority essentially differs from for-profit organizations or traditional business enterprises. Hence it is imperative to examine how national culture mediates the relationship between TQM implementation and the performance of the ADFCA in terms of quality performance, employee performance and society results.

Literature Review

In general, the concept of organizational performance is based upon the idea that an organization is the voluntary association of productive assets, including human, physical, and capital resources, for the purpose of achieving a shared purpose (Mandlburger, Pfennigbauer, Schwarz, Flöry, & Nussbaumer, 2020). Those providing the assets will only commit them to the organization so long as they are satisfied with the value they receive in exchange, relative to alternative uses of the assets. As a consequence, the essence of performance is the creation of value. So long as the value created by the use of the contributed assets is equal to or greater than the value expected by those contributing the assets, the assets will continue to be made available to the organization and the organization will continue to exist (Ericsson, Hoffman, & Kozbelt, 2018). Therefore, value creation, as defined by the resource provider, is the essential overall performance criteria for any organization. How that value is created is the essence of most empirical research" in management.

Quality Performance

A numerical measurement of the performance of an organization, division, or process; Quality of "performance can be assessed through measurements of physical products, statistical sampling of the output of processes, or through surveys of purchasers of goods or services. In addition, performance of an employee on a given job or task is strategic edifice of a business as a result, elements that "give rise to enriched performance must be dissected in a more critical dimension by the establishments for success, advancement and growth (Abbas & Yaqoob, 2009). Performance and productivity of an employee is seen an issue of momentous vitality for employers, managers and the entirety of an organisations as well (Helmreich, & Schaefer, 2018).

Total Quality Management (TQM)

Total quality management (TQM) is the system of activities directed at achieving delighted customers, empowered employees, higher revenues, and reduced costs (Dudin, Frolova, Gryzunova, & Shuvalova, 2015). A "recently published study (Saleh, & Sweis, 2017) reviews the variety of definitions of TQM available in the literature and concludes that it is a management approach which prescribes guidelines for organizations to operate and achieve high performance. The literature suggests that organisational excellence is a key stage on the TQM journey. Furthermore, it is often applied to TQM enabling actions as an effectiveness measure (Fonseca, 2015).

Total Quality Management (TQM) has evolved in four stages: Quality Inspection, Quality Control, Quality Assurance and Total Quality Management. Quality management has "been part of human activities as long as one can recall. However, the first evident quality management to be applied in the practice occurred in 1910s in Ford Motor Company in its production of the "T" model car. Ford Company employed teams of inspectors to test or compare product in accordance with the project standards (Yang, 2017). Inspectors compared the product to the set project standards in all stages covering production delivery and process. The aim of conducting the inspection was to separate poor-quality products detected by inspectors from acceptable quality products and either scrapping, reworking or selling them off as lower quality at lower prices. The second stage of quality and TQM development came as a result of industrial advancements. This stage was controlled through written specification, supervised skills, and standardization and measurement

Leadership Management

Leadership is cited as the most dominant and acknowledged dimensions of TQM strategy. According to Bush, Bell, & Middlewood, (2019), the success of an organization is largely "determined by the ability of leaders to utilize both human and social capital to create a competitive advantage. In view of Serin (2004), the top management commitment and the organization's leadership contribute towards the successful implementation of the organizational program. Management leadership is largely based on teamwork spirit, effective communication, participative decision-making process, effective training of employees and employee empowerment. The literature on TQM recognizes the relationship between the firm performance and management leadership.

Customer Focus

The key objective of using TQM strategy is to meet customers' latent and current needs by offering quality "services and products. Wilson, Zeithaml, Bitner, & Gremler, (2016) suggest that there should be effective and continuous communication between the firm and its customers. Staub, (2019) further suggests that an organization should also establish strong relationships with customers, directly interact with the customers, continuously monitor their satisfactory levels; and always try to meet their future expectations and changing needs. Others (Kiseleva, Nekrasova, Mayorova, Rudenko, & Kankhva, 2016) believe that a firm may have a competitive edge over others in the same industry by providing innovative and high-quality services and products that meet customer needs. Other

researchers demonstrated that customer satisfaction and firm performance are positively related in that high customer satisfactory may translate to higher profits, Kiseleva et al., (2016); enhanced organizational performance and reduced operating cost. Becker, & Brettel, (2017) assert that total quality management is the customer-oriented strategy that emphasizes on customer loyalty and customer satisfaction as it the core of the firm's success, generating high competitiveness and profits. Elsewhere (Karttunen, Hallikas, & Stek, 2017) demonstrated that customer focus and" business performance is positively and significantly related.

Hofstede's Model of Culture

National culture has a great influence on the work values (Minkov, 2018). Hofstede`s dimensions of national "culture, determined for 53 countries and regions of the world, led by the number of quotes and by importance in the field of cross-cultural management (Beugelsdijk, Kostova, & Roth, 2017). The basis of the model is the research conducted among employees of IBM on a sample of 60,000 workers in the period 1967-1969. The inclusion of the results of other authors who have used an identical methodology produced a sample that includes 71 countries and three regions. The extension of the model with the original four-dimensional culture of the society got one extra dimension. Database eliminates the differences that arise as the impact of corporate policies and procedures because of the impact of various strategies (Saleem, & Larimo, 2017). Therefore, any variation between countries can be reliably attributed to national culture. Hofstede also found that employees and managers vary according to the following dimensions of national culture: (1) power distance, (2) uncertainty avoidance, (3) individualism vs collectivism, (4) masculinity vs femininity, (5) long-term vs short-term orientation" (in a later phase of the study) (Hofstede, 1980).

Power Distance

Power distance "represents the degree of inequality in the distribution of power within societies to be considered socially acceptable and is derived from the fact that power in institutions and organizations is not evenly distributed (Taras et al., 2017). Societies with high power distance accept large differences in power within the organization.

Uncertainty Avoidance

Uncertainty avoidance dimension measures "the extent to which the members of a culture feel "threatened by uncertain and unknown situations". Uncertainty avoidance indicates the extent to which a society feels threatened by ambiguous situations and the extent to which a society tries to avoid these situations by adopting strict codes of behaviour, a belief in the absolute truths, establishing formal rules, and not tolerating deviant ideas and actions. Individuals with high uncertainty avoidance are concerned with security in life, feel a greater need for consensus and written rules, less likely to take risks while individuals in low uncertainty avoidance societies are less concerned with security, rules and they are more risk tolerant (Laitinen, & Suvas, 2016).

Individualism

Dimensions of individualism refers to societies in which the ties between individuals and the poor of every individual is expected to look after themselves and their immediate families, while collectivism refers to societies in which people from birth include the strong cohesive groups that are" protected throughout their life in exchange for unquestioning loyalty. It is noted that the degree of individualism in a country complies with the wealth of the country (Block, & Walter, 2017), and also countries with a high degree of individualism are more inclined to the Protestant ethic, individual initiative and progress to the market shift. Countries with low level of individualism are less prone to the Protestant ethic, show less individual initiative, while the progression of age-related / age.
Hypothesis of the study

H1: Customer focus positively affects performance.
H2: Leadership management positively affects performance.

H3: Strategic planning positively affects performance.
H4: Dose National culture dimensions mediate the relationship between TQM practices and performance

Methodology

The questionnaire was adapted from the scales used in the following studies (Ahmad *et al.*, 2013; Anil, 2019; Aziz & Morita, 2016; Syduzzaman *et al.*, 2016). The adapted questionnaire consists of an introductory section along with four main parts, namely Part A, B, C and D. Part A of the questionnaire was the demographic section. In this section, respondents were asked to provide information regarding their gender, experience in years and highest qualification as of the time of collecting the data for the study. In Part B, respondents were required to rate their perceptions of the TQM values implemented in the quality management process of the Abu Dhabi Agriculture & Food Safety Authority on a 5-point Likert scale from Very Low (1), Low (2), Moderate (3), High (4) to Very High (5). A total of forty-one (41) items corresponding to three (3) TQM dimensions were contained in Part. Furthermore, in Part C, respondents were asked to describe their national culture on a 5-point Likert scale also used. A total of twenty (20) items corresponding to three (3) national culture constructs (i.e. power distance, uncertainty avoidance, and individualism) were contained in Part C. Finally, in Part D, respondents were asked to give a self-report of the performance of the Abu Dhabi Agriculture & Food Safety Authority using three performance indicators of quality performance, society results and employee performance.

Thus, 350 questionnaires were distributed and 313 was valid usable survey used in this study. The target respondents were senior employees and managers. Those groups were selected to rate the extent to which they perceived the total quality management in the organization; as they have good experience on the quality performance as well as the organizational performance. However, the part-time employees, contract base and the employee that currently is not working in with The Abu Dhabi Agriculture and Food Safety Authority have not been included in the study. Therefore, Statistical Package for Social Sciences and the partial least squares path modeling or partial least squares structural equation modeling (Smart-PLS) were used for the data analysis.

The reliability coefficients of the pilot study shows that the TQM has a α value of 0.781, with all the underlying dimensions ranging between 0.718 to 0.794 respectively. Similarly, national culture and its dimensions had α value greater than the acceptable threshold of 0.7. Furthermore, performance had 0.835, which is also greater than the threshold and acceptable α value of 0.70. With these results, all the constructs and their dimensions as used in this study as considered reliable and adequate to elicit the needed data for the study. Therefore, the Table 1 shows the results of the pilot test of the study.

Table 1: Pilot test result

S/No	Constructs	Cronbach's Alpha
1	**TQM**	0.781
	Strategic Planning	0.718
	Customer Focus	0.794
	Leadership Management	0.759
2	**National culture**	0.766
	Power distance	0.779
	Uncertainty avoidance	0.943
	Individualism	0.836
3	**Performance**	0.835

Key Findings

Data collected was analyzed to investigate the mediating role of the national culture (i.e. power distance, uncertainty avoidance and individualism) between the TQM dimensions (i.e. leadership management, customer focus and strategic planning) and performance. Thus, Partial Least Squares Structural Equation Modelling (PLS-SEM) software used as the tool for the analysis.

Convergent Validity and Reliability

Reliability is the extent to which an assessment tool produces stable and consistent results. While validity refers to the extent to which the construct measures what it is supposed to measure (Valle & Assaker, 2016).

Table 2: Constructs Reliability and Validity

	Cronbach's Alpha	Composite Reliability	Average Variance Extracted (AVE)
Customer Focus	0.818	0.849	0.532
Individualism	0.759	0.845	0.646
Leadership Management	0.861	0.906	0.709
Performance	0.963	0.967	0.748
Power Distance	0.779	0.872	0.694
Strategic Planning	0.826	0.872	0.578
Uncertainty Avoidance	0.865	0.908	0.713

Table 2 presents the factor loadings and Average Variance Extracted (AVE) of each of the constructs in the study. All measured constructed had AVE scores greater than the threshold value of 0.50 and factor loadings ranging from 0.759 to 0.908 consecutively, indicating that convergent validity had been established according to (Byrne, 2013). Therefore, the Figure 1, illustrate the measurement model of the study.

Figure 1: Measurement model of the study

Discriminant Validity

Discriminant validity is one of the key building blocks of model evaluation (Henseler et al., 2015). Henseler et al (2015) sated that discriminant validity analysis ensures that a construct measure is empirically unique and represents phenomena of interest that other measures in a structural equation model do not capture (Hair et al., 2010).

Table 3: Discriminant Validity based on Fornell-Lacker criterion

	Customer Focus	Individualism	Leadership Management	Performance	Power Distance	Strategic Planning	Uncertainty Avoidance
Customer Focus	0.730						
Individualism	0.118	0.804					
Leadership Management	0.271	0.467	0.842				
Performance	0.134	0.469	0.465	0.865			
Power Distance	0.294	0.549	0.666	0.471	0.833		
Strategic Planning	0.085	0.020	0.191	0.056	0.171	0.760	
Uncertainty Avoidance	0.357	0.556	0.726	0.461	0.839	0.203	0.845

Besides, the cross-loading criterion, advocated by Chin (1998), required that items are required to load higher on their own construct that their cross-loadings on other construct. This approach is considered liberal in determining discriminant validity (Hair *et al.,* 2014). The discriminant validity is presented in Table 3 and Table 4 present Heterotrait-Monotrait Ratio (HTMT) to support the achievement of the discriminant validity.

The result of discriminant validity using Fornell and Larcker criterion is presented in Table 2 in which the square root of AVE inserted diagonally in bolded italics. Other figures, both horizontally and vertically, indicated the correlation among the research constructs. The result indicated that all the lower-order components achieved the stated condition. The lower-order component with higher correlation than the square root of AVEs are only with their highest order components which is expected (Sarstedt *et al.,* 2019).

Table 4: Heterotrait-Monotrait Ratio (HTMT)

	Customer Focus	**Individualism**	**Leadership Management**	**Performance**	**Power Distance**	**Strategic Planning**	**Uncertainty Avoidance**
Customer Focus							
Individualism	0.612						
Leadership Management	0.643	0.491					
Performance	0.124	0.463	0.484				
Power Distance	0.319	0.646	0.806	0.518			
Strategic Planning	0.127	0.136	0.200	0.074	0.199		
Uncertainty Avoidance	0.318	0.599	0.835	0.484	1.017	0.512	

The study therefore achieved discriminant validity based on Fornel and Larcker criterion. Likewise, the analyses of this study pass the HTMT criterion as presented in Table 4; all the values in the HTMT table are below both 0.85 and 0.9. Furthermore, after all the possible discriminant validity tests, it has been found out that discriminant validity is not a problem in this study.

Coefficient of Determinant (R2)

The coefficient of determination R^2 is considered as a measure of model's predictive accuracy, and is calculated as the squared correlation between dependent construct and predicted values (Hair et al., 2013).

Table 5: Coefficient of Determination (R^2)

	Constructs	**R Square Adjusted**
Exogenous variables	Total Quality Management Practices	0.910
Mediators	National Culture	0.789
Exogenous variables	Organizational Performance	0.875

Table 5 presents the R^2 results, the first column shows the R^2 when total quality management, national culture and performance are included into the model as higher-order components construct. It shows an overall R^2 for the major endogenous construct of the research, TQM, to be 0.910. The R^2 for the higher-order components was unity. This is expectable because the lower-order components are explaining same variance of the variables in the higher-order components (Sarstedt *et al.,* 2019). Thus, the R^2 are greater than 0.75 indicated substantial R^2 (Hair *et al.,* 2014).

Effect Size (f2) Assessment

The effect size (f^2) is the estimation of R^2 in a case when a given independent variable is taken out from the research model. Hence, the effect size is a measure used to assess the relative impact of a predictor variable on an endogenous variable. It specifically assesses how strongly one exogenous variable contributes to explaining a certain endogenous variable in terms of its R^2 (Memon & Rahman, 2013).

Table 6: Effect size assessment

	Customer Focus	**Individualism**	**Leadership Management**	**Performance**	**Power Distance**	**Strategic Planning**	**Uncertainty Avoidance**
Customer Focus		0.000			0.025		0.061
Individualism				0.075			
Leadership Management		0.269			0.649		0.911
Performance							
Power Distance				0.017			
Strategic Planning		0.006			0.003		0.008
Uncertainty Avoidance				0.007			

The categories for its calculation was provided by Cohen, (1988) which are 0.02, 0.15 and 0.35 representing small, medium and large effects respectively. As shown in Table 6, customer focus (f^2 = 0.000) has small effect on individualism; while it has medium effect ($f^2$0.025) on powder distance and also on uncertainty avoidance ($f^2$0.061). In addition, individualism has medium effect medium effect on Individualism (f^2 = 0.269) and large effect on power distance ($f^2$0.649) and also large effect on uncertainty avoidance (f^2 = 0.911). Power distance has medium effect on performance and strategic planning has small effect on individualism, power distance and uncertainty avoidance as shows in Table 6.

Path Coefficient

According to Hair et al., (2014), the level of strength of a relationship is measured by the magnitude and significance of the estimates. Path coefficients that are close to +1 represent strong positive relationships while those that tend towards -1 represent strong negative relationships (Hair et al., 2014).

Table 7: Relationships between TQM Dimensions and Performance

Path	Std β	Std Error	*t* Statistic	*p-v*alue	Decision
Direct Effects					
Leadership Management -> Performance	0.122	0.124	3.307	0.001	Supported
Customer Focus -> Performance	0.171	0.173	4.570	0.000	Supported
Strategic Planning -> Performance	0.283	0.286	5.817	0.000	Supported

From Table 7 with t-values exceeding the t-critical value of 1.96 and p-values value less than 0.05. Thus, all three of the direct effect had a strong positive relationship between total quality management dimensions.

Mediating effect of national culture on the relationship between TQM practices dimensions and performance

The essence of conducting mediation analysis is to establish the extent of indirect effect of the mediating construct through the direct paths (Hair *et al.,* 2014).

Table 8: Mediating Effect of National Culture Dimensions

Path	Std β	Std Error	*t* Statistic	*p-v*alue	Decision
Strategic Planning -> Power Distance -> Performance	0.625	0.625	21.438	0.000	Supported
Customer Focus -> Power Distance -> Performance	0.283	0.286	5.817	0.000	Supported
Leadership Management -> Power Distance -> Performance	0.482	0.484	12.060	0.000	Supported
Customer Focus -> Uncertainty Avoidance -> Performance	0.669	0.668	24.015	0.000	Supported
Leadership Management -> Uncertainty Avoidance -> Performance	0.208	0.207	2.583	0.010	Supported
Strategic Planning -> Uncertainty Avoidance -> Performance	0.012	-0.069	1.493	0.004	Supported
Customer Focus -> Individualism -> Performance	-0.006	-0.002	0.159	0.874	Not supported
Leadership Management -> Individualism -> Performance	0.061	0.063	1.912	0.056	Supported
Strategic Planning -> Individualism -> Performance	0.129	0.129	1.563	0.000	Supported

The specific indirect effect of national culture dimensions between TQM practices and performance is presented in Table 8. The result shows that there is significant indirect effect of power distance, Uncertainty Avoidance and Individualism between the leadership management, customer focus and strategic planning. However, Uncertainty Avoidance dose not mediate the relationship between the Strategic Planning and Performance. This shows that the three national culture elements significantly mediate the relationship between TQM practices and performance at The Abu Dhabi Agriculture and Food Safety Authority.

Discussion and Conclusion

Findings from the analysis revealed that there is a significant positive relationship between national culture and organizational performance; thus, the hypotheses were supported. However, only one sub-hypothesis was not supported (see Table 4.28). This shows that national culture significantly effects Abu Dhabi Food Control Authority performance. This finding is consistent with some studies reported in the literature. For instance, Mardani, Bagheri, Kish, Soltan, & Kazemilari (2013) investigate the relationship between national culture and TQM implementation, Case study: Iranian multinational electrical manufacturing companies. Findings from the study revealed that some national culture dimensions and the dimensions of TQM implementation are correlated. Uncertainty avoidance affects two TQM elements "(Information and analysis and human resources focus)". Individualism has a significant negative impact on "Information and analysis", but has a significant positive impact on process management and business performance. Power distance is the most influential cultural element and impacts all seven TQM elements. Masculinity has no significant affect to TQM elements except business performance. Long-term orientation significantly affects three TQM elements (strategic planning, process management and business performance) in positive ways (Mardani, Bagheri, et al., 2013). Likewise, Aziz & Morita (2016) suggested that a relationship exists between national cultures, and that they influence TQM implementation and performance. While there was no significant cultural difference between the companies, the implementation and organizational performance differed significantly.

In addition, Chen, Dou, Rhee, Truong, & Veeraraghavan, (2015) examine whether cultural dimensions explain the variation in corporate cash holdings around the world as well as within the United States. They concluded that individualism and uncertainty avoidance influence the precautionary motive for holding cash. Besides, firms in individualistic states in the United States hold less cash than firms in collectivistic states. And lastly, their results show that individualism is positively related to the firm's capital expenditures, acquisitions, and repurchases while uncertainty avoidance is negatively related (Chen et al., 2015). Therefore, Mourouzidou-Damtsa, Milidonis, & Stathopoulos, (2019) investigate the relation between national cultural values and bank risk. They report a positive (negative) association between the cultural values of individualism and hierarchy (trust) and domestic bank risk-taking. Similarly, Emin Huseyin Cetenak, Ayse Cingoz (2017) studied on the effects of national culture on financial decision-making. Emin et al. (2017) examined Hofstede's cultural dimensions among 20 countries around the world to explain the variation of financial decisions based on cultural differences.

Abstract

Tourism is a vulnerable sector in many aspects, either by nature factors or by human factors such as wars, rebellions, or terrorism, being the image of tourist destinations a fundamental asset for territories trying to attract tourists and wealth.
Some recent studies concluded about the obvious negative impacts from terrorism to tourism, affecting costs regarding later protection and promotion, while others consider that terrorism may not impact tourism because of the iconic destination reputation.
This article aims to discuss recent trends in the literature review addressing perspectives of 2019 and 2020 studies, published in the context of tourism, terrorism, political instability, and behaviour of tourists towards the intention of travelling. The conclusions present suggestions for approach in future studies, minimizing the impact of large destructive occurrences on destinations.

Keywords: Tourism – Terrorism – Destination – Travel Intention

Introduction

Tourism is a vulnerable sector in many respects, either by nature factors or by human factors such as wars, rebellions, or terrorism. At the same time, terrorism has gained new forms and purposes, being a practice long used by groups as an instrument of domination. That is why, recently, the sector and tourist areas have become the target of terrorism. According to the World Tourism Organization, tourism refers to activities carried out by individuals during trips and stays in places other than where they live or their usual circulation for a period of less than 365 days for leisure, work or other reasons, such as shopping or religious pilgrimage, for example (OMT, 2017).

Corbet, O'Connell, Efthymiou, Guiomard, and Lucey (2019) define terrorism as 'the creation of fear either by an act of violence or by threatening the destination with an act of violence, that causes disruption to the tourism flows, infrastructure and overall operations'. When a terrorist incident in one country involves citizens, targets, institutions or governments of another country, terrorism takes on an international character. In this case, actions conducted in each country may impose costs on people or property in other countries (Sandler and Enders, 2004).

Tourism destinations' demand is particularly influenced by tourists' concerns about their safety, health,

and well-being (Blake and Sinclair, 2003). To Seabra, Reis and Abrantes (2020), safety is one of tourists' main concerns, so when tourists travel, they do not want to be exposed to situations that will threaten their integrity. It is a basic human need. However, although natural disasters have a significant impact on changes in tourist demand and can prevent tourist flows, terrorist attacks and political instability have a more relevant intimidating role for tourists (Sonmez, 1998; Sonmez, Apostolopoulos and Tarlow, 1999). Still in this reasoning, it's possible to observe how terrorist actions have economically affected the tourist destinations, and which impacts the actions have left in the countries that have suffered attacks is what the numerous media and researchers have been trying to understand (Baumert, 2016). Attacks on tourists also represent ideological objectives, connected to positions of different values, cultures and social classes. Tourism has been the target of these actions on a recurring basis, as it is an important source of income for many regions, being able to reduce social inequality. Terrorism, wars and political instability have immediate negative consequences in some destinations, while increasing demand in other destinations (Russel and Faulkner, 2004), which are perceived as safer and thus chosen as substitutes (Enders and Sandler, 1991; Enders, Sandler, and Parise, 1992; Gu and Martin, 1992; Adeloye, Carr, and Insch, 2019; Asongu and Acha-Anyi 2019; Karamelikli, Khan, and Karimi, 2019).

Since the late 1960s, terrorist attacks have become more severe, better organized, more specialized, more violent, and geographically more dispersed (Reisinger and Mavondo, 2005). In the 1980s and 1990s, researchers already predicted a substantial increase in terrorist attacks in future times (D'Amore and Anuza, 1986; Jenkins, 1988). Experts speculated that terrorists would continue to select vulnerable targets, attacks would be more indiscriminate, terrorism would become more institutionalized and geographically broader as a method of armed conflict. On the other hand, because of media coverage, the public would be confronted with more terrorism than had ever been seen (Atkinson, Sandler, and Tschirart, 1987). In the 21st century terrorism assumed other dimensions. After the September 11, 2001 attacks in the U.S., security measures became more restricted and extended worldwide. The U.S. has come to dictate the new world order, with changes in the global geopolitical framework. Currently terrorist organizations, whether ethnic, religious, or political, are scattered throughout the world and have members infiltrated in any country (Júnior, 2013). Over the years, tourism has not only grown exponentially, but also experienced a notorious diversification, proving to be one of the fastest growing sectors in the world and becoming a key factor in socio-economic development and progress. Terrorism has been considered an almost millennial practice and carried out in different ways in which, after the attacks of September 11 and November 2015, many researchers try to understand how tourism has become the target of terrorist actions (Oliveira and Freitas, 2018).

Currently, there is an intimate relationship between tourism and terrorism, as tourism represents a significant socio-economic activity and terrorist attacks cause a substantial decline in revenues in the affected areas, thus causing an imbalance in governments. However, it allows terrorists to gain a political advantage over public authorities, i.e. greater visibility (Korstanje and Clayton, 2012). According to Drakos and Kutan (2001), the main economic consequences of terrorism within tourism concern the effects of contagion and substitution. The substitution effect can affect tourism, in the way that tourists can replace that place with another safer tourist destination, or else replace tourism with other services or goods. In this way, the consequences of terrorism can affect in such a way a tourist destination or any place since tourists can also replace international tourist destinations with national ones. In addition to the substitution effects, a large decline in tourism in neighbouring countries can lead to a decrease in tourism activity throughout the region, which is associated with the effect of negative propagation or externality, the so-called contagion effect (Drakos and Kutan, 2001).

Analysed the Global Terrorism Database (GTD), through the study "Trends in Global Terrorism: Islamic State's Decline in Iraq and Expanding Global Impact; Fewer Mass Casualty Attacks in Western Europe; Number of Attacks in the United States Highest since 1980s" it is possible to conclude the total number of terrorist attacks worldwide decreased by 43% between 2014 and 2018, and the total number of deaths decreased by 48%. However, Western Europe has suffered a relatively continuous occurrence of terrorist attacks - approximately 20 per month on average. Most of these attacks were not lethal. In 2015, 2016 and 2017, there were several incidents in Western European countries in which attackers killed more than five people, including mass attacks by jihadist victims in Paris, Brussels, Nice, Berlin, Manchester, London, and Barcelona. Terrorists killed more than 400 people in

Western Europe during this period.

Table 1: Western European terrorism, by country, 2018

Country	Total attacks	Total deaths
United Kingdom	100	0
Greece	27	0
Germany	22	0
Italy	14	0
France	13	2
Amsterdam	6	1
Ireland	5	0
Sweden	5	0
Belgium	3	1
Spain	2	1
Austria	1	1
Denmark	1	0
Finland	1	0
Switzerland	1	0
Total	**202**	**6**

Source: GDT, Adapted

The number of terrorist attacks in Western Europe decreased by 31% between 2017 and 2018, and the number of deaths decreased by 70%. In the following table (Table 1), it is possible to verify that the total number of attacks carried out and the number of deaths made per country. It should be noted that the largest country that has excelled is effectively the United Kingdom with around 100 attacks (2018), followed by Greece with a total number of 27 and Germany with 22 attacks. Approximately half of all attacks in Western Europe in 2018 occurred in the UK, 85 of them in Northern Ireland. Most of the attacks involved explosives or incendiary weapons and caused no injuries. In two attacks, civilians were killed. It is then possible to verify the main targets of terrorists (Table 2) at the time of their acts of violence/attacks. As can be seen in the table below, and being the theme addressed to tourists and tourism in general, there were in 2017 about 18 terrorist acts to tourists and 13 in 2018. Although there has been a decrease in the number of attacks, it is still worrying today.

Table 2: Targets chosen by terrorist groups, 2017-2018

Targets	2018	2017
Private citizens and property	3147	3552
Police	1623	1604
Government	977	932
Business	604	803

Total	**8053**	**8749**

Source: GDT, Adapted

Today's tourists seem to be "learning to live with terror" and world tourism continues to grow despite terrorism (IPK International, 2016). However, the choice of destinations is increasingly dependent on perceptions of terror and security. Also, the 2016 World Travel Monitor data (IPK International, 2016), observed that the choices of tourists from the main issuing markets have been influenced by this feeling of insecurity reflecting the choice of destinations such as Spain, Portugal or even travel within their own countries of origin rather than destinations such as Turkey, Egypt or Tunisia.

Indeed, analysing the most recent 2019 world travel monitor data (IPK International, 2019), like the 2018 figures, 38% of international travellers currently say that political instability and terrorist threats will influence their travel planning in 2019. Tourists visiting Asia feel much more impacted by terror threats than travellers from other continents. Regarding the type of influence that terrorism has on travel behaviour, concludes that they tourists will choose only destinations that they consider "safe". The security picture of most destinations has improved slightly in the last 12 months - also for Turkey, Israel, and Egypt. According to Ritcher and Waugh (1986), tourists are a target, to the extent that for terrorists they represent values of freedom of choice, wealth, independence, and consumption.

This article is divided in three parts, introduction to the theme of terrorism and concern for security in tourist destinations, the literature review that addresses perspectives of recent 2019 and 2020 studies, published in the context of tourism, terrorism, political instability and behaviour of tourists towards the intention of travelling. The conclusions present suggestions for approach in future studies and contribution to minimize the impact of large destructive occurrences on destinations.

Literature Review. Terrorism and safety concern in tourism destinations

Existing literature considers that, nowadays, the image of tourist destinations is a fundamental asset for territories trying to attract tourists and wealth (Oliveira and Huertas, 2019), being tourism an important tool in national economic development strategies in many developed and developing countries (Karamelikli, Khan, and Karimi, 2019). Tourism has turned into an expanding industry in recent years, which confronts various multifaceted challenges and demands of the modern era, showing a significative resilience with continuous growth despite many serious shocks and concerns (Karamelikli, Khan, and Karimi, 2019), namely the increasing terrorism phenomena across the globe (Asongu, and Nwachukwu, 2019). Karamelikli, Khan, and Karimi, (2019) consider that despite the growing and strict security measures discussed and applied, several countries like Egypt, Kenya, Pakistan, and Turkey have faced terrorist attacks targeting travel and tourist destinations, but now becoming also prevalent in Western tourism destinations, like France, Belgium, Germany, and the United States, as states Bacon and Buzinde (2019), Corbet, O'Connell, Efthymiou, Guiomard, and Lucey (2019), and Harb and Bassil (2020), influencing, not only tourism destinations in general, but also mega-sporting events (Choi, Kim and Leopkey, 2019). Also, Asongu and Acha-Anyi (2019) studied the relevance of military expenditure in mitigating the number and destructive effects of terrorist attacks, considering that military expenditure does not reduce the incidence of terrorism.

Recent empirical studies concluded about unidirectional negative impacts from terrorism to tourism (Adeloye, Carr, and Insch, 2019; Asongu and Acha-Anyi 2019; Karamelikli, Khan, and Karimi, 2019), and discussed terrorism-related risk as a major factor that influences tourist risk perceptions and travel decisions (Adeloye, Carr, and Insch, 2019), once terrorism externalities translate into perceived risk that discourages tourist arrivals (Asongu and Acha-Anyi 2019), affecting tourist destinations (Kapuściński and Richards, 2016; Asongu and Acha-Anyi 2019, Corbet, O'Connell, Efthymiou, Guiomard, and Lucey, 2019). Although these studies offer significant insights into tourism and terrorism risk, little research has been done with regards to terrorism and domestic tourism (Adeloye, Carr, and Insch, 2019). Two plausible explanations for the negative correlation between the lack of safety and security and tourist arrivals are that insecurity decreases the tourist's perceived satisfaction while the costs of protection increase, affecting the costs the tourist incurs

(Fourie, Rosselló-Nadal and Santana-Gallego, 2020), having the affected destinations to contend with issues like heightened tourist fear, negative changes in destination image perceptions, and even modified travel plans due to perceived risk (Bacon and Buzinde, 2019). Bassil, Saleh and Anwar (2019), also consider that, in addition to lost revenue, terrorism imposes high cost on tourism, namely, regarding additional advertising expenses to remedy the image of the tourism destination, increased security-related expenses to prevent future attacks and reconstruction cost (Bassil et al, 2019).

In opposition, Harb and Bassil (2020) consider that terrorism may not impact tourism or may increase tourist inflows, because of the uniqueness of a destination and the iconic reputation of some cities, the personality type of tourists, and previous terrorism experiences may reduce sensitivity to this factor (Harb and Bassil, 2020). In the same perspective, also Lutz and Lutz (2020), state that terrorist events did not always have the predicted negative results in some Caribbean countries, being this conclusion justified by the success of government efforts to mitigate the negative publicity that comes with terrorism, stabilizing tourist levels with lower prices or special promotions.

Table 3: Recent Research in Security evaluation and terrorism impacts in tourism destinations

Author	Goal	Research project	Notes and results (Main findings)
Adeloye, D., Carr, N., and Insch, A. (2020).	To explore the challenges of interviewing people about terrorism in sensitive situations.	Study of fifty-two Nigerians who took part in semi-structured, personal interviews on domestic travel risks associated with terrorism.	This paper contributes to the literature by explaining the strategies that were employed and their implications for researcher and participant wellbeing.
Harb and Bassil (2020).	To investigate the impact of terrorism on bilateral tourism flows within the Organization for Economic Co-operation and Development countries, and examine the moderation effect of immigration in the destination country on the terrorism–tourism relationship.	Using estimated gravity models.	The results obtained show that after reaching a certain threshold, terrorism negatively impacts tourist arrivals. This relation seems to be moderated by the share of immigrants in the country of destination: when the share of immigrants in a country is relatively high, the positive impact of immigration on tourist arrivals would counterbalance the adverse impact of terrorism on tourist arrivals.
Fourie, J., Rosselló-Nadal, J., Santana-Gallego, M. (2020).	To investigate the effects of security threats, namely terrorism, crime, and corruption, on international tourist flows.	Estimation of a gravity model to evaluate differences in the instability measures between country pairs quantifying not only how security threats in the host country have a negative effect on inbound tourism but also how conditions in the origin country also determine tourism flows to a particular destination.	Results show that tourists prefer traveling to countries with similar levels of safety and security as exist in their origin country. Tourists from stable countries prefer traveling to countries with the same conditions, while tourists from unstable countries are more tolerant with insecurity at the destination country. Greater knowledge about the destination country reduces the negative effect of security threats on inbound tourism. There exists a U-shaped relationship between security threats and tourism.
Lutz, B., and Lutz, J. (2020).	To evaluate the effects of terrorism on tourist arrivals in Caribbean countries and territories.	Several analyses based on simple variate correlations, with terrorism and number of arrivals.	Results show that terrorist events didn't always have the predicted negative results. Government provided efforts to mitigate the negative publicity that comes with terrorism, successfully maintaining tourist levels in the first three decades of the analyses with lower prices or special promotions.
Seabra, Reis and Abrantes (2020).	To examine the impact that terrorist attacks within a representative group of European countries can have on the tourism demand of a South European country with no record of terrorism attacks.	To analyse the connections between terrorist attacks and tourists' arrivals, occurred between 2002 and the end of 2016, an Unrestricted Vector Autoregressive model was used for multivariate time series analysis.	The main results show that terrorist attacks have a strong impact on tourist arrivals and confirm the existence of terrorism spillover, namely the substitution and generalization effects phenomena.
Ulucak, R., Yücel, A., Ilkay, S. (2020).	To explore the demand-side factors that affect the number of international tourist arrivals to Turkey	To this end, an augmented gravity model has been employed to analyse the factors affecting the number of international tourists visiting Turkey from the top 25 originating countries from 1998 to 2017.	Empirical findings suggest that per capita income of both origin country and Turkey, relative exchange rate, and globalization positively affect the demand for tourism, while it is negatively affected by consumer price index, violence/terrorism, household debt level, and bilateral distance between Turkey and the origin country. Empirical results show that terror attacks are the most dominant factor for tourism demand in Turkey, causing significant decreases in the number of tourist arrivals.
Asongu, S., and Acha-Anyi, P. (2019).	To understand how military expenditure can modulate the effect of terrorism externalities on tourism.	The geographical and temporal scopes are 163 countries and the period 2010–2015. The empirical evidence is based on negative binomial regressions. Measuring Terrorism externalities in	Military expenditure significantly lessens the destructive impact of these terror-related incidents to induce positive net effects on tourism. This finding is robust to all measurements of terrorism. Homicides and violent demonstrations reduce tourists' arrivals whereas the rate of incarceration of convicted offenders has the

Author	Goal	Research project	Notes and results (Main findings)
		terms of terror-related incidents, injuries, fatalities, and damaged properties.	opposite effect. The analysis is extended to income levels and regions to provide more opportunities for policy implications.
Asongu, S., Nnanna, J., Biekpe, N., and Acha-Anyi, P. (2019).	The examination of the effect of terrorism and peace on tourist destination arrivals using a panel of 163 countries with data for the period 2010–2015.	The empirical evidence is based on Generalised Method of Moments and Negative Binomial (NB) regressions.	Political instability, violent demonstrations, and number of homicides negatively affect tourist arrivals, while the number of incarcerations positively influences the outcome variable. Second, the effects of military expenditure, "armed service personnel," and "security officers and polices" are not positively significant.
Asongu, S., and Nwachukwu, J. (2019).	To investigate the role of security officers, the police and armed service personnel in dampening the effect of terrorism externalities on tourist arrivals.	The temporal and geographic scopes are respectively 2010–2015 and 163 countries. Four terrorism measurements are used. They include the number of incidents, injuries, fatalities, and property damages.	Armed service personnel can effectively be used to modulate the damaging influence of all four terrorism externalities to achieve a positive net effect on tourist arrivals. Conversely, the corresponding moderating role of security officers and the police is not statistically significant. Moreover, violent demonstrations and homicides have a harmful effect on tourist arrivals while the number of incarcerations displays the opposite effect.
Adeloye, D., Carr, N., and Insch, A. (2019).	To discuss the implications of domestic tourism and terrorism research for theories and models developed for understanding tourism and risk, as well as its significance for the planning and development of domestic tourism.	It, therefore, discusses the implications of domestic tourism and terrorism research for theories and models developed for understanding tourism and risk, as well as its significance for the planning and development of domestic tourism.	The recognition of the importance, for tourism and risk research to understand perceptions of domestic tourists (as a separate market) in order to provide a base for understanding domestic tourists' risk perceptions and attitudes towards terrorism (or other forms of risk).
Bacon, L. and Buzinde, C. (2019).	To understand and document perceptions held by tourists so as to inform destination recovery efforts post terror attack.	This exploratory study employs focus groups to examine American millennials' perceptions of risk and their intentions to travel to terror-stricken destinations, specifically Nice, France. Perceived risks related to general international travel articulated by participants included, health, theft, and safety concerns.	Participants indicated that they were willing to travel to Nice, post terror attack, except for one group that would choose to travel elsewhere in France. Participants' rank ordering of the sources they would consult during the decision-making process for travel to a terror-stricken destination included: family, people with lived experience of the destination, and government. This paper contributes to risk perception literature, particularly scholarship on the nexus between terrorism and tourism.
Bassil, C., Saleh, A. and Anwar, S. (2019).	To examine the impact of domestic and transnational terrorism on tourism demand (as measured by visitor arrivals) to Lebanon, Turkey and Israel.	Using a seemingly unrelated regression (SUR) model. Using a dynamic framework considering the intensity of terrorism and the associated spill over effects.	The empirical results, based on monthly data from 1995 to 2007, reveal that terrorism in one country affects visitor arrivals not only to that country but also to other countries: tourists view Lebanese and Turkish tourism markets as substitutes. Terrorism in Israel, domestic or transnational, and intensities, affects visitor arrivals to Lebanon and Turkey. In overall terms, terrorism showed a much larger negative impact on visitor arrivals to Lebanon.
Choi, K., Kim, M. and Leopkey, B. (2019).	To examine the relationship between tourists' risk perceptions and their intention to travel to an Olympic host country with apparent risks of terrorism and political instability during and around the event period using the case of the 2018 PyeongChang Olympic Games.	Using a convenience sampling technique prior to the hosting of the event in question from college students in the southeast region of the U.S. via an online survey software.	Terrorism risk was found to have a negative impact on travel intention while political instability did not. The results suggest that potential terrorism risk is a vulnerable point for the host country, and host organisations' collaborative risk management strategies for minimising potential threats and generating a safe destination image are necessary to attract a higher number of visitors around and during the Olympics.

Author	Goal	Research project	Notes and results (Main findings)
Corbet, S., O'Connell, J., Efthymiou, M., Guiomard, C., Lucey, B. (2019).	To estimate the influence of terrorist attacks on European tourism through the short-term post hoc response of the airline industry and passengers.	Using a seasonally-adjusted ARMA-GARCH methodology on unique datasets that examine changes in tourism as measured by ASKs, seats filled and changes in both fares and revenues. Traffic flows are found to fall despite significant fare reductions; however, this response varies substantially based on the flight origin and ticket-type purchased.	Business travel slows substantially due to duty of care legislation for corporate transport. Evidence indicating substantial airline fare reductions, in most investigated cases this response was unable to mitigate substantial reductions in passenger demand and flows across varying ticket types.
Ghosh (2019).	This paper investigates in a time series framework over the period 1995 to 2016, the impact of uncertainty on tourism.	The paper explores the causal association of both political uncertainty and economic uncertainty between tourism and other macroeconomic variables for the countries of France, Greece, and the United States.	The unit root test and the ARDL cointegration are applied for unknown structural breaks. In the long run uncertainty adversely affects the tourism industry in all the countries under study.
Karamelikli, H., Khan, A., and Karimi, S. (2019).	To estimate the long-run and short-run impact of terrorist incidents on inbound and domestic tourist arrivals in Turkey: to explore the relationship between terrorism and tourism in Turkey using a non-linear economic modelling approach for monthly data for the period 2007–2016, and to determine whether terrorism has obstructed tourism in Turkey.	Using a non-linear autoregressive lag (NARDL) model for the period between 2007 and 2016.	The results reveal unidirectional nonlinear relationships from terrorism to tourism in both the long-run and short run. Inbound and domestic tourists show different respond towards an increase or decrease in terrorist incidents. The findings are expected to help tourism management, planning, and forecasting regarding greater economic benefits for the country.
Kim, Choi, Leopkey (2019).	To examine and compare the influence of tourists' risk perceptions on travel intentions across mega sporting event host destinations with different levels (i.e. apparent risks, less imminent risks, and unidentified risks) of such risks.	Data collected from 571 potential tourists via an online survey software and analysed using a structural equation modelling technique.	The results indicated that perceived terrorism risk significantly influenced the tourists' travel intentions. Tourists' terrorism risk perceptions toward South Korea (apparent risks) most significantly impacted their travel intentions, followed by general destinations outside of the United States (unidentified risks), while political instability was not significantly related to travel intentions. These findings offer practical implications for mega sporting event organizers.
Oliveira, A. and Huertas, A. (2019).	To investigate how the destination marketing organizations (DMOs) of Barcelona and Cambrils communicated information about the terrorist attacks they suffered and what they have done to recover their image.	The tweets posted on the Barcelona and Cambrils profiles were examined following a content analysis method focusing on three categories of communication: (1) the terrorist attacks, (2) the actions by the DMOs to manage them, and especially (3) the tourism-related decisions that were taken in order to recover the image of the destinations.	The results reveal that to a great extent the destinations focused their communication efforts on managing the attack and to a lesser extent on messages to promote tourism in the region to recover their image.

Source: Authors

Several conceptual models have been presented in recent research, considering risk perception, namely through terrorism risk and political instability (Choi, Kim, and Leopkey, 2019; Seabra, Reis and Abrantes, 2020).

Figure 1: Structural equation modelling results measuring terrorism risk and political instability

Source: Seabra, Reis and Abrantes (2020)

Choi, Kim, and Leopkey, (2019) developed a study, in which, the main purpose was to examine the relationship between tourists' risk perceptions and their intentions to travel to an Olympic host country with apparent risks during and around the event period, presenting the following questions: does perceived terrorism and political instability risk influence tourists' intentions to visit an Olympic host country?; how do tourists' perceived anxiety and safety influence their intentions to travel to a host country when the country has apparent risks? (figure 2).

Figure 2: Structural equation modelling measuring terrorism risk, political instability, travel anxiety, and travel safety

Source: Choi, Kim, and Leopkey, (2019)

Curiously, Choi, Kim, and Leopkey, (2019) concluded that terrorism risk had a negative impact on travel intention while political instability did not.

Conclusion

Scientific research published in 2019 and 2020 about terrorism, political instability, and behaviour of tourists towards the intention of travelling, present several conclusions, namely, strategies proposals for citizens wellbeing; understand domestic tourists' risk perceptions and attitudes towards terrorism;

increasing of negative impacts of terrorism, regarding tourists arrivals; tourists prefer travelling to countries with similar levels of safety and security as exist in their origin country; successfully government efforts to mitigate the negative publicity that comes with terrorism, with lower prices or special promotions; terror attacks as the most dominant factor for tourism demand in Turkey; homicides and violent demonstrations reduce tourists' arrivals; political instability, violent demonstrations, and number of homicides negatively affect tourist arrivals, while the number of incarcerations positively influences the outcome variable; terrorism in one country affects visitor arrivals not only to that country but also to other neighbouring countries; terrorism risk has a negative impact on travel intention while political instability did not.

When tourists realize that a destination is unsafe, they replace it with others they consider safer (Seabra et al., 2020), being determinant to promote tourism investigation concerning the impact that terrorism may have on tourist arrivals in a regional perspective, considering also tourist behaviour (Seabra et al., 2020), and terrorism events effects on a safe country with no record of terrorism attacks (Seabra et al., 2020), as a result of a reject/replace destinations.

Professional Development of Employees in the Social Competence Context

Łukasz SKIBA

Czestochowa University of Technology, Czestochowa, Poland
lukasz.skiba@wz.pcz.pl

Abstract

The fact that man is a social creature is corroborated by a substantial portion of human behaviour of interpersonal nature. Individuals cooperate with others, either working for others or at least taking their opinion into account. Even when there is no direct interaction with others, human behaviour manifests interpersonal nature because the presence of other people may not only be actual, direct, but also symbolic or imagined. Therefore, in a situation when we make (allegedly) independent choices, we also take social standards into account and take heed of reactions of persons close and important to us, i.e. they indirectly influence our behaviour, decisions and choices, imbuing them with social character (Hamer, 2009, p. 229). This paper focuses on a goal which includes determination whether a relation exists between social competence of employees and their professional development, as well as pinpoints the nature of the impact of the former on the latter along the weakening - reinforcing axis.In order to present the performed survey and analyses in a transparent manner, the paper is divided into three sections, where the following issues are discussed: social competence, professional development and presentation of results and conclusions from empirical studies carried out via a diagnostic survey method with the use of a questionnaire.

Keywords: Social Competences, Professional Development

Introduction

Observation of social life of individuals makes one reflect on what makes some people cope better and others worse in inter-human contacts. This factor (or factors) determining the ability of shaping inter-human contacts translates to the feeling of happiness in personal life, as well as may affect development and, in its consequence, professional success.

Social competence has been discussed in the humanities (in particular psychology) for quite a long time (1920s, Thorndike) (Tomorowicz, 2011, p. 93), yet it seems that greatest interest in these aspects took place in the first decade of the 21st century (literature studies indicate that this refers both to the academic milieu and psychologists - practitioners (e.g. Strelau J., Goleman D., Cupach W.R., Spitzberg B.H., Wojcieszke B., Matczak A., Jaworowska A., Borkowski J., Oleś M., Sęk H. et al.). Popularity of this issue may result from searches for accurate predicates of extensively understood well-being and success in life, as it is known that there is no simple translation of good school results to professional success. Reference books lack a clear and generally accepted mode of defining social competence (one of such attempts was commissioned by the European Parliament and the Council on 23 April 2008). It may be assumed that there are few concepts in psychology with respect to which there is such great diversity of the proposed definitions. Researchers tackling the issue of social competence ask the following questions: *is social competence a certain general social skill manifested in various types of situations or does it encompass a number of specific, often unrelated, skills?* (Argyle, 2002, p. 38)

In this paper, primary attention (i.e. the goal of the paper) is focused on issues of relation/ correlation between social competence and professional development.

The direction of professional development in an organisation is determined not so much by the employee, but mostly by a superior, a manager, i.e. a person who is responsible for proper staffing of a company.

Management of human resources, and in particular their development, is a purposeful configuration of measures intended to: enrich knowledge, develop skills, shape values, stances, motivation and skills; as well as the ones whose goal is to take care of the physical and mental condition of persons performing work. Finally, such activities lead to increased efficiency and boost the market value of a given enterprise.

Strategic management of human resources is nowadays considered the most important factor which makes the organisation capable of facing up to the dynamically changing conditions of the economic environment, as well as adjusting to changes in stances and employee expectations. This is related to decisions pertaining to employees, which map out, in a long-term perspective, activities in the personal realm, also the ones that are of vital significance for meeting the enterprise's goals.

Employee development, carried out on the basis of knowledge about social competence of the employees (its level and possibilities of improving it) which was planned on a strategic level, may form a strong tool of the organisation on its path to accomplishing a competitive advantage.

Social Competence: Definitions and Formation Factors

Man's social nature (according to R. Hogan) is reflected in two fundamental needs: the need of approval (acceptance) and the need of status (power). The need of approval expresses the desire of affiliation to a group, experiencing acceptance on the part of its members and living in harmony with them. On the other hand, the need of status reflects the dream about influence over one's life and surroundings, primarily by creating new possibilities for self-fulfilment and the so-called "distinguishing oneself" i.e. moving up the steps of social hierarchy, gaining respect, authority or at least fame. These two primary social needs are the strong motives of inter-personal behaviour (Tillmann, 1996).

The aforementioned division of man's social needs is a basis for defining social competence, also in a dual manner.

One of them, emphasising the necessity of approval and acceptance, portrays social competence as the *ability to generate social behaviour which enables and facilitates creation and maintenance of advantageous interpersonal relations.* From this point of view, social competence is simply a relational skill with the use of which we initiate, negotiate, maintain, change and end interpersonal relations. In line with the above, a socially competent person is an individual who can establish mutually satisfactory relations with other people, both intimate/ close, as well as professional (Tillmann, 1996, p. 55).

The second mode of defining social competence refers to the need of status and power. Social competence is defined as efficiency in pursuing own intentions in contacts with other people and is related to the *ability to exert influence*, e.g. one of the hallmarks of professional effectiveness is the success in taking up job, especially the fi rst one. (Arnett, 2001, pp. 133-143) This approach emphasises that the level of social competence of an individual is most acutely evinced by the results which the individual accomplishes by contacts with other people and reputation (respect, authority) which the individual enjoys in his/ her social environment. It is also worth noting that interpersonal efficiency is not only related to exerting influence on others, but also with understanding benefits which follow from, e.g., taking the advice of a more experienced person or entering into a proper "coalition" with others. The core of this approach of defining social competence is thus emphasis on the significance of efficient social adaptation, whereas interpersonal skills are often examined in the categories of political skills (Argyle, 2002, p. 43).

Social competence is related to personal and social well-being which requires:

- awareness of how to secure an optimum level of physical and mental health, also understood as the resources of a given person and his/ her family and direct social environment, as well as;

- knowledge of how a proper lifestyle may contribute to this (Borkowski, 2003, p. 76).

Understanding of principles and rules of conduct generally accepted in various societies and environments such as, e.g., a work place, is crucial for success in interpersonal contacts and social participation. Equally important is the awareness of basic concepts pertaining to persons, groups, professional organisations, gender equality and non-discrimination, society and culture. It is necessary to understand multicultural and socio-economic dimensions of European societies, as well as mutual national interactions, cultural identity and European identity (Borkowski, 2003, p. 76).

Even though it may be claimed that researchers differ in their mode of comprehending social competence, yet all of them consider it a feature that conditions the efficiency of the individual's functioning, because competent individuals obtain valuable, high results without extensive effort connected with the undertaken activity. (Boyatzis, 1982)

The issue of social competence is located at the threshold of several sciences such as sociology, psychology, ethics, management, political studies, anthropology, etc. and thus we can speak about a mass of variables conditioning a man's competence effectiveness. Taking into account the framework limitations of this paper and the direction of undertaken research, it is necessary to mention at least two factors differentiating the level of social competence, namely: personality and emotional intelligence.

Researchers representing psychology identified thousands of features and personality dimensions on account of which people differ from one another.

In the second half of the 20th century and more precisely at the beginning of the 1980s, activities promoting the concept of the "Great Five" were undertaken on a broad scale (Goldberg, 1981) (however, the beginnings of its history date back to the 1940s and 1950s – Fiske, Christal, Norman, Tupes), namely five basic personality traits which have special significance for the organisation, i.e. agreeableness, conscientiousness, neuroticism, extraversion and openness (Oleś, 2000, pp. 7-18).

The outline of the "Great Five" personality traits still focuses the attention of both science and management practice. Its potential value consists in the fact that it encompasses an integrated set of traits that seem to be reliable indicators allowing to foresee certain behaviour in specific situations. Relative to this issue, managers who can understand the outline well, will be able to detect and assess occurrence of such personality traits in their employees and discern causes and mechanisms of their specific behaviour. However, managers should avoid overestimating their ability to assess five basic personality traits in others, as even when applying most rigorous and reliable measures, the assessment may be imprecise to a certain degree. Another limitation of the outline of five personality features is the fact that it primarily relied on the results of studies carried out in the United States, and therefore the issue of transferring it to other cultures remains open. However, even in the United States behaviour of people in organisations is affected by various factors and traits (not only psychological), in relation to which interpretative narrowing down of the human behaviour exclusively to the "Great Five" traits may be a significant misuse (Borkowski, 2003, p. 95).

The second factor listed before as clearly determining social competence is emotional intelligence. As opposed to some other types of intelligence, emotional intelligence should be, in a certain manner, related to higher emotional or mental skills. Even though such criterion seems to be obvious, some of the definitions of emotional intelligence do not take it into account, for example one of the more popular definitions of emotional intelligence which says that it includes "self-control, zeal, perseverance and the ability of self-motivation" (Śmieja, Orzechowski, 2008, pp. 23-27). The above-quoted definition is

centred on motivational aspects (zeal and perseverance), and not on emotions, and thus corresponds to certain definitions of motivational intelligence.

For the purpose of this paper, an abbreviated version of the definition of emotional intelligence was adopted, determining it as the "capacity to perceive emotions, accessing them and such activation of emotions that they accompany thinking; capacity to understand emotions and having emotional knowledge which allows for control of emotions and is conducive to emotional and intellectual development" (Epstein, 1998, pp. 25-30). This definition combines the ideas that emotions may be conducive to better thinking and that by thinking about emotions, we make use of intelligence, i.e. it juxtaposes intelligence with emotions, making them inter-dependent.

Professional Development: Description of Significance of the Concept and Leading Theories

Man's professional development may be understood as the process which takes place in two dimensions. The first of them is a compilation of opportunities and threats set before him/ her by the organisation and the other is the resultant of his/ her potential and aspirations in this respect. Thus, factors aiding an employee's professional development, i.e. motivating him/ her to raise his/ her qualifications, will have both external and internal nature (Balcerek, 2004, pp. 31-38).

Nevertheless, it must always be remembered that work is a natural element of man's life, such as birth, ageing and death.

Work influences the possibility of man's development and if this is so, man's professional development occupies a special place in such development. This is a characteristic process exclusively with respect to people, unarguably confirming and enriching the essence of humanity. Until recently, a tendency to treat the issue of professional development as a specific form of pro-social development was perceptible (Gladding, 2001, pp. 21-25).

Nowadays, work is mainly focused on the teamwork of its course, and not on organizational functions. Therefore, the employee is expected to be flexible, resourceful, and also self-employed in various areas of work, taking into account the diversity of sectors and their regulations. (Hall, 1996, 8-16)

Due to the significance of the sphere of professional work in man's activity, studies and in-depth analyses of this area seem to be necessary. Such discussion most often refers to the role of the process of development in the element of work, and less frequently to the element of work in the process of a man's life (Balcerek, 2004, pp. 51-55).

When analysing dependencies and looking for relations between personal and professional development, it is worth referring to the systematics which was in this respect prepared by I. Korcz and which juxtaposes subsequent categories of development of man, an individual and professional activity. Man's development in this approach is understood as: "a multidimensional process, conditioned by various factors with subjective and objective nature"; whereas personal development as "(...) a process of systematic and lasting, throughout the entire period of man's life, transformations, taking place in various conditions of his activity and manifested in proper forms of man's conduct" (Korcz quoted in Plewka, 2016, p. 30).

In relation to the above, professional development forms a part of characteristics of conscious and intentional activities the essence of which is the process of socially desired and directed quantitative and qualitative transformations, conditioning purposeful, active, controlled and responsible participation of man in the profiling of oneself and, through this, one's own closer and further surroundings (Janiga, Pietrulewicz, 2004, p. 77).

Being guided by the logic of the above breakdown, it is necessary to adopt a view that the general development of man is related to the evolution of the entire *Homo sapiens* species, starting from primary forms. Such development on a macro scale on the axis of time designates the possibilities and the potential predispositions of a specific individual which, in turn, determine the mode of fulfilling a professional career. However, answers to questions: *which relations and ties occur between these areas?* are to be searched for in the concepts explaining such dependence by the dynamics of changes in the behaviour of an individual with respect to work (Adamiec, Kożusznik, 2000, p. 102).

In the era of rapid transformations in man's life which are the consequence of implementation of modern technologies, work places cannot merely train employees; first and foremost, they have to take care of ongoing improvement of the employees' qualifications.

Due to the special role in the professional development which is attributed to qualifications, it is worth mentioning several definitions of this term referring to man's physical and psychical features.

And thus, A. Polańska, analysing the concept of qualification relies on the encyclopaedic definition (*Mała encyklopedia prakseologii i organizacji*): "qualification is the overall familiarity with the performed work, proficiency in it, modes of intellectual work, as well as experiences collected by the employee during the work processes as a premise of social activity. By taking the physiological and psychological dexterity of the employee into account, qualifications determine his/ her skills and ability to work" (Polańska, 1999, p. 126).

Other approach to the concept is found in a publication of T. Oleksyn who does not use the term "qualifications" as "in many enterprises, it is associated with the so-called qualification scale, where only requirements with respect to education and job seniority are entered." Thus, the author decided that the word competence has a broader meaning than the term qualifications and uses this term. He defined it in the following manner: "competence is education, experience, skills, talents and predisposition and other psycho-physical features, as well as behaviour expected by the employer and important in professional work" (Oleksyn, 1997, p. 47). The first three are measurable and comparable; the subsequent ones cannot be measured or compared, but the author treats them all as equal.

Qualifications have a structure composed of multiple elements; they are a dynamic construct, subject to evolution on account of changes occurring in the economy and in man's life.

During analysis of individual qualifications, three different clusters are distinguished, composed of numerous ingredients: - man's psycho-physical features, his/ her talents, predisposition, character; - various types of general and life knowledge, professional and specialist knowledge; - various types of life and professional skills (Polańska, 1999, p. 128).

To accomplish and retain qualifications with a high market value, correct improvement of the elements from every cluster is necessary, along with their integration; it is not enough to work only on one cluster.

By analysing the labour market in Poland and in Western countries, A. Polańska distinguished three categories of market value of qualifications: - *rare*, also known as scarce, unique, potentially strategic (they are held by creative people who improve economic, technical and organisational processes); - *universal*, which are characterised by high efficiency in keeping organised teams, companies and work positions, whereas their main task consists in retaining competitive efficiency in the existing organisations; - *weak*, characterised by low efficiency, which is often on the level of labour costs. Progress of technology reduces the number of simple and easy work positions which, in turn, generates the risk of unemployment for a group of people with low qualifications (Polańska, 1999, p. 125).

A significant element of shaping professional development is the motive for embarking on it. Scientific interest in the issue started in the first half of the 20th century in the United States (Amstrong, 2000, p.

19). The created concepts may be grouped into three thematic blocks referring to: *theory of professional choice:* analysis of the course of pre-orientation and vocational orientation processes, along with indication of factors determining choices in this area (e.g. A. Roe - relations inside a family; J. Holland - role of personality and degree of identification with social stereotypes; M. Ginzberg - long-term process of the individual's adjustment to the changing reality); *theory of learning a profession:* from the stage of becoming acquainted with the areas of human economic and cultural activity, through stages of pre-vocational preparation, up to the period of vocational preparation, which are followed by subsequent stages which are the periods of professional development; - *theory of professional work*: analysis of the individual's entire life, with special attention to these manifestations which are related to work; necessity of synthesis of an individual's personal development with professional development, thus forming a platform combining the accomplishments of knowledge developed in individual areas of science (D. Super who determines professional development as a process of growing and learning, with all manifestations of professional behaviour subjected to it) (Griffin, 2007, p. 89).

The presented concepts discussing the motives of professional development seem to overlook the question about the dynamics and purposefulness of these activities (their function) in the analysis. This gap is filled by W. Łukaszewski who tackles the problem of location of personality development in the context of human activity and indicates the existence of three types of possibilities in the system of goals and means of human actions: - development as a goal of an action; - development as a means leading to another goal; - development as the so-called side product of an action (Gladding, 2001, pp. 21-25).

Choice made by managers and application of specific development practice is the outcome of coherence or a compromise accomplished between the employees' aspirations and goals of the organisation. The undertaken development activities must also take into account and be adjusted to the specific determinants of the environment. Modes and directions of handling employee development are thus the outcome of co-existence and flexible adjustment of factors located in the environment and characteristic for the organisation and the employees.

Social Competence Vs. Professional Development in the Light of Own Study

Methodological Study Bases

A production company was selected as the research area for supplying household products to the market (soap, detergents, toothpaste and toothbrushes, etc.). The company sells its products in 222 countries around the world, employing approximately 40,000 employees and achieving annual sales revenues exceeding USD 10 billion. The concern's factory employs 650/700 people in the Polish branch. The aim of the study was to analyze the impact of social competences on the employee's professional development.

The subject of the study were social competences of employees, and above all those that have an impact on the employee's professional development [see tables No. 1, 2 and 3; the set of key social competences used for the study was inspired by the division according to M. Argyle (Argyle, 1999, 133-141, 247)]

The research was carried out using the diagnostic survey method, the survey technique was a survey method, and the questionnaire was a tool that correctly filled in 150 employees of one of the Polish branches of the examined international concern. The survey was conducted in a distributed, anonymous, individual and direct way (during a break from work) and took the respondents about 15 minutes. The survey questionnaire contained 14 questions (and so-called metrics - independent variables: age, gender, education, seniority, position held).

An important element of the adopted methodology was the formulation of the following research problems:

- What social competences are the most educated among employees?
- What social competences are the least educated among employees?
- Is there a relationship between your level of social competence and your position in the company's hierarchy?

These questions set the direction and nature of the questionnaire contained in the questionnaire, and the answers provided to them constituted the basis for the final conclusions on the relationship between the impact of social competences on professional development.

Results and Analysis of Collected Study Material

A summary breakdown of the presented questions asked and answers given to them is presented in *Tables 1, 2* and *3*.

Data collected in *Tables 1* and *2* allow for answering which competence is developed the most and the least among the employees. On the other hand, *Table 3* allows for determining the correlation of social competence and professional development.

Table 1: Most/ least developed social competence among employees (part 1 out of 2)

Question	**How do you assess your skills:**				
	to motivate yourself to take action?	of verbal interpersonal communication ?	in the area of non-verbal communication ?	in the area of behaving in an assertive manner?	of coping with emotions?
answer to question:	N = 150				
Very high	36	51	54	36	54
Quite high	54	57	66	57	66
Average	24	27	24	33	24
Quite low	30	15	6	18	6
Very low	6	0	0	6	0

Source: author's own study based on the results of questionnaires.

The majority (approx. 60%) of respondents highly assess their own ability of self-motivation to work, communication, being assertive and controlling emotions.

Correlating the answers given by employees with independent variables (both from *Table 1* and from the others), it is difficult to see any significant trends or regularities in relation to: age, sex or education (therefore their presentation was omitted in this study). The only variable that differentiates the employee behavior undertaken in the study is the position taken, which will be presented in *Table 3*).

However, the data in *Table 1* indicate the fact that there are people (4%) in the organization who have problems with motivation and assertiveness, while none of the respondents rated their communication skills and control of emotions as "very low. "

Table 2: Most/ least developed social competence among employees (part 2 out of 2)

Question	How do you assess your skills:				
	of setting short-term goals and accomplishing them?	of long-term planning and accomplishing goals that were set?	of coping with failures?	of adapting to new situations?	of working in a team?
answer to question:	N = 150				
Very high	24	36	36	24	63
Quite high	39	54	57	39	72
Average	81	24	33	81	15
Quite low	6	30	18	6	0
Very low	0	6	6	0	0

Source: author's own study based on the results of questionnaires.

Not all of the company's employees are capable of setting goals and accomplishing them. As far as short-term goals are concerned, the majority of respondents concede that they cope with this skill on an average (54%) or high (42%) level. On the other hand, in case of accomplishing long-term goals, we are dealing with a greater polarisation of answers towards high (60%), as well as low (24%) assessment of own skills. Lower rank employees, i.e. those whose goals in professional life are set by the superiors, assessed their ability to set goals on the lowest level.

It is necessary to pay attention to the fact that exactly the same distribution of answers as in the case of the ability to accomplish short-term goals is applicable with respect to the declaration about adapting to new situations (average assessment 54% and high 42%). The relation between the answers to these two survey questions seems to be non-accidental and logical, as accomplishing short-term goals induces rapid changes, adequate to current needs and the necessity of adapting to new circumstances, and this was primarily assessed on the average level by the respondents.

On the other hand, the distribution of answers given with respect to accomplishing long-term goals seems to reflect the assessment of coping with failures. Here, one might posit a thesis that the efficiency of accomplishing long-term goals is assessed by the respondents in the categories of coping with failures, i.e.: "if I can cope with failures, then I efficiently accomplish long-term goals" and vice versa.

Among all questions asked, the respondents were the most optimistic about their own ability to work in a team (high 90%, average 10%). This may only testify to the high level of awareness of accomplishing goals by a corporation.

Table 3: Level of social competence and the position in the company's hierarchy

N = 150					N = 150				
Question		Do you have any ambitions about professional promotion?		Is professional development important for you?	Question	Were you promoted in the last 5 years?			Did you complete any additional professional training in the last year?
Answer to question:	Agree strongly	24	**44%**	21	Answer to question:	Agree	42	**28%**	33
	Agree slightly	42		48					
	Disagree slightly	36	56%	45		Disagree	108	72%	117
	Disagree strongly	48		36					

Source: author's own study based on the results of questionnaires.

46% of respondents believe professional development to be important and almost the same number (44%) has ambitions related to professional promotion. Thus, considering something important, the respondents are striving to accomplish it.

It also follows from the collected research material that every second employee with professional ambitions had extra training in the course of the last year, and almost two out of three persons aspiring for promotion received it in the course of the last 5 years of work.

Final Conclusions

The performed analyses of questionnaire material allow for answering the research questions that were set in the paper.

According to the respondents' answers, most developed social competence of employees is related to building emotional bonds with other people. In the discussed aspect, it is also noticeable that employees with lower social competence take more care of interpersonal relations, whereas persons with a higher level of social competence are more intent on self-fulfilment and accomplishing professional promotion.

The research has also shown that there is a dependence between the level of social competence and the position held in a company. Social competence definitely affects professional development of employees (analysis of this aspect was the goal of this paper) as the survey has shown that there is a dependence between the level of social competence and the mere desire for professional development. It goes without doubt that more developed social competence leads to higher professional development of an employee. The research has shown that among lower rank employees whose social competence is less developed, there is smaller interest in professional development. Their status and their position in the company fully suffice them and they do not need to strive for professional promotion and thus improve their living conditions, wage or social situation. On the other hand, employees with more developed competence manifest a tendency to compete for better positions; they are striving for

promotion and better life. This is caused, to a significant degree, by more developed social competence which makes such employees want to develop in the realm of professional life.

The competence responsible for interpersonal communication is most developed among the respondents. Along with subsequent levels of professional development, non-verbal communication plays an increasing role and thus it is improved more and more.

Mere building of emotional ties with other people offers a feeling of affiliation and acceptance on the part of the surrounding environment. This is very important in the case of team work. Better effects and higher efficiency of work are noticeable provided people have good relations and emotional ties. If there are some emotional ties among them, people are more willing to help one another, they strive to accomplishing a common goal (good base for synergy).

Summing up, it may be concluded that the conducted study allows for confirming that the influence of social competence on professional development of employees is high. This is significantly reflected in desires and the potential of employees' development. Hence, it is important to develop social competence since the very beginning, as it significantly affects our later life, both social and professional.

Evaluation of Consumer Preferences of Czech Shoppers with at least Secondary Education

Kamila VESELA
CULS Prague, Prague, Czech Republic, veselakamila@pef.czu.cz

Lucie SEVEROVA
CULS Prague, Prague, Czech Republic, severova@pef.czu.cz

Abstract

Cross-market changes in consumer preferences go hand in hand with the development of society, the advent of technology and globalization. Household consumption has long been on the rise and the term "consumer society" has become increasingly popular. As market supply and competition increase, consumers are faced with a sea of options which in turn both stimulate aggregate consumption and affect the factors considered by consumers when making a purchasing decision. It is no longer true that product price or availability is the primary criterion; today's consumers place increasing importance on quality, brand or whether the products they purchase meet environmental standards. The objective of this paper is to present the results of a survey of Czech consumers' behaviour in terms of their shopping preferences and factors influencing their consumer habits. Only respondents with at least secondary education were included in the survey.

Keywords: shop, preferences, consumer, market

Introduction

Consumer behaviour changes in response to the development of society and the advent of modern technology. This affects both the type of shops preferred by consumers and the factors that determine their choices. There is a trend towards increasing use of the Internet, while, for many people, price is no longer the primary factor influencing their purchasing decisions. In addition, people (especially the younger generation) have recently become more interested in food quality and organic healthy food, which is reflected in the growing interest in farmers' markets and health food stores. Researches demonstrate how general societal attitudes affect the value of green consumption and consumer's shopping behavior (Paço, Shiel and Alves, 2019). Consumer habits are also changing, as are the types of advertisement that affect consumers. In this regard, an important role was played by Facebook and others social networks, resp. effectiveness of advertising on social media (Anastasiei and Dospinescu, 2017).

The objective of this paper is to present the results of a survey of Czech consumers' behaviour in terms of their shopping preferences and factors influencing their consumer habits. The research includes only respondents with at least secondary education. The aim of the research is achieved by testing hypotheses focused on the analysis of the influence of gender, age and income on the choice of the type of businesses in which consumers shop and on the factors influencing the consumer behaviour of these citizens.

Literature Review

Given the present state of society – characterized by high consumption, the wasting of resources and climate change (Moravcikova, et al., 2017) – many consumers prefer specific goods, including green or fair-trade products, and are less inclined to consider standard factors such as price, quality, etc. Studies focusing on the analysis of students' decisions have directly proven that price does not affect their decision-making (Ting, Thaichon, Chuah and Tan, 2019). This is naturally reflected in the way producers respond to these changes. As the world develops, so does marketing. Nowadays, we often

hear about global marketing, where the basic element of innovative marketing strategies is their content, which is developing and changing at a fast rate due to the Internet and social media (Poradova 2020; Krizanova, Majerova, Kliestik and Majercak, 2013). With up to 55 % of consumers watching online videos on a regular basis, the significance of video marketing has been on the increase (Achen, Kaczorovski, Horsmann and Ketzler, 2018). Furthermore, businesses find online retailing particularly attractive since its effectiveness can be measured with relative ease (Abeywardana, Ginige, Herath, Somarathe and Thennakoon, 2018). This is also one of the reasons why online shopping is booming. Another characteristic of the present times is the increasing pressure on brand building. This is primarily reflected in the preferences and purchasing behaviour of consumers who base their purchases on the prestige of a particular brand (Moravcikova and Kliestikova, 2017; Kicova, Kral and Janoskova, 2018). As Anastasiei and Dospinescu (2018) points out, for company strategies it is crucial to be familiar with the character and personality traits of its customers, as these have a direct influence on their consumer behaviour. Possession of this kind of information enable companies to communicate with customers in the most appropriate way.

Methodology, Data Sources

All background information relating to the article was processed by the analysis and subsequent synthesis of secondary sources. The basic method applied in the research consisted of examining various documents, especially scientific papers and professional publications. Statistical data and some additional information were gleaned from sources currently available online. Information concerning current consumer preferences and shopping habits was obtained via a questionnaire survey.

Primary data were generated through quantitative research using the questionnaire data collection method. The selected sample of respondents was obtained through deliberate selection, only including respondents with at least secondary education. The research was carried out in the period from January to March, 2019. The target group was limited in particular to reflect the growing level of education among Czech people; therefore, it can be said to constitute a representative sample, as it is made up of the predominating population group (Ondrušová, 2020). The questionnaire survey involved a total of 324 respondents, representing an 82 % return rate after discarding empty or incomplete questionnaires. The gender composition of the respondent group was 174 men (54 %) and 150 women (46 %). The respondent group was divided into the following age-based categories: 0–20 years, 21–30, 31–40, 41–50, 51-60 and 61 and over. The largest was the 21-30 age group, including 146 respondents (45 %), while the 31-40 age group had 88 respondents (27 %). The 41-50 age group contained 58 respondents (18 %). To achieve the most accurate analysis, the age categories of respondents in the productive age were divided by 10 years intervals. The 0-20 year category is set more or less artificially, as persons aged 0-14 are not active shoppers yet and with regard to the requirement of at least secondary education, the research in this group therefore concerns practically respondents from 17 to 20 years of age. Likewise, the age group from the age of 61 is left so wide, as these are seniors, which can be assessed collectively due to the similarity of their shopping habits.

In addition, the respondents were monitored based on their region of residence. Majority of respondents came from the Central Bohemian Region (126 respondents, 39 %) and Prague (86 respondents, 27 %). The Pardubice, Liberec, South Bohemian and Vysočina Regions were represented by 14 respondents each, while the Hradec Králové and Ústí nad Labem Regions each had 12 respondents. Since the survey also examined the correlation between the consumers' level of income and their decision-making, the respondents were similarly classified based on their monthly income into the following categories: CZK 0–15,000; CZK 15-20,000; CZK 20-30,000; CZK 30-40,000; CZK 40-50,000; and over CZK 50,000. The largest was the CZK 20-30,000 group (134 respondents, 41 %), while the CZK 15-20,000 group was represented by 64 respondents (20 %) and the CZK 30-40,000 group by 60 respondents (19 %).

In terms of descriptive statistics, both absolute and relative frequency values were applied, and the obtained data were analysed using contingency tables and the $\chi 2$ test. The contingency tables list the frequency values from the questionnaire survey of individual character combinations. The differences (residuals) between observed frequencies and frequencies obtained based on the null hypothesis assumption were used to calculate the total standardized residual. If its value is less than the critical

distribution value $\chi 2$ at the significance level of 0.95 for the appropriate degree of freedom, the null hypothesis cannot be rejected at the 95 % significance level.

The following hypotheses were tested to meet the objective:

$H0_1$: The choice of shop is not influenced by gender.

$H0_2$: The choice of shop is not influenced by age.

$H0_3$: The choice of shop is not influenced by the level of income.

$H0_4$: The factors influencing purchasing decisions are not affected by gender.

$H0_5$: The factors influencing purchasing decisions are not affected by age.

$H0_6$: The factors influencing purchasing decisions are not affected by the level of income.

Results and Discussion

Contemporary society is often referred to as a consumer society. This notion is further reinforced by the number of newly emerging shops and businesses and the rising household expenditures for consumables (Širmer, 2019). Moreover, as the Association of Small and Medium-Sized Enterprises and Crafts CZ (2020) corroborates, we can expect continuing development in the retail sector and further growth in sales, which is associated with increasing household consumption.

$H0_1$: The choice of shop is not influenced by gender

In absolute terms, the majority of the respondents shop in supermarkets (154 respondents in total, 76 men and 78 women). In relative terms, the numbers translate to 37.3 % of men and 41.94 of women. Online shopping was the least prevalent. Small retail shops are used by 72 men (35.29 %) and 56 women (30.11 %).

Tab. I. Questionnaire survey results – The preferred types of shops – Classification based on gender

Gender	Small shops	Supermarkets	Internet	Total
Men	72	76	56	204
Women	56	78	52	186
Total	128	154	108	**390**

Source: Questionnaire survey, own research

$H0_1$: The calculated $\chi 2$ statistical value (1.35) is lower than the critical $\chi 2$ value of distribution for 2 degrees of freedom at a probability level of 0.95 (5.99). Therefore, the null hypothesis cannot be rejected. There is no correlation between the choice of shop and gender.

$H0_2$: The choice of shop is not influenced by age.

Small shops were most preferred by respondents in the 21-30 and 31-40 categories, as expressed in absolute terms. In relative terms (expressed as the proportion of respondents in the relevant age category favouring small shops), small shops are most preferred by individuals over 61 (50 %) and by individuals in the 41-50 category (47 %). With respect to the Internet, the majority of respondents engaged in online shopping were in the 21-30 category. This is also confirmed by the behaviour of the C Generation, i.e. people born between 1980 and 2000 who trust online media and spend a significant portion of their Internet time on social networks (Kusá and Piatrov, 2020). This group is not as interested in the content as it is in authenticity.

Tab. II. I. Questionnaire survey results – The preferred types of shops – Classification based on age

Age	Small shops	Supermarkets	Internet	Total
0-20	2	4	4	10
21-30	38	86	50	174
31-40	46	42	20	108
41-50	33	12	25	70
51-60	6	10	6	22
over 61	2	0	2	4
Total	127	154	107	**388**

Source: Questionnaire survey, own research

$H0_2$: The calculated $\chi 2$ statistical value (36.20) is higher than the critical $\chi 2$ value of distribution for 8 degrees of freedom at a probability level of 0.95. Therefore, the null hypothesis can be rejected. The degree of dependence as measured by Cramer's V is 0.22; there is a direct correlation between age and the choice of shop.

$H0_3$: The choice of shop is not influenced by the level of income.

Respondents in the lowest-income category, i.e. CZK 0–15,000/month, decidedly favour supermarkets (18 respondents, 52.94 %). People with the highest income shop in supermarkets the least. The high-income population clearly prefer small shops (44.4 % of respondents in the over CZK 40,000 category).

Tab. III. I. Questionnaire survey results – The preferred types of shop – Classification based on income

Income level in CZK	**Small shops**	**Supermarkets**	**Internet**	**Total**
0-15,000	8	18	8	34
15,001-20,000	30	38	18	86
20,001-30,000	56	58	44	158
30,001-40,000	18	24	18	60
40,001-50,000	4	2	6	12
over 50,000	8	4	6	18
Total	124	144	100	**368**

Source: Questionnaire survey, own research

$H0_3$: The calculated $\chi 2$ statistical value (11.57) is lower than the critical $\chi 2$ value of distribution for 8 degrees of freedom at a probability level of 0.95 (15.51). Therefore, the null hypothesis cannot be rejected. There is no correlation between the choice of shop and the level of income.

The following text focuses on analysing the factors influencing consumer decisions regarding purchases. The respondents could indicate the product price, discount level, quality, references and country of origin as determining factors. The absolute majority of respondents identified quality (45.04 % of all respondents) and price (26.44 % of respondents) as the principal reasons for choosing a particular product. In contrast, the discount level and country of origin play the least part in choosing a product. Recently, there has been an increasing emphasis on quality, while media campaigns in particular reinforce the trend towards food quality and composition, for example (Nadanyiova, 2015).

$H0_4$: The factors influencing purchasing decisions are not affected by gender.

Quality is a key factor for 63.79 % of men (111) and 71.33 % of women (107). A total of 65 men (37.36 % of all men) and 63 women (42 % of all women) indicated price as a key factor.

Tab. IV. I. Questionnaire survey results – What are the key factors influencing your purchasing decision? Classification based on gender

Gender	Price	Discount level	Quality	References	Country of origin	Total
Men	65	8	111	35	29	248
Women	63	6	107	33	27	236
Total	128	14	218	68	56	**484**

Source: Questionnaire survey, own research

$H0_4$: The calculated $\chi 2$ statistical value (0.22) is lower than the critical $\chi 2$ value of distribution for 2 degrees of freedom at a probability level of 0.95 (5.99). Therefore, the null hypothesis cannot be rejected. There is no correlation between the factors influencing the purchasing decision and gender.

$H0_5$: The factors influencing purchasing decisions are not affected by age.

Price was indicated as a key factor by respondents mostly in the 21-30 and 31-40 age categories. In relative terms, this translates into 42.86 % of respondents aged 0-20 and 31.75 % of respondents aged 31-40. In comparison, price is the least important factor in the over 61 and 51-60 categories. Quality is a significant factor which, in relative terms, is key for respondents in the 21-30 (52.47 %) and 41-50 (52.38 %) categories.

Tab. V. Questionnaire survey results – What are the key factors influencing your purchasing decision? Classification based on age.

Age	Price	Discount level	Quality	References	Country of origin	Total
0-20	6	0	0	6	2	14
21-30	58	8	108	22	18	214
31-40	40	2	46	24	14	126
41-50	16	4	44	10	10	84
51-60	6	0	14	4	10	34
over 61	0	0	4	0	0	4
Total	126	14	216	66	54	**476**

Source: Questionnaire survey, own research

$H0_5$: The calculated $\chi 2$ statistical value (49.54) is higher than the critical $\chi 2$ value of distribution for 10 degrees of freedom at a probability level of 0.95. Therefore, the null hypothesis can be rejected. The degree of dependence as measured by Cramer's V is 0.16; there is a direct correlation between age and the factors influencing consumer decisions regarding purchases.

$H0_6$: The factors influencing purchasing decisions are not affected by the level of income.

As has already been mentioned, price and quality are the most frequently quoted factors influencing the respondents' purchasing decisions. Price is most frequently indicated by respondents in the CZK 0-15,000 category (34.78 % of all respondents in this category). In absolute terms, the CZK 20-30,000 category had the most respondents (96) identifying quality as the key factor. In relative terms, quality was most frequently mentioned by respondents in the CZK 30-40,000 category (57 % of respondents).

Tab. VI. I. Questionnaire survey results – What are the key factors influencing your purchasing decision? Classification based on income.

Income	Price	Discount level	Quality	References	Country of origin	Total
0-15,000	16	2	14	6	8	46
15,001-20,000	32	2	40	14	10	98
20,001-30,000	52	4	96	28	22	202
30,001-40,000	14	4	40	8	4	70
40,001-50,000	4	0	6	6	6	22
over 50,000	6	2	10	4	4	26
Total	124	14	206	66	54	**464**

Source: Questionnaire survey, own research

$H0_6$: The calculated $\chi 2$ statistical value (28.63) is higher than the critical $\chi 2$ value of distribution for 10 degrees of freedom at a probability level of 0.95. Therefore, the null hypothesis can be rejected. The degree of dependence as measured by Cramer's V is 0.12; there is a direct correlation between the level of income and the factors influencing consumer decisions regarding purchases.

Conclusion

The conducted research focused on analysing the consumer behaviour of shoppers in the Czech Republic with at least secondary education. 91 % of the presented sample were secondary school leavers.

Tab. VII. Summary results of the questionnaire survey

Hypothesis	Degree of freedom	$\chi 2$	Critical value	Cramer's V	Result
H01	2	1.35	5.99	-	sustained
H02	8	36.2	15.51	0.22	rejected
H03	8	11.57	15.51	-	sustained
H04	2	0.22	5.99	-	sustained
H05	10	49.54	18.31	0.16	rejected
H06	10	28.63	18.31	0.12	rejected

Source: Questionnaire survey, own research

The completed research has established a direct correlation between the choice of shop and the age of respondents. Even though the majority of people do most of their shopping in supermarkets, the results have shown that small shops especially are used by people in higher-age groups and, by contrast, people in the 0-20 and 21-30 categories do more shopping online. Furthermore, the research has demonstrated a correlation between factors influencing purchasing decisions and age/income level. Price and quality are by far the most frequently mentioned factors influencing consumer behaviour. By contrast, the discount level was shown to be the least important. The outcomes of this study can be used, for example, for marketing directors of companies focused on a complex marketing activities and advertisement appropriately targeted at selected consumers.

Abstract

Natural hazards have significant results in material and human losses. Due to the increasing intensity of weather phenomena, the national hydrological and meteorological services, which play an important role in national crisis management structures, are obliged to provide rapid and precise warnings about extreme phenomena in the hydrosphere and atmosphere. Based on this information, other participants involved in the functioning of the national crisis management system plan and implement tasks having a direct effect on the level of health, life and property protection. To meet growing demands, national services must boldly reach for solutions related to Big Data analysis, artificial intelligence (AI) and machine learning (ML) more often. The article presents a general concept of an IT system aimed at comprehensive support for the process related to issuing and distributing warnings about hydrological and meteorological hazards at the Institute of Meteorology and Water Management - National Research Institute (*Polish* - IMGW-PIB), acting as the national hydrological and meteorological service in Poland.

Keywords: Big Data, crisis management, hydrological warnings, meteorological warnings.

Introduction

In the member states of the European Union, extreme forms of natural weather hazards caused losses of almost EUR 426 billion (according to the value from 2017), which constituted 83% of total monetary losses and contributed to the death of over 87,000 people in the years 1980–2017. Despite being a country in a temperate climate zone, Poland is exposed to phenomena in the hydrosphere and atmosphere, and recorded over EUR 15 billion in material losses and over 1,200 fatalities, respectively [European Environment Agency 2019], in the mentioned period.

One of the greatest responsibilities of the state is to ensure the safety and protection of citizens [Constitution of the Republic of Poland (Journal of Laws) 1997] through public administration bodies and institutions established for this purpose. The national hydrological and meteorological services have a growing share in the risk management process related to natural hazards [Rogers, Tsirkunov 2011]. They are responsible for analysis of prevailing weather conditions, prediction of phenomena and continuous provision of information to the public and government administration units responsible for safety in the country. If the phenomena meet the criteria of intensity, the national services are obliged to create alerts. The speed of creation and publication, as well as quality, have a significant effect on minimizing the effects caused by weather hazards. In Poland, the national

[1] The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

hydrological and meteorological service is the Institute of Meteorology and Water Management - National Research Institute (IMGW-PIB) operating on the basis of Water Law [Water Law (Journal of Laws) 2017].

In the process of creating warnings about hydrological [WMO-No. 168 2015] and meteorological hazards [WMO-No. 49 2015], it is necessary to acquire, collect, process and analyse (qualitative and quantitative) data from ground measurement systems managed by IMGW-PIB and other national hydrological and meteorological services, marine systems, satellite images, as well as hydrological and meteorological forecasting models. This diverse set of sources contains formatted text, photos, videos. They are analysed by employees of Meteorological Forecast Offices and Hydrological Forecast Offices. Despite instructions, procedures and recommendations, the human factor makes it a subjective assessment. The same set of data assessed by different employees may result in different results. The aim of the conducted research work presented in this manuscript was to develop a general concept of an IT system that comprehensively supports the process of issuing warnings about hydrological and meteorological hazards based on data obtained using Big Data techniques, including artificial intelligence (AI) and machine learning (ML).

Creating warnings about hydrological and meteorological hazards

IMGW-PIB supervision over the issue of information on current hydrological and meteorological conditions to institutions and citizens is executed by the Ministry of Maritime Economy and Inland Navigation [RCB 2019]. The minimum catalogue of stakeholders of warnings about dangerous phenomena occurring in the atmosphere and the hydrosphere, meteorological and hydrological forecasts, meteorological and hydrological messages, bulletins and yearbooks is set out in relevant regulations. The stakeholders include the President of the Republic of Poland, parliament marshals, the prime minister and elected government ministers, heads of services and key state institutions, province marshals, voivodes, heads of public media [Regulation of the Minister of Maritime Economy and Inland Navigation (Journal of Laws) 2019].

Meteorological Forecasts Offices (*Polish* - BPM) and Hydrological Forecasts Offices (*Polish* - BPH) operating in IMGW-PIB develop and provide warnings about dangerous phenomena that occur in the atmosphere and the hydrosphere. The creation process is shown in the form of a diagram in Figure 1.

Fig. 1: Diagram of the process of creating meteorological and hydrological warnings at IMGW-PIB

Source: own study based on IMGW-PIB internal procedures and instructions

The process of creating and distributing alerts is a multi-step one. Before preparing products, BPM and BPH review the necessary hydrological and meteorological data and information for their completeness and correctness. The result of the work is a report on the review of completeness and correctness of data, saved in electronic form.

Data and information from various sources, which are presented in Table 1, are used to create warnings.

Table 1: Summary of input data necessary to create warnings of dangerous phenomena that occur in the atmosphere and the hydrosphere

Hydrological warning	Meteorological warning
1. Data from the measurement and observation network managed by IMGW-PIB 2. Data from the measurement and observation network of hydrological and meteorological stations managed by the national hydrological and meteorological services in neighbours of Poland 3. Results from numerical prognostic models operated at IMGW-PIB 4. Results from numerical forecasting models operated by other global centres with which IMGW-PIB has relevant agreements and arrangements 5. Results from numerical forecasting models available as part of WMO international exchange	1. Data from the measurement and observation network managed by IMGW-PIB 2. Data from the global measurement and observation network managed by national meteorological services 3. Results from numerical prognostic models operated at IMGW-PIB 4. Results from numerical forecasting models operated by other global centres with which IMGW-PIB has relevant agreements and arrangements 5. Results from numerical forecasting models available as part of WMO international exchange 6. Radar data from the POLRAD system managed by IMGW-PIB

6. Data from other measuring and information systems, internal and external, domestic and foreign, including: a. synoptic meteorological forecasts; b. warnings and meteorological messages	7. Data from radar systems managed by the European national meteorological services 8. Data from the PERUN lightning detection system managed by IMGW-PIB 9. Data from lighting detection systems managed by the European national meteorological services 10. Satellite data available from the systems receiving data from NOAA, Metop, Meteosat, Terra/Aqua satellites 11. Data from other measuring and information systems, internal and external, domestic and foreign, including: a. synoptic meteorological forecasts; b. warnings and meteorological messages

Source: own study based on IMGW-PIB internal procedures and instructions

Based on the data listed in table 1, using available tools (mainly dedicated, manufactured inside or for the needs of IMGW-PIB) and methods (based on WMO guidelines [WMO-No. 834 1999; WMO-No. 49 2015; WMO-No. 168 2015, WMO-No. 471 2018]), the following is carried out:

- analysis of the current hydrological situation and the forecast meteorological situation - for hydrological warnings. Created by authorized BPH employees;
- analysis of the current hydrological situation and the forecast meteorological situation - for meteorological warnings. Created by authorized BPH employees;

In the next stage, results from forecasting models are analysed. If the expected development of the hydrological situation indicates the occurrence of a dangerous hydrological phenomenon, the synoptic hydrologist on duty decides to issue a hydrological warning. If necessary, before making a decision, he can conduct an additional consultation with a meteorologist on duty. Warnings, depending on the intensity of a phenomenon, are graded from 0 (no threat) to 3 (very high threat).

Table 2: Degrees of hydrological warnings

Degree	Description
0	No warnings
-	*Hydrological drought threat.*
	Flows are in the zone below SNQ for the contractual period. The hydrological drought warning does not specify the degree of danger.
1	*Moderate threat*
	Water levels (observed or forecast) are in the zone below the warning states - $H_{WARNING}$, with a forecast dramatic increase in water levels
2	*High threat*
	Water levels (observed or forecast) are in the zone above the warning states - $H_{WARNING}$, but below alarm states - H_{ALARM}
3	*Very high threat*
	Water levels (observed or forecast) are in the zone above the alarm states - H_{ALARM}

Source: own study based on IMGW-PIB internal procedures and instructions

The situation is similar when creating a meteorological warning. If the analysis of the meteorological situation indicates the occurrence of a dangerous phenomenon, the synoptic meteorologist on duty decides to issue a meteorological warning. He does so after arrangements (video conference) with representatives of other local Meteorological Forecast Offices. Warnings, depending on the intensity of a phenomenon, are graded from 1 (no threat) to 3 (very high threat).

Table 3: Degrees of meteorological warnings

Degree	Description
No warnings	Weather hazards that have a significant effects on everyday life are not forecast.
1	Conditions conducive to the occurrence of dangerous meteorological phenomena that may cause material losses and threat to health and life are expected. Conducting business in conditions of exposure to these factors is difficult and dangerous. Expect difficulties resulting from activities in the area of threat, including delays caused by traffic jams, disruptions in the course of outdoor events or even cancellation. Caution, messages and weather conditions tracking are recommended.
2	Dangerous meteorological phenomena that may cause great material losses and threat to health and life are expected. Dangerous phenomena or the effects of their occurrence significantly limit economic activities. Expect disruptions in everyday functioning. High caution, messages and weather conditions tracking are recommended. Follow all instructions given by emergency services in an emergency situation. Adapt your plans to weather conditions.
3	It is predicted that serious meteorological phenomena will occur, causing great damage or damage at the level of disasters and life threatening situations. Dangerous meteorological phenomena or the effects of their occurrence will prevent business operations. Be prepared for significant disruptions in your daily functioning. Extreme caution, messages and weather conditions tracking are recommended. Follow all instructions given by emergency services in an emergency situation. Adapt your plans to weather conditions.

Source: own study based on IMGW-PIB internal procedures and instructions

Regardless of the type of warning, they are created according to a specific pattern containing the following sections:

1. Origin identifier (office name)
2. Type identifier (message title, phenomenon and degree of danger)
3. Content (area, validity, mileage, probability of occurrence, comments, duty officer, date and time of publication)
4. Text message (text message identifier, phenomenon and degree of danger, area, importance, course)
5. RSO message[2] (RSO message identifier, area, phenomenon, content)

Warnings are saved on local workstations and in databases (archived for the time resulting from the Office Instructions), published on websites, IMGW-PIB social media. Distribution to stakeholders takes place using dedicated software. The IT Center is responsible for its timeliness and efficiency.

Every quarter, the Hydrological and Meteorological Forecast Offices assess the implementation of the process of developing and issuing warnings. At the end of the year, an assessment of implementation of the warning development and issue process throughout the year is made.

[2] Regional Warning System (RSO) - free, universal service of the Ministry of the Interior Affairs and Administration that allows informing citizens about threats. It covers all of Poland.

System supporting the process of issuing warnings about hydrological and meteorological hazards

Big data

One of the first publications in which the term Big Data can be found appeared in 1997 and defined it as a maximally large data set for analysis, from which a maximum of useful information can be taken [Cox, Ellsworth 1997]. In 2001, the Big Data concept appeared based on the 3V model (Volume, Velocity, Variety) [Douglas 2001], wherein [Williams et al. 2014]:

- Volume - refers to a large amount of data that can be used to formulate new concepts;
- Velocity - indicates high speed of data incoming and processing;
- Variety - draws attention to data heterogeneity.

In subsequent years, this model was expanded with other elements characterizing:

- Veracity - the accuracy of raw data and its integrity (4V model) [Czajkowski 2014];
- Value - value, significance, usefulness for analysis from the user's point of view (5V model) [Tabakow et. al 2014].

The very concept of Big Data literally refers to the size of the data. Key features for Big Data have been identified in HACE theory [Tamhane, Sayyad 2014]:

- magnitude and diversity of data sources;
- autonomous, distributed, controlled data sources;
- complex and evolving connections.

Large sets are usually formed in areas related to the data obtained, for example, from extensive measuring systems, imaging systems. These fields include atmospheric sciences, geophysical sciences, and health and medicine [Cox, Ellsworth 1997].

In the process of creating warnings about phenomena in the atmosphere and the hydrosphere, large sets of various data appear from many sources (from within IMGW-PIB, from other national services and from WMO exchange). From the analysis of the input data set, necessary to create warnings about dangerous phenomena that occur in the atmosphere and the hydrosphere (Table 1), it can be seen that all types of data structures appear. Dominant data is data that can be stored, consulted and processed in the form of a fixed format (e.g. numerical value of the measured wind speed). This is the so-called structured data [Drosio, Stanek 2016]. Data, and to be more specific - partially structured sets [ITPedia 2017], is synoptic forecasts, warnings and meteorological and hydrological messages. This data is prepared according to a pattern, but in addition to the content that exhausts the definition of structural data, it contains a descriptive part in the form of a commentary presenting additional information, such as a more detailed description of a phenomenon, its expected development or a mention of the planned next release of information.

The last group is unstructured data, which is not present now but will soon appear in the form of cyclical images of the sky from which information about cloudiness and the type of clouds will be extracted.

Analysis cycle

Data from the IT system (with embedded, among others, Big Data analysis) that supports the process related to issuing warnings about hydrological and meteorological threats will be valuable if key stakeholder groups with clear roles, responsibilities and expectations are defined. At this stage of the discussion, the life cycle of an analysis can be used [Schmarzo 2013] (Fig. 2) with the following users:

1. Business user. In this process, business users are recipients of warnings about:

a. Defined by law [Regulation of the Minister of Maritime Economy and Inland Navigation (Journal of Laws) 2019].
b. Commercial.
c. Users using websites and social media (Facebook, Twitter).

Dominant recipients defined by law are state institutions and bodies involved in ensuring Poland's security, participating in the implementation of tasks included in the National Crisis Management Plan. The next group is commercial users who need data for business activities. These are companies from the road and construction industries, energy companies, etc. The last group is made up of individual users who look for weather information on institute websites and social media profiles. They do not need this data in business processes, but based on data they make decisions affecting many areas of the economy - they buy goods and services that depend on weather conditions. Apart from the external stakeholders mentioned above, internal stakeholders should not be forgotten. These are organizational units at IMGW-PIB that carry out processes for which warnings about hydrological and meteorological hazards are very important. An example of the service of maintaining key measuring systems and data acquisition.

Business users who use warnings about hydrological and meteorological hazards begin and end the life cycle of the analysis. The effectiveness of their decisions testifies to the quality of work of other stakeholders of the cycle - data warehouse administrator, data analyst and BI analyst.

2. The data warehouse administrator defines, develops and manages the data platform. Platform:
   a. It supports structured data (e.g. from the terrestrial measurement network), partially structured data (e.g. synoptic forecasts, meteorological and hydrological warnings and messages), unstructured data (e.g. sky imagery).
   b. It provides access to internal IMGW-PIB data (e.g. from the POLRAD meteorological radar system), and external sources operating outside the Institute's structures (e.g. from data receiving systems from NOAA, Metop, Meteosat, Terra/Aqua satellites).
   c. It supports the ability to download and analyse data streams in real time (e.g. from the PERUN lightning detection system).
   d. It allows adding new data sources smoothly (e.g. from new forecasting models).

   In addition, the stakeholder uses historical data warehouses (Central Historical Database) and operational data warehouses (Hydrology System, Telemetry System, Data Collection System from Synoptic Stations, and others).

3. A data analyst looks for valuable relationships and connections in various data sources. For this purpose, he explores structured and unstructured data, both internal and external. An example is the hydrological rainfall - outflow model, which connects the water level on a selected section of the river with precipitation on a specific surface.

4. The Business Intelligence (BI) analyst is responsible for:
   - the process of collecting, recognizing, interpreting and analysing data that directly translates into improving the decision-making process of the business user;
   - *key performance indicators*;
   - collecting and standardizing data from various areas and sources. Identification and presentation of data; on its basis, business users will monitor, verify and evaluate activities;
   - Development of reports and dashboards that are a tool for data visualization and analysis for business users;
   - Dynamic modification and update of business standards and reports;
   - Conduct of periodic checks on the operation of reports;
   - Implementation of new functionalities;

- User support, especially business support in the use of the system.

Fig. 2: Analysis life cycle at IMGW-PIB

Source: own study based on [Schmarzo 2013]

Business System Requirements

The IT system supporting the process related to issuing warnings about hydrological and meteorological hazards at IMGW-PIB in a comprehensive manner should meet the following requirements:

1. Be a source of structured data.

2. Integrate data from various sources (e.g. telemetry system, aerological measurements, terrestrial remote sensing, satellite remote sensing, actinometric, evaporometric, hydrological and other measurements).

3. Ensure secure access for users (recipients of warnings).
4. In terms of information, generate (in automatic mode) or support creation (in supervised mode):
    a. Hydrological and meteorological warnings according to the catalogue of threats.
    b. Hydrological and meteorological reports according to the catalogue, procedures and internal guidelines of IMGW-PIB.
    c. Additional information, e.g. anticipated development of situation, indications for preparation (readiness levels) for individual recipients (e.g. emergency service officer monitoring the flow of warnings and messages, local government units and crisis management centres, fire brigades, police, etc.).
    d. Dedicated products created by users themselves, configured by checking the appropriate boxes (checkbox), according to the catalogue of available data and parameters.

5. Generate warnings and messages for:
    a. Provinces
    b. Poviats

6. Enable distribution of warnings, messages, information according to the distribution list to stakeholders:
    a. Defined by regulations [Regulation of the Minister of Maritime Economy and Inland Navigation (Journal of Laws) 2019].
        i. Central authorities
        ii. Crisis management centres
        iii. Central services (fire brigade, police, etc.)
        iv. According to the situation - local government units at provincial levels and in poviats,
        v. According to situation (poviats) - services in the form of poviat fire brigades, police, etc.
    b. Commercial
    c. Users using websites and social media (Facebook, Twitter).

7. Depending on the type and dynamics of a phenomenon (in the atmosphere or/and the hydrosphere), select time intervals for verification of the development of a phenomenon and updating information for individual groups of recipients.

8. AI analysis of data changes and the need to update the data - automatic data verification and notification of the need to introduce significant changes in parameters. Over time, implementation of automatic data update and elimination of obvious errors according to particular criteria.

9. Enable data to be added and integrated with other systems (e.g. systems of other institutions) flexibly.

10. Allow boxes (checkboxes) appropriate for a given type of data, limit parameters for analysis, time of information transfer and recipient groups to be checked.

11. Allow for "individualization" of area warnings, creation of combined warnings.

12. Enable the system to be supplied with structured and unstructured data from heterogeneous sources of variable intensity, including video streams.

System Architecture Proposal

The IT solutions used in IMGW-PIB hardly support the process of creating warnings about meteorological and hydrological hazards. Their role is to provide and send data, as well as to archive and partially distribute products to stakeholders. The very process of assessing the completeness and correctness of data from various sources, as well as the creation of warnings, takes place with the full involvement of the hydrologist and the meteorologist. Some of the necessary tasks are not implemented, e.g. redundant data elimination. The system proposal presented below is aimed at meeting business requirements through a suitable set of tools that are used to:

- eliminate existing restrictions,
- minimize the human factor in the process (and ultimately eliminate it),
- enrich the process with elements that are not implemented (the above-mentioned elimination of redundant data),
- speed up the implementation of individual process steps (e.g. data assessment and issuing a warning taking into account the scope of individualised information required for a given recipient),
- enable dynamic system adjustment to the needs of the recipient.

The system has the following layers:

1. Data sources.

Data sources in the proposed system are, among others:

a. Data from the measurement and observation network managed by IMGW-PIB
b. Data from the measurement and observation network of hydrological and meteorological stations managed by the national hydrological and meteorological services.
c. Results from numerical prognostic models operated at IMGW-PIB
d. Results from numerical prognostic models used by other global centres.
e. Results from numerical forecasting models available as part of WMO international exchange
f. Radar data from the POLRAD system managed by IMGW-PIB
g. Data from radar systems managed by the European national meteorological services
h. Data from the PERUN lightning detection system managed by IMGW-PIB
i. Data from lighting detection systems managed by the European national meteorological services
j. Satellite data available from the systems receiving data from NOAA, Metop, Meteosat, Terra/Aqua satellites
k. Data from other measuring and information systems, internal and external, domestic and foreign, including:
    i. Synoptic meteorological forecasts;
    ii. Warnings and meteorological messages

2. Data Integration.
In this layer, data coming from various sources is processed into formats in which it can be analysed.
Data integration understood as a set of processes, technologies, control mechanisms, automated tasks and skills necessary to standardize and connect data from various sources takes place here.
Three components are proposed in the solution:
    a. ETL that is usually used to integrate structured data in Business Intelligence, which involves data extraction from source systems, transforming them and loading data into a data warehouse.
    b. The Big Data type is used to integrate unstructured data and load it into non-relational databases.
    c. An intermediate area used to store data obtained from the source layer to preserve it in its original format, but enabling the addition of data from other sets (e.g. results of previous analyses and scenarios) before passing it for transformation and analysis.

3. Data storage in which data is stored and made available based on technologies:
    a. Relational databases - for storing e.g. data from telemetry networks, historical measurement and observation data.
    b. File databases - for storing e.g. satellite images, sky photographs, warning texts and other unstructured data.
    c. In Memory Data Grids (IMDG) - for storing data in RAM which is more efficient than using disk. The use of a key or/and value storage gives the application developer more flexibility. The data model and application code are inextricably linked. More than a relational structure. It is easier to provide and maintain scalability and resistance. Software and/or hardware can be updated without interference. The technology works well for operations and collections that require high variability, fast data update and modification. However, close attention should be paid to data consistency, which may prove to be the weak point of IMDG.

4. Data analysis, which consists of:
    a. AI and ML component [Qadir et al. 2016] performing tasks related to:

- data verification - checks the correctness of data and eliminates errors based on, among others, detection of outliers, e.g. incorrect results in measurement series, mistakes when entering information into database;
- detecting patterns of coexistence of phenomena, e.g. the effect of precipitation in a given area on the level of river levels;
- generating hydrological and meteorological warnings using prediction mechanisms - classification (assigning a given level of warning based on boundary parameters, e.g. 2nd degree warning with strong winds that exceeds 72 km/h), regression (predicted value of the continuous variable due to the current development of raising or lowering the level of warning based on boundary parameters for each level, tendency - e.g. due to the forecast intensification of gusty winds, regression to the 3rd degree due to forecast gusty winds exceeding 90 km/h), recommendation (issuing recommendations - e.g. Cleaning the environment cleaning, fixing objects and staying indoors to minimize the risk of health and life loss and material losses).

b. Real-time analysis component responsible for handling data from satellite systems, meteorological radar systems, lightning detection systems.
c. Component of textual (descriptive) analysis of some hydrological and meteorological warnings. Based on the defined and calculated statistics for words and phrases appearing in warnings, the structure of the text is expressed in numerical categories. The statistics received are then analysed using data mining methods.
d. An alert distribution component that sends alerts to stakeholders in a specific format. Depending on the operating mode, automatically or after being authorized by a synoptician, a hydrologist or a meteorologist.

5. System management, which includes:
   a. Metadata management component.
   b. Data management component.
   c. Security component.
   d. Data resource management component.
   e. Relationship management component.
   f. Qualification management component.

6. Design and implementation tools.
   Currently, there are many tools available for designing and implementing this class of system on the market. They should be selected according to the assumed requirements but also competences of a team performing such a task. Ready-made, closed solutions can be used or everything can be started from scratch by writing the data migration program in the selected framework. Due to the repeatability of the processes, it is reasonable to consider using ready-made and tested solutions that are best known to teams building and maintaining the system.
   Therefore, it seems optimal to base on open, but existing and tested solutions, with an extension of own proprietary solutions and algorithms that allow implementing services and requirements that are unique for the system. However, the simplest possible solutions should be followed and too much complexity of the system architecture avoided.

7. User interface.
   The user interface should be as intuitive as possible, close to commonly encountered and known interfaces. Choose between GUI (graphical interface) and WUI (website interface) - depending on the system architecture option selected. Where possible, it should be automated, limited to check boxes using dictionaries and checkboxes. It should give wide possibilities of own configuration with integrity of architecture and connections within the system.

Fig. 3: The architecture of the IT system supporting the process of issuing warnings about hydrological and meteorological hazards

Source: own study

Summary

Due to the progressing climate changes and the resulting increasing dynamics of weather phenomena, national hydrological and meteorological services are becoming an increasingly important link in national crisis management systems. IMGW-PIB and twin services operating in other countries are expected to be more and more precise in monitoring and forecasting phenomena and issuing accurate and constantly updated warnings about dangerous weather phenomena. Based on this information, other participants of crisis management systems plan and implement their activities, which at the end of the process translate into the level of protection of health, life and property.

The purpose of the research work presented in the manuscript was to develop a general concept of an IT system that is to comprehensively support the process related to issuing and distributing warnings about hydrological and meteorological hazards by the national service on the example of the Institute of Meteorology and Water Management - National Research Institute.

In the context of crisis management, the capabilities of such a system and Big Data capabilities cannot be overestimated. The most important aspect for crisis management bodies and services is timely and quick provision of information. Information based on the most current data and its current comprehensive analysis. A quick analysis of scenarios that can occur with a given event configuration and selection of the most probable one. This is very important when making real decisions regarding preventive and rescue measures. Big Data gives a wide range of fast and accurate forecasts of events and their development, but also correction of predictions of developments. In active actions, this should bring real benefits from the possibility of ongoing correction of behaviour, and hence in more effective and precise action and better decisions. This will not only help to better protect and protect human health and property, but also to reduce the costs incurred.

The use of modern methods and IT tools will allow analysing incomparably more data from various sources, obtaining a more detailed and multi-variant perspective of the possible development of a forecast situation in the hydrosphere and the atmosphere. A multi-faceted overview of scenarios will be available in a short time. A wide range of input data and a large number of possible variables will be used for the compilation.

This will allow choosing the most suited, predicted course of events and quickly correcting it when additional variables or additional information are found, and verifying the course and development of phenomena, if any occur.

For IMGW-PIB, the implementation of the system in the company will definitely improve the process of creating and distributing information, messages, forecasts, as well as hydrological and meteorological warnings. The data reaching the recipient will be personalized and adapted to its needs without any additional effort. It will be faster to analyse the course of events in the past and forecast possible development, depending on the input data received and the circumstances of its occurrence. Correcting the course of events as well as updating forecasts and warnings will be faster and more effective.

A great advantage of such a system is an extensive analysis of data and current and historical information. In such a wide range it is not possible to be implemented by man. Quick correction and update of data, taking into account various variables to provide information that allows for a quick and effective protection of human life and property against the negative effects of a natural event is crucial.

Abstract

Currently, the electronic wallet (e-wallet) payment method has been commonly used in Indonesia and slowly has been replacing cash as a payment method. *Fintech* companies, which mostly operate e-wallet services in Indonesia, are able to make short-term investments using their consumers' e-wallet balances. However, the money balances tend toward small amounts. This research aims to evaluate whether perceived values affect Indonesians' willingness to save more money in their e-wallet accounts. Perceived values here consist of perceived benefits and risks. We define perceived benefits as perceived monetary and convenience values. Meanwhile, we define perceived risk as encompassing economic, privacy, service, and psychological risk. We analyze the primary data from a total 103 respondents collected via online survey across Indonesia. We have conducted validity and reliability tests of the data collected before performing the main analysis using the regression method with SPSS Statistics 22. We found that perceived value affects users' willingness to save more money in their e-wallets. However, we found that convenience benefit has a significantly positive affect on users' saving intentions, while monetary benefit does not have the same effect. Meanwhile, service risk is only risk that is relevant to users' willingness to save money. These findings indicate that convenience and service are the most critical values for e-wallet users in Indonesia.

Keywords: E-wallet, perceived value, benefits, risks.

Introduction

E-wallet has been used as a common payment method today and is slowly replacing cash. Based on 2019 data, the volume and amount of electronic money transaction in Indonesia have been increasing almost exponentially for the last couple of years (Bank Indonesia, 2019). Also, the utilization of e-wallet in Indonesia is projected to replace cash payments and bank transfers in the upcoming years (Jayani, 2019). *Fintech* companies, which run most e-wallet services in Indonesia, are also growing; in 2019, there were 61 e-payment *fintech* companies in Indonesia (Wijaya, 2019).

The total transactions of electronic money in Indonesia reached 47.1 trillion rupiahs by 2018 within 2.9 billion transactions. As of 2019, around 500.000 merchants have accepted e-wallet payments, almost the same as the amount of EDCs spread across Indonesia (Wijaya, 2019). The growth of the e-wallet usage was supported by the high penetration of the Internet across the nation (64.8% of the population in 2018) and also the high percentage of smartphone/tablet users in Indonesia (50.08% of the population in 2017) (APJII, 2017; 2018).

Many studies have been conducted to determine which factors affect the development of mobile-based online payment, especially e-wallet, which has been growing rapidly in Indonesia. Similar to the case of mobile banking, even though people are aware of the advantages of the service, some are still unsettled and reluctant to use the offered service. Research in mobile-based payments has been conducted in different regions like China (Zhou, 2013), India (Singh, Sinha, & Liébana-Cabanillas, 2020), and Indonesia (Azizah, Handayani & Azzahro, 2018). Those studies found factors that affect one's intention and continued usage of e-wallet. Zhou (2003) found that flow and switching costs affect performance expectancy and switching barriers, which in turn affect continued usage. Singh et al. (2020) found that high stress negatively influences users' perceived satisfaction, and social influence affects users' adoption and recommendation to mobile wallet services. Azizah et al. (2018) found that users' trust and the system's flow affect satisfaction and thus the usage of e-wallet services.

However, the majority of the previous research focuses on the technological aspects, using the Technology Acceptance Model (TAM) and Unified Theory of Acceptance and Use of Technology (UTAUT2) models to determine factors affecting behavioral intention, customer satisfaction, and continuance usage of mobile payment and e-wallet. Other research has enhanced the TAM and UTAUT2 models with several new aspects such as security, privacy, and trust to learn about the intention to adopt such technology and service (Merhi, Hone & Tarhini, 2019; Syakiela, Triono & Arif, 2019). However, we have yet to find a study focusing on the relation of value-based factors in e-wallet service. Given the limited value-oriented research related to e-wallet, this study tries to fill the existing gap and to look deeper into other motivational values beyond technological ones.

Furthermore, this study aims to analyze what values might affect the willingness to save money in e-wallet. In Indonesia, companies that operate e-wallet services utilize the saving balance for short-term investment. Thus, they compete to offer the best promotion to attract people to use their products as the fastest way to gain people's trust, which usually takes many years to build. This research offers insights into the perceived values that mater so companies can strategize better to ensure customers to save more in their e-wallet accounts. Perceived value is the balance of the benefits and sacrifices of using a service (Zeithaml, 1988).

Literature Review

E-wallet is a payment technology accessed through an application installed on a mobile device that allows customers to save money and make online transactions (Madan & Yadav, 2016). It is also described as a cashless and paperless payment instrument, such as cards, and it directs transfers and transactions through electronic channels (Singh, 1999). E-wallet payment in Indonesia is regulated by the central bank, Bank of Indonesia.

Perceived Value

Perceived value is defined as a judgment or a valuation by the customer of the comparison between the benefits (or utility) and the perceived sacrifices (or cost) to obtain a product or service (Zeithaml, 1988). Another perspective defines perceived value as a trade-off between quality and sacrifices (Monroe, 1990), but still holds the same meaning. First, perceived benefit falls into two categories, direct and indirect benefits (Lee, 2008). Direct benefits refer to tangible paybacks that customers can get immediately, such as lower interest rates, gifts, and cheaper transaction costs. Indirect benefits are harder to measure, like 24-hour service, news service, and investment. Second, perceived risk is defined as the expectation of losses associated with purchase and serves as an inhibitor to purchase (Peter & Ryan, 1976).

Many studies found a link between perceived value with intention to repurchase and to use mobile service, satisfaction, word of mouth, and willingness to buy (Hartline & Jones, 1996; Oh, 1999; Sweeney, Soutar & Johnson, 1999; Syakiela et al., 2019). However, we are unaware of any prior research on the effects of perceived value on willingness to save money in e-wallet. Some research in countries like China (Zhou, 2013), India (Singh et al., 2020), and Indonesia (Azizah et al., 2018) tend

to focus on the technology aspect of the product and use the TAM and UTAUT2 models in their analysis. Some have added several factors such as security, privacy, and trust in order to learn about the intention to adopt such technology and service (Merhi et al., 2019).

Of course, the concept of perceived value, or the variable building it, will vary with different types of products and services. One of previous studies developed a value-based adoption model (VAM) in adopting mobile commerce (Kim, Chan & Gupta, 2007). In the said research, the benefit was defined by usefulness and enjoyment, while the sacrifice was defined by technicality and perceived fee. Other research on e-commerce defined benefits from value as perceived quality and experience with the product or service, while the sacrifices are perceived risk and cost of the product or service (Chen & Dubinsky, 2003).

The dimensional view applied in this research comes from five dimensional conceptualizations of consumption values by Sheth, Newman, and Gross (1991). Those five dimensions are functional, social, emotional, conditional, and epistemic. The functional value represents the value obtained from finishing a task effectively, usually related to monetary and convenience value. Social value is defined as the benefit of social acceptance and the increase of one's self-image in his or her relationships. Emotional value is related to how a product and service can ignite feelings or affect the emotions of the user. Conditional value refers to the value gained from a specific situational context, such as location and social situation. Finally, the epistemic value is the capability of the product or service to arouse curiosity and satisfy the desire for new knowledge.

In a prior study linking perceived value in mobile service (Pura, 2005), the value dimensions are structured into two groups: context-related perceived value (conditional and epistemic) and content-related perceived value (emotional, social, convenience, and monetary). Later studies by Beatty, Shim, and Jones (2001) and Lee (2009) indicate that perceived benefit has a positive relation with intention to adopt and use online-based services. From the five dimensions mentioned before, only functional (separated to monetary and convenience), conditional, and epistemic are considered relevant. However, Sweeney and Soutar (1999) consider epistemic and conditional dimensions to be less significant than the others. Therefore, this research will focus on assumedly relevant content-related value, which refer to monetary and convenience value. We hypothesize that (a) monetary value positively affects users' willingness to save money and (b) convenience values also positively relate to one's willingness to save money.

Perceived Risks

Five key facets of perceived risk are financial, performance, social, and physical, and psychological risk (Jacoby & Kaplan, 1972). However, due to the nature of the research, we can omit physical risk. Financial (economy) risk is the potential monetary loss related to the initial purchase of the product and the following maintenance costs. Performance (functional) risk lies in the risk of a malfunctioning product. Social risk is the risk of losing status in a social group due to adopting or not adopting a product. Psychological risk is the negative effect from a customer's self-perception due to the decision or performance of a product or service provider.

In 1971, Roselius determined the notion of time risk, and it also has been adapted as a dimension of perceived risk. Time risk is the risk of losing time due to the need to learn how to use a product. Furthermore, the growth of Internet-based products and services has led to new dimensions of risk: security and privacy risk (Pikkarainen et al., 2004). Security risk is the risk of losing control of transactions and financial information. Meanwhile, privacy risk is the risk of losing control of personal information.

A study conducted by Yang et al. (2015) on the effect of perceived risk and trust on online payment in China develop dimensions of perceived risk that better suit the nature of online payment. Their model consists of eight dimensions that are divided into two group. The first is system dependent risk, which includes functional, security, time, and social risks. The second is transactional dependent risk, which includes economy, privacy, service, and psychological risks. Perceived risk on e-service

and online payment reduces customers' trust and lowers their intention to use the service (Featherman & Pavlou, 2003; Zhou, 2013). However, system-dependent risk tends to be uncontrolled by service providers and is closely related to the technology as well as the supporting infrastructure of the applications. This kind of risk will eventually diminish with the development of technology and the environment of service. Consequently, in this research, we will only use the dimension of transactional risk.

Based on previous studies, we hypothesize that (a) economic risk negatively affects users' willingness to save, (b) privacy risks negatively affect users' willingness to save, (c) service risk negatively affects users' willingness to save, and (d) psychological risk negatively affects users' willingness to save.

Taken together, we propose a hypothesis based on the model described as Figure 1 below.

Figure 1: Research Model

Data and Research Methodology

Research Methods

This research uses a quantitative approach. Data for this study was collected via online survey as the research instrument. Due to the minimum qualification for the respondents, the sample was chosen using convenience and snowball techniques while keeping the demography of the sample to represent the population. Before the distribution, an internal test was conducted in which the questionnaire was scrutinized in order to eliminate any errors, typos, or ambiguities. The survey link was spread out conveniently through messenger application groups and social media.

Table 1: Descriptive Statistics of Respondent's Characteristics

Measure	Items	Subjects	
		Frequency	Percentage
Gender	Female	41	60,2%
	Male	62	39,8%
Age	< 21 years old	26	25,2%
	21-40 years old	60	58,3%
	40-60 years old	17	16,5%
Education	Primary to high school	30	29,1%
	Under graduate	64	62,1%
	Post graduate	9	8,7%
Occupation	Student	31	30,1%
	Civil worker	11	10,7%
	Private worker	53	51,5%
	Entrepreneur	2	1,9%
	Housewives	4	3,9%
	Unemployed	2	1,9%
Usage frequency	< 1 time a week	17	17%
	1-5 times a week	50	50%
	6-15 times a week	28	28%
	> 15 times a week	5	5%

The respondents in the sample are from different demographies: gender, age, education background, and job. The total sample consists of 103 respondents, in which 100 respondents are users of e-wallet, and thus are qualified for this research. The detailed characteristics of the respondents are shown in Table 1. The pre-condition for respondents is that they have to use one of ten major e-wallet services in Indonesia: GoPay, OVO, Dana, LinkAja, DOKU, Jenius, Paytren, i.saku, Sakuku, or dan Uangku.

Main Concept Measurement

The main concepts to be explored in this study are perceived benefit, perceived risk, and willingness to save money in the context of e-wallet service usage, as shown in Figure 1. The perceived benefit consists of two variables: monetary and convenience value, measured using 8 indicators adapted from Pura (2005) and Sheng, Parker, and Nakamoto (2014) and then customized to fit the context of e-wallet services in Indonesia. The perceived risk that was adapted from Yang et al. (2015) consists of 12 indicators that were also customized for the context of e-wallet services in Indonesia. Lastly, willingness to save money is measured using 6 constructs adapted from Lim et al. (2006) and customized to fit the context of this research. In areas in which the constructs have been developed or adjusted, we followed strict procedures: specify the domain of the construct, and the constructs were developed based on the conceptual definition. All items were measured on a five-point scale. The perceived risk variables use a Likert-type scale, and others are adjusted according to each construct.

Data Analysis Approach

This research used a two-step data analysis approach. First, we used factor analysis to check the reliability and validity of the construct. Factor analysis will help to determine whether independent variables are valid and reliable to measure the dependent variable and to test the validity and reliability of every construct that composed each variable. Following the results of previous tests, these variables were tested with regression analysis using the SPSS Statistics 22 application.

Data Analysis and Results

Reliability and Validity of Instruments

We conducted factor analysis for dependent and independent variables. All variables showed high KMO levels above 0.5, which are also significant under 0.01, except for one variable, which is monetary value (MF). Based on the factor analysis for MF, the indicators were split into two components. According to the indicators, both component consists of two type of values, fee and promotion. Thus, we split the variable into two different variables, fee value (MFV) and promotion value (MFP). After MF was split, all items for all variables showed convergent validity above 0.6, as in Appendix B.

All variables have Cronbach's alphas of more than 0.7, which shows good reliability. Validity of variables was measured using Pearson correlation test. The correlation result for all variables was higher than the *r* table 0.1946, based on the number of sample and α=0.05, as shown in Appendix A. Therefore, the results of the test indicate that the reliability and validity of variables were satisfactorily met.

Hypothesis Test

Table 2 shows the results of the multiple regression analysis. First, the multicollinearity test was examined using the collinearity statistics: variance inflation factor (VIF) and tolerance. The highly collinear variable, which means it has a VIF that exceeds 10, will pose a problem for regression analysis (Hair, et al., 1998). All of the variables show tolerance > 0.100 and VIF < 10.00, meaning the multicollinearity was verified.

The regression result shows an R^2 of 0.164 and an *f* value 3.036, which is higher than the *f* table value of 2.10. Furthermore, the hypothesis is evaluated based on the *t* value, which is 1.984 on the significance level of 0.05, and 1.660 on the significance level of 0.10. Hypothesis test results show that Hypothesis 1b is accepted on the significance level of 0.05, and Hypotheses 1b and 2c are accepted on the significance level of 0.10.

Table 2: Result of Hypothesis Testing

Hypothesis	Independent Variables	Dependent Variables	Tolerance	VIF	*t* value	Sig.
H1a	MVF	WM	0.876	1.141	0.774	0.441
	MVP	WM	0.722	1.385	-0.499	0.619
H1b	CV	WM	0.756	1.322	3.063	0.003
H2a	ER	WM	0.527	1.897	1.848	0.068
H2b	PR	WM	0.371	2.698	-0.672	0.503
H2c	SR	WM	0.459	2.179	-1.824	0.071
H2d	PSR	WM	0.408	2.451	0.142	0.888

Discussion

Based on the data analysis result, we found that, at significant level 0.05, perceived value as a whole has an effect on the dependent variable, which is the willingness to save more money. At the same significance level, convenience value proved to positively affect the dependent variable. In addition, at a lower significance level, besides convenience value, service risk also had a negative effect on the dependent variable, which aligns with our hypothesis. However, contrary to the hypothesis, monetary value, economy, privacy, and psychological risks were not proven to have an effect on willingness to save money.

To enrich the research analysis, we conducted regressions on each WM indicator as dependent variables. The results are shown in Table 3. Each WM indicator represents different conditions (what-ifs) that may be applied to e-wallet service (details in Appendix B). Based on the result, WM1, WM5, and WM6 are accepted at the significant level of 0.05, and WM4 is also accepted at the significance level of 0.10. WM1 is the willingness to save money if e-wallet offers an interest rate equal or more than bank savings; WM4 and WM5 are for whether e-wallet is provided by big private banks and international banks, respectively; and lastly, WM6 is for if the e-wallet offers more promotion and discount price.

Table 3: Regression Result for Each WM Indicators

Parameter	R^2	F-value	sig.
MV, CV, ER, PR, SR, PSR → WM1	0.131	2.328	0.039
MV, CV, ER, PR, SR, PSR → WM2	0.096	1.645	0.144
MV, CV, ER, PR, SR, PSR → WM3	0.090	1.541	0.173
MV, CV, ER, PR, SR, PSR → WM4	0.120	2.104	0.060
MV, CV, ER, PR, SR, PSR → WM5	0.205	3.987	0.001
MV, CV, ER, PR, SR, PSR → WM6	0.236	4.736	0.000

There are limitations in this study that may restrict the generalizability of the research result, which could be addressed in future studies. First, more than 50% of the respondents are 21-40 years old and are workers. They might be not as constrained by monetary and cost issues as students or unemployed people. They also might be more indifferent about privacy or service risks due to high exposure to technology development. Second, the research was geographically limited to one country, which is Indonesia. Future studies could be conducted at the cross-national level, since e-wallet has been adopted worldwide. Replication of the research in a different geographical context is also encouraged.

Implications

This research is done in response to the need for more value-oriented research in e-wallet services, beyond the technological perspective that has been used in many previous studies. The main

contribution of this research is the involvement of value-based variables in understanding e-wallet usage compared to previous studies that examines e-wallet adoption as more of an IT service. While models such as TAM could help to explore factors affecting the shift from traditional to technology-based service, this research has explored more factors that are determined by the value offered by the service. We believe that the findings will be useful in marketing, since almost all kinds of e-wallet services, especially in Indonesia, have about the same performance and sophistication level in terms of technology.

This study showed that perceived value, which consists of benefits and risks, affects customer's willingness as a whole to save more money using e-wallet. Having more money in one e-wallet will increase the usage of said e-wallet, since almost all e-wallets already provide transfer fund service. Amongst all variables in this study, we found that convenience value has consistently proven to positively affect saving intention. Consequently, e-wallet service providers may want to improve the accessibility of their service with more offline and online merchants, which can also enhance integration across platforms. It is important to note that, in Indonesia, two of the most often-used e-wallet services initially started as internal wallet services for the two biggest online transportation service platforms. As the services on the platform as well as the integration of the platform with offline and online merchants grew, so did the usage of these two e-wallet services.

At lower significance levels, service risk was also found negatively to affect savings intention. Improvement in customer service is the most important driver to enhance users' trust and willingness to use the product more. Service providers shall enhance the presence of the companies and also provide a faster response to inquiries and complaints. This aligns with the results of this study that the willingness to save money is positively affected by the profile of the company that provides the service, in which the respondents chose big, private, and international banks that are usually known for providing better service than state-owned banks in Indonesia.

We found that monetary value, economy, privacy, and psychological risk do not affect users' willingness to save money. We suspect that this finding is matched with the profile of most respondents, most of whom are under 40 years old and workers with steady incomes. The questionnaire also explores the various channels used to top up the e-wallet. The highest channel chosen was mobile banking. This shows that respondents must have been familiar with technologies and do not hesitate to use technology-based services. This is consistent with previous research findings (Kim et al., 2007; Singh et al., 2020) that the usefulness of the service affects adoption intention and continuous usage.

Conclusion

This study aimed to identify the factors of perceived value in the usage of e-wallet service from the perspective of service consumers, not technology users. This research found that perceived value, which consists of benefits and risks, has an effect on customers' willingness to save more money in their e-wallet. Convenience value has consistently proven to positively affect savings intention. Additionally, at a lower significance level, service risk was also found to negatively affect savings intention. If customers save more with e-wallet, it will increase the usage of the e-wallet. Hopefully, these findings will encourage further research and more in-depth analysis and also involve or develop more variables that could enrich this study.

Relationships with The Superior as An Element of An Organisation's Employer Branding Communication – The Example of Poland

Elzbieta ROBAK

Czestochowa University of Technology, Czestochowa, Poland
elzbieta.robak@pcz.pl

Abstract

Interpersonal relationships between employees are fundamental in contemporary organisations. The quality of those relationships, and in particular relationships with the superior, affects not only the wellbeing of individuals but also the functioning of the entire company. The advantages of good relationships in the workplace are hard to overestimate. They translate to a higher productivity, employee engagement, innovation stimulation and higher job satisfaction. Positive employee relationships, in particular relationships with the superior, build the market success of an organisation and at the same time are a value that may constitute an important element of the brand of a valued employer. Employer branding (EB) measures associated with the creation of a positive employer brand, addressed to both job candidates and existing employees, in order to be effective must take into account their respective expectations and needs. According to studies and reports, a positive atmosphere in the workplace, and in particular good relationships with the superior, constitute one of the highest values for contemporary employees. The purpose of this paper is to show the importance of relationships with the superior for the development of the EB proposition – based on the example of Polish TOP 500 enterprises. The study presents the results of a nationwide quantitative survey of companies from the TOP 500 list. The results of the conducted research indicate that the great importance that employees attach to positive relationships in the workplace is noticed by leading companies and taken into account in shaping their employer branding offer.

Keywords: employer branding, relationships with the superior

Introduction

The picture of the contemporary labour market shows that many organisations find it difficult to attract and keep valuable employees. This forces employers to pay more attention to the needs and expectations of both employees and job candidates. It turns out that currently, they expect not only to receive attractive wages and benefits, be able to develop and have stable employment but also work in a positive atmosphere (Earle 2003, pp. 244-257; Młokosiewicz 2015, pp.103-116.). Especially representatives of the youngest generations in the labour market want to feel that their work makes sense and they want to know what is going on in the organisation they work for and to be able to influence that. However, in the first place, they expect to work in a place where there exist good relationships between employees on the same level and, in particular, between the superior and the employees (Employer Brand Research 2019).

The purpose of this paper is to show the importance of relationships with the superior for the development of the EB proposition based on the example of Polish TOP 500 enterprises. The TOP 500 list, developed by the portal of the Polish *Rzeczpostpolita* newspaper, includes organisations that achieved the biggest market and financial success in a given year. The first part of the paper presents the importance of relationships with the superior for contemporary employees and how they can contribute to the development of the EB proposition. The analysis of this issue is based on the literature on the subject as well as studies and reports presenting employee expectations concerning relationships in the workplace. The empirical part of the paper presents the results of surveys conducted under a Polish quantitative research among TOP 500 enterprises.

The importance of relationships with the superior and their role in developing the EB proposition

Interpersonal relationships at work cover all the mutual relationships between the employees of various levels in a given organisation, including: behaviour, standards of conduct, the way of addressing others determined by the position in the organisation, joint performance of tasks and ensuring the welfare of the company and the people who work there (Jakimiuk 2016, p. 45). Relationships at the workplace help achieve specific goals and the parties to those relationships influence one another, realising their individual needs and expectations as well as common tasks and projects. They are implemented by means of the links between individuals or groups and specific ways of communicating knowledge, information, emotions, attitudes, values and convictions between two or more partners of interaction. Relationships at work may be personal and individualised and they are unique, not replaceable by other interactions, and involve interdependence and disclosing of personal information, thoughts or feelings. Their opposite are impersonal interactions that result from socialisation, politeness or acquired norms and standards of conduct towards people (Adler et al. 2011). In personal relationships, employees establish closer contacts, deepen their mutual bonds and are more engaged and willing to help one another. This type of relationships makes it possible to experience the support of others and build a friendly atmosphere at work (Raport Fun at work 2018).

Good atmosphere at work is created by a community built on the basis of shared values and employee relationships stimulated by mutual respect and trust. Such atmosphere is associated with organisational culture founded on values and relationships, among which the understanding of employee needs, appreciation of employees and openness in contacts are accentuated. The advantages of building positive relationships at work may be analysed in the individual, as well as team and organisational contexts. The main idea of positive relationships in an organisation is to help and support one another. Significantly, such help is provided even if it is not formally required in a given situation, because the important thing about such type of relationships is their reciprocity. Concerning the organisational profits of positive employee relationships, it is worth noting their impact on innovation, higher productivity – associated with effective communication and stimulating employee engagement (Glińska-Neweś et al. 2017, pp. 25-37). Meanwhile, individual advantages of maintaining good interpersonal relationships at work and a friendly atmosphere are important not only for increasing job satisfaction but also for developing a sense of self-esteem in employees. Positive relationships constitute a huge source of support, build a sense of security and satisfy the need for belonging and acceptance.

Employers who want to distinguish themselves in the labour market and build competitive advantage over other companies must create organisations founded on people and organisational culture that stimulates an emotional bond between the employee and the employer. Contemporary employees not only expect to be treated as partners and understood but they also want to feel that the employer cares about their opinion and considers them to be an important part of the company. Especially representatives of the youngest generations in the labour market expect their work to be meaningful and the company philosophy to be coherent with their own values and compatible with their lifestyle. Those young employees also find it attractive if a company supports local projects and its activities correspond to its declared values (Singh and Dangmei 2016). In order to meet the needs of mainly young employees, many companies introduce well-being services that are supposed to improve their health and condition. However, taking care of the health and wellbeing of young employees of the generations Y and Z must not disregard the aspects of their functioning at work that they consider to be crucial, namely the atmosphere at work associated with relationships with the superior and colleagues.

An important factor affecting the development of positive relationships at the workplace, and in particular relationships with the superior, is the appreciation of employees. Research reports clearly show that employees want to know that their efforts are noticed and their work is recognised by their superior (Employer Brand Research 2019). This creates an atmosphere that is conductive to cooperation and development, and stimulates creativity. Employees who feel appreciated are more

willing to identify with the employer, more engaged and loyal. Importantly, in the contemporary competitive labour market, where talented employees are highly valued, employee turnover is much lower in companies that have a culture of appreciation. The importance of employee appreciation is proven by the results of studies concerning the expectations especially of persons of the generations Y and Z (Raport Index Doceniania 2019). Considering the nature and needs of the youngest generations in the labour market, this issue is particularly important and even decisive for their perception of the working environment as friendly and relationships with the superior as satisfactory.

Positive employee relationships, including relationships between employees and their superiors, contribute to the market success of an enterprise, at the same time being an extremely precious organisational value. The special importance of this value means that eventually, it may constitute a crucial element of the development of the brand of the organisation as a valued employer. Contemporary enterprises that want to effectively compete with others should include employer branding (EB) measures associated with the creation of a positive employer brand in the important areas of organisational management (Backhaus and Tikoo 2004, pp. 501-517: Barrow and Mosley 2006). They relate to the fulfilment of such important needs of an enterprise as attracting and maintaining talented employees who would identify with the employer.

Employer branding covers organisational measures focusing on existing and potential employees and their goal is to build the image of an organisation as an attractive employer and to support its strategic business goals (Lievens et al. 2007, p. 548; Moroko 2008, p. 161; Kozłowski 2012, p. 13; Francis and Reddington 2012, p. 269). EB projects may be divided into external EB – focusing on persons potentially interested in working for a given organisation and internal EB – focusing on company employees (Backhaus and Tikoo 2004 pp. 502-503; Lievens and Slaughter 2016, pp.407-440). External EB targets future employees of an organisation and provides substantial information and opinions about the company to a potential candidate. Measures undertaken as part of external EB may be divided into activities associated with image creation and recruitment, respectively. Image-related measures are supposed to increase the awareness of the target group of the organisation and the potential advantages of working for that organisation. Meanwhile, recruitment-related measures arise from ongoing recruitment processes and their goal is to reach valuable candidates and to persuade them to apply for a specific job. On the other hand, the most important goal of internal EB is to increase employee productivity, which is achieved through various initiatives aimed at improving working conditions and highlighting the benefits of employment in a given organisation. The tools that support the implementation of internal EB include the following: wage and non-wage incentives, professional training and development, internal communication, employee satisfaction surveys and measures that stimulate their integration as well as CSR projects focusing on the employees and the organisational value system (Katoen and Macioschek 2007). Building the employer brand among employees helps increase employee job satisfaction, as a result of which employees become the ambassadors of the company and create its positive image among potential job candidates (Martin et al. 2005, p. 79; Lievens et al. 2007, p. 548). One of the effective contemporary methods of building the employer brand is whisper marketing. It means reaching a potential job candidate through immediate, spontaneous communication. Whisper marketing in blogs, fora or social networks, by triggering discussion about a given company, makes people recommend the company in a natural and genuine way (Mistewicz 2011; Kozłowski 2012, p. 131-132).

An important element of the EB proposition is the Employee Value Proposition (EVP), which is a description of the features and attractiveness of jobs offered by a given employer. An increasingly frequent element of the EVP are organisational measures that highlight personal treatment of the employee (Heger 2007, pp. 109-121; Browne 2012, pp. 29-36). This is due to the fact that contemporary employees not only expect to be treated as partners and understood but they also want to feel that the employer cares about their opinion and considers them to be an important part of the company.

Research shows that it is profitable for an employer to create a good brand. Implementation of EB programmes stimulates recruitment, because such programmes attract valuable candidates to an organisation, reduce employee turnover and have a positive impact on work motivation. As a result,

the company profits financially, especially as a result of reduced employee turnover thanks to employees being satisfied with their work and good communication between the employee and the employer (Barrow and Mosley 2006; Sokro 2012, pp. 164-173).

Methodology

The empirical part of the paper is based on the results of research that was a part of the Polish quantitative research of enterprises under the project: "Innovative trends in human resource management in large enterprises". The research population were the top 500 Polish companies (according to the *Rzeczpospolita* portal 2018 ranking). The research was conducted in 2019 at the Faculty of Management at the Częstochowa University of Technology in collaboration with the specialist outsourced company MRW Market Research World. Random sampling was used by the company conducting the research. Following the sampling, the representative sample was examined based on the following parameters: the size of the general population 500, the estimation error 6%, the level of trust 95%. If a certain company refused to participate in the research, another company was randomly selected.

The research used quantitative survey methods with mixed techniques: the Computer Assisted Web Interview (CAWI) and the Computer Assisted Telephone Interview (CATI). The research tool used in the research was a standardised questionnaire. It contained a set of closed-ended and semi-open-ended questions formulated both as questions and statements. The closed-ended questions were constructed taking into consideration their theoretical, logical and substantial correctness. The questions contained answers in the Likert scale, which enabled determining the relative intensity of various answers. The part of the survey concerning the employer branding (EB) used the five-level Likert scale. The questions relating to the EB were original and they were formulated by the members of the research team of the Chair of Psychology, Sociology and Communication in Management of the Faculty of Management of the Częstochowa University of Technology.

This paper uses the part of the research results concerning the EB proposition of the analysed enterprises, and in particular relationships with the superior as an element of an organisation's EB communication. The following research problem was formulates regarding this issue:

Are relationships with the superior an essential element of the EB proposition of the TOP 500 enterprises?

The following four research assumptions were made in association with this problem:

1. Whisper marketing concerning relationships with superiors in an organisation is very important for the development of the EB.

2. Healthy atmosphere at work constitutes an essential element of an organisation's emotional communication regarding the EB.

3. The organisation promotes a caring and partnership style of management.

4. Communication competencies are more important than professional competencies in performing managerial functions.

For the purpose of examining and describing the significance of differences in relation to the above-mentioned independent variables and the correlation existing between them and other variables STATISTICA software was used. Spearman's rank correlation coefficient was used to assess the strength of correlations between variables.

Results and Discussion

Questions concerning the organisations under review were answered by representatives of senior managerial personnel (HR departments) or employees delegated by the employer. They represented 179 companies, of which: 41.8% were manufacturing companies, 14.5% were manufacturing and service providing companies, 27.4% were service-providing companies, 8.4% were trading companies and 7.8% were manufacturing and trading companies. Most of the responding organizations generate annual revenue ranging from 51 to 200 million PLN (68.1%), the second most numerous group were organizations with revenue ranging from 5 to 50 million PLN (17.9%) annually, and the least numerous group were organizations with annual revenue exceeding 200 million PLN (14%). In terms of the number of employees, the most enterprises employed from 201 to 500 persons (73.18%), and the other 26.82% were companies with more than 500 employees.

The information obtained from employers from the TOP 500 group concerning their EB proposition led to a number of interesting conclusions on the issue of relationships with the superior. The main research problem was directly linked with the issue of whisper marketing associated with relationships with the superior. Representatives of most of the responding companies, asked for their opinion on the importance of whisper marketing concerning relationships with the superior for the development of the EB proposition, emphasised its crucial role (53.07% of responses). Of this, 34.07% respondents partly agreed with the statement that "whisper marketing concerning relationships with superiors in an organisation is very important for the development of the EB" and nearly every 5th representative of the responding enterprises (18.99%) strongly agreed with this statement. Only 18.99% of the respondents were of different opinion and 27.93% did not give an explicit answer on this issue (table 1).

Table 1: Respondents' opinions on the relationships with superior as an element of the EB proposition

Relationships with the superior as an element of the EB proposition	strongly agree	partly agree	neither agree nor disagree	partly disagree	strongly disagree
Whisper marketing concerning relationships with superiors in an organisation is very important for the development of the EB	34	61	50	27	7
	18,99%	34,08%	27,93%	15,08%	3,91%
Healthy atmosphere at work constitutes an essential element of an organisation's emotional communication regarding the EB	84	52	27	9	7
	46,93%	29,05%	15,08%	5,03%	3,91%
The organisation promotes a caring and partnership style of management	32	63	54	17	13
	17,88%	35,20%	30,17%	9,50%	7,26%
Communication competencies are more important than professional competencies in performing managerial functions	20	63	60	26	10
	11,17%	35,20%	33,52%	14,53%	5,59%

Source: own study based on research results

These results mean that leading Polish companies are aware of the importance of opinions on relationships with the superior expressed by satisfied employees through whisper marketing. This method of delivering information on employee relationships constitutes a reliable source of information for potential candidates. Thus, in order to attract valuable employees, who can choose from numerous job advertisements, the examined companies create their EB proposition on the basis of very reliable recommendations that often come directly from employees. Representatives of the surveyed organizations were also asked to assess the situation of their company on the market. These statements were correlated with the adopted EB indicators using the Spearman's rank correlation coefficient. Using the statistical analysis of the obtained data, it was shown that there is a statistically significant correlation between the EB offer of the surveyed enterprises relate to relations with superiors and the increase in enterprise resources ($p = 0.040056$) and the implementation of new technologies ($p = 0.003357$).

Relationships with the superior, being a key element of interpersonal relationships at work, have a very strong impact on the perception of the overall work atmosphere. Thus, representatives of the examined organisations were also asked to respond to the statement that healthy atmosphere at work constitutes an essential element of an organisation's emotional communication regarding the EB. The results clearly show that the respondents appreciate the importance of good atmosphere at work for EB measures – as many as 75.97% of them emphasised the significance of that factor. It should be noted that as many as 46.92% of the representatives of the responding of leading Polish enterprises strongly agreed that good atmosphere at work constituted an essential element of their EB communication. The low percentage (8.93%) of contrary responses suggests a uniform image of the examined enterprises and unanimity of their opinions concerning this aspect of developing the employer brand (table 1). Positive perception of the work atmosphere in an organisation is, according to studies and reports, one of the most important factors affecting the choice of the future place of work or the decision to stay with the current employer (Raport Fun at Work, 2018; Employer Brand Research 2019). According to the available data, companies from the TOP 500 group are aware of the trends in the labour market and, in their emotional EVP communication, they include an image of healthy work atmosphere, meaning good employee relationships. Friendly work atmosphere, being an important element of the emotional communication of a company, draws on the key expectations of employees, which is in line with the contemporary employee expectations. Statistical analysis of obtained data showed that there is a statistically significant correlation between the EB offer of the surveyed enterprises regarding a good work atmosphere and the increase in enterprise resources ($p = 0.005381$) as well as an increase in productivity ($p = 0.044524$) and the implementation of new technologies ($p = 0.007360$) and greater innovation of the company compared to competitors ($p = 0.034639$). Leading Polish companies owe their market success and further opportunities for successful development, related to innovation and new technologies, to the atmosphere of work that promotes the productivity and creativity of employees. In such an atmosphere of work, employed people are more willing to cooperate and share their knowledge, which affects organizational benefits.

The relationships between superiors and employees belong to the most important factors that affect both productivity and job satisfaction. Positive perception of those relationships by employees is influenced, among other things, by their expectations regarding the superiors and their style of management. According to reports presenting the expectations of the youngest generations in the labour market, they mainly opt for a superior-patron who is sympathetic and helps employees do their job or a superior-partner who discusses tasks with his employees and works together with them to complete those tasks. The least popular is the traditional style of management, in which the superior mainly gives orders and controls their performance. Considering these employee preferences, representatives of the examined companies from the TOP 500 group were asked to respond to the statement that their organisation promotes a caring-partnership style of management. The information suggests that the majority (53.07% of responses) of successful enterprises prefer relationships between superiors and employees based on partnership and supporting the employees. Of this, 35.19% of the respondents partly agreed that their organisation promoted a caring-partnership style of management, and 17.87% strongly agreed with this statement. Only 16.75% of the respondents were of different opinion and 30.16% did not give an explicit answer on this issue (table 1). Using

statistical analysis, it can be concluded that there is a statistically significant (p = 0.034369) correlation between promoting a caring and partnership style of management and increasing in company's resources.

The studies and reports available in the literature on the subject suggest that contemporary employees, and in particular representatives of the youngest generations in the labour market, pay special attention to issues associated with communication. In this context, the superior's communication skills are relevant to employee expectations and relationships with employees. A competent superior should thus not only be experienced and knowledgeable and share their knowledge with employees but, more importantly, they should have good communication skills. Accordingly, the survey could not omit the question of the competencies associated with the superior's communication with employees. In order to visualise this issue in the best Polish companies, the respondents were asked to comment on the statement that communication competencies are more important than professional competencies in performing managerial functions. Such response seemed to be quite provocative, however, the opinions of the representatives of the examined organisations prove the special role of communication skills in performing managerial functions. The largest percentage of the respondents (46.37%) agreed with this statement, while 33.52% chose the option: "I neither agree nor disagree". The lowest percentage of the organisations (20.11%) stated they did not agree with this statement (table 1). Professional knowledge and job-related skills, although valuable in leading the enterprise to success, proved to be less essential in performing the role of the superior than communication competencies. The carried out statistical analysis in relation to this issue allowed to make some important observations. It turns out that the importance assigned to the manager's communication competences is statistically significantly correlated with the increase in enterprise resources (p = 0.009802); an increment in product sales (p = 0.005981) as well as an increase in productivity (p = 0.002532) and the implementation of new technologies (p = 0.011450); an increase in the market value of the enterprise (p = 0.001356) and higher market shares compared to the competition (p = 0.045475). Although the strength of the correlations between the studied variables is rather weak, the existence of theme indicates the importance of managers' communication competences in shaping the market success of the enterprise.

An analysis of the results leads to the conclusion that Polish enterprises from the TOP 500 group, in order to successfully compete with other companies in the labour market, carefully build their EB proposition and regard relationships with the superior as an important element of EVP communication. It could be presumed that one of the reasons for such measures are the generational changes in the labour market and the related transformations of employee values and expectations, reflected not only in the wording of formal contracts, but also with respect to psychological contracts. Such contracts, containing both the obligations of an employee in an organisation and the things the employee expects in return, also provide for the issues of the development of the working environment and employee relationships (Rogozińska-Pawełczyk 2019, pp. 171-184). According to the reports of HR specialists, changes in contractual obligations concern, in the first place, more independence and the possibility to enrich one's professional experiences and develop one's competencies, but they also highlight the key importance of work atmosphere and positive employee relationships, especially relationships with the superior (HRM Institute https://www.hrminstitute.pl/raporty-eb). The preferences of young employees demonstrated in studies clearly show that, on the one hand, they want to experience the help and support of their superiors but, on the other hand, would like to have a partnership relationship with them. These preferences of young employees are noticed by leading enterprises, which use their knowledge of this issue in developing their EB proposition. However, it is not certain whether such positive employer image is only an element attracting job candidates or it is coherent with the entire EB and actually reflects the organisational reality. This is important, because employees who experience the coherence of measures undertaken by an organisation in both areas of the EB (internal and external) are more likely to be involved with the company for longer (Andreassen and Lanseng 2010, pp. 212-236; Wilska 2014, pp. 46-54).

Conclusion

Considering the conclusions of relevant studies and reports (Stach 2014, 33-59) and the results of research presented above, it should be noted that leading enterprises are aware of employee expectations concerning positive relationships at the workplace and take them into account when developing the employer branding proposition. Such attitudes of employees, especially the youngest generations of employees, whose representation among all employees is increasing, forced some changes in the labour market (Albrychiewicz-Słocińska and Robak 2017, pp. 147-161). HR specialists agree that those persons particularly value relationships with superiors. Young employees pay a lot of attention to their superiors' ability to appreciate employees and make them feel important for the implementation of organisational goals. In this context, appreciating employees for their good work must not be treated as a redundant measure or loss of time, because, apart from strengthening the employee-employer relationship, it also increases employee job satisfaction, engagement and loyalty to the company. Establishing good relationships with employees based on open communication by employers and frequent provision of feedback, and in particular appreciating the achievements of employees, are examples of good ways to ensure a friendly work atmosphere.

Currently, leading enterprises try to create the image of an attractive employer by building and implementing an effective employer branding strategy, both inside and outside the organisation. Building an employer brand that will not only attract the desired job candidates but also help keep talented employees for longer is becoming an essential challenge and at the same time – a necessity. Thus, creating the image of the employer of choice is increasingly often included in the range of practices supporting human resource management in organisations in the Polish market. The question is how the EB proposition in the labour market will change after the COVID-19 epidemic. It seems that the forecasted economic slowdown and increase in the unemployment rate will not eliminate the problems companies have with attracting and keeping valuable specialists. It should be expected the EB propositions will remain important and relationships with the superior will continue to play an important role among EVP preferences.

Abstract

Generation Z presents people born after 1995 and is also called digital generation, generation of media and generation.com. Its members have specific attitudes and expectations as consumers, employees and citizens. They are the youngest consumers who participate on labour market. Also, they have specific savings habits and a level of financial literacy. To understand how members of Generation Z are saving, their attitudes towards saving and their own financial capacity, a research was conducted using a survey questionnaire on a suitable sample of 250 respondents, adult members of Generation Z born between 1995 and 2001. Examined variables relate to attitudes towards savings, their own financial capacity and tendency to save. It is concluded Generation Z has positive attitudes towards saving, believe they can make their own financial decision and have tendency to save. Most of Generation Z is saving and mostly by themselves, not in the bank. They are familiar with types of saving available on the market, but they do not use them on a larger scale. To raise the number of savings in banks and in general, and to increase awareness of saving between young adults of Generation Z it is necessary to enhance their knowledge about personal finances and saving strategies and to adjust saving offer according to their needs.

Keywords: Saving Behavior, Saving Habits, Generation Z, Young Adults

This paper is based on research undertaken in the frame of the Project of the Croatian Science Foundation - "UIP-2019-04-3580" EfFICAcY - Empowering financial capability of young consumers through education and behavioural intervention

Introduction

The generation is defined as groups of individuals with the same or similar traits (Berkup, 2014). So far, according to the period of time when they were born, five generations of people have been defined: Traditionalists, Baby Boomers, Generation X, Generation Y and, at the end, Generation Z, the centre of many modern research. They have specific attitudes and expectations as a consumers, employees and citizens (Gaidhani, Arora and Sharma, 2019). Presents people born after 1995 and is also called digital generation. They were born in the period of time when technological development was already in full swing and social networks are of great importance for communication and sharing information (Berkup, 2014). Accordingly, the best way to understand, communicate and make an impact on members of Generation Z are social networks (Center for Generational Kinetics, 2018).

Due to their efforts to understand and adapt to the rapidly changing environment, Generation Z represents the generation of the future. They have an educational plan and start their education at a younger age, hence they are exposed to a large amount of information ever since (Berkup, 2014). Moreover, they are aware of the importance of financial literacy and consider the implementation of financial education into the learning programmes crucial (Loveland, 2017). Furthermore, Generation

Z's members also have specific savings habits, a level of financial literacy and an attitude towards financial responsibility as well. To understand how members of Generation Z are saving, their attitudes towards saving and their own financial capacity, a research *Motives, Attitudes and Behavior of Generation Z in the Context of Savings* was conducted.

By the research conducted, attitudes towards saving, perceived financial capacity and tendency to save of Generation Z were investigated. Also, it was researched if they are familiar with the types of savings offered by financial institutions of the Republic of Croatia. Finally, it is analysed how the Generation Z are saving. Due to importance of saving for personal finances and standard of living for individual but also for the whole economy it is necessary to adopt savings habits at an earlier age. Accordingly, it is crucial to research how members of Generation Z are saving, the reasons of their saving and are they capable of saving and prone to saving. The oldest members of this generation are just finishing their education, entering the labour market and earning their own income. To improve the saving structure of a young people, increase their awareness of savings and introduce them savings products, it is necessary to explore their savings habits.

Members of Generation Z understand the importance of saving and they keep in mind the effect of purchase on the saving (TransUnion, 2017). While making financial decisions and, consequently, saving decisions, they mostly gather information through the conversation with their parents (UPCEA, 2019). Previous research has also concluded that members of Generation Z have specific savings goals and save for their further education, but also to secure financial stability in retirement (Center for Generational Kinetics, 2017).

However, most of the research were conducted in the United States and there are no enough relevant researches conducted about Generation Z in Europe and, consequently, in the Republic of Croatia as a member of the European Union. Also, the savings goals of Generation Z have not been sufficiently examined, but only a few of specific goals of saving have been identified. On the other hand, although previous research found that members of Generation Z are saving, their way of saving and familiarity with types of savings, as crucial factors of saving offer modelling, have not been adequately inquired into.

Therefore, the aim of the paper is to analyse the attitudes towards saving, tendency to saving and saving habits of Generation Z's young adults, on the market of the Republic of Croatia, as a member of the European Union. Also, the goal is to examine in details savings goals of Generation Z and whether its members understand importance of saving for retirement. Also, it is necessary to investigate how members of Generation Z save and whether they have knowledge of types of savings offered on the market of Republic of Croatia. By this insight the savings offer will be formed by financial institutions in the most efficient way consequently increasing the number of savings and raising awareness of saving in general.

Theoretical basis

Private savings is the main domestic source for founding of capital investments, the primary initiator of long term economic growth. It is also important for the financial stability of the household. The importance of saving is in ensuring a certain standard of living in the future, realization of the financial goals and creating of a fund for emergency and crisis (Barbić and Lučić, 2018). Due to importance of saving for the economy and personal finances, it necessary to examine Generation Z attitudes towards saving and whether they can understand importance of saving in the context of personal finances and, consequently, present and future consumption.

Generation Z's attitude and behavior is significantly affected by their financial literacy. They are aware of the necessity to avoid debt (Center for Generational Kinetics, 2017.) which has great impact on developing of positive attitudes in the context of savings. Furthermore, adopting of this mindset at an earlier age is also evident in earlier understanding of the importance of saving. When spending, members of Generation Z are considering the amount of money saved before they made purchase (TransUnion, 2017.).

Members of Generation Z, according to Chaston (2012), have optimistic views on their future financial situation (Vojvodic, 2018) and they are confident about their future financial stability (Nielsen, 2015).

They are also optimistic about their careers and believe that studying at universities and colleges is crucial for its development. Members of Generation Z start working at an earlier age, which enables them to acquire work habits earlier as well (Center for Generational Kinetics, 2017). Optimism and self-confidence in the context of making financial decisions and their own careers, as a result, leads to optimistic attitudes towards their own saving performance.

To explore the tendency for saving of Generation Z, it is extremely important to consider the influence of social factors on formation of their spending and savings decisions. The attitudes of parents and friends, as environmental factors, influence the financial decisions of Generation Z (Lincoln Financial Group, 2016). The parents present the most important social factor for Generation Z. Through conversation with parents, Generation Z gains insight into the possibilities and importance of saving, different ways of saving and eliminates any concerns about saving (UPCEA, 2019). Environmental factors such as friends or peers also influence on their saving decision through conversation, advice, but also through their own example (Lincoln Financial Group, 2016).

Members of Generation Z are characterized as experienced consumers and a rapidly maturing generation. Factors and conditions in the market, such as globalization, digitization, social networking, improving quality of life and government incentives, create motivation for Generation Z in the context of retirement savings (Reutova and Gorlovskaya, 2019). According to previous research, Generation Z members are already considering retirement and it motivates them for saving. They are aware of necessity of saving for retirement and need to be prepared in case state pension programs will not be in function. It is extremely important for Generation Z to start saving as early as possible, so they have sufficient time to raise funds until retirement (Center for Generational Kinetics, 2017). Considering, most of the research has been conducted on the United States market, it is important to investigate how Generation Z of the Republic of Croatia perceive the importance of saving for retirement.

According to previous research most of members of Generation Z are saving. Specifically, 83% of respondents were saving at the moment of research conducting and 52% of them were saving for specific goal. Furthermore, 35% did not have a specific goal of saving. For Generation Z saving presents the method of reaching goals that are determined (TransUnion, 2017) which is characterized as a positive saving habit. Although they strongly against borrowing, Generation Z still wants to own a house and a car, but also to provide their family financial stability. With high expectations, aspirations and distancing from borrowing, saving presents the way of achieving life goals (Synchrony Financial, 2018).

Members of Generation Z, are motivated for saving by a variety of life and financial goals. Therefore, to create the saving offer and to popularize the usage of savings among young adults of Generation Z, it is necessary to identify their savings goals, way of saving and to investigate what drives them towards saving.

Methodology and sample

Data used in a one-off descriptive research called *Motives, Attitudes, and Behavior of Generation Z in the context of saving* were collected between August and November 2019. The survey was conducted using a survey questionnaire on a suitable sample of 250 subjects represented by adult members of Generation Z born between 1995 and 2001. Of the total number of respondents, 69.2% were women and 30.8% were men. Also, more than half of the respondents, 52.4%, are resident in Zagreb, the capital of the Republic of Croatia. By age structure, most of the respondents were born in 2000, or 23.2% of them were 19 years old at the time of the survey. Considering the current employment status of respondents, 83.6% are students and 15.6% are employed. In other words, the current structure of employment following the age of the respondents who were currently from 18 to 24 years old. Also, the age structure following an educational structure according to which the highest percentage of respondents, 64%, have graduated the high school, 19.2% are undergraduates, 14.8% graduates and 2% have graduated the elementary school.

The variables examined in the survey relate to savings attitudes, attitudes toward their own financial capacity, and tendency to save (Table 1). The stated variables represent concise sets of statements that were measured by 7-point Likert-type scale, where number 1 represented disagreement with the

statement completely and number 7 agreed with the statement completely (1 - Strongly disagree, 7 - Strongly agree).

Table 1: Variables used in the study

Variables	MEAN	ST DEV
Generation Z attitudes towards saving		
Day-to-day action	**4,28**	**1,25**
Saving lifestyle	**4.55**	**0,96**
Generation Z attitudes towards their own financial capacity		
Subjective norms in the context of financial ability	**5,51**	**1,06**
Behavioural norms in the context of financial ability	**4,62**	**1,40**
Index of responsible financial behavior	**5.25**	**1,04**
Generation Z propensity to save		
Descriptive norms in the context of saving related to parents	**5,45**	**1,41**
Descriptive norms in the context of saving related to friends	**4,37**	**1,33**
Prescriptive norms in the context of saving related to parents	**5,65**	**1,27**
Prescriptive norms in the context of saving related to friends	**4,54**	**1,45**
Behavioural intentions in the context of saving	**5,45**	**1,54**
Self-efficacy in the context of saving	**5,62**	**1,30**
Controllability in the context of saving	**4,87**	**0,84**

Source: Author's own figure

Attitudes toward saving were examined using sets of statements relating to day-to-day activities in the context of saving and saving as a lifestyle (Dholakia et al., 2016). Also, a semantic differential, a scale consisting of a series of seven-step agreement scales on the far ends of which are adjectives of the opposite meaning (Marušić, 1992), was used. This way, the importance of saving and attitudes towards saving formed by the members of Generation Z has been examined (Ajzen, 2002).

Generation Z's perceptions about financial capacity were examined using attitudes (Barbić, Lučić & Chen, 2019; Ajzen, 2002, 2006). This set of statements is divided into statements regarding subjective and behavioural norms in the context of financial capacity and statements relating to the index of responsible financial behavior.

Generation Z's tendency to save has been studied by a set of statements relating to descriptive and prescriptive norms regarding the parents and friends of the respondents. Descriptive norms represent an individual's perception of the ordinary behavior of people in their environment in a given situation, while prescriptive norms refer to an individual's perception of behavior that people in their environment will approve or disapprove (Cialdini, Kallgren, & Reno, 1990). Statements for measuring tendency to save are also relate to the behavioural intentions, self-efficacy, and controllability of respondents in the context of saving (Ajzen, 2006).

By the conducted research the goals and the way of saving of Generation Z were also researched. It was examined whether the members have specific or unspecified savings goals and if they have specific goals, are they long-term or short-term. Also, it was examined whether the respondents regularly save, what percentage of monthly income they save and where they save.

Results

Generation Z members' savings attitudes were examined using two sets of statements. The first set refers to the day-to-day activities of respondents related to saving, while the second set refers to saving as a lifestyle (Dholakia et al., 2016) (Table 2).

Table 2: Generation Z attitudes towards saving

Generation Z attitudes towards saving	MEAN	MOD	ST DEV	ST ERR
Day-to-day action				
I keep a careful watch over my spending on a daily basis.	4,72	5	1,49	0,09
I do not spend money thoughtlessly, I would rather save it for a rainy day.	4,34	5	1,51	0,10
Putting money into personal savings is a habit for me.	4,21	5	1,89	0,12
I actively consider the steps I need to take to achieve my personal savings goals.	4,62	6	1,73	0,11
I like to discuss the topic of saving money with my family and friends.	3,50	4	1,84	0,12
Saving lifestyle				
I usually save money without having a specific goal in mind.	3,74	4	1,89	0,12
The goal of saving money is always at the back of my mind.	4,33	3	1,81	0,11
Saving money on a regular basis should be an important part of one's life.	5,37	6	1,43	0,09
Saving money is like a lifestyle, you have to keep at it.	4,76	5	1,55	0,10

Source: Author's own figure

Regarding statement related to day-to-day savings activities, 58.4% of respondents rate the statement they carefully control their spending on a daily basis with high degrees of agreement, while 56% of respondents chose high levels of agreement with the claim they actively consider the steps they must take to achieve saving goal. The statement saving on a daily basis should be an important part of everyone's life, 52.4% of respondents rated with a high degree of agreement, 6 or 7. Another important statement refers to saving as a way of life which is rated by 57.6% of respondents with a high degree of agreement, indicating that the majority of respondents agree with the stated statement (Table 2).

Furthermore, using semantic differential (Ajzen, 2002) for analysing attitudes considering two opposite adjectives, 69.6% of respondents strongly agree saving money is useful, 64.4% confirm saving is positive, and 68% strongly agree that saving money is good.

The set of claims relating to financial capacity (Barbić, Lučić, and Chen, 2019; Ajzen, 2006) is divided into statements regarding subjective and behavioural norms in the context of financial capacity, and statements regarding to the index of responsible financial behavior (Table 3)

Table 3: Generation Z attitudes towards their own financial capacity

Generation Z attitudes towards their own financial capacity	MEAN	MOD	ST DEV	ST ERR
Subjective norms in the context of financial ability				
I consider myself qualified to manage my financial situation and financial decision-making.	5,14	7	1,69	0,11
I think it is extremely important to create a financial plan for the future.	5,72	7	1,22	0,08
I think it is extremely important to adhere to personal financial budget.	5,68	7	1,21	0,08
Behavioural norms in the context of financial ability				
I feel free to make my own financial decisions.	5,47	7	1,51	0,10
My financial situation is entirely within my control.	4,36	5	1,97	0,12
I have the necessary resources and means to achieve financial success.	4,03	4	1,68	0,11
Index of responsible financial behavior				
I live in accordance with my financial possibilities.	5,44	7	1,38	0,09
I pay my monthly bills before on their due date.	5,66	7	1,47	0,09
I try to anticipate and plan future financial income and expenses.	5,24	5	1,47	0,09
In everyday purchases of consumer goods, I am informed to make rational decisions that are in line with my financial possibilities.	5,28	6	1,45	0,09
I try to be informed and educated in the field of successful management of personal finances.	4,31	5	1,71	0,11
When buying an item, the first think I think about is whether I can afford it.	5,60	7	1,52	0,10

Source: Author's own figure

Furthermore, 70% of respondents with high degrees of agreement, from 5 to 7, rated themselves as being qualified to manage their own financial situation and make their own financial decisions. Moreover, 76.8% of respondents rated with a high degree of agreement the statement they were free to make their own financial decisions. Also, it is observed how respondents care about their future finances (Table 3).

To investigate Generation Z attitudes towards saving, statements related to the descriptive and prescriptive norms in the context of saving regarding parents and friends of the respondents and statements related to behavioural intentions, self-efficacy, and controllability in the context of saving were used (Table 4).

Table 4: Generation Z tendency to save

Generation Z propensity to save	MEAN	MOD	ST DEV	ST ERR
Descriptive norms in the context of saving related to parents				
My parents are saving money	5,32	7	1,74	0,11
My parents talk about saving.	5,06	7	1,76	0,11
My parents think saving is a good idea.	5,96	7	1,32	0,08
Descriptive norms in the context of saving related to friends				
My friends are saving money	4,28	5	1,44	0,09
My friends talk about saving.	3,81	4	1,79	0,11
My friends think saving is a good idea.	5,02	5	1,50	0,10
Prescriptive norms in the context of saving related to parents				
My parents would support my intention of saving money.	6,37	7	1,05	0,07
My parents think I should start saving money.	5,37	7	1,64	0,10
My parents would like me to start saving money.	5,20	7	1,75	0,11
Prescriptive norms in the context of saving related to friends				
My friends would support my intention of saving money.	5,38	7	1,55	0,10
My friends think I should start saving money.	4,23	4	1,72	0,11
My friends would like me to start saving money.	4,00	4	1,79	0,11
Behavioural intentions in the context of saving				
I plan to start saving money in the next 3 months.	5,25	7	1,76	0,11
I will try to save some money in the next 3 months.	5,65	7	1,52	0,10
Self-efficacy in the context of saving				
I am confident that I will be able to save some money in the next 3 months.	5,60	7	1,60	0,10
I am confident that I will be able to overcome obstacles that may make it difficult for me to save.	5,34	7	1,47	0,09
I believe I have the ability to save money.	5,92	7	1,29	0,08
Controllability in the context of saving				
Whether or not I will be able to save money in the next year depends only on me.	5,80	7	1,39	0,09
I can decide by myself how to spend or save money.	6,06	7	1,15	0,07
Saving money is not under my control.	2,76	1	1,88	0,12

Source: Author's own figure

The parents of the respondents save and talk more about saving than their friends. Furthermore 35.2% of respondents confirmed they strongly agree with the statement their parents are saving, while a significantly smaller percentage of respondents strongly agree with the statement that their friends are saving. Moreover, twice as many respondents, 47.2%, strongly agree with the statement that their parents think saving is a good idea while, on the other hand, only 20.8% of respondents strongly agree with the statement that their friends think that saving is a good idea (Table 4).

There is a similar trend in prescriptive norms in the context of saving. Twice as many respondents, 66.8%, strongly agree with the statement that their parents would support them in the intention of saving. Due to the results stated, that respondents have or expect more support from their parents than from their friends in the context of saving (Table 4).

Attitudes related to behavioural intentions, self-efficacy, and controllability in the context of saving were also rated with high degrees of agreement. Therefore, 67.6% of respondents rate the statement they have a plan to start saving in the next 3 months with high degree of agreement. Also, 41.2% of respondents completely agree they will try to save some money in the next 3 months. Additionally, 42% of respondents are strongly convinced they will be able to save some money in the next 3 months. Likewise, 72% of respondents rate with a high degree of agreement the statement they would be able

to overcome obstacles that may occurred during saving and 85.2% chose a high degree of agreement for the statement they believed they had the ability to save money. Finally, 43.6% of respondents strongly believe their savings will depend only on themselves, while 48.4% strongly believe they can decide how to save or spend their money. Also, 59.2% rated the statement their own savings is not under their control with a high degree of disagreement. Therefore, the respondents consider the saving is completely under their control (Table 4).

Of the total number of respondents, 71.2% confirmed they are currently saving, while the remaining 28.8% confirmed they are not saving. For analysing the significance of differences between the attitudes of Generation Z members who are saving and those who are not, a t-test for large independent samples was conducted. In the analysis were included twelve dependent variables represent previously examined statements and one independent variable, whether the respondent was saving at the time of the survey or not.

Table 5: T-test results

Dependent variables	Independent variable	MEAN	STDEV	p value
Day-to-day action	Saves	4.65	1.07	0.0000000000007
	Do not save	3.35	1.19

	Do not save	4.69	0.76	

Source: Author's own figure

To examine the significance of the differences, a theoretical significance level, α, of 5% was considered. According to t-test, there is a significant difference between the attitudes towards saving, financial capacity, behavioural intentions, self-efficacy and controllability in the context of saving. Also, there is a significant difference between attitudes towards descriptive norms related to parents and friends in the context of saving, while there is no significant difference between attitudes towards prescriptive norms related to parents and friends (Table 5).

According to the survey, most respondents are currently saving and 45%, save up to 20% of their monthly earnings, while 35.2% save between 20% and 40%. By researching saving goals, 63.5% of respondents confirmed they save so in the future they would have more money for their needs. In other words, they do not have a specific savings goal. Furthermore, 62.1% of respondents save money so they can buy something specific in the near future, for example, to go on a short trip, buy clothes, shoes

or a mobile phone, and 57.3% of respondents save money for contingencies. Finally, 53.6% of respondents save money so they can buy something specific in the distant future, such as car, apartment or house. Besides, 49% of them save for travel as long-term goal, 42.3% for education, while 35.6% save for house or car. Additionally, 19.1% saves for starting their own business and 9.8% for retirement.

On the other hand, 71.2% of those respondents who are not currently saving consider specific goals, such as purchase in the distant future as encouraging factor that could motivate for saving. Furthermore, 49.2% of the them stated purchase of an apartment or house as a long-term goal that would encourage them to save, while 46.8% stated a travel. Also, 45.2% cited purchase of a car, 37.6% education, 23.3% starting of their own businesses and 11.2% saving for retirement as a goal that will encourage them for saving.

Most of respondents confirmed they were saving on their own. In other words, Generation Z do not primarily save money in banks (Figure 1.).

Source: Author's own figure

Figure 1: Way of saving of Generation Z

Most of Generation Z is familiar with the types of saving available by the Croatian National Bank. But even though they are familiar with them, they do not make extensive use of them. The largest number of respondents, 67.1%, heard about the types of savings they had when talking to their family, 65.3% through the media, 41.4% at school or college and 23.9% when talking with friends.

Discussion

By the conducted research, it is concluded how members of Generation Z have positive attitudes towards savings. They believe saving is useful, good, positive and gives them pleasure. In addition to careful control of their spending, members of Generation Z actively consider steps they must take to achieve their saving goals. Thus, Generation Z monitors the impact of consuming on saving (TransUnion, 2017). The members of Generation Z perceive saving as a lifestyle and they are aware of the importance of its implementation in the daily activities. Hence, Generation Z's attitudes indicate their willingness to save and consequently increase savings of young adults of Generation Z.

Observing the attitudes towards Generation's Z own capacity to make financial decisions and their understanding of the importance of financial security in the future, it can be concluded that Generation Z considers themselves capable of making their own financial decisions and qualified to manage their own financial situation. They care about their financial future and understand the importance of creating of a financial plan. Stated results follows previous findings about Generation Z members who are confident in their financial future (Nielsen, 2015). Therefore, confidence in their own financial capacity leads to a belief in their own savings performance. So, investment in Generation Z financial literacy is crucial for matching of perceived and real financial capacity.

In the context of the saving tendency of Generation Z, it is observed that parents have bigger influence on members of Generation Z than their friends. So, parents are saving more and talking about saving in a larger scale. Also, members of Generation Z have or expect more support in the context of saving from parents than friends. These results are following previous conclusion by which the most important environmental factor for Generation Z are parents or family. Also, it is confirmed that members of Generation Z mostly discuss about savings with their parents (Center for Generational Kinetics, 2017; UPCEA, 2019). So, to encourage Generation Z to save it is necessary to educate and inform their parents about benefits of saving for their children.

Members of Generation Z plan and believe they are capable and efficient and they will be able to save a certain amount of money. By conducted research it is confirmed that members of Generation Z believe they save a sufficient amount of money every month and are effective in the context of savings (Nielsen, 2015). Therefore, it is necessary to present them the full potential of savings, so they could achieve their goals and maximize their benefits through the saving.

Most of Generation Z is currently saving. According to conducted t-test it can be concluded there is a significant difference between attitudes towards savings, their own financial capacity, attitudes regarding descriptive norms related to parents and friends, behavioural intentions, self-efficacy, and controllability of saving of respondents who are saving and who are not. On the other hand, there is no significant difference between attitudes about prescriptive norms. So, it can be concluded there is no significant difference between attitudes towards behavior in context of saving that parents or friends will whether approve or not.

Generation Z is equally saving for specific and unspecified savings goals. For members of Generation Z saving represent the way of reaching the goals and reflect on their future (TransUnion, 2017). When saving for their long-term goals, they are saving for travels, education, buying an apartment, home or car, starting their own business and retirement. It is not following previous studies according to which Generation Z is aware of the importance of saving for retirement and dedicate to saving for retirement as early as possible. In order to raise the awareness of necessity of saving for retirement among the young people in the Republic of Croatia, it is crucial to educate them to start saving as soon as possible. Otherwise, they could face a sharp decline in their living standard in old age.

Most of the members of Generation Z who are saving do not make savings in banks, but on their own. However, they are known to the types of savings offered to them by banks largely and they are most likely to be heard about them during conversation with their parents and through the media. Therefore, to increase the number of savings of Generation Z in banks, it is necessary for banks to communicate with Generation Z members and their parents, who would pass on information about particular types of savings, savings methods and savings opportunities to their children. Furthermore, financial institutions to communicate with members of Generation Z and present their savings products to them, they must use the most common type of communication for Generation Z, social networks. This way, banks are able to provide information about the types of savings to members of Generation Z, while, on the other hand, members of Generation Z can provide banks feedback on their own perceptions of each type of savings.

Furthermore, in order to bring Generation Z members closer to savings products and savings types, it is necessary to adjust savings products to their specific needs. In other words, since Generation Z make extensive use of mobile applications for money management (Business Insider Intelligence, 2019), it is extremely important for banks to upgrade their mobile applications constantly to present their savings products to Generation Z and facilitate their usage.

By advertising in media and informing in affiliates, banks can present the types of savings they offer and their benefits to the parents of Generation Z. If parents understand and perceive the importance of the advertised types of savings, they will, through their own example and through the conversation, show and inform the children about importance and benefits of types of savings, but also about importance of saving in general. Because parents strongly influence their children's behavior in the context of making financial decision and saving, they can directly influence on their knowledge of types of savings and increase their savings in general.

Limitation and Conclusion

Previously research on saving habits of Generation Z were mainly conducted on the USA market. On the other hand, in the Republic of Croatia, the same topic has not been satisfactorily covered which represent the limitation of the research. Furthermore, Generation Z living in the USA is more aware of importance of saving for retirement than the one living in the Republic of Croatia. Therefore, it is highly important to strengthen education and raise awareness of saving for retirement to avoid possible disruption of living standards once members of Generation Z will retire.

Generation Z has specific saving habits and behavior in the context of saving. They have positive attitudes towards saving and believe it should be an integral part of life. They perceive themselves capable of making their own financial decisions and they are described as determined, confident and optimistic in the context of their financial future. Also, members of Generation Z believe they can decide if they will save or spend their money. Furthermore, they are prone to saving and most of them are saving.

Members of Generation Z save for both, specific and unspecified savings goals. Among specific goals those who are more common, are related to purchase in the near future. On the other hand, members who are not saving, as goals that would encourage them to save are pointing out those goals related to purchase in the distant future. Besides impact of parents, friends and media on their saving goals, the impact of education is necessary as well.

The oldest members of Generation Z are in their early twenties, have just finished their education and entering the labour market. They are starting to earn their own income. Considering, they need to be focused on the importance of saving and what they can achieve with it. Therefore, education needs to strengthen the awareness of the importance of saving for retirement and other saving goals related to financial stability in the future.

Generation Z is mostly saving on their own, not in the bank. They are familiar with types of saving available on the market and collect the information about saving by talking to their parents and through the media. Although they are familiar with the types of saving, they do not use them on a larger scale. Therefore, to maximize usage of different types of saving, the key is presentation of saving types and communication between banks and members of Generation Z and their parents, as well as educating of Generation Z about savings in general. Banks need to advertise saving products through social media and continuously work on developing mobile money management applications through which these products are available to Generation Z.

To raise awareness of saving among Generation Z and to increase the number of savings in banks and in general, it is necessary to invest in curriculum of educational institutions. Therefore, it is necessary to educate Generation Z about personal finances and to explore their saving goals in detail. Also, it is crucial to detect which factors encourage them to save in order to shape savings offer by their preferences and in that way achieve benefits for the individual and the economy as a whole.

Abstract

This paper discusses the state of feed production in Russia. The effective development of animal husbandry directly depends on the fodder base, featuring a balanced diet for animals according to the content of nutrients. Currently, large agricultural organizations have seen trends in the separation of feed production from animal husbandry, which prompted the development of international feed trade. However, the purchase of feed from the outside is not profitable for most of the small farming enterprises in Russia; organizing their own feed preparation from crop production is a more effective solution. As for the technical provision of fodder preparation, various technologies are currently used that are aimed at the maximum preservation of nutrients.

Keywords: Agribusiness, Animal Husbandry, Feed Choppers, Fodder Preparation.

Introduction

The article discusses the need for the introduction of modern technologies for the preparation and feeding of fodder to increase production of livestock products. A feasibility study of the effectiveness of the use of feed preparation machines of domestic brands was carried out. The possibility of entering the foreign market with feed preparation equipment was considered.

Materials and Methods

The main factors affecting feed preparation are considered. The qualitative characteristics of the main domestic brands of animal feed choppers are analyzed. The level of livestock production development was predicted for the year of 2025according to the trend line equation, which would require an increase in the production of feed preparation equipment.

Research Results and Discussion

Based on benchmarking and the assessment of various production lines by the total score, it was found that the most preferred option is the proposed feed preparation line (TL3), developed by scientists at the Nizhny Novgorod State University of Engineering and Economics, the payback period will not exceed 4.6 years. To expand the sales of equipment to small farms, it was proposed to use not only the domestic market, but also the foreign one.

For small farms, the most profitable option is to purchase a production line for the preparation of dry, loose, wet loose bulk fermented feeds with a capacity of up to 1 ton per hour which are more competitive than their analogues.

The effective functioning of the agricultural sector largely depends on the mechanism of the agricultural production management system, adapted to modern economic conditions. An analysis of the development strategy of the agricultural company shows that ensuring the implementation of the goals depends on the awareness of the leadership of the role of the technological strategy and its compliance with the level of progress.

At the same time, it should be noted that domestic management is characterized by a lack of a clear understanding of the economic part of the technological strategy and its place in the agricultural production management system. The strategic management of technological development is carried out, as a rule, intuitively and is not always linked to the competitive advantage of the enterprise and its dynamic development. Therefore, the strategic management of technological development in modern conditions is the most important factor affecting the final result of the activities of each agricultural enterprise. Only a focus on advanced technologies will ensure success in the markets, due to a significant improvement in the quality characteristics of the product, for which you can get a high price. Regardless of the specific direction of the regional or state economy, all managers must rely on innovation, as new technologies become the most important factor in the increaseof productivity and competitiveness. Without a scientifically sound and balanced state investment policy and system mechanisms guaranteeing investment and scientific and technical support for production, it is impossible to turn the agricultural sector of the economy into a dynamically developing and efficiently managed industry.

At the same time, the continuity of innovation activity related to the introduction of process innovations (modern technological lines, production technologies and automated systems) should be given special importance in agricultural activity, which allows to reduce production costs, labor costs, optimize the number and improve the quality of products.

In modern conditions, agriculture solves an important problem in animal husbandry providing the population with products of their own production. The increase in livestock production requires the introduction of the latest technologies that contribute to lower labor costs and funds for its production. An extremely costly element of the technological operation is the preparation and distribution of feed.

Historically, the basis of the agricultural sector is grain production. Grain stocks in international practice are considered, first of all, as strategic food reserves. The food security and global prestige as a whole depend on the level of development of the country's grain economy.

At the same time, grain is the most important part of the animal diet, which usually makes up 1/3 of the total diet. Science has repeatedly proved that the grinding of feed and grain helps to accelerate the digestion process and the absorption of nutrients.

Currently, considerable experience has been gained with the use of feed mixers in many domestic farms and significant results have been obtained: in dairy farms, average daily milk yields increase in the range of 19–26 kg with an improvement in product quality.

In the practice of balancing feeding diets, it is extremely difficult to achieve their full balance, this requires the use of mathematical dependencies for standardized components, as well as accounting for losses arising from deviations from the norms for individual components.

The economic feasibility of preparing feed in a farm is not in doubt, since this process is associated with low transport costs, the efficient use of its feed base, and the ability to quickly change the diet, one of the main components of which is grain.

In these conditions, in order to increase the efficiency of the livestock industry, it is extremely important to choose a technical device that performs operations on the preparation and feeding of fodder. For these purposes, domestic AKM-9, ISRK, KIS, KRFchoppers-mixers-distributors,KR-03 and KR-01 grinders (BIO RESOURCE of the Chelyabinsk Region) IK-07U and IKK "Kubanets" (ZAO Avtomash, Moscow), IKP-1.5root-cutting of packing and machine-building holding (Voronezh region), as well as mixers of Ukrainian (Ikor-5) and Belarusian manufacturers (Elikor 1-4 M) can beused.They, like domestic choppers, have low productivity and are intended to produce a porridge-like product. Most of them chop the tubers to a pulp state, while in screw choppers, a large amount of juice is released due to squeezing, which affects the quality and nutritional value of the feed.

Therefore, the design of disk grinders with plate knives that cut feed into slices are most promising today. A similar type of equipment was inventedby the scientists from the Nizhny Novgorod State University of Engineering and Economics: a technological line for preparing dry, loose, wet loose fermented feeds with a capacity of up to 1 t per hour. The technological line of preparation and distribution of feed includes a number of machines which givea certain productivity. Arrangement and installation of them in a certain sequence provides a continuous process of work and ensures constant cycle of operation.

In order to assess the prospects for the production and sale of feed choppers for households and farms of the Russian Federation, it is necessary to assess the composition of the livestock and the state of production of livestock products (Table 1).

Table 1: Dynamics of the number of cattle and pigs in Russia

Years	Large cattle, millionheads	Pigs, millionheads	Total livestock, millionheads
2010	19,8	17,3	25,8
2014	18,9	19,5	26,4
2015	18,6	21,4	27,2
2016	18,3	21,9	27,4
2017	18,3	23,1	28,2
2018	18,1	23,7	28,2
Growthrate	91,4	137	109

Analyzing table 1, it can be noted that in 2018, compared with 2014, there was a decrease in the number of cattle by 8.6% and an increase in the number of pigs by 37%. In general, the total number of livestock increased by 9% due to the intensive growth in the number of pigs. It should also be noted that due to the growth of animal productivity, production increases, which is undoubtedly associated with an improvement in the quality characteristics of the feed base (Table 2).

Table 2: Dynamics of agricultural production by categories of farms in Russia, billion rubles

Name	2010	2014	2015	2016	2017	2018	Growthrate,%
Farmsofallcategories							
Agriculturalproducts	2465,4	4031,1	4794,6	5112,3	5109,5	5119,8	207,7
including: livestock	1375,2	2044,4	2307,3	2402,0	2509,8	2550,8	185,5
Agriculturalorganizations							
Agriculturalproducts	1102,9	2083,0	2588,6	2818,4	2818,5	2819,6	255,6
including: livestock	644,6	1142,3	1324,7	1390,0	1482,2	1532,3	237,7
Households							
Agriculturalproducts	1185,7	1538,4	1654,9	1659,2	1655,4	1687,7	142, 3
including: livestock	678,9	807,6	873,5	890,3	891,2	877,0	129,2
Peasant (farm) enterprises[2]							
Agriculturalproducts	176,8	409,7	551,1	634,7	635,6	612,5	346,4
including: livestock	51,7	94,5	109,1	121,7	136,4	141,5	273,7

The data in table 2 indicate that livestock production in 2018 compared with 2010 increased in all categories of farms. In the households of the past two years, production has declined slightly, but compared to the level of 2010 it increased by almost 30%. In farms, steady dynamics of annual growth is observed, the total increase in gross output amounted to almost 90 billion rubles compared to the base year or by more than 2,7 times. High growth rates in the livestock industries indicate the possibility of increasing the demand for feed chopping equipment in Russia, both of high productivity and low productivity for small farms.

Having considered the dynamics of livestock development in farms for 2005 - 2018 and given the high coefficient of determination coefficient R2 = 0.9166, one can predict the planned level of development of livestock production for 2025 using the trend line equation y = 20.007x + 16.429

Table 3: Linear statistics of the dependence of the value of gross livestock production for 2005-2018

Name	Indicatorvalue	Name	Indicatorvalue
Coefficient C1	20,00714286	Coefficient C2	16,42857143
Standard error values for the coefficient	2,699571017	Standard error values for the coefficient	12,07284861
Coefficientofdetermination	0,91656423	Standarderrorfor*y*	14,28478711
F statistics	54,92633644	Degreeoffreedom	5
Regression sum of squares	11208,00143	Residualsumofsquares	1020,275714

Forecast for 2025 ry = 280.1 + 16.429 = 296.53 billion rubles.

However, given that the indicators of 2005, 2010, 2018 below the indicators of the trend line, it is necessary to determine the average deviation of these indicators from these indicators of the trend line.

$y(2005) = 20{,}007 + 16{,}429 = 36{,}436$, $\Delta y = 36{,}436 - 20{,}3 = 16{,}136$

$y(2010) = 40{,}014 + 16{,}429 = 56{,}443$ $\Delta y = 56{,}443 - 51{,}7 = 4{,}743$

$y(2010) = 140{,}049 + 16{,}429 = 156{,}478$ $\Delta y = 156{,}478 - 141{,}5 = 44{,}978$

$$\Delta y_{cp} = \frac{16{,}136 + 4{,}743 + 44{,}978}{3} = 21{,}95$$

$$x_{CP} = \frac{20{,}3 + 51{,}7 + 94{,}5 + 109{,}1 + 121{,}7 + 136{,}4 + 141{,}5}{7} = 96{,}46 \text{ billion rubles.}$$

$$K = 1 - \frac{21{,}95}{96{,}46} = 0{,}772$$

Figure 1: Dynamics of livestock production in Russian farms in 2005 – 2018

The forecast indicator taking into account deviations from the trend line for 2025 will be y = 296.53y = 296.53 · 0.772 = 228.92 billion rubles. Based on the presented dynamics of the cost of livestock production (Fig. 1), the growth rate in 2025 in comparison with 2018 will be 161.8%, which indicates the active development of livestock farming in Russia.

The dynamics of the share of farms in the general structure of farms of all categories for 2015-2017, presented in table 4, showed that the share of peasant farms in the total number of farms is insignificant, but increased by 1.6 percentage points. It also creates favorable opportunities for expanding chopper sales.

Table 4: Dynamics of the proportion of farms of all categories in total

Name	years			Deviation (+, -)
	2015	**2016**	**2017**	
Farmsofallcategories,%	100	100	100	
including:				
agriculturalorganizations,%	51,5	52,5	52,7	1,2

households,%	37,4	35,4	34,6	-2,8
peasant (farm) enterprises,%,	11,1	12,1	12,7	1,6

The federal scientific and technical program for the development of agriculture for 2017-2025 is aimed at ensuring the growth of agricultural production, including through the use of technologies for the production of high-quality feed, feed additives for animals, processing and storage of agricultural products, raw materials and food. At the same time, a decrease in the level of import dependence due to the introduction and use of technologies for the production of high-quality feed and feed additives for animals should be at least 25%.

In 2018, 1485,310 grinders for coarse and succulent feed were sold to domestic agricultural producers, which is 329,274 grinders more than in 2017 or an increase of almost 30%. This increase shows that the demand for this equipment is growing. This is due, first of all, to an increase in the production of agricultural products in animal husbandry, which directly depends on the feed preparation technology used, which ensures its quality.

The Russian market is represented by a variety of different types of feed choppers, models differ in power, size, are divided into portable and stationary, vertical and horizontal mixers, and also differ in the performance and the duration of the cycle.

Consider the technical and economic indicators of the main types of food choppers sold in Russia and compare with the indicators of the proposed equipment developed at the Nizhny Novgorod State University of Engineering and Economics.

Table 5 : Comparative analysis of the main domestic brands of animal feed choppers

Name of the chopper	**Manufacturer**	**Price, rub (estimated indicator)**	**Electricity consumption, sq / h (estimated indicator)**	**Netpower, W**	**Weightkg**	**Performance**		**Total score**
						Roots	**Corn**	
KP-03	OOO Technomash, Chelyabinsk	3200 (1)	0,9 (1)	900 (1)	11 (0,72)	900 (1)	300 (0,6)	5,32
Cyclone IZKB-2	OOO Cyclone,St. Petersburg	5690 (0,56)	2, 0 (0,45)	2000 (0,45)	22 (0,36)	400 (0,44)	400 (0,8)	3,06
Optimus 3 in 1	OOO FermerPlus, Miass	6080 (0,52)	1,2 (0,75)	1200 (0,75)	10 (0,9)	280 (0,31)	155 (0,31)	3,54
Niva IK-07U	ZAO Avtomash,Moscow	3200 (1)	0,9 (1)	1100 (0,82)	8 (1)	600 (0,66)	250 (0,5)	5,98
IZK-500 M "Kubanets"	ZAO Kuban Elektromash, Krasnodar region	16500 (0,01)	2,0 (0,45)	2000 (0,45)	50 (0,16)	300 (0,33)	500 (1)	2,4
DKU 03	ZAO Avtomash,Moscow	23000 (0,139)	1,6 (0,56)	1600 (0,56)	45 (0,17)	500 (0,55)	300 (0,6)	3,57

Based on table 2 of the assessment of the total score for each indicator in the context of feed choppers, the advantages of the feed chopper Niva IK 07U are obvious in comparison with analogues. This equipment is preferable to the others at a price of 3200 rubles, because of electricity

consumption. At the same time, with the lowest weight, its useful power amounts to 1100 watts, which is significantly lower than analogues. The total score is 5.98, which is higher than that of analogs by 0.66-3.58 points.

Using benchmarking, which is a way to study the activities of business entities, especially their competitors, in order to identify sources of competitive advantage, increase competitiveness and formulate effective business strategies, the competitive advantages of equipment developed at Nizhny Novgorod State University of Engineering and Economics were determined. It is benchmarking that allows you to develop new strategies for success, based on already gained experience.

We will consider various production lines for feed grinding, including using the Niva IK 07U feed chopper and the feed preparation line developed at the Nizhny Novgorod State University of Engineering and Economics. A comparative analysis of the proposed equipment is presented in table 2.

Table 6: Comparative analysis of the technical and economic efficiency of the feed preparation machines (in 2017 prices)

Indicators		**Carrying amount*B*, RUB (estimated indicator)**	**Weight*M*, kg (estimated)**	**Electricity consumption qE, kW · h / t (estimatedindicator)**	**Productivity$W_{ЭК}$, t / h (estimated indicator)**	**Installed power P, kW (estimated indicator)**	**Occupied area Snom., m^2 (estimated indicator)**	**Totalscore**

	Mixer-fermenter (TL 3)	650000 (1)	1220 (0,95)	1,36 (1)	10 (1)	10 (1)	5,6 (0,7)	5,65

TL1 - traditionalfeedproductionline
TL2 - feed preparation line using the Niva IK 07U feed chopper
TL3 - proposed feed preparation line

Summing up the scores for each presented technological line, we determine the most preferred option.

Table 7: Definitions of the most preferred feed preparation line

	Name	Totalscore
TL1	Traditionalfeedpreparationline	16,44
TL2	Feed preparation line using the Niva IK 07U feed chopper	19,77
TL3	Feed preparation line proposed by Nizhny Novgorod State University of Engineering and Economics	21,61

Based on the presented assessment of the total score for the considered option technological lines of table 7, the most preferred is the proposed technological line for the preparation of feed (TL3).

The total annual cash savings from the fodder preparation line being introduced into production due to changes in product quality and a decrease in energy costs, according to the calculations of scientists from the Nizhny Novgorod State University of Engineering and Economics, will amount to 236 thousand rubles (in 2017 prices), and the payback period will not exceed 4.6 years.

Each enterprise is looking for solutions on how to convince customers to purchase its products, and thereby ensure a safe and stable market position. Satisfying customer expectations is determined by their attitude and preferences. Assessment of customer satisfaction allows you to determine what features should be included in the products and services offered by the company.

The production efficiency of the feed preparation line will directly depend on sales volumes. Therefore, in order to expand sales, it is proposed to organize access to foreign markets with this equipment. To begin, consider the volume of world trade in raw materials for the preparation of feed, as well as ready-made feed for animals. In 2017, according to the estimate of the International Independent Institute of Agrarian Policy, it amounted to about $ 68 billion (Fig. 2).

Figure 2: Structure of the world trade in feed and raw materials for their production in 2017

Analyzing the presented structure, it can be seen that the trade in animal feed occupies the second position and accounts for 37% of the total value of the world trade in feed and raw materials for their production.

Since 2014, there has been a decline in world trade. According to the International Independent Institute of Agrarian Policy, in 2017 the volume of the international feed market amounted to 68 billion dollars, which is 13 billion dollars less than in 2014. The main reason is the growth of national livestock production in many developing countries and, accordingly, an increase in feed demand due to own production. An example is China, for which the development of feed production is one of the national priorities.

Figure 3: Dynamics of the international market of feed and raw materials for its preparation.

The decline in world trade is primarily due to a decrease in exports from countries - leading feed suppliers. Thus, Argentina reduced supplies by 9%, Brazil and the USA - by 3%. In 2017, Russia also reduced this indicator by 8% compared to 2016. At the same time, countries with a stable market and developed processing industry, on the contrary, are increasing exports. Holland increased by 10%, France - by 7%. The record was set by the United Kingdom, which increased exports by 17% in

2017.

Figure 4 : Structure of export of feed and raw materials for their production by countries

Despite the decrease in feed and raw materials for their preparation in Argentina and the United States in 2017, they were the leading exporters of these products. In 2017, Russia was on the 15th place in the world in terms of export of feed and raw materials for their production.

Analyzing the import of feed and raw materials for their preparation in the context of countries, one can single out the highest dynamics in 2017 compared to 2016 for such countries as Thailand, Germany, Holland and Belgium.

Figure 5: The volume and dynamics of imports of feed and raw materials for their production

Analyzing Figure 5, it can be noted that countries such as China, Vietnam, Indonesia do not import feed, and in Mexico and Korea there is a decrease in the import of feed and raw materials for their production - by 4% and 8%, respectively. In our opinion, the absence of imports in a number of countries indicates that in these countries animal feed is produced in sufficient quantities in domestic farms. The development of livestock production in these countries is mainly based on small-scale production, where livestock and milk production are not separated from the production of feed and raw materials for their preparation. Therefore, these farms need to supply modern technological lines

of feed choppers of small capacity at an affordable price, allowing to produce feed for various types of farm animals.

As such equipment, a technological line is proposed for the preparation of dry, loose, wet loose bulk fermented feeds with a capacity of up to 1 ton per hour, which was invented by scientists of the Engineering Institute of the Nizhny Novgorod State University of Engineering and Economics.

Conclusion

Thus, sales channels for these technological lines of feed shredders with a capacity of up to 1 ton per hour should be searched both in Russia and in the markets of China, Vietnam, Indonesia, and Korea, these markets will be more preferable compared to European countries. In order to increase the efficiency of the lines is necessary to organize systematic process control at all stages of production, from reception of raw materials to distribution of finished products, as the quality of prepared feeds depends on the smooth running of all manufacturing operations and components of mechanisms. Technological control should be inextricably linked with sanitary control as an important measure for the prevention of animal diseases. In conditions of high competition, it is necessary to constantly monitor the performance of equipment, improve the technology of feed preparation in order to reduce energy consumption, metal consumption and improve quality characteristics

Abstract

A direct connection between the organization and the repairs of the machine and tractor park (MTP) and the effectiveness of its use requires an appropriate engineering system. The existing engineering services were simplified; the organization of maintenance in most cases was left to chance. However, the physical need of the machine and tractor park remained, since it is objectively inherent in equipment and machines. A systemic contradiction arose between the required maintenance organizations and its actual implementation. Its modernization is an urgent task. In order to increase the efficiency of the organization of technical maintenance of the MTP of agricultural organizations, the system and organizational relationships of repair and maintenance services are investigated. Improving the efficiency of the operation of the MTP can be achieved by modernizing the organization of its maintenance in accordance with the adopted regulatory acts and the proposed structure of the maintenance system.

Keywords: Agriculture, Agricultural Organization, Machine and Tractor Park, Operation, Maintenance, Repair.

Introduction

Numerous studies in the field of agricultural engineering confirm the direct relationship between the organization and repairs of the machine-tractor park (MTP) and the effectiveness of its use. In the previous period of the planned economy, the organization of repairs was regulated in detail by various recommendations, norms and standards, which were canceled during the market period, since privatized agricultural enterprises became private in accordance with the adopted laws on privatization [10], the interference with which is prohibited by law. The existing engineering services were simplified; the organization of maintenance was left to chance. However, the physical need of the MTP remained, since it is objectively inherent in equipment and machines. A systemic

contradiction arose between the required maintenance organizations and its actual implementation. The task of its modernization, provided for by the Decrees of the President of the Russian Federation and Government Decisions, has become urgent.

Materials and Methods

Abstract-logical and structural analysis is applied. In the research, we relied on the basic maintenance concepts, the fundamental works of academicians A.I. Selivanova, M.S. Runchova, V.M. Kryazhkova, A.E. Northern, V.I. Chernoivanov, professors Yu.K. Kirtbay, V.P. Vedenyapina, N.I. Agafonova and others.

Research Results and Discussion

The organization of technical services (maintenance) and repairs depends on the operating conditions and the availability of the park of serviced machines, on the direction of production activity and the size of the agricultural organization, on the natural and climatic conditions. The agricultural enterprises of livestock and grain areas differ significantly from each other in terms of marliness and structure of the MTP, therefore, they have different flows of failures and service requests, a different amount of work per 100 hectares of arable land, which requires a different material and technical base. In this case, the volume of repair and maintenance work differs in the structure of operations and equipment required.

The size factor of agricultural organizations is manifested in a different volume of repair and maintenance work. In large enterprises, the number of machine and tractor parks is higher; travel in the total mileage is greater.

Natural and climatic factors affect the need for repair and maintenance through the duration of use in the field, the duration of the frost period, since low temperatures accelerate the wear of equipment.

Currently, the directions of agricultural activity, the size of the agricultural organization and their share in the structure of agricultural production vary significantly across regions of the Russian Federation. For example, in the Krasnodar territory, substantial areas are occupied under sugar beets, and in the Belgorod Region, the share of forage crops is high. In the Rostov Region, field work begins in March, and in the central black earth zone a month later, therefore, the development of MTP is less, the north the enterprise is located. Different conditions determine the different requirements for the organization of maintenance of the MTP. The above facts became the basis for the study of agricultural enterprises of the Rostov region.

Research Results

Due to the factors of specialization, size and location, the organization of maintenance should be differentiated. We examined the organization of maintenance on the example of the Rostov Region, which is located on an area of 101.0 thousand km², of which 84.3% are agricultural land, 4.64 million hectares of sown area. In 2018, agricultural products of all categories were produced for 255.1 billion rubles, of which 184.3 of crop production and 70.9 billion of livestock were produced. Crop production prevails, exceeds the volume of livestock production by 2.6 times. Agricultural organizations produce 1.6 times more than households, twice as much as peasant farms. The structure of production in 2018 is as follows: grain - 7.07 (64.7%), sunflower seeds - 0, 84 (62.8%), meat - 0, 14 (53.3%) and milk - 0, 13 (11.5%) million tons. Large and medium-sized agricultural organizations, occupying 18.8% of the total number of agricultural producers in 1231 units, produce the majority of crop and livestock production. Based on the structure of the production, the number of MTPs in agricultural organizations is higher. The above factors of production determined the organization of maintenance in agricultural enterprises (AE) of the Rostov region as an object of the study.

We examined the material and technical base of agricultural enterprises and concluded the following: they have machines and equipment worth 50.1 billion rubles, and in the year preceding these studies, the renewal coefficient reached 11.5% with a liquidation coefficient of 2.6%, which indicates the finding in the operation of the MTP for depreciation periods requiring service to a greater extent than new ones. In total, agricultural organizations have 12.4 thousand tractors, 4.6 thousand combine harvesters, 2.2 thousand forage harvesters, agricultural machines and agricultural implements. The presence of a significant number of machines and equipment with a service life of more than 5 years, according to the experience of engineering services, causes an increase in the volume of maintenance and repair, for which it is necessary to have not only the material and technical base, but also an engineering structure that ensures the reliability of the operation of the MTP.

In accordance with GOST R 27.001-2009 [4], it should focus on the flow of service requests and be based on the following principles: the integrated nature of solving the problems of technical operation of the MTP, the distribution of responsibility between engineering and technical workers, the identification and prevention of failures by the application of preventative systems, change management, providing the necessary material and technical base in the form of fixed maintenance points and mobile maintenance units, distribution of responsibilities among engineering personnel technical and technical services, monitoring of maintenance and repair performance and documenting commissioning, technical operation (including maintenance and repair), storage and removal from it, decommissioning. Therefore, the organization of maintenance includes: engineering and technical personnel, material and technical base, information and software for diagnostics, accounting of maintenance and repairs, documentation of technical operation of the MTP (Fig. 1).

Fig. 1: Organization of maintenance and repair in agricultural enterprises in accordance with GOST R 27.001-2009

The functioning of the organization shown in the figure should provide the operating conditions for the operation of machine-tractor units (MTA) and combines, regulated by the operating instructions, thereby ensuring the general functioning conditions of the agro-industrial sectors [11]. The organization must comply with innovative scientific and technical support for crop production [12], ensure that state standards [1, 3] are provided; the claims of machine and equipment owners regarding the inadequate quality of sold or repaired equipment during the warranty period [8] should be considered.

It is known that the organization of maintenance should include not only the formation of the technical policy of the organization, but also the determination of the scope and composition of repair and maintenance work.

The volume and composition of these works is determined by the number and structure of the MTP of the agricultural organization in accordance with the standards.

We calculated the average size of the MTP, which falls on one enterprise. It compiled on tractors - 66, combine harvester - 22, forage machines 10 units. Given the prospect of increasing the number of MTPs, it is necessary to have a central workshop for 75 tractors, which will provide repairs not only to tractors, but also to combine harvesters and agricultural machines. For storing equipment during the non-working period, it is necessary to have a central machine yard and production machine yards in production units.

Conclusion

The effectiveness of the operation of the ICC of agricultural organizations significantly depends on its technical operation, which includes the organization of maintenance and repair. Improving the efficiency of operation of the ICC of agricultural organizations can be achieved by modernizing the organization of its technical maintenance in accordance with the adopted regulatory acts, which provide for the observance of the planned preventive maintenance system, managing the reliability of the ICC through maintenance and its provision, filing claims of the owners of ICCs regarding inadequate quality sold or repaired equipment during the warranty period.

Abstract

Today the country's economy is inextricably linked with the environment. This situation is due to the negative impact of industry on the environment. As a result the population suffers. Reducing environmental pollution is possible only with the use of clean and environmentally friendly sources of energy. Increasingly renewable energy sources have been mentioned as the most economically advantageous but also the most expensive at the initial stage of implementation. In this regard not every organization can use them. The most difficult situation is in agricultural production: due to the seasonality of production, dependence on climatic conditions and disparity in prices this industry is not considered profitable and investment attractive. As a rule, agricultural organizations do not have free cash that could be spent on introducing renewable energy sources thereby bringing the production process closer to more effective results. In this case the main role is given to the state as the main regulator of market relations and the source of financing. It is government subsidies and grants that can support organizations in the transition to the use of renewable energy sources. This requires the development of public financing mechanisms for each industry separately with allowance for the influence of all possible factors.

Keywords: State Support, Agriculture, Efficiency, Agricultural Land, Agro-Industrial Complex, Rational Use of Agricultural Land.

Introduction

The main supplier of food resources in the country is agricultural production. In fact, it is the basis for addressing environmental food production problems. All production in agriculture is inextricably linked to natural processes. Work with natural soil processes occupies a special place in all production activities. Existing agricultural mechanisms are aimed at making a profit while the resource potential is not always rationally used. In the world the first priority is the greening of all production processes including agricultural ones. To do this ecosystems and the rational use of natural resources are being thoroughly studied. It is possible to minimize or even avoid harming the environment through the use of nutrients and water in the soil, the attraction of natural energies, the use of natural pest control in the production process. The goods produced in this way will be safe for humans and more attractive in the food market. The sale of environmentally friendly products will allow you to receive a stable income. Such agricultural production is called sustainable.

Agriculture plays a significant role in meeting the world population food needs. The successful and environmentally friendly development of the country's agro-industrial complex as a whole contributes

to the production of environmentally friendly and healthy products. In the minds of every agricultural commodity producer a production process scheme should be developed aimed at developing sustainable agricultural production. That is why it is important to evaluate all the production processes taking place in the organization. Today every agricultural enterprise actively uses chemicals in fertilizers and pesticides, animal medicines. A lot of fuel is spent on cultivating agricultural land, planting and maintaining crops, and later on for harvesting and delivering the grown products to the final consumer.

Each machine in the processing of fuel emits into the atmosphere about 700 grams of harmful substances per day [1]. Moreover, as a rule, several tractors work in the fields, and during the harvesting season combines and trucks are added to transport products from the fields to warehouses or drying plants. The latter, in turn, work almost continuously spending huge amounts of energy to bring products from the fields to the desired humidity. And this is only a branch of crop production. The livestock industry also spends large amounts of energy and causes significant harm to the environment: the use of equipment for the transport of feed and the export of organic fertilizers, pig farms that pollute nearby lands with ammonia, and the air with unpleasant odors and dust. All this together requires the adoption of significant measures aimed at greening the agriculture of Russia. The use of renewable energy sources in the agro-industrial complex around the world is called environmentally friendly energy agriculture [2].

Authors increasingly use the concept of sustainable agriculture in their works. The main purpose of such way of production is to maximize the use of the land's resource potential but at the same time ensure environmental safety and constant restoration of ecosystem fertility [3, 4, 5, 6]. The principles of sustainable agriculture are:

- competent use of renewable and recyclable resources;
- control over the continuous restoration of natural resources;
- the standard of living in rural areas (it should be increased in order to avoid migration of the population from village to city);
- profitability of the final result (with the competent use of renewable resources);
- rational use of land resources (land is the basis of all agriculture).

The totality of the principles discussed above will ultimately yield an annual increase in the profitability of agricultural production. However, the presence of clearly defined principles does not solve the problem of developing sustainable agricultural production. The main problem is the lack of funds for the purchase of equipment and machinery, as well as technologies for the development of sustainable agricultural production. The country's agro-industrial complex is not able to independently solve these problems. The main sources of funds may be investments but with investment unattractiveness of agricultural production as a whole this source of funds is considered unattainable. In this case the main support should come from the state in the form of subsidies and grants. Acting as a regulator of market relations the state at the legislative level can regulate the introduction of renewable and processed resources in agriculture, designating areas of responsibility for all participants in the production process, contributing to the development of infrastructure near agricultural enterprises.

Materials and Research Methods

The Researchers

Today many scientists have already paid attention to the development of outsourcing in their works: Tanwar Kavinder, Dagar Harender Malik Kapil [3], Helmers Glenn, Hoag Dana [4], Khan Shahrukh [5], Lloyd Pauline [6], Palsova Lucia [7], Gamulescu Oliviu-Mihnea, Rosca Sebastian, Leba Monica, Ionica Andreea [8], Kiseleva S.P. [9], Столярова, М. А. [10].

Information Research Base

The basis for the study is the work of both domestic and foreign authors. In their writings they reveal the results of theoretical and practical research in the field of state support for sustainable agriculture in Russia. These questions are raised in the materials of scientific conferences, articles in scientific journals, dissertations, monographs.

Method

Different approaches and methods are used in research, such as abstract and logical, monographic, comparison method.

Research results and discussion

Condition of agricultural land in Russia

The economic development of any agricultural region directly depends on its land and resource potential. Despite all the achievements of science and technology agricultural production involves a high risk. It is due to biological and climatic factors that have a negative impact on crop yields, reducing the economic performance of the organization. 10% of all arable land in the world is in Russia. According to the 2016 census 44% of farmland in Russia is not used but the area of arable land is increasing annually [11].

In order to control the use of agricultural land a Federal Fund for the Redistribution of Land has been created. According to Rule 80 of the Land Code of the Russian Federation this fund includes lands of federal and municipal property, ownerless plots and territories seized from private owners [12].

The work of this fund contributes to the coverage of all agricultural lands with their further involvement in agricultural circulation but does not guarantee that in the coming years all these lands will begin to work. There are many problems that slow down the process of putting these lands into agricultural circulation. Firstly, “waste” lands require additional costs to bring them to a suitable state. These lands are overgrown with forest or shrubs, depleted and polluted. Secondly, they are far from roads, settlements, which increases the cost of transporting equipment and labor. Thirdly, the quality of these lands may not meet the requirements for growing crops as a result of which costs arise to bring the soil balance to an acceptable level. And of course, a special place is given to legislation, which often contradicts itself and does not contribute to the development of land relations. This situation does not contribute to the active involvement of agricultural land in the turnover although the creation of a land redistribution fund is already a big step in this direction (Fig 1).

Fig.1: Change in land area of the redistribution fund, agricultural land in its composition, including arable land (thousand ha) [13]

In the process of its activities the fund carries out work on the transfer of forest land from agricultural organizations to the management of forestry enterprises, and also accepts land on a voluntary basis from agricultural organizations with unsatisfactory economic conditions.

Rational use of Agricultural Land

The next step should be monitoring the quality of agricultural land. Agricultural land should not only be involved in agricultural circulation but also used in it in such a way as not to lose its beneficial properties. To achieve this goal each agricultural producer must adhere to a single methodology for the rational use of farmland, which, unfortunately, has not yet been developed.

Europe is also concerned about the state of agricultural land. In recent years there has been a significant increase in soil degradation processes which will only increase annually if no action is taken. As a rule the degradation of agricultural land is caused by human influence, the content of organic substances in the soil is increasingly reduced and more often it is subject to pollution [7].

One of the solutions to the problem of rational use of agricultural land is the use of precision farming. The implementation of precision farming has become available due to the development of scientific and technological progress. Devices have been developed for assessing the state of soil, soil moisture, microclimate [8].

The use of precision farming is possible with the appropriate equipment and technologies, while in most agricultural organizations the equipment is not only worn out morally, but also physically so much that more funds and resources are spent on processing a unit of land than planned. And we even do not mention the damage done by these outdated machines to the environment.

Rational land use in agriculture depends not only, and not so much on internal factors as on external ones. Of course a lot depends on how competent a leader is at the head of the organization but even the most advanced leader is not able to influence conflicting legislation, the constantly growing interest on loans, prices for fuel, agricultural machinery, fertilizers, animal feed. All this together contributes to

the fact that all actions are aimed at surviving, and issues of improving the environmental status of the organization as a whole are fading into the background.

Many devices are currently available and used to collect data or provide information in the implementation of the precision farming project. These devices can evaluate soil condition , for example : Arent soil application

measure electrical conductivity (EC), e.g. radiometric sensors, and soil moisture give information about the weather and microclimate (thermometer, hygrometer etc.). Special meaning has attached to sensors developed in Quantitative physiological state from cultures (Senso nitrogen RS). These sensors contribute in the imaging using remote sensing [1]. Real-time and worldwide monitoring of agricultural vegetation includes processing a large volume of spatial data ranging from weather data in satellite image and enhancement Global plant growing. AGRIFISH analysts work primarily for estimating and interpreting spatial datasets, are also involved in the purchase, storage and redistribution of them. Together with foreign partners have developed large geographic databases and according to INSPIRE (http://inspire.jrc.it). paying attention to п

Legislative framework for rational land use

The Land Code of the Russian Federation is the main document regulating relations in the field of land resources of the country. According to the Land Code “Agricultural lands are recognized as lands located outside the boundaries of a settlement and provided for agricultural needs, as well as intended for these purposes.” The concept of rational use of agricultural lands is also reflected in the Land Code of the Russian Federation [14]. There is no exact concept of "rational use of land" as such in the legislation therefore there is no obligation for the right holders to rationally use land. But according to Rule 12 of the Land Code of the Russian Federation the rational use of land is considered as land protection: “The goals of land protection are the prevention and elimination of pollution, depletion, degradation, damage, destruction of lands and soils and other negative impacts on lands and soils, as well as ensuring the rational use of lands including for restoration of soil fertility on agricultural lands and land improvement”[14]. It turns out that the owners of land including agricultural land must take care of protecting their land from pollution, depletion, degradation, etc. The absence of clearly established requirements for the rational use of land entails many difficulties in holding to account for violation of land legislation, primarily agricultural land.

Over the past year the government has begun the development of several bills that will simplify the withdrawal of ownerless land and agricultural land not used for its intended purpose. The issue of introducing fertility rates and passports for each agricultural plot is being considered. It was proposed to strengthen state control over the state of agricultural lands and soil fertility [15].

The Ministry of Economic Development has also developed two bills that spell out the mechanism for withdrawing private land plots if their owners do not comply with fire safety standards during their operation. The bill does not spell specific violations for which you can withdraw the site. However, the authors of the document cited examples of violations in the synthesis report - “burning of crop residues, overgrowing of land with weeds, accumulation of household waste” [16].

In February 2020, a new bill enters into force, the purpose of which is to establish a uniform procedure for determining the types of permitted use of land plots, reducing the number of disputes which arise when determining the types of permitted use of land plots when they are provided and formed. It is expected that the bill will supplement the Land Code with a chapter that regulates on a systematic and integrated basis the issues of establishing and changing the types of permitted use of land. The bill provides:

- definition of the concept “permitted use of the land plot”, its types (main, auxiliary, conditionally permitted);
- the establishment of a ban for tenants and land users to change the types of permitted use of land;
- determination of the procedure for termination of rights to land plots;

- clarification of certain provisions of the Land Code and other federal laws regarding the formation and provision of land in state or municipal ownership [17].

The Ministry of Agriculture has developed a state program for the effective involvement of agricultural land in the circulation and development of the reclamation complex. The main goal of the program is the collection and systematization of data on agricultural land. It is assumed that during the implementation of the program land management schemes of 44 million hectares of agricultural land of municipalities will be approved. In addition, involvement in the turnover of at least 12 million hectares by 2030 with an increase in reclaimed land by at least 1.6 million hectares compared to the level of 2018. It is planned that the program will enter into force in March 2020 and will be implemented until 2030. Its value exceeds 1.41 trillion rubles, including 887.9 billion rubles from the federal budget [18].

The federal scientific and technical program aimed at the development of agriculture for 2017-2025 considers the development of the agro-industrial complex with regard to the use of seeds of new domestic varieties and breeding products (material), production technologies for high-quality feed, feed additives for animals and medicines for veterinary use , pesticides and agrochemicals of biological origin, processing and storage of agricultural products, raw materials and food, modern media TV diagnostics, methods of quality control of agricultural products, raw materials and food, and examination of genetic material. One of the objectives of this program is to increase the investment attractiveness of the agricultural sector [19].

Investment attractiveness of agricultural land

Due to the peculiarities of the production process and its dependence on climatic conditions, the agro-industrial complex is an unattractive object for investment. But given the fact that Russia strive for an innovative type of development, the current situation can be changed. The production process in agriculture is based on the use of land. The problem of its most effective and rational use in the new conditions is directly related to increasing their investment attractiveness for all forms of capital, which is ready to take part in innovative projects. Considering land resources from this point of view, it turns out that they act both as an object of investment and as an integral part of the mechanism for attracting capital to the innovation sphere. Upon entering the Russian land market, both domestic and foreign investors are faced with a number of problems hindering their active work:

- the level of protection of land property rights is low;
- the activities of state authorities, municipal bodies in terms of land management is ineffective;
- the level of land development in the country is relatively low, mainly due to poor transport infrastructure.

Involving the agro-industrial complex in innovative projects on sustainable agricultural development will attract more investors. The use of renewable energy sources in the agro-industrial complex, as well as throughout the world, will lead Russian agriculture to environmentally friendly energy agriculture. The effectiveness of agriculture is significantly affected by the investment attractiveness of agricultural land use, depending on a number of factors (Fig 2).

The influence of objective and subjective factors in different agricultural areas is not the same. Fertile soils look more investment attractive than soils with less fertility, since at the same cost the yield from 1 ha of fertile soils will be higher. However, on infertile soils, innovative technologies can be used in conjunction with competent management, which can level the chances or even increase the investment attractiveness of a less fertile land. A focus on the sustainable development of agricultural production contributes to the development of not only the agricultural organization itself but also the infrastructure around it. And support from the state will contribute to the development of the agricultural organization in the innovation field. In any case, to attract investment it is necessary to make efforts, work both on the object of investment itself (agricultural land), and on the entire agricultural production as a whole. Only a set of measures, together with support from the state, will achieve the desired results.

Fig. 2: Investment Attractiveness of Agricultural Land Use

State support for rational land use

The requirement for the protection of agricultural land is an integral part of the land legislation of the USA, Germany, Poland, Australia, Czech Republic, Portugal, Switzerland, Canada. In the United States, they are pursuing a policy of supporting agricultural producers and protecting soils and rational use of agricultural land, controlling the targeted use of land in agricultural zones and enforcing a farm protection law. The Swedish government has implemented a series of programs to improve the environmental efficiency of agricultural land use. In accordance with the approved programs, peasants are provided with certain financial compensation for not plowing land near rivers, ponds and forests, for the construction of dams, and conservation of swamps. All this contributes to an increase in the area of ecologically clean lands. Financial investments in the agricultural sector in developed countries are 1.5–2 times higher than the market value of products. In foreign countries there is a division of the land fund into three types: land of settlements, agricultural land, and environmental land [9].

In Vietnam, the mechanism of state administration of land in general and agriculture in particular includes:

- administrative mechanism - the direct impact of the state on an object related to agricultural land through the use of administrative methods and decisions of a mandatory nature, binding;
- economic mechanism - the indirect impact of the state through economic interests on an object using agricultural land, so that the latter independently chooses the most efficient method of production;
- a mechanism for training and disseminating knowledge - an impact on the views of land users in order to increase their self-awareness in the work on the regulation and use of agricultural land [9].

In Europe, there are programs that support rural development through:

- soft loans (lower interest rates, easier approval of loans and the adequacy of the size and purpose of funds),
- tax system (real rates and base, as well as the introduction of benefits),

- subsidies (food prices, insurance premiums, etc.).

In highly developed countries, the state affects four main areas:
- determines the appropriate price policy for agricultural products;
- determines the measures of subsidizing costs for specific types of costs;
- determines adequate models for financing agricultural production and stocks;
- subsidizes the export of agricultural products [20].

State support of various countries comes down to the mechanism of subsidizing specific objects. The very mechanisms of distribution of subsidies for each country are unique for several reasons. Agricultural land, acting as an object of subsidies, should be evaluated not so much in terms of area as in terms of their quality use. An indicator for determining the amount of subsidies from the federal budget should be a differentiated approach, focusing on land efficiency and taking into account its quality.

The efficiency of agricultural organizations depends on the quantity and quality of the resources at their disposal, but even the most equipped and efficient agricultural enterprises will not be able to function for a long time if they do not strive to constantly modernize their resources. A balance is needed for the development of agribusiness and ecology [21].

To assess the quality of a unit of land area, M. A. Stolyarova proposes to use the efficiency of a hectare according to the proposed author's formula, and further recalculation of the area of agricultural land in conventional cadastral hectares based on the total soil score will make it possible to equalize land of different quality for conducting objective and real assessment of the effectiveness of its use. When comparing the actual management indicators based on the physical area of land with the calculated data on the rate of hectare efficiency, one can determine how efficiently and rationally agricultural land is used [10].

The algorithm for subsidizing agricultural organizations for the rational use of agricultural land with regard to the rate of hectare efficiency can have the following form (Fig 3).

1. Federal budget
Budget appropriations for state support for the rational use of agricultural land
2. Ministry of Agriculture of Russia
Distribution and provision of subsidies from the federal budget to the budgets of the constituent entities of the Russian Federation
3. Management body of the agro-industrial complex of a constituent entity of the Russian Federation
Formation of a request (terms of reference) for a subsidy for the restoration of soil fertility with the application of the necessary documents in accordance with the list approved by the regulatory legal acts of the subject of the Russian Federation
4. Department of Agriculture of municipalities
Formation of a request (terms of reference) for a subsidy for soil fertility restoration with the application of the necessary documents in accordance with the list approved by regulatory acts of the constituent entity of the Russian Federation among agricultural producers of the municipality
5. Agricultural producer
-submission to the governing body of the agro-industrial complex of the constituent entity of the Russian Federation an application for a subsidy for the restoration of soil fertility with the necessary documents in accordance with the list of approved regulatory legal acts of the constituent entity of the Russian Federation
6. Department of Agriculture of municipalities
Collection and transmission of applications to the regional governing body of the agro-industrial complex
7. Department of Agriculture of municipalities
- consideration of documents (applications of agricultural producers).

At the stage of consideration of documents, an assessment is made of the quality of the land claiming a subsidy taking into account the rate of hectare efficiency. In fact, the amount of the subsidy claimed by the organization is multiplied by the ratio of the hectare efficiency to the average district indicator - decision to submit a subsidy or a reasoned refusal - transfer of subsidies - reporting to the Ministry of Agriculture of the Russian Federation

Source: Compiled by the author.

Fig. 3: Algorithm for subsidizing agricultural organizations for the rational use of agricultural land

Subsidizing of agricultural land should be based on the quality of use of a unit of land. Only in this case can a continuous process of reproduction of soil fertility be achieved. It is the reproduction of soil fertility that is the basis of green agriculture.

Conclusion

As a rule, land use in various countries is diverse and has its own specifics. Therefore, for the rational use of agricultural land, the experience of a single country cannot be applied. It is necessary to approach in a balanced way, competently combining state and market mechanisms for managing land resources, protecting highly productive agricultural zones and supporting low-productive ones, controlling soil pollution by harmful industrial waste and developing a system of fines for soil pollution by waste, developing economic incentives for improving soil quality. It is government support that plays a special role in the development of environmentally friendly agriculture.

Abstract

In the conditions of the global changes caused by an increase in a role of information as a production factor, universal application of IT technologies, one of necessary conditions of effective functioning of any economic sphere is the knowledge of laws of its functioning. In this research laws of short-term dynamics of the cost expenses in the agricultural organizations of the Nizhny Novgorod Region of the Russian Federation engaged in production of one type of agricultural product - grain are investigated. Various indicators of the amount of economic resources at the disposal of the organization, their ratios and financial results of a production activity were considered as the influencing factors. During research it was established that different sets of the influencing variables work for different agricultural organizations (broken down into 4 groups according to their size – ultra-small, small, mid-sized, large as to their production volume). For each group the corresponding equations were formulated, the statistical analysis of the importance of coefficients was carried out, and conclusions were drawn on character and degree of regressor influence on dynamics of costs of production. During research previously expressed assumption that different patterns of the reproductive process are identified for different sized agricultural organizations and further directions for the research are defined.

Keywords: Reproduction, Economic Resource, Regression Equation, Agricultural Organization, Financial Results

Introduction

The scientific mainstream, like most of the world's phenomena, is cyclical. The first studies on ecoomics mostly described agricultural economics, or placed a very large emphasis on agricultural production processes, processes of agricultural products sale, exchange, etc. The development of the economy as a system had logically led to an increase in the number of relevant studies and a change in their focus. Thus, at the beginning of the XXI century in the world economy researchers started to focus on other important issues. However, as recent review studies show, for example, (Fitz-koch et all, 2017), this trend has changed in recent years. Currently, there are a number of works that highlight issues within the competence of agricultural economics. (Czyzewski, Matuszczak, 2016) discusses a new theory of rent, (Chamberlain, Anseeuw, 2019) considers the theory of cooperation, (Dias et all, 2019; Lans, Seuneke, Klerkx, 2017; Shane, Venkataraman, 2000) reinterprete the concept of agricultural entrepreneurship and examine the environmental impact of agricultural production, (Britz et all, 2012) studies the landscape and general issues of land use efficiency, (Daugstad, Rønningen, Skar, 2006) consider the conservation of biodiversity and the preservation of cultural research through land use, (Meador, Skerratt, 2017) studies the theory of the rural development.

All this is superimposed on the widespread use of network-centric systems in agriculture, the emergence of big data in this industry, the need to adapt them to improve the efficiency of agricultural systems (Bessler et all).

Under these conditions, a revision of theories of the content and essence of economic resources is inevitable. At present, it can be noted that these attempts are actively undertaken by Russian and foreign researchers, in particular, the theory of reproduction of agricultural lands (Stevens, 2018; Aparin, 2018), the theory of reproduction of fixed capital (Zolotareva et all, 2018), and the theory of labor resources are being modified (Maltseva , 2017).

Rethinking the essence of production factors and the structure of social relations due to the virtualization of society and the economy leads to attempts to rethink the classical theory of reproduction by K. Marx (Burkett, 2004; Christophers, 2014).

At the same time, it is worth noting the fragmentary nature of these attempts. According to the authors, today there is a need to rethink individual elements and expand the provisions of reproduction theories as applied to agriculture, which, in terms of access to big data and as part of rethinking the essence of economic resources, will lead to identification of the corresponding patterns of changes in the number of resources in agricultural systems of various levels, which will significantly increase economic system performance (Shamin et all, 2019)

Materials and Methods

The classical interpretation of the reproduction process involves the study of economic processes at only one level - in kind or in value (as in works, for example (Adadimova, 2017; Ivanova, 2017)). However, as noted in (Pronyaeva, 2016), the modern interpretation of the reproduction process involves the study of reproduction at two levels - value and natural. At the cost level, reproduction processes are expressed in the change in production costs, which are based on the value of the fixed, working capital involved in the agricultural production process.

Currently, according to the authors, the consideration of the cost level of the reproduction process is relevant for two reasons:

- according to generally accepted approaches, the assessment of the state of the economy as a whole and the identification of signs of crisis in the economic system of any level occurs precisely on the basis of the analysis of cost indicators;

- there are objective difficulties in quantifying the properties of economic resources at the natural level (for example, currently there are no generally accepted methods for assessing the parameters of human capital and information as economic resources).

Historically, most research on the reproductive process was related to macroeconomics. However, the emergence of a large amount of information on the activities of individual organizations and other subjects of microeconomics allows us to focus on the processes of reproduction in microeconomics, at the level of individual agricultural organizations in order to identify relevant patterns.

The current specifics of agricultural production, which consists in increasing the number of types of agricultural products produced by an individual economic entity, leads to a complication of the structure of reproduction processes. Proceeding from this, the authors decided to distinguish a separate category of agricultural producers - those organizations that are engaged in the production of only one type of agricultural product. A preliminary analysis showed that in the study pool among the producers of mono agricultural products, grain producing organizations dominate (more than 90%). Thus, based on the foregoing, the following purpose of the study can be formulated: to identify the patterns of cost reproduction in agricultural organizations of the Nizhny Novgorod region of the Russian Federation that produce only grain.

During the study, the authors put forward several assumptions:

1. For different-sized organizations, there are different patterns of reproduction (for example, this assumption was proved by a number of foreign scientists (Gabre-Madhin, Haggblade, 2004; Ahmed, 2004; Mignouna, 2011) for the process of introducing innovations in agricultural production;
2. The direction of the reproduction process is influenced by the number of economic resources, their correlation, financial results of the organization and the effectiveness of its activities;

When selecting agricultural organizations and information for research, the authors were guided by the following theses:

- The cycle of the reproduction process was taken equal to 1 year. Thus, the reproduction processes in agricultural organizations of the Nizhny Novgorod region in 2016-2017 were analyzed.
- The key indicator (dependent variable), reflecting the dynamics of reproduction processes, was the indicator of the growth rate of production costs of an agricultural organization;
- The following indicators were taken as influencing factors (independent variables):

1. The number of manufactured products, centner
2. Amount of land, ha
3. Number of employees
4. Power of fixed assets, hp
5. Per 1 agricultural worker, ha
6. Amount of land cultivated by 1 hp, ha
7. Power of the machine-tractor fleet (MTP) per 1 worker, hp
8. Profit, thousand rubles
9. Profitability,%
10. Profit per unit of output, rubles / centner

- The indicator reflecting the size of the agricultural organization was the amount of grain produced in centners.

The sources of information were the data of the annual reporting of agricultural organizations of the Nizhny Novgorod region for 2016-2017.

The information base for the research was formed according to the data of organizations which met the following criteria:

- for 2 years, the agricultural organization was engaged in the production of grain only;
- none of the indicators considered above is equal to 0 or undefined;

Based on these criteria, 51 agricultural organizations were selected.

In dynamics over the past six years, the area of arable land decreased by 0.02% and in 2017 amounted to 2035.7 thousand ha. As compared to 1990, the area of arable land decreased by 9.53%, or by 214.4 thousand ha.

In general, we can state the general stability of the land fund used by agricultural organizations of the region in their activities During this period, the number of workers employed in agricultural production decreased and in 2017 amounted to 65.2 thousand people, which is 35 thousand people less than in 2010, and 40.8 thousand people. less than the 1990 level.

An analysis of the dynamics of the cattle amount indicates that the trend of a decrease in the number of livestock in agricultural organizations of the Nizhny Novgorod region continues. From 2009 to 2017 total cattle amount decreased by 20%.

The decrease in cattle amount significantly reduces the production potential of the region. However, means of labor are also very important in the production process. One of the means of labor in agriculture is the basic production assets, which include machine and tractor fleet, which at the end of 2017 in agricultural organizations of the Nizhny Novgorod Region consisted of 4443 tractors, 1161 combine harvesters, 431 forage harvesters, 152 potato harvesters with a total capacity of 1857, 6 thousand hp. For 2008 - 2017 the number of tractors decreased by almost half (for the period 2013 - 2017 by a quarter), combine harvesters - by 44% (the peak of decline fell on the period 2008 - 2013), forage harvesters - by a third, potato harvesters - by a quarter. This led to a reduction in the total capacity of mobile equipment by 33% (Shamin, 2015; Shamin, Vasil'ev, 2016; Shamin. Shamin, 2015).

Next, we turn directly to the characteristics of agricultural organizations of the Nizhny Novgorod region engaged in grain production in comparison with the total population (table 1).

Table 1: General characteristic of the organizations producing grain of the Nizhny Novgorod Region

Indicator	2016	2017	Deviation
Total of the agricultural organizations, units	499	452	-47
Total of the agricultural organizations which are engaged in production of grain, units	383	358	-25
Total of the produced grain in all agricultural organizations, one million c	9.413	11.027	1.614
General balanced financial result of all organizations, billion rubles	1.491	2.889	1.398
The general balanced financial result of all organizations from production of grain, million rubles	595.9	12.1	-583.8
The general balanced financial result of the organizations which are engaged in production of grain, billion rubles	1.671	1.775	0.104
Average profitability of the agricultural organizations of the Nizhny Novgorod Region, %	14.5	23.3	8.8
Average profitability of the agricultural organizations of the Nizhny Novgorod Region making grain, %	-2.9	10.0	12.9
Total of the produced grain the agricultural organizations which are engaged only in production of grain, in one million c	1.452	1.915	0.463
The general balanced financial result of the organizations which are engaged in production only of grain, billion rubles	110.38	-26.45	-136.83
Average profitability of the agricultural organizations of the Nizhny Novgorod Region making only grain, %	-6.26	-6.49	-0.23

Thus, for the period 2016-2017 we have recorded:

- a general decrease in the number of agricultural organizations did not lead to a decrease in grain production;
- the general increase in the profitability and efficiency of agricultural production in the region over the period under review has formed two various trends. On the one hand, organizations that grow not

only grain, but also engage in other sectors of agriculture, showed an increase in the overall balanced financial result, profitability, and production volumes. On the other hand, organizations engaged in the production of grain alone showed a significant increase in production volumes (31%, a total increase in the total volume of produced grain - 17%), but showed a decrease in profitability and a negative overall balanced financial result.

The dynamics of the amount of resources for selected agricultural organizations of the studied region is shown in table 2.

Table 2: Quantity of resources in the agricultural organizations of the Nizhny Novgorod Region which are engaged in production only of grain

Indicator	2016	2017	Deviation
Costs of production, billion rubles	1.21	1.47	0.26
Area of agricultural grounds, one thousand hectares	94.94	113.52	18.58
Number of workers	695	926	231
Power of fixed assets, one thousand h.p.	142.8	179.1	36.3
General fund of compensation, million rubles	130.9	192.3	61.4
Fixed capital, billion rubles	2.21	3.19	0.98

A significant increase in the number of resources was recorded in agricultural organizations engaged in the production of only grain for the study period: production costs increased by 21%, sown area - by 19.5%, number of employees - by 33%, fixed assets - by 25 %, wage fund - by 47%, the cost of fixed capital - by 44%. This indicates positive dynamics of the development of these agricultural organizations.

At the same time, it is obvious that not all the considered organizations showed exclusively positive trends. The structure of the totalpopulation of the studied organizations according to the dynamics of the amount of resources is presented in Figure 1.

Fig. 1: Structure of the organizations making grain of the Nizhny Novgorod Region on dynamics of volumes of resources for the considered period

(symbols: 1 - Costs of production, billion rubles; 2 - Area of agricultural grounds, one thousand hectares; 3 - The number of workers in the organization, people; 4 - Power of fixed assets, one thousand h.p.)

The share of organizations that increased production costs and agricultural land area exceeds the same indicator for organizations that reduced production costs and agricultural land area; however, the opposite is observed in terms of the number of employees in the organization and the capacity of fixed assets, which, against the background of a general increase in their values, indicates a significant increase in the differentiation of the organizations under study in terms of the volume of these resources.

Results

At the first stage of the study of the laws of reproduction, a table of correlations between reproduction indicators at the cost and natural levels was compiled (table 3). All calculations were performed using the STATISTICA 10 program.

Table 3: Correlations of indicators of reproduction of resources of the agricultural organizations at the cost and natural levels

Indicators	Reproduction of costs	Reproduction of the land	Reproduction of workers	Reproduction of power
Reproduction of costs	1.000	0.774	0.342	0.447
Reproduction of the land	0.774	1.000	0.195	0.283
Reproduction of workers	0.342	0.195	1.000	0.081
Reproduction of power of equipment	0.447	0.283	0.081	1.000

The most correlated among themselves are indicators of land reproduction and production costs, which is logical, since it is land that is the basis of agricultural production. No significant relationships were found between the remaining indicators.

Thus, we can conclude that a separate study of the laws of cost reproduction is logical, since it is highly independent of reproduction at a natural level.

Table 4: Correlations of reproduction of resources of the agricultural organizations with quantity, structure of their resources, and also with financial results of activity of the organization

Indicator	Correlation level with reproduction of expenses
Quantity of the made production, c	0.006
Volume of the land, hectare	-0.050
Number of workers, people	-0.046
Power of fixed assets, h.p.	-0.074
The hectare	-0.006
1 h.p. of the earth, hectare	-0.083
The power of MTP falling on 1 worker, h.p.	0.028
Profit, thousand rubles	-0.022
Profitability, %	0.139
Profit on unit of the made production, rub/c	-0.034

An analysis of the correlations of reproduction costs with the selected indicators reflecting the size of the agricultural organization, the amount of resources in it, their ratio, financial performance, showed

the absence of strong correlations. Consequently, a deeper study of correlations depending on the size of the organization is needed.

As the main indicator characterizing the size of the organization, the authors decided to use the volume of grain produced. This is because the adopted dependent variable (the growth rate of production costs) is cost-based, and the order of its magnitude is determined precisely by the volume of output, regardless of the type of production (extensive or intensive). In addition, since reproduction is a controlled process, including making managerial decisions, the difference in thinking between the heads of large and small agricultural organizations may appear in the dependencies studied, and the volume of manufactured products is traditionally considered the criterion for determining the size of an organization in the community of agricultural company leaders.

Subsequently, the following classification was used to draw conclusions:

- organizations with a production volume of up to 10,000 c are considered ultra small in this study;
- organizations with a production volume of 10,000 to 20,000 c are considered small in this study;
- organizations with a production volume of 20,000 to 40,000 c are considered medium-sized in this study;
- organizations with a production volume of 40,000 to 60,000 are considered large in this study.

Accordingly, this allowed us to formulate the following conclusions:

- a significant correlation of the volume of land at the disposal of the agricultural organization and the reproduction of costs is observed in ultra-small organizations producing about 5,000 centners (-0.41);
- a significant correlation of the number of workers at the disposal of the agricultural organization and the reproduction of costs is observed in ultra-small organizations producing about 1000 centners of grain (-0.5);
- a significant correlation of the capacity of the machine and tractor fleet at the disposal of the agricultural organization and cost reproduction is observed in ultra-small organizations producing about 1000 centners of grain (-0.63);
- a significant correlation of the amount of agricultural land per 1 worker and cost reproduction is observed in ultra-small organizations (-0.45);
- significant correlation of the cultivated amount of land by 1 hp and cost reproduction is observed in large organizations (-0.37);
- a significant correlation of machine and tractor fleet capacity per 1 employee and cost reproduction is observed in ultra-small organizations (-0.67);
- a significant correlation of the organization's profit indicator and cost reproduction is observed in small organizations (-0.41);
- a significant correlation of the profitability of organizations and cost reproduction is observed in ultra-small organizations (0.45) and medium-sized organizations (-0.44);
- a significant correlation of the organization's profit indicator per unit of output and cost reproduction is observed in medium-sized organizations (-0.5);

Next, 6 regression equations were formulated for different groups of agricultural organizations in terms of output. In models (1) - (6), the following conventions are used:

y - Cost reproduction rate
v_1 - The amount of land, ha
v_2 - Number of employees, people
v_3- Power of fixed assets, hp
v_4 - Per 1 agricultural worker, ha
v_5 - The amount of land cultivated by 1 hp, ha
v_6 - The power of the machine-tractor fleet per 1 worker, hp
v_7 - Profit, thousand rubles
v_8- Profitability,%
v_9 - Profit per unit of output, rubles / c

For ultra-small organizations, three regression equations were formulated.

It is revealed that organizations with a production of up to 1,500 centners have the patterns of reproduction described by the formula

$$y = a_1 + a_2 v_3 + a_3 {v_3}^2 + a_4 {v_4}^2 + a_5 v_3 v_6 + a_6 v_4 v_6 \quad (1)$$

The values of the coefficients of the model and their statistical characteristics are presented in table 5.

Table 5: Values of coefficients of model (1) and characteristic of their importance

Coefficient	a_1	a_2	a_3	a_4	a_5	a_6
Value of coefficient	1.14E+00	-2.03E-04	1.00E-06	2.00E-06	-3.00E-06	7.00E-06
Standard error of coefficient	5.80E-02	9.30E-05	0.00E+00	1.00E-06	1.00E-06	2.00E-06
t-value	1.96E+01	-2.17E+00	3.43E+00	2.56E+00	-3.77E+00	3.22E+00
Lower 95% value of coefficient	1.01E+00	-4.18E-04	0.00E+00	0.00E+00	-5.00E-06	2.00E-06
Top 95% value of coefficient	1.27E+00	1.30E-05	1.00E-06	3.00E-06	-1.00E-06	1.20E-05
p-value	0.00E+00	6.18E-02	9.00E-03	3.38E-02	5.45E-03	1.22E-02

Equation (1) is statistically significant, the determination coefficient was 83.535%. An analysis of the significance of the coefficients of equation (1) showed that at a 5% significance level, all model coefficients are significant, except for the coefficient a2.

Organizations with a production volume of 1,500 to 4,000 centners are subject to the laws of reproduction described by the formula

$$y = a_1 v_2^3 + a_2 v_2^2 + a_3 v_2 + a_4 v_8^3 + a_5 v_8^2 + a_6 v_8 + a_7 v_2 v_8 + a_8 {v_2}^2 v_8 + a_9 v_2 {v_8}^2 + a_{10} {v_2}^2 {v_8}^2 + a_{11} \quad (2)$$

The values of the coefficients of the model and their statistical characteristics are presented in table 6.

Table 6: Values of coefficients of model (2) and characteristic of their importance

Coefficient	a_1	a_2	a_3	a_4	a_5	a_6	a_7	a_8	a_9	a_{10}	a_{11}
Value of coefficient	-0.26	1.85	-1.94	-454.99	-5166.38	993.03	-537.54	67.39	2942.92	-388.29	-2.67
Standard error of coefficient	0.11	0.71	0.66	199.73	2183.81	413.08	225.74	28.47	1251.21	165.60	1.82
t-value	-2.48	2.60	-2.96	-2.28	-2.37	2.40	-2.38	2.37	2.35	-2.34	-1.47
Lower 95% value of coefficient	-0.60	-0.42	-4.03	-1090.62	-12116.24	-321.56	-1255.96	-23.23	-1038.98	-915.29	-8.47
Top 95% value of coefficient	0.08	4.12	0.14	180.64	1783.47	2307.63	180.88	158.01	6924.83	138.71	3.13
p-value	0.09	0.08	0.06	0.11	0.10	0.10	0.10	0.10	0.10	0.10	0.24

Equation (2) is statistically significant, the coefficient of determination was 84.386%. Analysis of the significance of the coefficients of equation (2) showed that at a 5% level of significance all the coefficients of the model are not significant, which indicates the need to include other variables.

Organizations with a production volume of 4,000 to 10,000 centners are subject to the laws of reproduction described by the formula

$$y = a_1 + a_2 v_1 + a_3 v_1^2 + \frac{a_4}{v_8} + \frac{a_5}{v_8^2} \quad (3)$$

The values of the coefficients of the model and their statistical characteristics are presented in table 7.

Table 7: Values of coefficients of model (3) and characteristic of their importance

Coefficient	**a_1**	**a_2**	**a_3**	**a_4**	**a_5**
Value of coefficient	2.027640	-0.004361	0.000003	0.065813	-0.000967
Standard error of coefficient	0.708850	0.002202	0.000002	0.035432	0.000574
t-value	2.860465	-1.980529	2.025699	1.857421	-1.684891
Lower 95% value of coefficient	0.424110	-0.009342	0.000000	-0.014341	-0.002264
Top 95% value of coefficient	3.631169	0.000620	0.000007	0.145967	0.000331
p-value	0.018766	0.078992	0.073443	0.096208	0.126293

Equation (3) is statistically significant, the determination coefficient was 52.517%. An analysis of the significance of the coefficients of equation (3) showed that at a 5% significance level, only the free term of the equation is significant, which indicates the need to include other variables in the model
For small agricultural organizations, the pattern of reproduction is described by the formula

$$y = a_1 + a_2 v_7 v_2 + a_3 v_7^2 \quad (4)$$

The values of the coefficients of the model and their statistical characteristics are presented in table 8.

Table 8: Values of coefficients of model (4) and characteristic of their importance

Coefficient	**a_1**	**a_2**	**a_3**
Value of coefficient	1.58669902	-0.00002324	-0.00000004
Standard error of coefficient	0.22014160	0.00000834	0.00000002
t-value	7.20762927	-2.78746817	-2.34210580
Lower 95% value of coefficient	1.10705168	-0.00004140	-0.00000008
Top 95% value of coefficient	2.06634635	-0.00000507	0.00000000
p-value	0.00001075	0.01642145	0.03724294

Equation (4) is statistically significant, the determination coefficient was 48.475%. An analysis of the significance of the coefficients of equation (4) showed that at a 5% significance level, all model coefficients are significant.

For medium-sized agricultural organizations, the pattern of reproduction is estimated by the formula

$$y = a_1 + a_2 v_8^2 + a_3 v_9^2 \quad (5)$$

The values of the coefficients of the model and their statistical characteristics are presented in table 9

Table 9: Values of coefficients of model (5) and characteristic of their importance

Coefficient	**a_1**	**a_2**	**a_3**
Value of coefficient	1.15080	6.67970	-26.08045
Standard error of coefficient	0.13399	2.08436	10.89888
t-value	8.58849	3.20467	-2.39295
Lower 95% value of coefficient	0.85885	2.13826	-49.82706

Top 95% value of coefficient	1.44275	11.22113	-2.33384
p-value	0.00000	0.00757	0.03395

Equaion (5) is statistically significant, the determination coefficient was 59.182%. An analysis of the significance of the coefficients of equation (5) showed that at a 5% significance level, all model coefficients are significant.

For large agricultural organizations, the pattern of reproduction is estimated by the formula

$$y = \frac{a_1}{\frac{1}{v_3{}^2} + \frac{a_2}{v_8^2 + a_3} + a_4} + a_5 \quad (6)$$

Table 10: Values of coefficients of model (6) and characteristic of their importance

Coefficient	**a_1**	**a_2**	**a_3**	**a_4**	**a_5**
Value of coefficient	0.02964	-31.49654	3801.37596	8567.80226	-0.44277
Standard error of coefficient	0.00020	0.11387	0.16285	3.70059	0.00019
t-value	150.36875	-276.59178	23343.02197	2315.25325	-2309.25895
Lower 95% value of coefficient	0.02920	-31.75026	3801.01311	8559.55684	-0.44320
Top 95% value of coefficient	0.03008	-31.24281	3801.73881	8576.04769	-0.44234
p-value	0.00000	0.00000	0.00000	0.00000	0.00000

Equation (6) is statistically significant, the determination coefficient was 50.215%. An analysis of the significance of the coefficients of equation (6) showed that at a 5% significance level, all model coefficients are significant.

Thus, using models (1) - (6), the previously mentioned assumption that different patterns of reproduction operate for different sized agricultural organizations has been proved. The presence of significant coefficients allows us to identify their economic meaning and draw appropriate conclusions.

Discussion

A study of the significance of the regression equations coefficients (1) - (6) led to the following conclusions:

- For ultra-small organizations with a production volume of up to 1,500 centners, there is a positive quadratic relationship between the indicator of cost reproduction and the capacity of fixed assets in the organization. So, with an increase in fixed assets capacity by 100 hp the growth rate of costs increases by $0{,}02v_3$ % - i.e., at a capacity of 500 hp, additional 100 hp increase the reproduction rate by 10%, and at a capacity of 4000 hp - by 80%;
- For ultra-small organizations with a production volume of up to 1,500 centners, there is a positive quadratic relationship between the indicator of cost reproduction and the indicator per agricultural worker. So, with an increase of this indicator by 50 hectares / per person the growth rate of production costs increases by an amount equal to $0{,}005v_4$ % - i.e., with the value of this indicator of 50 ha / person a twofold increase in this indicator will lead to an increase in the indicator of cost reproduction by 0.25%, with a value of 500 g / person - by 2.5%;
- However, high values of the fixed assets power indicator lead to a negative impact on the results of the reproduction process - there is a negative relationship between the product of the variables v_3 and v_6, which in fact are private from dividing the square of the fixed assets capacity by the number of employees - that is, with a small number of employees, positive effect of the amount of fixed assets is reduced to 0;

- At the same time, it is worth noting that, in the general case, for ulta-small agricultural enterprises in terms of production, a general increase in the level of manufacturability of production and labor (estimated by indicators of the ratio of fixed assets, amount of land and workers) leads to an increase in the cost reproduction rate;
- For small agricultural organizations, there is an inverse quadratic dependence of the indicator of reproduction of production costs and profits. On average, at zero profit margins, the rate of growth of production costs with a 95% probability ranges from 1.1 to 2.07, and with increasing profits it will decrease by an amount positively related to the number of employees - the larger the number of employees, the sharper reproduction rate will decline with increasing profit;
- In medium-sized agricultural organizations, the indicator of cost reproduction depends on the financial results of the organization. So, with a zero value of profit, the reproduction rate with a 95% probability will range from 0.86 to 1.44, an increase in the profitability of the organization leads to an increase in the growth rate of cost reproduction; however, with small volumes of production, this relationship is reversed;
- An analysis of dependence (6) for large organizations allows us to say that when the capacity of fixed assets decreases, the denominator of the fraction (6) increases, and, therefore, the rate of cost reproduction decreases. With small values of the modulus of profitability (tending to zero), the value of the indicator of reproduction of production costs also decreases.

Conclusion

The study proved the previously expressed assumption that different patterns of the reproductive process are identified for different sized agricultural organizations. Among the further directions of the analysis of the reproductive process in agricultural organizations, one can single out the analysis of the laws of natural reproduction, the analysis of reproduction in agricultural organizations involved in the production of heterogeneous agricultural products, as well as the analysis of the impact of the characteristics of human capital on company management, which may affect management decisions (Dias, Rodrigues, Ferreira, 2019; Mignouna et all, 2011; Jorge, Douglas, Huang, 1994; Fernandez-Cornejo et all 2017; Keelan et all, 2009).

Abstract

The article substantiates the need to develop a methodology for assessing the effectiveness of cluster interaction using housing and communal services as an example. The relevance of the study is obvious, since the creation of clusters in this area will improve the quality of services in rural areas, and assessing the effectiveness of the cluster's activity will develop a mechanism for its optimal management. Based on the analysis of domestic and foreign experience, it is concluded that it is advisable to evaluate the synergistic effects arising from the functioning of the cluster. The use of the Harrington desirability function and the method of pairwise comparisons of alternatives for calculating the cluster state index is proposed. Conclusions are made about the appropriateness of applying the cluster functioning efficiency index in assessing cluster interactions.

Keywords: Housing and Communal Services, Cluster, Performance Evaluation, Rural Area, Synergistic Effect, Desirability Function.

Introduction

Creating conditions for a comfortable and safe living of a person is the basis of the policy of the social state. The standard of living of the population is directly proportional to the quality of the provided housing and communal services. Thus, the sphere of housing and communal services is the foundation of the socio-economic life of society. Despite constant reforms in the industry, significant improvements in this sector of the economy do not occur. The low investment attractiveness due to state regulation of tariffs does not contribute to the introduction of innovations, the development of competition and a change in the approach to managing enterprises in the field of housing and communal services (Skripnik O., 2017; Mottaeva A., 2019).

Cluster formation in this area can significantly improve the situation in the housing and communal services market and attract private investors. Of particular interest is not only the mechanism of formation and development of the cluster in the field of housing and communal services, but also the assessment of the effectiveness of its functioning.

Currently, due to the lack of a single generally accepted approach to assessing the economic efficiency of enterprises in various sectors, including the field of housing and communal services, it is difficult to predict the need for a cluster. As practice shows, a comprehensive assessment of cluster programs is carried out extremely rarely, due to the cost of this event. In addition, the lack of consistency in the opinions of experts leads to incorrect assessment results (Oborina E.D., 2016).

The purpose of this study is to develop a system of indicators and a description of the methodology for assessing the functioning of the cluster in the field of housing and communal services in rural areas of the Russian Federation.

Materials and Methods

Analyzing domestic and foreign experience in implementing cluster policies in various sectors of the economy, we can conclude that one of the most successful methods for assessing the effectiveness of a cluster is to evaluate the so-called synergistic effect (Skoch A.V., 2008; Zhdanov S.A., etc., 2018). The synergistic effect in this context is understood as the total arithmetic sum of the value of the assets of the united organizations included the cluster, which exceeds the sum of the costs of the individual assets of these enterprises.

The concept of “synergetics” was first introduced by the founder of the theory of synergetics, Nobel laureate Herman Haken in 1969 (HakenG., 1980). The main types of synergistic effects arising from the functioning of the cluster include managerial, financial, innovative, infrastructural and operational. At the same time, many scientists, when assessing cluster effects, are guided both by the performance indicators of organizations included into the cluster and by the development indicators of the region as a whole (Buyanova M.E., Dmitrieva L. V., 2012; Leonova L. B., 2015; Zhdanov S.A., etc., 2018).

However, the sphere of housing and communal services, primarily, the socially significant sphere and improving the quality of these services will have a significant impact on the development of rural areas (Provalenova N.V., 2018, 2019; Egorov E.E. etc., 2019). We’ll draw attention to the fact that the provision of, for example, housing services involves the direct participation of consumers in their provision. Features of the services must be considered when forming performance indicators features of cluster functioning (Sri Herliana, 2015; Niusha Esmaeilpoorarabietal, 2017; Agapitova E. etal; Derbasova E. etal, 2019).

The work of many researchers noted the importance of including the results of interviewing experts as an integral part of the information security and reliability of the assessment results (Lyubushin N.P. Brigach G. E., 2014; Bezborodova T.I. 2014) In our opinion, to increase objectivity analysis of the cluster, it is important to take into account the views of all experts interested in the cluster, both external and internal.

Results

Evaluation of the effectiveness of the functioning of the cluster is necessary. It is a difficult task due to the multicomponent and heterogeneous performance indicators of cluster entities. The assessment process should be conducted systematically, sequentially and continuously, including all stages of the implementation of cluster projects from creation to control. At the same time, it is not enough to rely solely on economic data; one must take into account both the social and innovative components.

Discussion

The authors identified three groups of indicators of the cluster functioning efficiency in the field of housing and communal services in rural areas, among which are indicators of economic, social and innovative efficiency (Table 1).

Table 1: performance indicators cluster in the sphere of housing and communal services

№ п/п	Name of the indicator	Symbol of the indicator	Value of the indicator
	Economic performance indicators		
1.	The profitability of organizations included in the cluster	$П_1$	x_1
2.	Return on investment	$П_2$	x_2
3.	Capital productivity	$П_3$	x_3
	Social performance indicators		
4.	The average monthly accrued nominal wages of employees of organizations included in the cluster	$П_4$	x_4
5.	The number of newly created jobs	$П_5$	x_5
6.	The level of provision of the population with services	$П_6$	x_6
7.	The proportion of dilapidated and emergency housing stock in the total area of the entire housing stock	$П_7$	x_7
8.	The proportion of communal infrastructure facilities (heat, water and sewer networks) that are in a worn state	$П_7$	x_8
9.	The number of accidents at the facilities of municipal infrastructure in the field of water, heat supply and sanitation in the production, transportation and distribution of public resources	$П_9$	x_9
	Innovation Performance Indicators		
10.	The number of innovative, research and development projects implemented in the field of housing and communal services, including environmental protection	$П_{10}$	x_{10}
11.	The savings received by organizations included in the cluster from the measures taken to save energy	$П_{11}$	x_{11}
12.	The proportion of residential premises equipped with meters for the consumption of communal resources in the total area of the entire housing stock	$П_{12}$	x_{12}

The choice of these indicators is justified, which is confirmed by correlation analysis. So, based on 52 observations, a correlation matrix of economic efficiency indicators was obtained, which confirms the absence of their linear dependence and multicollinearity. Similarly, indicators of social and innovative effectiveness were tested.

$$\begin{pmatrix} 1 & - & - \\ 0{,}34 & 1 & - \\ 0{,}24 & 0{,}17 & 1 \end{pmatrix},$$

The proposed performance indicators do not have normative values, which leads to uncertainty and creates the risk of making non-optimal managerial decisions when evaluating the effectiveness of the functioning of the cluster. The theory of fuzzy sets makes it possible to operate with similar concepts that differ in heterogeneity. The use in the tasks of constructing an integrated performance assessment based on an analysis of the totality of the considered indicators is justified (Lyubushin N. P. Brigach G. E., 2014; Puryaev A.S., 2018).

From the point of view of the theory of fuzzy sets, the process of evaluating the effectiveness of cluster interactions is to establish the rules of correspondence between the elements of the set of input indicators and the elements of the set of output parameters. As a solution to this multicriteria problem, it is proposed to use the procedure for finding a certain generalizing indicator that can coordinate different-sized, heterogeneous indicators, bringing them together. The most successful way of calculating this indicator is the Harrington desirability function (Harrington E.C.Jr., 1965), which consists in converting the values of private indicators into a dimensionless scale of preference with psychophysical characteristics (Table 2).

Table 2: Harrington Desirability Scale

Desirability	The value of the desirability function
Very well	1,00 – 0,80
Good	0,80 – 0,63
Satisfactorily	0,63 – 0,37
Poorly	0,37 – 0,20
Very bad	0,20 – 0,00

The desirability function obtained as a result of empirical observations has the necessary properties, such as continuity, monotony, and smoothness (Heike Trautmann, Claus Weihs, 2006; Başak Akteke-Öztürk, Gerhard-Wilhelm Weber, Gülser Köksal, 2019). Values of the function range from zero to one. Moreover, “0” corresponds to the extreme degree of undesirability, and “1” corresponds to the absolute preference of the attribute. It is worth noting that the “sensitivity” of the function is significantly higher in the middle part of the graph (scale) and significantly decreases when approaching the boundaries. The value of the function $d_i = 0{,}37$ is the extreme acceptable value (Fig. 1).

Fig. 1: Harrington's Desirability Function Graph

Let us turn to the description of the main points of the methodology for assessing the cluster functioning efficiency. Initially, it is important to analyze the indicators and set the boundaries of acceptable values for all private indicators of the assessment. The restrictions imposed on the parameters are of two types: unilateral (y_{min} или y_{max}) and bilateral (y_{min} и y_{max}). In our case, all of the indicators listed above belong to the first group. For now, the Harrington function has the form:

$$d = e^{-e^{-y'}},$$

where y' is the coded (dimensionless) value of the indicator obtained from the equation y' = a + b · x. Coefficients a and b are obtained if we set the equation for two standard values of the indicator of a dimensionless scale in accordance with the values of their natural indicators x_i. The lower value is selected according to the initial value of the parameter, the upper - the final one, unless otherwise provided by the standard or legal regulation, while it is preferable to consider values that belong to the range (0.2; 0.8) with the greatest "sensitivity", for example:

$$\begin{cases} -0{,}5 = a + b \cdot x_{i(min)} \\ 1{,}5 = a + b \cdot x_{i(max.)} \end{cases},$$

where $x_{i(min.)}$ is the smallest (or worst) value of the indicator x_i, $x_{i(max.)}$is the largest (or best) value of the indicator x_i,

Based on the results obtained, intragroup generalized indicators of the desirability function are calculated, which are geometric mean partial indicators for groups characterizing economic, social, and innovative effectiveness:

$$D_j = \sqrt[\Sigma_{i=1}^{n} k_i]{\prod_{i=1}^{n} d_i^{k_i}},$$

where $d_i$are the values of particular preferences; k_i- is the weight coefficient of the indicator; *n* is the number of indicators; *i* - indicator number; *j* is the number of the indicator group.

Next, the intergroup generalized indicator of the desirability function is calculated - the cluster state index at time moment *m*, the values of which satisfy the desirability scale presented in Table 2:

$$I_m = \sqrt[\Sigma_{j=1}^{l} K_j]{\prod_{j=1}^{l} D_j^{K_j}},$$

where D_j- intragroup particular values of the desirability function; $K_j$is the weight coefficient of the indicator group; *l* is the number of indicator groups; *j* is the number of the indicator group.

The weight of the importance of the coefficients can be calculated in any convenient way, but the use of expert assessment methods (in particular, pairwise comparisons) will reduce subjectivity in the field of propositions and make an independent decision in view of checking the consistency of expert opinions. The indisputable advantage of the method of pairwise comparisons is a clear mathematical argumentation of the calculations and the relative prostate of the calculations. In accordance with the above method, a group of experts is created, which includes representatives of municipal authorities, heads and specialists of enterprises providing housing and communal services, representatives of small business and the population.

The obtained index of the cluster state $I_m$does not characterize its functional purpose in full, but only allows us to draw conclusions about work at a certain point in time *m*. In this connection, we introduce the cluster operation efficiency index E_m, which is determined not only by its state I_m, but also by the increment $Q_m = I_m - I_{m-1}$:

$$E_m = \alpha I_m + (1 - \alpha) Q_m, \;\; \alpha \in (0; 0{,}9)$$

The coefficient α takes on a value depending on the period of operation, i.e., α*=0,n*, where *n* is the number of years the cluster has been operating, and the maximum value of the coefficient is 0.9. Thus, during the formation of the cluster, and this period can be considered up to three years, α takes a value of no more than 0.3, i.e., the cluster operates taking into account the state of the service sector before its formation, the so-called “inheritance” ". In the heyday (from three to nine years), both condition and growth are significant. After nine years of cluster operation, the state of the cluster is more important. In addition, with a state above average, growth opportunities become limited.
Before creating a cluster and evaluating the effectiveness of its functioning, it is advisable to analyze the state of the sphere in terms of indicators of the socio-economic and innovative activities of enterprises.

Consider the calculation method on the example of organizations of housing and communal services of the municipal regions of the Nizhny Novgorod region, on the territory of which there are all the prerequisites for creating a cluster in the service sector (Table 3).

Table 3: performance Indicator Values

№ п.п.	Indicators	Units rev.	The values of indicators for the periods preceding the formation of the cluster					
			m-6	*m*-5	*m*-4	*m*-3	*m*-2	*m*-1
Economic performance indicators								
1.	The profitability of organizations in the cluster	%	0,8	1,2	2,8	4,1	5,2	4,8
2.	Return on investment	%	13,8	20,1	32,3	64,1	27,8	30,7
3.	Return on assets		0,3	0,3	0,3	0,4	0,4	0,5
Social performance indicators								
4.	Average monthly accrued nominal wages of employees of organizations included in the cluster	rub.	27638,8	30558,7	32700,9	35073,2	39761,6	42498,6
5.	Number of newly created jobs	units	2590	2317	2017	3127	2449	983
6.	The level of provision of the population with services	%	64,9	65,8	67,5	68,3	68,8	69,2
7.	The proportion of dilapidated and emergency housing stock in the total area of the entire housing stock	%	1,8	1,9	1,2	1,2	1,1	1,1
8.	Depreciation of communal infrastructure facilities (heat, water and sewer networks) that are in a worn state	%	58,7	59	63,1	67,22	67,02	67
9.	The number of accidents at the facilities of communal infrastructure in the field of water, heat supply and sanitation in the production, transportation and distribution of communal resources	units	2256	1540	1121	815	723	576
Innovation Performance Indicators								
10.	The number of innovative, research and development projects implemented in the field of housing and communal services, including environmental protection	units	1	1	1	2	2	2
11.	Savings received by organizations included in the cluster from measures taken to save	thousands rub.	-	419874	741842	978595	820640	846770
12.	The proportion of residential premises equipped with meters for the consumption of communal resources in the total area of the entire housing stock	%	29,5	28,3	23	24,3	26,5	27,9

We will calculate the encoded values of y 'for each indicator, having previously compiled a system of two linear equations, the matrix representations of which are of the form:

- for indicator Π_1: $\left(\begin{array}{cc|c} 1 & 0{,}8 & -0{,}5 \\ 1 & 5{,}2 & 1{,}5 \end{array}\right)$;
- for indicator Π_2: $\left(\begin{array}{cc|c} 1 & 13{,}8 & -0{,}5 \\ 1 & 64{,}1 & 1{,}5 \end{array}\right)$;
- for indicator Π_3: $\left(\begin{array}{cc|c} 1 & 0{,}3 & -0{,}5 \\ 1 & 0{,}5 & 1{,}5 \end{array}\right)$;
- for indicator Π_4: $\left(\begin{array}{cc|c} 1 & 37891{,}53 & -0{,}5 \\ 1 & 42498{,}6 & 1{,}5 \end{array}\right)$;
- for indicator Π_5: $\left(\begin{array}{cc|c} 1 & 2590 & -0{,}5 \\ 1 & 3127 & 1{,}5 \end{array}\right)$;
- for indicator Π_6: $\left(\begin{array}{cc|c} 1 & 64{,}9 & -0{,}5 \\ 1 & 69{,}2 & 1{,}5 \end{array}\right)$;
- for indicator Π_7: $\left(\begin{array}{cc|c} 1 & 1{,}9 & -0{,}5 \\ 1 & 1{,}1 & 1{,}5 \end{array}\right)$;
- for indicator Π_8: $\left(\begin{array}{cc|c} 1 & 67{,}22 & -0{,}5 \\ 1 & 58{,}7 & 1{,}5 \end{array}\right)$;
- for indicator Π_9: $\left(\begin{array}{cc|c} 1 & 2256 & -0{,}5 \\ 1 & 576 & 1{,}5 \end{array}\right)$;
- for indicator Π_{10}: $\left(\begin{array}{cc|c} 1 & 1 & -0{,}5 \\ 1 & 2 & 1{,}5 \end{array}\right)$;
- for indicator Π_{11}: $\left(\begin{array}{cc|c} 1 & 419874 & -0{,}5 \\ 1 & 978595 & 1{,}5 \end{array}\right)$;
- for indicator Π_{12}: $\left(\begin{array}{cc|c} 1 & 23 & -0{,}5 \\ 1 & 29{,}5 & 1{,}5 \end{array}\right)$.

As a result of their solution, we obtain the coefficients of the equations of the optimization parameters:

- for indicator Π_1: $y'_1 = -0{,}863 + 0{,}455x_1$
- for indicator Π_2: $y'_2 = -1{,}049 + 0{,}039x_2$
- for indicator Π_3: $y'_3 = -3{,}5 + 10x_3$
- for indicator Π_4: $y'_4 = -16{,}949 + 0{,}00043x_4$
- for indicator Π_5: $y'_5 = -1{,}417 + 0{,}00093x_5$;
- for indicator Π_6: $y'_6 = -30{,}686 + 0{,}465x_6$
- for indicator Π_7: $y'_7 = 4{,}25 - 2{,}5x_7$
- for indicator Π_8: $y'_8 = 15{,}279 - 0{,}235x_8$
- for indicator Π_9: $y'_9 = 2{,}186 - 0{,}0012x_9$;
- for indicator Π_{10}: $y'_{10} = -1 + 0{,}5x_{10}$;
- for indicator Π_{11}: $y'_{11} = -2{,}003 + 3{,}58 \cdot 10^{-6}x_{11}$;
- for indicator Π_{12}: $y'_{12} = -7{,}577 + 0{,}308x_{12}$

As noted above, indicators that assess the state of the housing and communal services sector have various meanings, which should be taken into account before performing calculations to find the values of the functions of particular desirability. We carry out the differentiation of the weighting coefficients through the application of the algorithm of pairwise comparisons of indicators, which allows us to reveal the relative degree of their importance, with a further check on the consistency of opinions.

The expert group was asked to fill out the matrix of pairwise comparisons (Table 4-6) and determine the level of advantage of one indicator over others on a scale of relative importance. The authors calculated the normalized vector (priority vector) by dividing the geometric mean of each row by the sum of geometric mean.

Table 4: matrix of pairwise comparisons of economic performance indicators

	П₁	**П₂**	**П₃**	**Specific indicator weight**
П₁	1	1	2	0,40
П₂	1	1	2	0,40
П₃	0,5	0,5	1	0,20
			Consistency Ratio	0<0,1 (acceptable)

Table 5: matrix of pairwise comparisons of social performance indicators

	П₄	**П₅**	**П₆**	**П₇**	**П₈**	**П₉**	**Specific indicator weight**
П₃	1	1	0,(3)	0,5	0,5	1	0,10
П₄	1	1	0,(3)	0,5	0,5	1	0,10
П₅	3	3	1	2	2	3	0,32
П₇	2	2	0,5	1	1	2	0,19
П₈	2	2	0,5	1	1	2	0,19
П₉	1	1	0,(3)	0,5	0,5	1	0,10
						Consistency Ratio	0,0029<0,1 (acceptable)

Table 6: matrix of pairwise comparisons of innovation performance indicators

	П₁₀	**П₁₁**	**П₁₂**	**Specific indicator weight**
П₁₀	1	0,51	1	0,25
П₁₁	2	1	2	0,50
П₁₂	1	0,5	1	0,25
			Consistency Ratio	0<0,1 (acceptable)

Initially, any matrix of judgments in general terms is not consistent, due to experts making subjective decisions and the existing risk of computational errors. Therefore, it is important to assess the degree of consistency of the results.

A matrix is considered consistent if the consistency ratio $OC = \frac{ИС}{СИ}$ is less than or equal to an acceptable value of 0.1. In our case, all judgment matrices are consistent.

Similarly, we calculate the weighting coefficients for the matrix of pairwise comparisons of groups of indicators of economic, social and innovative effectiveness (Table 7).

Table 7: matrix of pairwise comparisons of groups of indicators of economic, social and innovative effectiveness

	Economic performance indicators	Social performance indicators	Innovation performance indicators	Specific indicator weight
Economic performance indicators	1	0,5	2	0,30
Social performance indicators	2	1	3	0,54
Innovation performance indicators	0,5	0,(3)	1	0,16
			Consistency Ratio	0,0079<0,1 (acceptable)

When analyzing the effectiveness of the functioning of the cluster, it is sufficient to assess the state of the sphere of housing and communal services (activities of housing and communal services enterprises) only for the period (year) preceding the creation of the cluster. The calculation data for the indicators of the (m-1) period are presented in table 8.

Table 8: the results of the calculation of the desirability function

№	Indicators	k_i	y'_i	d_i	K_j	D_j
Economic performance indicators						
1.	The profitability of organizations in the cluster	0,40	1,32	0,76	0,30	0,61
2.	Return on investment	0,40	0,17	0,43		
3.	Return on assets	0,20	1,5	0,8		
Social performance indicators						
4.	Average monthly accrued nominal wages of employees of organizations included in the cluster	0,10	1,5	0,8	0,54	0,53
5.	Number of newly created jobs	0,10	-0,5	0,19		
6.	The level of provision of the population with services	0,32	1,5	0,8		
7.	The proportion of dilapidated and emergency housing stock in the total area of the entire housing stock	0,19	1,5	0,8		
8.	Depreciation of communal infrastructure facilities (heat, water and sewer networks) that are in a worn state	0,19	-0,44	0,21		
9.	The number of accidents at the facilities of communal infrastructure in the field of water, heat supply and sanitation in the production, transportation and distribution of communal resources	0,10	1,5	0,8		
Innovation performance indicators						
10.	The number of innovative, research and development (projects) implemented in the field of housing and communal services, including environmental	0,25	0,37	0,368	0,16	0,59

	protection					
11.	Savings received by organizations included in the cluster from measures taken to save	0,50	1,028	0,7		
12.	The proportion of residential premises equipped with meters for the consumption of communal resources in the total area of the entire housing stock	0,25	1,008	0,69		
A generalized indicator of the function of desirability						0,56

The obtained generalized indicator of the desirability function indicates a satisfactory state of the services sector in rural areas of the Nizhny Novgorod region in the pre-cluster period, which indicates the presence of potential for growth, a significant increase in the performance indicators of the enterprises of housing and communal services provided they participate in the implementation of cluster programs.

Let us turn to a graphical representation of the state in which organizations that provide housing and communal services in the (*m*-1) period are located (Fig. 2).

Fig. 2: Condition diagram of enterprises in the field of housing and communal services

The vertices of the polygon correspond to the normalized exponents of the values of the desirability function. Note that this diagram not only shows the state in which the system is located, but also shows what you need to pay attention to and what you should strive for.

Conclusion

Thus, the work considers a methodological approach to assessing the effectiveness of the functioning of the cluster in the field of housing and communal services, based on the use of the desirability function.

The presented technique allows you to:

– take into account the specifics of housing and communal services when choosing indicators for assessing the effectiveness of the functioning of the cluster;

– eliminate uncertainty in the heterogeneity and multicomponentness of indicators by translating them into a coded dimensionless scale using the desirability function;

– take into account the significance of the indicators under consideration using weighting coefficients calculated on the basis of expert assessments of pairwise comparisons of indicators;

– check the judgments for consistency and to eliminate possible subjectivism when making decisions;

– carry out the process of evaluations in a planned, consistent and continuous manner, taking into account all stages of the functioning of the cluster;

– greatly simplify the assessment procedure, due to simple mathematical calculations.

Abstract

The analysis of the economic efficiency of various agricultural practices (application of herbicides in the nursery when growing hop seedlings by green cuttings, planting of new plantings with various types of planting materials and using setting up as crop supports in the first year) in the conditions of the Chuvash Republic. Various doses of herbicides were used when growing planting material at certain times in order to exclude the phytotoxic effect on young shoots of green hop cuttings. According to the results of the study, the high efficiency of the use of herbicides in plantings was established, which eliminated manual weeding and significantly reduced labor costs per 1 hectar. The survival rate of stem cuttings and annual seedlings depended on the timing of planting, the type of planting material and weather conditions. On the hop of 1 year of laying with traditional technology, production costs are 620 people / hour, and when using crops as supports, they are reduced to 36 people / hour. With a yield of more than 2 kg / ha due to increased costs for mechanized and manual work; cleaning; for the purchase of twine, wire and protective equipment, growing hops becomes unprofitable. The differences in costs, with a certain productivity, are caused by additional expenses for harvesting. As productivity increases, profits increase to 61.5 thousand rubles.

The use of crops as a supporting material is a profitable technological technique, since the costs of mechanized and equestrian work are reduced to 3.3 thousand rubles, and for the purchase of materials and protective equipment up to 10 thousand rubles.

Keywords: Agricultural practices, traditional technology, herbicides, green cuttings method, supporting crops, planting stock, efficiency.

Introduction

Improving existing techniques and developing new most effective methods of cultivation is relevant in hop cultivation. Zakharov A.I., Makushev A.E., Zakharov D.A., Tolstov M.L. (2017) note that special attention is paid to technological factors of resource saving: the use of industrial technologies for growing high-quality planting material, creating optimal conditions for plant growth and development, the use of highly efficient types of trellis and plantings, cultivating intensive cultivars, mastering industrial production technologies, etc. in the production of hop raw materials. The efficiency of production of marketable hops is possible while reducing the cost and production costs per unit of output.

Milosta G.M., Lapa V.V. (2010) indicate that the use of herbicides allows you to maintain the degree of weediness and yield at the level of the option with the use of manual weeding, but significantly reduces labor costs. Some scientists believe that herbicides have a phytotoxic effect on hops. However, according to the conclusions of V.V. Kozina (1985) herbicides stomp, dual and bazagran are not phytotoxic for hops and effectively suppress weeds.

Under production conditions, a reduction in the period of low commercial fruiting and obtaining a good crop of hop cones in the second year is possible only when using annual seedlings with high plant survival after planting as planting material.

In hop breeding, the issues of using soil herbicides in nursery breeding when planting plantings with various types of hop planting material is of great importance mainly because the cultivation of planting material, the state of hoppers, and the technology of care during the growing season in the first and subsequent years largely depend on this. Alexandrov N.A. (1991, 1989). notes that hops are planted only with one-year-old seedlings grown in open and protected ground nurseries. Also, E.P. Libatsky (1984) believes that it is better to plant hops by annual seedlings, although planting by cuttings is also used.

The most progressive and reliable method, as well as ensuring high survival rate, is considered to be the method of laying hops with annual seedlings grown from stem and green cuttings in the autumn period in the second decade of October. In recent years, in the preparation of planting material, a method of growing seedlings from green cuttings has been successfully applied. According to V.P. Prokopyev (2008) athis method has a significant advantage for the quickest propagation of new, promising hop varieties.

Spring laying hops with stem cuttings, especially in a dry year, is a risky operation. Often, under such conditions, the survival rate of stem cuttings is reduced to 50%. In the future, such hoppers are difficult to bring in density to a full state, and as a rule, from year to year they remain low-yielding. However, under favorable weather conditions, the laying of hops with stem cuttings should not be discarded. Nikonova Z.A., Korotkova Z.P. (2017) note that the new collection nursery was laid with freshly cut stem cuttings from manual trimming of samples of the old collection. So, in the research of Korotkova A.V. (2008, 2019) it is proved that with the correct implementation of agricultural measures that ensure the survival of plants and create conditions for the growth and development of the root system, such hoppers are able to provide up to 2-6 kg / ha of hops in the first year of fruiting.

Hop is a liana-like climbing plant, so a special trellis is needed to cultivate it. According to the methodological recommendation “Perspective Resource-Saving Production Technology” each bush must be provided with supports for normal growth and development of plants.

Materials and Methods

The studies were carried out in the nursery of seedlings breeding when growing by the method of green cuttings, when laying new plantings with various types of planting material, and on the hop of 1 year of laying using crops as a supporting material. Various elements of the technology of

cultivation of common hop are summarized with a combination of agronomic assessment of techniques. The studies used methods of direct counting, visual assessments and field observations of plants. The identification of the economic efficiency of agro-activities carried out on hoppers was carried out at the cost of labor and funds provided by technological maps.

Research Results and Discussion

The control of weeds is of great importance in the cultivation of hop seedlings in the breeding nursery using the green cuttings method. Timely weeding eliminates inhibition, contributes to better growth and development of green cuttings. Currently, agronomic measures against weeds in breeding nurseries of the farms of the Chuvash Republic engaged in the cultivation of planting material are carried out exclusively by hand and labor costs in this case reach 185 people / days per 1 ha. Therefore, the use of herbicides in the nursery is relevant and is of some interest. Various doses of soil herbicides were applied at certain times in order to exclude the phytotoxic effect on young shoots of green hop cuttings. According to the results of the study, the high efficiency of herbicides on hop plantings was established (Table 1). After the opening of the film shelters in the control variant - without the use of herbicides, the number of weeds was 14 pcs / m². As the dose was increased and when used earlier, the weediness decreased by 64.3%. And when applying gaitan, a week before planting green cuttings, the weediness of plantings was up to 2-3 pcs./m². By the digging of seedlings on plots without treatment with herbicides, the number of weeds increased to 25 pcs / m². When spraying rows with a corsair on seedlings, the complete destruction of vegetative weeds occurred. Gaitan has proven effective in controlling cereal and dicotyledonous weeds.

As a result of visual observations in variants with a late period of application of herbicides, a phytotoxic effect was observed on young shoots of green hop cuttings. Some of them completely died, yellowing of the leaves took place, and further oppression of plants continued during the growing season.

Table 1: Effect of timing and doses of herbicide application on the weediness of hop plantings in the breeding nursery, 2019

Option	Thetiming		Weedweight		Totalweediness	
	After opening the films, pcs / m²	Before digging seedlings, pcs / m²	After opening the films, kg	Beforediggingseedlings, kg	Minors, pcs.	Perennial, pcs.

Only individual farms are engaged in the cultivation of planting material in the Chuvash Republic. The volume of produced planting material at the enterprises of the republic is on average 20 thousand pieces, which will occupy the planted area up to 1117 m². Consequently, labor costs for manual weeding will amount to 21 people / days. When using soil herbicides, manual weeding is eliminated, labor costs per 1 ha are significantly reduced.

According to the results of studies, it was found that the survival rate of stem cuttings and annual seedlings depended on the planting time, type of planting material, and weather conditions. On 1-year-old hop plantations of layingwith stem cuttings, the yield was low compared to planting with annual seedlings. In the conditions of the dry summer of 2018, a significant part of the stems reached only the middle, and very few to the top of the trellis, the cones were small. In 2019, on the hoppers of the first year of laying with stem cuttings did not form cones, and with annual seedlings the yield was only 1.0-1.5 c / ha. Therefore, growing hops with traditional technology, including the cost of buying twine, pesticides and caring for plants, becomes unprofitable.

For the growth and development of hops, each bush must be provided with supporting material. So, when planting is left unsupported during inter-row cultivation, tramming of creeping shoots occurs and work on hilling bushes as a result of landfill is difficult.

According to the results of the 2019 study, it was found that in the variant with supporting crops, by the end of the growing season, the stems grew to 2.45 m, with twine - 2.66 m, and the seedling mass was 10.0 g., 26.3 g. respectively. The number of main roots formed up to 2-3 pcs.,and the length - 2.45-2.66 m and 3-5 buds of renewal. Cones did not have time to form.

On the hop of 1 year of laying with traditional technology, production costs are 620 people / hour, and when using crops as supports, they are reduced to 36 people / hour. With a yield of more than 2 kg / ha due to increased costs for mechanized and manual work; cleaning; for the purchase of twine, wire and protective equipment, growing hops becomes unprofitable. The differences in costs, with a certain productivity, are caused by additional expenses for harvesting. As productivity increases, profits increase to 61.5 thousand rubles.

The use of crops as a supporting material is a profitable technological technique, since the costs of mechanized and equestrian work are reduced to 3.3 thousand rubles, and for the purchase of materials and protective equipment up to 10 thousand rubles (Table 2).

According to many years of research in the conditions of the Chuvash Republic, under adverse weather conditions, on the hoppers of 1 year of laying, the average yield is 0.5-2 kg / ha.

Consequently, in such conditions and with a lack of labor, that is currently characteristic of agriculture, hop-growing enterprises on the hoppers of 1 year of laying with planting by stem cuttings, it is recommended to use supporting crops as hop supports.

Table 2: Economic efficiency of using agricultural material as a supporting material on hoppers of 1 year laying with stem cuttings

Option	**Mechanized and equestrian work, (thousand rubles)**	**Mechanized harvesting, drying and pressing of hops, (thousand rubles)**	**Cost of materials and means, (thousandrubles)**	**laborcosts, (people / hour)**	**Cost of production, (thousand rubles)**	**Profit, (thousandroubles.)**
Productivity 2 kg / ha						
When hanging hops with polypropylene twine	42,0	10,4	20,0	492/128	70,0	-2,4
Productivity 3 kg / ha						
When hanging hops with polypropylene twine	42,0	14,5	30,0	492/172	105,0	+18,5
Productivity 4 kg / ha						
When hanging hops with polypropylene twine	42,0	18,0	40,0	492/216	140,0	+40,0
Productivity 5 kg / ha						
When hanging hops with polypropylene twine	42,0	21,5	50,0	492/260	175,0	+61,5
When using agricultural crops as a supporting material	3,3	-	10,0	36/0	0	-13,3

Conclusion

The high efficiency of the use of herbicides on plantings was established, which eliminated manual weeding and significantly reduced labor costs per 1 ha. The survival rate of stem cuttings and annual seedlings depended on the timing of planting, the type of planting material and weather conditions.

On the hop of 1 year of laying with traditional technology, production costs are 620 people / hour, and when using crops as supports, they are reduced to 36 people / hour. With a yield of more than 2 kg / ha due to increased costs for mechanized and manual work; cleaning; for the purchase of twine, wire and protective equipment, growing hops becomes unprofitable. The differences in costs, with a certain productivity, are caused by additional expenses for harvesting. As productivity increases, profits increase to 61.5 thousand rubles.

The use of crops as a supporting material is a profitable technological technique, since the costs of mechanized and equestrian work are reduced to 3.3 thousand rubles, and for the purchase of materials and protective equipment up to 10 thousand rubles.

Abstract

The article explores the specifics of innovation processes in the regional agro-industrial complex, considers approaches to a comprehensive assessment of the level of development of a regional innovation system, offers recommendations for stimulating innovation processes in the agricultural sector of the Republic of Mari El based on the level of sustainability of innovative development of agricultural enterprises.

Keywords: Innovation Process, Regional Innovation System, Innovative Development, Sustainability of Innovation Development

Introduction

The agro-industrial complex (AIC) is one of the significant elements of the Russian economy. In the agro-industrial sector, socially important products are produced, the significant industrial and economic potential of the country is concentrated. As a macroeconomic system, the complexity and heterogeneity of the structure of the agricultural processing industry and the specifics of its development processes depend on the characteristics of agricultural production and the agricultural economic structure. This actualizes the need for clarification and justification of conceptual and methodological approaches to the study of innovative processes carried out in the agricultural system.

The strategic goal of implementing innovative activities in the agricultural sector is to introduce models of the knowledge economy in the agricultural sector, create innovative cultural ideologies at the federal and regional levels, and create innovative agricultural production integrated into the global economic system. In this process, the development of regional innovation systems plays an important role. In the framework of this study, regional innovation systems in agricultural complexes are defined as organizations and institutions designed to implement the innovation process in the agricultural sector of a particular region. These systems are designed to provide:

- ✓ the potential for creating and diffusing innovations in the agricultural sector;
- ✓ technical and technological renewal of agricultural production due to the active development of advanced scientific and technical developments;
- ✓ formation of a competitive agribusiness.

When developing a regional innovation policy, it is necessary to focus primarily on the innovative potential of key enterprises in the territory. In this regard, the problem of forming a system of indicators for assessing the level of innovative development of the regional economic system, especially for enterprises of the industry, arises. Understanding the innovative nature of local production potential can lay the foundation for ensuring coherence in regional organizational and economic development, as well as determine the development and integration based on innovation.

According to a study conducted by the Institute for Statistical Studies and Economics of Knowledge (ISSEK) of the Higher School of Economics, large and medium-sized agricultural organizations of the Russian Federation are characterized by a low level of innovative activity. The share of agricultural enterprises introducing technological innovations in 2018 amounted to only 3.4%. In comparison, in industrial production this indicator is 9.2%. The maximum value of the level of innovative activity in agriculture was recorded in the field of animal husbandry (3.9%) and crop production (3.7%).

Agriculture and industrial sectors play an important role in the formation of the central link of the territory's economy, which attracts support services and other related industries. Therefore, the creation of conditions for innovation and development of the agricultural sector of the region is one of the most important factors affecting the competitiveness of the country's socio-economic system, the standard of living of the population and the quality of its life, which undoubtedly determines the relevance of the research topic.

The object of the research is the innovative processes of the regional agro-industrial complex in the context of the transformation processes taking place in the Russian and world economies.

The subject of the research is the problems of the influence of innovative processes on the development of macro- and microeconomic systems and the efficiency of their reproduction.

The influence of the innovation process on the efficiency of the development and regeneration of macro- and microeconomic systems has become a research topic for many scientists.

The purpose of the study is to develop proposals for stimulating innovative processes in the regional agro-industrial complex based on assessing the level of sustainability of innovative development of leading enterprises in the industry.

Research results and Discussion

A characteristic feature of modern macroeconomics is the dynamic development of innovative processes, the deepening of the social division of labor and the development of vertically integrated forms. In this regard, large intersectoral complexes are actively formed and developed. An important place among them is taken by the agro-industrial complex as a subsystem of market macroeconomics.

The complexity and heterogeneity of the agri-food complex as an economic system, the specifics of its development processes, determined both by the specifics of agrarian production and the agrarian structure of the economy, require substantiation of conceptual and methodological approaches to the formation of the innovative development system of the agro-industrial complex of the Russian Federation (Table 1).

Table 1: the Conceptual framework for the development of the industry innovation system of the agro-industrial complex of the Russian Federation

Term	Strategic priorities	Results
Medium term	-the creation of a regulatory framework for the regulation of industry-specific innovation processes in the agricultural sector; - building a system for the development of the technological and scientific research basis of the economy; - import of technologies and development of infrastructure of innovation transfer; - formation of the basic segments of the domestic market for innovative products	- continuous, accelerating growth in the need for skilled workers; - orientation of the business in the agricultural sector to high-tech production; - optimization of zoning of both agricultural production and the entire infrastructure of the agro-industrial complex, including primarily related to the development and implementation of innovations
Long-term perspective	- formation of an internal innovative industry market; - development and creation in the village of the middle class, focused on high professional culture as a living standard; - modernization of the agro-industrial sector of the country's economy; - strengthening the position of the industry in terms of reducing the imbalance in development between industries and agriculture	- steady growth of the information segment of agro-economy as the basis of the progress of the economic system; - investments in human capital, knowledge as an effective form of social accumulation; - transformation of knowledge into an economic and production resource; - development of new models of reproduction to accelerate the processes of society development

The combination of economic and biological processes determines the specifics of expanded reproduction. Therefore, when managing innovations in the agro-industrial complex, it is necessary to take into account not only the requirements of financial laws, but also the natural influence of the laws of nature: indispensability, equivalence and a combination of life factors.

For the agricultural sector, there are many factors that can stimulate the development of innovative processes. Among them, it seems appropriate to single out the following:

- availability of natural resources,
- significant scientific and educational potential,
- capacious domestic food market,
- ability to produce environmentally friendly natural foods.

The factors restraining the innovative development of the agro-industrial complex include:

- decrease in domestic demand for food,
- reduction of state support for the agricultural sector and state funding of scientific and technical programs,
- high interest rates on loans, lack of innovative infrastructure;
- insufficient level of training for agricultural organizations in the field of innovation management.

The Republic of Mari El (RME) is part of the Volga Federal District and is part of the Volga-Vyatka Economic Region. According to the main indicators of socio-economic development, the RME until 2016 steadily occupied the last places in the ranking of the regions of the Volga Federal District.

Nevertheless, it should be noted that the growth rate of agricultural production in 2015-2018 the Republic of Mari El demonstrates the highest rates, taking second or third places among the Volga regions, and is among the ten most active in this sphere entities of the Russian Federation. Most of the agricultural products (more than 60%) are produced by enterprises of the Republic.

In general, in the Volga Federal District for 2018, the following results were obtained for agricultural production (Table 2).

Table 2: agricultural products in the Volga Federal District in 2018, million rubles

Territory	Agriculture	Including:		Reporting year in% to the previous year (in comparable prices)		
		plant growing	animal husbandry	agricultural organizations	households	peasant (farmer) economy, entrepreneurs

For the first time in recent years, the Republic of Mari El has taken first place in the Volga Federal District and fourth in Russia in terms of agricultural production. The production index in farms of all

categories amounted to 110.3%, including in agricultural organizations - 109.6%. In January-October 2018, 240.2 thousand tons of cattle and poultry meat were produced, which is 5% higher than the same period last year. The average milk yield per cow in agricultural organizations increased by 201 kg and amounted to 6000 kg.

Nevertheless, the issue of intensification of agricultural production is very relevant for the Republic, since these processes are active only in individual farms of the Soviet and Zvenigovsky districts, where advanced technologies and resource-saving technologies are used.

At the end of 2018, 100 agricultural enterprises, 2060 peasant (farm) enterprises and individual entrepreneurs, 241 food and processing enterprises, 35 agricultural consumer cooperatives operated in the territory of the Mari El Republic. According to the rating of agricultural enterprises in 2018, the national indicator for the average milk yield per cow amounted to 6883 kg. Table 3 presents the rating of agricultural enterprises of the Republic of Mari El by the average milk yield per cow according to the results of 2017 and 2018. For several years now, ZAO Semenovsky has beenthe leader in the industry with an average milk yield of 7866 kg per cow.

Table 3: rating of agricultural enterprises of the Republic of Mari El by average milk yield per cow for 2017-2018

Name of the farm	Municipal area	Average milk yield per cow, kg		
		2017	2018	Change, +/-
1. ZAO p/z "Semenovsky"	**Medvedevsky**	**7597**	**8135**	**+ 538**

The current economic situation in the Mari El Republic determines the choice of the agro-industrial sector as a growth driver. To assess the level of innovative development of the Republic, an approach based on the use of system indicators is applicable.

System indicators reflect the state of the region's innovative potential, the level and orientation of the process of innovative development. System indicators are divided into four groups according to the key characteristics of the innovation process:

Group I: indicators of educational and scientific activity;

Group II: indicators of innovative activity of enterprises and organizations;
Group III: indicators of the effectiveness of innovation in the region;
Group IV: indicators of the state and development of innovative infrastructure.

The structure of system indicators to determine the level of innovative development of the Mari El Republic is summarized in table. 5.

Table 5: indicators for assessing the level of innovative development of the Republic of Mari El

Group	Indicators (according to 2018)
Group I - indicators of educational and scientific activity	1. The share of people employed in the region's economy with higher professional education in the total number of employed population: *2017 - 26.3%; 2018 - 29.3%* 2. The number of researchers by field of science: *researchers - 102 people; Doctors of Sciences - 5 people; Candidates of Sciences - 50 people*. 3. The number of personnel engaged in research and development: *187 people.*
Group II - innovative activity of enterprises and organizations of the region	1. The proportion of organizations implementing technological, organizational and marketing innovations, in the total number of organizations in the region: *4.6%* 2. The volume of innovative goods, works, services, in the total volume: *14.2%* 3. Costs of technological innovation: *1123.9 million rubles*.
Group III - the effectiveness of innovation in the region	1. The proportion of organizations implementing technological, organizational, marketing innovations, in the total number of organizations examined: *8.3%* 2. Internal costs of research and development: *199 million rubles*. 3. The volume of shipped innovative goods, work, services (excluding VAT, excise taxes and other similar payments): *14926.4 million rubles*.
Group VI - availability of developed innovation infrastructure	1. The presence of a cluster development center in the region: *none* 2. Existing infrastructure: ANO *"Business Incubator of the Mari El Republic", Volgatekh Science and Technology Park, Technology and Innovation Support Centers*

Based on the results of assessing the level of innovative development of the regional innovation system of the Mari El Republic, profiles of the region's innovative development are constructed (Fig. 2) and conclusions are drawn (Table 6) and the type of innovative development of the region is determined.

Fig. 1: Classification of regions by type of innovative development

According to the type of innovative development, the regions are divided into four types (Fig. 1):

- the first type - regions with a high level of innovative potential;
- the second type - regions with an average level of innovative potential;
- the third type - regions with a low level of innovative potential;
- the fourth type - regions with a low level of innovative potential.

Fig. 2: Profiles of innovative development of the Republic of Mari El for 2018

The type of innovative development of the region must be taken into account when developing a strategy for innovative development and the selection of specific instruments to stimulate innovative processes in a particular region.

Table 6: results of the SWOT analysis of the regional innovation system

STRENGTHS	WEAKNESSES
1. Attractive economic and geographical location. 2. A sufficiently high level of development of small and medium enterprises. 3. Political stability in the region. 4. The presence of mechanisms of state support for investors, developed regional legislation in the field of investment. 5. The proximity of potentially large consumer markets in neighboring regions.	1. Low innovation activity of business entities. 2. Insufficient attraction of funds from support funds in the innovative activities of economic entities in the region. 3. Reduction of subsidies from the federal budget in the total cost of research and development. 4. The trend of the outflow of qualified personnel and youth from the region.

According to the results of the analysis, we can conclude that the innovation system of the Mari El Republic belongs to the third type - regions with a low level of innovative potential. For the effective development of innovative processes in regions of this type, a significant amount of attracting financial resources and the development of special measures of state support for innovative activities are required. The aim of the regions of this group is to partially provide innovative products to the domestic market.

Therefore, when developing a regional innovation policy for the Mari El Republic, first of all, it is necessary to raise issues of innovative development of key enterprises in the region, which primarily include agricultural enterprises.

Sustainability of innovative development is a comprehensive assessment of seven interrelated components describing the types of market, industry and technology, investment, organization and management, society, innovation and individual sustainability of consumers. The level of innovative development of the production potential of enterprises allows us to determine the total innovative

potential of the industry and highlight the main locomotives of innovative development of the regional economic system. Knowledge of the innovative characteristics of the production potential of the region's enterprises will create the basis for ensuring the coherence of the organizational and economic development of the region, determine the directions of development and integration on an innovative basis.

Assessing the level of innovative development of the production potential of industry enterprises in the region is a characteristic of the material conditions necessary for updating products and improving their quality and can be used as a basis for predicting the volume of industrial production in the region.

The proposed methodology for assessing the level of innovative development of the enterprise's production potential is based on a systematic approach that allows us to consider the studied object from the point of view of assessing the state and development of its internal structure and the influence of the external environment on the current and future situation in the structure of the regional economic system.

The methodology for analyzing the level of innovative development of an enterprise includes the following steps:
1. Formation of criteria and indicators characterizing the state and innovative nature of the development of the production potential of the enterprise and its economic subsystems

The sustainability characteristic of the innovative development of an enterprise includes an assessment of seven interrelated components:
- market stability;
- sustainability of the production and technological level;
- investment stability;
- organizational and managerial stability;
- innovative sustainability;
- social sustainability;
- consumersustainability.

The criteria for evaluating the values of indicators for each group are industry average standards and / or industry average indicators, estimated using the expert assessment method (from 0 to 3 points).

2. Calculation of the integral indicator and determination of the sustainability class of innovative development of the enterprise's production potential

According to the integrated enterprise, one of the four sustainability classes of innovative development of its production potential can be assigned (Table 7):

• enterprises with high sustainability of innovative development;
• enterprises with normal sustainability of innovative development;
• enterprises with the maximum permissible sustainability of innovative development;
• enterprises with crisis sustainability of innovative development.

Table 7: sustainability classes of innovative development of the enterprise

Sustainability class	Indicator value	Description	Recommended Innovation Development Strategy
High Stability	$У_{integr} \geq 60$	Efficiency of implementation of innovative product development programs, stability and social satisfaction of the workforce, high level of innovative culture, efficient organization of labor and production	Leadership strategy in mastering new products and technologies
Normal Stability	$45 \leq У_{integr} < 60$	High investment activity, stable market position, stable staff, acceptable level of innovative culture, market potential sufficient to implement development programs	Both a follower strategy and a leader strategy in the development of new or improving technologies and products can be implemented
Maximum permissible stability	$30 \leq У_{integr} < 60$	The market situation is unstable, the efficiency of the production process and the organization of labor are low, the level of innovative culture is insufficient, the innovative infrastructure is underdeveloped	Follower strategy for improving products and technologies
Crisis stability	$У_{integr} < 30$	There is no innovative direction of development, production processes are characterized by low efficiency, social security of personnel is not ensured, demand for products is unstable or low	No resources for innovation

Depending on the stability class, strategic mechanisms and programs for innovative development of the enterprise are determined or adjusted.

Testing of the methodology for assessing the level of sustainability of innovative development was carried out on the example of one of the leading agricultural enterprises of the Republic of Mari El ZAO stud farm “Semenovsky”.

The object of the study - Closed Joint-Stock Company (ZAO) stud farm "Semenovsky" - operates in the territory of the Medvedevsky district of the Republic of Mari El. The company is a diversified economy. In terms of agricultural land, the company ranks first in the Republic occupying 19,770 hectares (as of 01.01.2019). The main activity of ZAO Semenovsky Stud Farm is the production of agricultural products: in animal husbandry - the production of milk, cattle, breeding livestock; in horse breeding - production of koumiss, breeding of young animals and pedigree horses (Lithuanian and Russian heavy breeds); in crop production - fodder storage for livestock needs.

The main indicators for calculating the level of sustainability of innovative development of ZAO “Semenovsky” according to the results of 2018 are presented in table. 8.

Table 8: indicators of sustainability of innovative development of ZAO "Semenovsky"

Analysis criterion	Indicator	Value	Expert grade
1.Production and economic sustainability			
1.1.Market sustainability			
Patent Portfolio	Coefficient of change in patent portfolio	1,1	2
Market share	Coefficient of change in market share	1,4	2
Non-operating income	Non-operating income growth rate	1,1	2
Company value	The coefficient of change in the value of the company	1,45	3
1.2.Sustainability			
Productive capacity	Workability of fixed assets	0,97	2
Product update	Product update rate	1,6	3
Production efficiency	Production profitability	29%	3
1.3.Investment sustainability			
Investment activity	Coefficient of investment activity	1,9	3
Investments in fixed capital	Fixed capital investment ratio	1,18	3
Innovation costs	R&D investment ratio	0,55	2
2.Organizational and managerial sustainability			
Efficiency of labor organization	Net profit per 1 managerialemployee	440,83thous.rub.	3
Management	Equity ratio	0,88	2
Marketing	The coefficient of bringing the product to the consumer	1,4	3
3. Social sustainability			
Workforce social satisfaction	Staffstability ratio	1,6	3
Staff stability	Personnel retirement rate	0,1	3
The degree of material satisfaction of employees	The ratio of the average salary in the enterprise to the average salary in the industry	1,6	3
4. Innovative culture			
Staff motivation system	Non-financial and financial motivation system	available	3
Employees perception of company values	The degree to which employees perceive company values as their own	high	2
Communicative system	Level of development of the enterprise communication system	high	3
5. Consumer sustainability			

Analysis criterion	Indicator	Value	Expert grade
Consumer deficit	The presence / absence of a shortage of consumers of products	absent	3
Sales volumes	Return on sales	38%	3
Price level	Customer acceptance of price levels	average	3

To calculate the value of the integral indicator of the sustainability of innovative development of the ZAO "Semenovsky" we will use the method of grading, which allows us to formalize the indicators proposed for the study (Table 9).

Table 9: assessment of the level of sustainability of innovative development of ZAO "Semenovsky"

Indicator	The maximum value of the indicator for enterprises in the industry	The actual value of the indicator for the enterprise	The number of expert points for each indicator	The ratio of the actual indicator to the maximum	The number of points for the actual indicator (product of expert assessment and the ratio of the actual indicator)
Coefficient of change in patent portfolio	1,4	1,1	2	0,79	1,58
Coefficient of change in market share	1,5	1,4	2	0,93	1,86
Non-operating income growth rate	1,2	1,1	2	0,92	1,84
Coefficient of change in the value of the company	1,6	1,45	3	0,91	2,73
Workability of fixed assets	0,97	0,97	2	1	2
Product update rate	1,8	1,6	3	0,89	2,67
Production profitability	29%	29%	3	1	3
Coefficient of investment activity	1,9	1,9	3	1	3
Fixed capital investment ratio	1,3	1,18	3	0,91	2,73
R&D investment ratio	0,55	0,55	2	1	2
Net profit per 1 managerialemployee	440,83 т.р.	440,83 т.р.	3	1	3
Equity ratio	0,88	0,88	2	1	2
The coefficient of bringing the product to the consumer	1,6	1,4	3	0,88	2,64
Staff stability ratio	1,6	1,6	3	1	3
Personnel retirement rate	0,1	0,1	3	1	3
Ratio of the average salary in the enterprise to the average salary in the industry	1,8	1,6	3	0,89	2,67
Non-financial and financial motivation system	Yes	Yes	3	1	3
Degree to which employees perceive company values as their own	high	high	2	1	2

Indicator	The maximum value of the indicator for enterprises in the industry	The actual value of the indicator for the enterprise	The number of expert points for each indicator	The ratio of the actual indicator to the maximum	The number of points for the actual indicator (product of expert assessment and the ratio of the actual indicator)
Level of development of the enterprise communication system	high	high	3	1	3
Presence / absence of shortage of consumers of products	is absent	is absent	3	1	3
Return on sales	38%	38%	3	1	3
Customer acceptance of price levels	average	average	3	1	3
Integral indicator					**56,72**

The ratio "indicator value - number of points" is established by experts and has a non-linear relationship. The expert commission included representatives of the Federal State Budgetary Educational Institution of Higher Education "Volga State University of Technology"and the Ministry of Industry, Economic Development and Trade of the RME.

As a result of the assessment, it was revealed that ZAO Semenovsky belongs to the class of normal sustainability of innovative development, since the value of the integrated index $Y_{interg} = 56.72$. In this case, the enterprise can be both a follower and a leader in the development of new or improving technologies. It is advisable forZAO "Semenovsky" to focus on the active improvement of existing production technologies, the development of the product portfolio (table. 10):

Table 10: strategic guidelines for innovative development of ZAO "Semenovsky"

Sustainability class	Recommended Innovation Development Strategy
High stability	It is recommended to adhere to a leadership strategy in the development of new products and technologies.
Normal stability	**Enterprises can be both followers and leaders in the development of new products and technologies.**
Maximum stability	The enterprise can only be a follower in the development of improving technologies and products.
Crisis stability	The enterprise is not ready to conduct independent innovation

Conclusion

To optimize the results of the innovation development strategy of the Mari El Republic, we recommend that you focus on developing a set of measures aimed at increasing the production and technological potential of the leading enterprises in the region by updating their capital base. In addition, in order to increase the level of innovation sustainability, local companies should pay special attention to improving the efficiency of organizing financing of innovation and services through the development of their own sources.

In order to develop a comprehensive innovation structure of the local economic system, the Mari El Republic is recommended to focus its efforts on developing a system to stimulate innovative activity

of enterprises in the region. Incentive programs should include support for all stages of the innovation cycle: development and generation of ideas, commercialization, promotion and use of innovation. The tools for the formation and development of the innovation policy of the region will improve the quality of the innovation environment and solve problems that hinder the accelerated development of the territory.

Abstract

Currently, the priority of the national economy is the course towards its accelerated innovative development. In this regard, there is an increased interest on the part of business entities not only in the problem of generating innovative business ideas, but also in their commercialization. Therefore, the issues of formation and development of technological entrepreneurship are becoming key at the present stage of economic development.

As part of the study, the essence and content of the process of technological entrepreneurship, its investment and design aspect, are examined. The study reflects the logic of building a business model based on an innovative business idea. The presented conceptual business model of the project reflects the aspects of project management, the value proposition to the market, the main risks of the project, the stages of the project development are identified and the conditions for its viability are formulated. As a business case for the design decisions, a financial model is presented that proves the economic efficiency of the project and its investment attractiveness. The constructed business model will help the entrepreneur understand the logic of creating profit and evaluate the technical, market and economical feasibility of the project.

Keywords: Innovation, Technological Entrepreneurship, Strategic Integration, Innovative Development, Project Management, Business Model.

Introduction

Most modern companies associate their strategic development with innovation. The term “innovation” was widely used thanks to Joseph Schumpeter, who noted that “innovation is a new scientific and organizational combination of production factors motivated by an entrepreneurial spirit”. The implementation of business ideas in the form of innovative commercially successful products is facilitated by the establishment and development of technological entrepreneurship.

As part of technological entrepreneurship, innovative solutions are being developed for complex engineering problems associated with the invention of new equipment and technologies, design and engineering, market research and the development of new materials, products and services. Technological entrepreneurship can take various forms, for example, in the form of licensing, start-ups, commercial R&D, but it is invariably accompanied by the creation of a business model that turns a business idea into an innovative investment project or an innovative product.

Materials and Research Methods

The object of research is the process of technological entrepreneurship in the conditions of innovative development of the national economy and its most important investment and design aspects related to the construction of a business model.

The subject of the research is the processes of innovative transformations taking place at enterprises and in the national economy as a whole, causal relationships and consequences of this process, as well as objective and subjective factors contributing to its development.

The theoretical basis of the study was the scientific and methodological works of foreign and Russian researchers, which reveal the essence of innovation and innovation, conceptual approaches to the development of strategic integration of innovation and technological entrepreneurship.

The fundamental principles that reveal the essence of innovation were formulated by the Austrian scientist J. Schumpeter in his work on the theory of economic development, where he highlighted the typical changes characteristic of innovation.

Among modern foreign researchers covering the problems of innovative development in recent decades, it should be noted the works of S. Blanck, E. Ries, M. Johnson, K. Christensen, H. Kagermann, A. Osterwalder, I. Pigne, in which they analyze the scientific methodological approaches to testing innovative ideas and building business models that contribute to their implementation.

A significant contribution to the development of methodological support for innovative management and technological entrepreneurship was made by Russian scientists. Barykin, V.O. Ikryannikov proposed a functional-dynamic model of technological startup management and methodological approaches to business modeling in the management of innovative projects. M.V. Kovaleva, L.V. Silakova, V.V. Shirokovara developed a classification of technological startups by functional areas of activity and proposed managerial approaches to their creation and development. N.N. Ilysheva, S.I. Krylov developed a balanced scorecard for the strategic management of innovation. B.E. Tokarev has developed a startup model with a feedback loop, characteristic of innovative products.

The methodological basis of the study was the historical and logical, formal and substantive approaches, methods of analysis and economic modeling.

Research Results and Discussion

Technological entrepreneurship is the process of creating a new business, focused on the implementation of innovative high-tech ideas, the implementation of which will create a sustainable competitive advantage in the market for the company.

Technological entrepreneurship is an innovative process characterized by the iteration of the stages shown in Figure 1.

Fig. 1: Technology Entrepreneurship Process

To achieve the goals of innovative development, an economic entity must turn an innovative business idea into a commercially viable and competitive product. However, often the traditional approach to organizing a business is untenable in relation to innovation. The main reason for this lies in the high degree of uncertainty of the situation - the issue of acceptance of an innovative product by the market remains not fully clarified. Thus, the process of creating and scaling up a business should be cyclical and iterative. When developing a product, a constant connection with the market and a consumer reaction to the presented version of the product are needed, which can be finalized until a competitive sample is received. The basis of such an activity may be the strategic integration of innovation and technological entrepreneurship, focused on the formation of a successful business model.

Technological entrepreneurship and innovation are becoming major factors in the development of modern companies. Conducted research opens up new promising areas for the development of technological entrepreneurship and helps to increase the innovative activity of Russian business entities. In turn, technological entrepreneurship contributes to the flexibility and adaptability of business systems, and innovation creates a solid foundation for effective development and increased competitiveness.

As part of the study, a project was developed for the production of recycled plastic products. Currently, the issue of recycling plastic waste is very acute, since plastic is widely used as containers and packaging of various products. The situation is aggravated by the fact that the plastic practically does not decompose and the accumulation of plastic waste poses a serious environmental threat. Thus, the disposal, recycling and reuse of plastic waste are the most important environmental tasks and a promising direction for the development of technological entrepreneurship.

The essence of the design business idea lies in the use of polymer-sand technology, which allows the production of products of any shape and size from composite materials. Polymer sand composite is an innovative material consisting of a mixture of sand, polymers and safe oxide paint, which has a high degree of environmental friendliness. Building materials and various architectural forms for improvement of house territories, recreation areas, summer residences and other objects can act as a product brought to the market. Products made from this material look like wood traditionally used in construction and beautification, which contributes to the adoption of innovation by a target group of consumers.

Competitive advantages of products from polymer-sand composite materials are as follows:

- safety and environmental friendliness of the polymer included in the raw mix;
- resistance to atmospheric influences (frosts, temperature changes, high humidity);
- low flammability;
- strength and high wear resistance, which increases the life of the product;
- low cost.

The conceptual business model of the project reflects the following elements: value proposition, key resources, key processes, profit formula.

The value proposition is as follows:

- the consumer receives environmentally friendly, safe and durable products with a fairly low cost;

- the company gets a way to solve the problem of the accumulation of plastic waste and preserve the environment, the development of technological entrepreneurship and increase production efficiency.

Creating an innovative project and planning the stages of its development should be based on the professionalism of the project team. This will reduce the risks associated with starting a new business. Thus, an important condition for success is the competent project management at all stages of its creation and implementation.

The task of effective management of an innovative project is complicated by the variety of areas of activity that are affected during the work. The variety of functions implemented by the project team requires careful selection of specialists and makes the work of the project manager unique.

The team of the innovation project was made up of specialists with complementary roles and competencies that are implemented at all stages of the project (Table 1).

Table 1: innovation project team

The project team	**Functionality Implemented**
Leader - Project Leader	A key figure in project activities, forms goals, provides strategic and ongoing leadership, coordinates the actions of team members
R&D Specialist	Conducts research, develops engineering solutions, provides technical support for the project, embodies ideas in specific products
Analyst	Carries out the economic feasibility of the project, calculates the financial consequences of decisions made, assesses the risks of the project
Marketer - communicator	Conducts market research, forms a marketing strategy for an innovative product, interacts with contact audiences
Consultant - Lawyer	Develops IP-strategy of the project, provides legal support

Team members perform the following functions: project management, research and technical support, financial and economic justification of the project, marketing and legal support of the project.

Market research of composite building materials showed that Japan is the world leader in the use of recycled materials in production, where in some areas the share of recycled plastic products reaches 95%.

In Russia, this indicator barely approaches 3%, which indicates that the market has great growth potential. In 2018, the market growth amounted to about 12% and according to forecasts, the growth rate in the near future will increase to 16%.

Building materials and products for the improvement of local areas is a basic consumption product, the potential consumers of which are government agencies (B2G segment), construction companies (B2B segment), as well as individuals (B2C segment).

Market research of the Mari El Republic showed that the products have high sales potential in the B2G segment. Among the priority national projects is the project "Formation of a comfortable urban environment", the purpose of which is "to create conditions for systematic improvement of the quality and comfort of the urban environment throughout the Russian Federation by implementing annually a set of priority improvement measures in the constituent entities of the Russian Federation." During implementation of the national project, federal guidelines were developed that establish the beautification rules for municipalities in the Russian Federation. The range of priority improvement measures includes basic and alternative measures, including:

- improvement of territories adjacent to residential buildings, including courtyards;

- improvement of urban environment facilities;

- encouragement of improvement projects initiated by citizens;

- creation of co-financing instruments for public improvement projects;

- improvement of popular trade areas.

The budget of the priority national project "Formation of a comfortable urban environment" for 2020 provides for financing in the amount of 12,500 million rubles, including 5,000 million rubles at the expense of the federal budget and 7,500 million rubles at the expense of the consolidated budgets of the constituent entities of the Russian Federation. An analysis of public procurement showed that over the 11 months of 2019, 167 tenders were held in the Republic of Mari El for landscaping and landscaping, requiring small architectural forms.

A study of the B2B segment showed that the volume of housing construction in 2018 in the Republic of Mari El amounted to 136,000 sq.m. Upon commissioning of construction projects, improvement of the courtyard and adjacent territory is necessary. Outdoor furniture and other small architectural forms made of polymer-sand composite are elements of the arrangement of territories. According to the recommendations for the improvement of courtyards, outdoor furniture should be assembled from processed and durable materials with high strength. In addition, in order to increase safety and improve space, it is necessary to provide a sufficient number of recreation places in the yards, equip leisure areas with benches and ballot boxes, and equip children's and sports grounds. These requirements contribute to the formation of demand for products. According to the Portal of the Housing and Utilities of the Republic of Mari El, in 2019 5941 apartment buildings and 42 housing and communal services organizations were registered.

The product sales potential was determined on the basis of a marketing analysis of 50 cities of Russia with a population from several hundred to several million people, conducted by UmnayaSREDA. Assessment of the sales potential of products in the Republic of Mari El is presented in table 2.

Table 2: assessment of the marketing potential of products from polymer-sand composite for landscaping

Parameters	Indicators
The population of Yoshkar-Ola on 01.01.2019	282800 people.
The population of the Republic of Mari El on 01.01.2019	680380 people.
Number of apartment buildings (courtyards)	5941 yard
Number of parks, squares, gardens	25
Number of pedestrian areas in need of improvement	42
Number of city cemeteries	5
Points of consumption of products (total territory need for products)	
When landscaping courtyards (benches)	5941*10=59410
At improvement of park territories (benches)	25*50=1250
At improvement of cemeteries (benches)	5*120=600
Monthly sales potential	
When landscaping courtyards (benches)	59410/7/12=708
At improvement of park territories (benches)	1250/7/12=15
At improvement of cemeteries (benches)	600/7/12=7
The total sales potential of manufactured products, based on all the listed points of consumption per month	
Number of benches	708+15+7=730
Number of rubbish bins	730/2=365

Thus, there is great market potential. More than 90% of the market for recycled plastic products is free.

The product has a high degree of market novelty. The price of the product ensures its availability to the target group of consumers and competitiveness.

It is necessary to organize active product promotion by generating demand both from end consumers and from the professional community. When promoting products from innovative materials on the market, the idea of saving natural resources and environmental protection should be used.

Prediction of sales was made taking into account the following conditions (table. 3).

Table 3: the Structure and conditions of sales

Sales conditions	Share in sales%	Price by type of product, rub.				
		Bench (product 1)	rubbish bins (product 2)	Park sofa (product 3)	Flower pots (product 4)	Road border (product 5)
Retail	20	16000	8000	20000	800	350
Small wholesale	30	12000	6000	16000	600	300
Large wholesale and dealers	50	8000	5000	12000	500	250

At the first stage, one production line is launched, which allows to produce 100 benches and 50 rubbish bins every month. At the second stage, 6 months after the start of production, the second line will be purchased and launched, which will increase production volumes by 2 times. With the expansion of the line, 3 new positions will be introduced into the production program: a park sofa, a flowerpot, a road curb with monthly output volumes of 10, 300 and 500 pieces, respectively. The forecast of sales volumes for three years in the context of individual types of products is presented in table 4.

Table 4: sales forecast

Indicators	1st year	2nd year	3rd year	Total
Product 1 - bench				
Total quantity, pcs.	1200	1200	1200	3600
Total revenue, rubles	12960000	12960000	12960000	38880000
Product 2 - rubbish bins				
Total quantity, pcs.	600	600	600	1800
Total revenue, rubles	3540000	3540000	3540000	10620000
Product 3 - park sofa				
Total quantity, pcs.	30	120	120	270
Total revenue, rubles	444000	1776000	1776000	3996000
Product 4 - flower pots				
Total quantity, pcs.	900	3600	3600	8100
Total revenue, rubles	531000	2124000	2124000	4779000
Product 5 – road border				
Total quantity, pcs.	1500	6000	6000	13500
Total revenue, rubles	427500	1710000	1710000	3847500
Total revenue, rubles	17902500	22110000	22110000	62122500

Organized production must meet the following conditions (table 5).

Table 5: production specifications

Production Room Parameters	Required
Area, sq.m	not less than 100
Ceiling height, m	not less than 3
Power supply in the workshop	220 V and 380 V with power from 50 kW
Possibility to equip the workshop with ventilation	there is
Floor covering	Concrete

The set of basic technological equipment includes an extruder for preparing the raw material mixture, a hydraulic press, a molding table for the press, molds, a sawing machine, a drilling machine, a rack for assembling products, and a set of tools.

The calculation of the depreciation amount is made taking into account the useful life of the equipment and the depreciation rate (table. 6).

Table 6: calculation of depreciation

Name	Amount	Cost, rub.	Useful life, months	Monthly depreciation rate,%	Amount to be debited per month
A set of basic technological equipment	1	4200000	60	1,67	70140
Set of equipment for launching the 2nd line	1	2500000	60	1,67	41750
Total					111890

For the manufacture of the polymer-sand mixture, crushed recycled materials of the following types of plastic are used:

- HDPE (high-density polyethylene of low pressure, from which disposable tableware, bottles for cosmetics, packaging bags, bags, toys, cans, etc.) are made;

- LDPE (low-density polyethylene of high pressure, from which buckets, plastic bags, compact discs, linoleum are made).

The staffing required by the project is presented in table 7.

Table 7: the staffing of the enterprise

Position	Number of staff	Salary (permanent part), rub.	Labor remuneration fund per month, rub.
At the initial stage			
1. Head	1	70000	70000
2. Sales Manager	1	30000	30000
3. Team Leader	1	15000	15000
4. Worker	2	12000	24000
Total permanent part of payroll per month			139000
After the launch of the second line and the transition to a round-the-clock two-shift schedule for 12 hours			
1. Head	1	70000	70000
2. Sales Manager	1	30000	30000
3. Team Leader	2	15000	30000
4. Worker	4	12000	48000
Total permanent part of payroll per month			178000

Organization of remuneration will be constructed as follows (table. 8)

Table 8: organization of remuneration

Position	Remuneration per month
1. Head	70,000 rub. + 6% of value added (revenue - material costs)
2. Sales Manager	30000 rub. + 2% of value added (revenue - material costs)
3. Team Leader	Salary of 15,000 rubles. + 2% of value added (revenue - material costs)

4. Worker	Salary 12,000 rubles. + 1% of value added (revenue - material costs)

The risk map of the innovation project clearly represents the main risks identified during the risk management procedures and risk management strategies (Fig. 2).

	Low probability	**Medium probability**	**High probability**
High losses	Production risks: Problems of organization of production and work Risk sharing strategy	Technological risks: There is no way to go into mass production, a high level of marriage Risk reduction strategy	
Average losses	Management and social risks: Problems with the project staff Risk reduction strategy	Market Risks: The emergence of direct competitors Price increase due to rising costs End-product acceptance Risk preservation strategy	Market Risks: Problems finding suppliers of raw materials (plastic waste) Risk sharing strategy
Low losses		Environmental risks Change of law Risk avoidance strategy	

Fig. 2: Map of project risks

The most significant are production and technological risks, for the management of which a risk sharing strategy through insurance and a reduction strategy, that is, risk reduction, are recommended.

The total investment need is 7,500,000 rubles (Table 9).

Table 9: investment costs

Investments	**Amount, rub.**	**Source of funds**
1. Purchase of a set of processing equipment	4200000	Credit
2. Training, technology, technical documentation, development of a business plan, website, procurement of CRM	400000	Own funds
3. Replenishment of working capital (raw materials for 3 months)	300000	Grant funds
4. System of forced ventilation of the workshop	100000	Own funds
5. Purchase of a set of equipment for launching the second line	2300000 200000	Subsidy, equity
Total investment requirement:	7500000	

The structure of project financing sources is presented in table 10.

Table 10: sources of project financing

№	Source Name	Amount, rub	Share in the overall structure,%
1.	Equity	700000	9,3
2.	Borrowed funds (credit)	4200000	56,0
3.	Other support (grant)	300000	4,0
4.	Subsidy in the form of a return on investment in production	2300000	30,7
	TOTAL sources of investment:	7500000	100

Six months after the start of production, it is planned to receive subsidies in the form of a return on investment in production in the amount of up to 50% of 4,600,000 rubles, that is, from initial investments in fixed assets and preparation of premises. The funds received are planned to be invested in the expansion of the production line. After the installation of the additional line, it is planned to receive subsidies in the form of a return on investment in production in the amount of 50% of 2,500,000 rubles, which will amount to 1,250,000 rubles. The planned date of receipt of funds for 2020 is the middle of 2021 (1.5 years after the start). Funds may be used for early repayment of a loan.

In order to optimize the taxation of financial and economic activities of the newly organized enterprise during 2020-2022. the company will operate in a simplified tax system. The tax burden for this period will be as follows: deductions to social funds - 30.2% of the salary fund, income tax - 15% of the difference (income - expenses).

The financial model of the project is presented in tables 11 - 13.

Table 11: cash flow from operating activities

Period	**0**	**1st year**	**2nd year**	**3rd year**	**Total**
Cash flow from operating activities					
Revenue		17902500	22110000	22110000	62122500

Communication services		36000	36000	36000	108000

Marketing expenses		480000	480000	480000	1440000
Administrative expenses		144000	144000	144000	432000
Payout% on the loan		672737,48	257559,4		
Unexpected expenses		200000	200000	200000	600000
Profit before tax		5689432,52	7399368,6	7656928	21676026
Income tax		853414,878	1109905,29	1148539,2	3111859,4
Net profit		4836017,642	6289463,31	6508388,8	17633870
Operating Flow Balance		5802947,642	7632143,31	7851068,8	21286160

Table 12: cash flow from investing activities

Period	**0**	**1st year**	**2nd year**	**3rd year**	**Total**
Cash flow from investing activities					
Equipment for polymer processing and production of mortar	-4200000				
Training, technology, technical documentation, business plan, website, CRM	-400000				
Equipment for launching the second line		-2500000			
Working capital replenishment	-300000				
Workshop forced ventilation system	-100000				
Balance of flow from investment activities	-5000000	-2500000			

Table 13: cash flow from financing activities

Period	0	1st year	2nd year	3rd year	Total
Cash flow from financing activities					
Receipt of own funds	500000				
Grant proceeds	300000				
Getting a short-term loan	4200000				
Receiving a subsidy in the form of a return on investment in production		2300000	1250000		
Loan repayment payments		-1892410,96	-257559,4		
Net cash flow	5000000	607589,04	992440,6		

Based on the financial modeling of cash flows and the assessment of financial and economic indicators, it was established that the project is investment attractive. Project performance indicators are presented in table 14.

Table 14: project performance indicators

Period	0	1st year	2nd year	3rd year	Total
Total flow balance	0	3910536,682	8624583,91	7851068,8	21286160
Cumulative Flow Balance	0	3910536,682	12535120,59	20386189,39	20386189
Net cash flow from operating and investing activities	-5000000	3302947,642	7632143,31	7851068,8	21286160
Cumulative net cash flow	-5000000	-1697052,358	5935090,952	13786159,75	13786160
Discount coefficient at E = 15%	1				
Discounted flow on operating and investment activities	-5000000	-2126435,551	5800428,916	3956938,675	7630932
NPV	-5000000	-2126435,551	3673993,364	7630932,039	7630932
ID	3,7				
Return on investment,%	375,7				
Return on sales,%		31,78	33,46	34,63	34,89

The project meets the criteria of effectiveness. So in any time interval there is a positive balance of total cash flow cumulatively, where the investor makes expenses or receives income. Net discounted income takes a positive value, the profitability index is 3.7. For the entire billing period, the project generates a net present value of 7630932 rubles. The estimated payback period of the project is 15 months.

In the development of the project, several stages can be distinguished:

- preparatory stage;

- the stage of analysis of the conformity of the product to the expectations of the target market and its refinement;

- reaching the design capacity, expected by the end of the second year of implementation;

- scaling and market capture;

- sale of a business share to a strategic investor.

This business model is viable subject to a number of conditions:

1) products made on the basis of polymer-sand composite should be accepted by the mass consumer;

2) the entrepreneur should be able to organize mass production;

3) over time, it is necessary to develop product options for various consumer segments.

The second stage of assessing the investment attractiveness of the project showed that it is technically feasible. Currently, a technology for processing plastic waste and manufacturing polymer-sand composite material has been developed. At the initial stage, you can organize small-scale production and carry out test sales.

Market feasibility is confirmed by the sufficient capacity of the market and target segments, the willingness of the consumer to accept innovation; the low price of products from recycled plastic waste, which ensures its availability for consumers, as well as a sustainable and scalable business model.

Economic feasibility is confirmed by the high values of indicators of economic efficiency of the project.

Thus, the presented business model is quite formalized and allows you to understand the logic of creating profit. In addition, it contains a value proposition to target consumer groups, which makes it viable and commercially feasible.

Conclusion

The development of technological entrepreneurship is of great importance from the point of view of the strategic development of the Russian economy. As a process of creating a new business, technological entrepreneurship should be accompanied by the construction of a business model, which is based on the investment and project aspect and related characteristics: team interaction and functional addition of specialists participating in the project team, focus on creating the customer value of an innovative product due to new knowledge, characteristics of key resources, key processes, profit formula. Strategic integration of innovation and technological entrepreneurship creates the basis for the development of business modeling and contributes to the successful commercialization of innovations, which ultimately leads to increased competitiveness of enterprise structures and the national economy as a whole.

Abstract

The article discusses the organizational and methodological foundations of intra-school education quality management in the system of municipal educational institutions of Russia. The Federal Law of the Russian Federation "On Education" defines the need for the functioning of the system of assessment activity in an educational organization (VSOKO). However, a national regulation on the formation of such a model and its inclusion in the activities of an educational organization in Russia has not yet been formed. The analysis of the practice of introducing the model of internal assessment of the quality of education in general education organizations of the Vologda Oblast, the study of the level of satisfaction with the quality of the educational process of all subjects of the educational process allowed us to develop a system of requirements for the formation of a model of intra-school education quality management, which allows for the development of effective management decisions.

Keywords: Education Quality Management System, Intra-School Management System, Municipal Level, Education Quality Assessment.

Introduction

The changes taking place in Russian education in general and in school education in particular are aimed at improving its quality. Any innovation, whether it is the introduction of the Federal State

Educational Standards, the professional standard of a teacher, changes in the state final certification procedure, or any other, results in a certain transformation of the properties of the educational process, the educational system of one or another level: adaptability, manageability, openness, coherence, etc. At the same time, the quality of education remains the leading one of the priorities, which found its expression in the national doctrine of Russian education, in the law "On Education in the Russian Federation" (Article 2, paragraph 29 of the Federal Law-273).

At present, education quality management systems are being built at all levels of government in Russia in order to ensure the fulfillment of a social order, guarantee students and their parents a certain level of quality, reduce the likelihood of unintended results, and ensure managed development.

State programs for regional development become a guarantor and, at the same time, a driver for achieving national goals. Of particular importance is the formulation of the problem in the face of uneven socio-economic development of the Russian regions and the growing pace of digitalization and innovative development of the global economy. In modern Russia, the formation of a knowledge economy is directly related to the implementation of the “Strategy for the Development of the Information Society in the Russian Federation for 2017-2030," which sets as a strategic guide the development of human potential by creating conditions for creating a knowledge space and providing access to it, and improving knowledge dissemination mechanisms, their application in practice in the interests of individuals, society and the state.

The ambitious goals of national projects and programs in a strategic perspective should be confirmed by the successful practice of implementing regional programs. The study of a number of regional programs for the development of educational systems made it possible to establish that in the education management system at all levels a unity of understanding of the strategic orientation of its development path towards achieving high quality standards has been achieved. In accordance with the state program "Development of Education of the Vologda Oblast for 2021-2025" the development of the regional education system is "... increasing the availability of quality education that meets the requirements of innovative development of the regional economy, the modern needs of society and every citizen.” The state program of the Republic of Mari El “Development of Education” for 2013 - 2025 stated as the main goal “... ensuring high quality and accessibility of education in accordance with changing demands of the population and promising tasks of the development of innovative activity in the Republic of Mari El”. The state program of the Chuvash Republic "Education Development" is focused on "... ensuring the availability of quality education, focused on the formation of a competitive personality that meets the requirements of innovative development of the economy, has the skills to design its own professional career and achieve modern standards of quality of life based on universal values and an active citizenship".

A whole range of functions is implemented in the quality management loops: from forecasting, modeling, goal setting, coordination to control, assessment, analysis, and accounting. Each of the functions is built into the management cycle, ensures the adoption of a certain managerial decision to improve quality (warning, corrective).

Effective management of the quality of education is possible only through the use of objective assessment procedures. The correctness of the assessment is determined by the quality of the measuring materials, the reliability of the data collected, the validity of the interpretation and use of the information received. But the directions of improving the procedures for assessing educational achievements of students reflect only part of the tasks that need to be solved for the effective functioning of the system of internal assessment of the quality of education. The quality management system should contain blocks that reflect the effectiveness of the educational organization, namely: strategic and operational planning of processes, intra-organizational assessment, decision-making on the adjustment based on the identified quality problems of the provision of educational services.

Of particular importance is the problem of effective management of the quality of education at the level of organizations providing training in the educational programs of primary, basic and secondary

education, that is, the school system. Between 2005 and 2018, the number of such educational organizations in Russia decreased by almost 35% (from 63174 organizations to 41349 organizations), while the number of students enrolled in primary, basic and secondary general education programs, despite the temporary decline in the second half the first decade of the 21st century, from 2005 to 2018 increased by 3% (from 15630.9 thousand people to 16137.3 thousand people) and has a tendency to further increase, since in the country's preschool educational institutions the number of children is much larger than the number of high school graduates and students of universities and professional educational institutions (7.5 million vs. 6.7 million). Russia overcame the period of the "demographic pit", but emerged from it with a significantly weakened school system.

Materials and Research Methods

The purpose of the study is to develop a system of requirements for the formation of a model of intra-school education quality management, which allows for the development of effective management decisions based on a reasonable assessment of the quality of education in municipal educational institutions of the Russian Federation.

The object of the study is the system of state management of the quality of education, the subject is the system of intra-school quality management of education in the municipal comprehensive school of Russia. The Vologda Oblast was chosen as the experimental testing ground for the region, where a tactical document was developed at the regional level to provide a solution to the identified problem - "Methodological recommendations for the formation of a model of the internal system for assessing the quality of education in educational institutions of the Vologda Oblast" (hereinafter referred to as the VSOKO model). The study was tested on the activity data of the Vologda municipal secondary school "Gymnasium No. 2", which implements educational programs at all three levels (primary general education; basic general education; secondary general education) that are most typical for such an institution in the educational system of school education in Russian Federation.

Problems of the quality of education in the managerial aspect are investigated in the works of Bermus A.G. (2003), Bolotov V.A. (2018), Arkhipova T.V. (2017), Sagdieva M.S. (2017), and others. The specifics of the concept of "quality of education" at the level of an educational institution is revealed in the works of Zagvyazinsky V.I. (2010), Kulemin N.A. (2005), Panasyuk B.P. (2000), Shcherbo I.N. (2005). Foreign experience in researching the problem of measuring the quality of educational services and developing competent management decisions on its basis is well diversified and deserves the undoubted attention of Russian scientists. Of particular note is the framework for education quality indicators proposed by UNESCO. However, the issues of turning off the model for assessing the quality of education in the system of intra-school management, developing managerial decisions in the context of the innovative development of educational systems and the formation of a knowledge economy in Russia remain insufficiently studied and therefore acutely relevant.

The methodological basis of the study was a complex of general scientific and special methods of cognition. In the course of the study, such general scientific methods were used as analysis, synthesis, generalization, historical, graphic method; special methods of cognition: formal-logical method and specific sociological.

Research Results and Discussion

The Federal Law "On Education" defines the need for the functioning of the system of evaluation activity in an educational organization (VSOKO). However, a national regulation on the formation of such a model and its inclusion in the activities of an educational organization in the Russian Federation has not yet been formed. It is understood that the educational organization is able to independently develop a similar model. Currently, in most regions of the Russian Federation, it was decided to develop this model at the regional level, however, the development of regulations and provisions on the use of the model did not become a sufficient basis for its effective inclusion in the process.

According to the methodological recommendations on the formation of a model of internal assessment of the quality of education in general education organizations of the Vologda Oblast, developed by specialists of the Vologda Institute for Educational Development, the VSOKO model should include:

1. Regulatory and documentary unit. This block includes local regulatory legal acts, the main task of which is to regulate the application of the internal system for assessing the quality of education, its individual assessment procedures, establishing the functionality and powers of officials, public administration bodies of a general educational organization, and other subjects of educational quality assessment;
2. Organization block. This unit is formed by the structures of linear-functional and program-targeted management of the educational institution and the educational process when implementing the functions of assessing the quality of education or procedures, which include an element of assessing the quality of education (self-examination, internal administrative control, examination, monitoring);
3. The process unit. This unit is responsible for describing the procedures by which the quality of education in an educational institution will be assessed, both in general and in its individual aspects;
4. Instrumentation unit. This block is a combination of the whole set of evaluation and measuring tools, control and measuring materials, evaluation technologies, techniques, technical resources, software and hardware used to carry out procedures for assessing the quality of education;
5. Information and presentation block. This unit has the task of systematizing information according to the results of internal and external evaluation procedures.

Local regulatory legal acts may include provisions, rules, instructions, requirements, and regulations. The composition of local acts is determined by the Charter of an educational organization, depends on the requirements of Russian legislation in the field of education, and follows from the conditions for the application of Federal state educational standards in practice. The volume of local regulatory acts that a general educational organization develops and applies directly depends on the number of students implemented in its educational programs, the level of development of the document management system, the level of qualification of administration representatives, and other factors. A study of a set of documents developed by a number of Russian municipal educational institutions showed that the most common local regulatory legal acts are:

- Regulation on the internal system for assessing the quality of education;
- Regulation on the system of internal monitoring of the quality of education;
- Regulation on intra-school control;
- Regulation on criteria-based assessment;
- Regulation on the assessment system, forms and procedure for conducting current, intermediate and final certification at the level of primary, basic general education;
- Regulation on extracurricular activities;
- Regulation on the forms and frequency of current control and intermediate certification of students;
- Regulation on design and educational research activities of students;
- Regulation on the provision of information on the student's current performance, maintaining an electronic diary and an electronic performance journal.

It is important to emphasize that for the effective functioning of the internal system for assessing the quality of education in a general educational organization, together with local regulatory legal acts, a number of documents should be developed and systematically applied that are aimed at implementing the managerial functions of planning, control, evaluation, analysis, and accounting. These documents establish the functionality and responsibilities of officials. The organizational unit is provided for by the Charter and staffing of the educational organization. The powers, responsibilities and duties of officials (director, deputy directors, class teacher, psychologist, etc.) are established in job descriptions.

The procedures included in the process unit are usually called internal procedures, since they are initiated, performed in accordance with the internal plans of the school. Such procedures may include

examination of various materials, pedagogical council, student and graduate portfolio, administrative control in various areas, career guidance testing and other materials.

The information collected based on the results of internal and external evaluation procedures should be convenient and technological for use by various consumers and stakeholders. It can be self-examination reports, various certificates, etc. For ease of use in managing the quality of education, it is important to structure all received data in a timely and periodic manner, to protect against unauthorized removal, distortion, loss.

The development and improvement of the internal system for assessing the quality of education existing in an educational organization today needs to be built on ensuring a combination of an approach that implements the principles of a qualitative assessment and an approach that traditionally represents technologies for the quantitative assessment of the parameters of educational services. However, a significant problem in the formation and application of such a model is also its adequate compliance with the interests of students and their legal representatives (parents, guardians), since assessment procedures should not create restrictions on the effective course of the educational process, since according to the modern logic of effective educational management, control is a function management should not prevail over other functions, reducing their effectiveness and importance. Ultimately, educational organizations, which include municipal educational institutions, are agents of the educational services market, who have as their primary task the high-quality rendering of these services in accordance with the needs of customers and spokesmen of their interests. Thus, the study of the level of satisfaction with the quality of the educational process in the current academic year of all subjects of the educational process should be an important tool for improving the model of intraschool education quality management. Obviously, in this regard, the study of the results of studying the level of satisfaction of subjects of the educational process in municipal educational institutions of Russia that have a fairly long experience in introducing the VSOKO model in the management of the educational process, which was undertaken during the study on the basis of an experimental training ground - the municipal educational institution, is gaining relevance. Gymnasium No. 2 "of Vologda. This educational institution, on the one hand, in terms of its organizational structure, the number of teachers and students is a typical Russian municipal educational institution, on the other hand, has successful experience in introducing innovative educational process management technologies. According to the results of the academic year 2009-2010, the gymnasium was included in the national register "Leading educational institutions of Russia" (certificate No. 10167 of January 13, 2011). In 2011, the gymnasium won the competition of educational institutions of the Vologda Oblast implementing innovative educational programs and received a grant in the amount of 1 million rubles. In 2017, this gymnasium was included in the list of 500 best schools in Russia.

In the course of the study, satisfaction with the quality of the educational process will be understood as the emotional and evaluative attitude of the individual and the team towards the work performed, the services provided, and the conditions for its flow, the receipt of these services (depending on the subject of the educational process), since, as a rule, it is important for a person not only the product of the activity, but also how satisfied or dissatisfied with this product is, is it satisfied or not satisfied with the process of the activity, the relations between its participants. It is important to understand that the level of satisfaction is subjective in nature and is associated with people's perception of their personal educational status, depending on cultural characteristics, value systems and social standards existing in society. The socio-psychological characteristics of the parent community of the gymnasium indicate a high level of claims and expectations regarding the quality of education provided by the institution, as well as the social adaptability of school graduates. The level of satisfaction of teachers with working conditions and the level of the socio-psychological climate serves as a kind of indicator of team cohesion, its potential to make collective decisions and cope with difficulties, and its willingness to bear responsibility for the common cause. Of course, all parties interested in quality education are clearly aware that recognizing the school successfully working if you can achieve high levels of training and education of students, and at the same time students and teachers show a positive attitude towards school life, they feel comfortable and confident enough for productive work.

During the study in 2019, a continuous survey was conducted of students, their parents, teachers of the Vologda Grammar School No. 2 municipal educational institution in order to study the level of satisfaction of all subjects of educational activity with the quality of educational services provided. In total, more than 500 people took part in the questionnaire, of which 42% were students' parents, 47% were students, and 5% were teachers of the gymnasium, which corresponds to the structural units of the abundance of these categories of participants in the educational process of the gymnasium. The questionnaire was developed during the study on the basis of the study and analysis of existing methodological approaches to assessing satisfaction with the quality of education and the implementation of activities as a teacher. Figure 1 presents the main results of the survey.

As can be seen from the results, a high level of satisfaction with the educational process of the gymnasium was shown by 65% of students, 83% of parents, 70% of teachers of the gymnasium, positively assessing the educational activities of the institution. In general, a high level of satisfaction amounted to 74% of the total number of all respondents. A score of 26% of students, 16% of parents, and 26% of teachers indicate an average level of satisfaction. The overall average satisfaction rate among survey participants was 22%. 4% of respondents are unsatisfied with the quality of education, working and studying conditions, and relations within the school team. Of these, a rather high percentage of students with a low level of satisfaction, which made up 9% of the total number of school students surveyed, deserve attention, which is quite different from the assessments of other groups of subjects of the educational process. It can be assumed that the internal processes of development of an educational institution have constraining factors in development in terms of quality, which reduces the overall assessment of the favorableness of schooling.

The questionnaire questions reflected 4 priority positions characterizing the quality of the educational process:
- satisfaction with the institution as a whole;
- satisfaction with the organizational side of the educational process;
- satisfaction with the active, substantive side of the educational process;
- satisfaction with the socio-psychological climate of the educational process.

For each block, a satisfaction index was calculated with a maximum value of 5 points. A comparative analysis of the results allowed us to identify trends in the decrease and increase in the satisfaction index for various aspects of the institution's activity relative to the average indicators for the gymnasium. So, among the parents of students assessment of the main criteria of the educational process distributed fairly evenly. Students of some classes clearly showed a decrease in satisfaction by various criteria. It is important to pay attention to the results in grades 6, 8, 10, where students note insufficient communication in children's groups and interaction with teachers. The most favorable results of satisfaction were in grades 4.

Level of satisfaction with the educational process,%

The results of the study of the creative potential of teachers of the gymnasium,%

Level of satisfaction of teachers of the gymnasium with the profession of teacher,%

The level of involvement of teachers in professional competitions and innovative projects,%

Figure 1: Results of a study examining the level of satisfaction of all subjects of educational activity with the quality of educational services and self-examination of the municipal educational institution "Gymnasium No. 2" in Vologda (Vologda Oblast, Russia)

The survey procedure provided for proposals to improve the work of the municipal educational institution. The analysis of the questionnaires made it possible to single out a number of acute issues requiring the attention of the leadership of the gymnasium and the teaching staff. Students and their parents made suggestions on a number of parameters of the organization of the educational process, which, in their opinion, can improve its quality. Among the noted positions, quite a lot of attention is paid to the problems of infrastructure quality (repair of premises, improvement of the school yard, a variety of sports facilities, compliance with sanitary standards in public places) and the comfort of living in the gymnasium (quality of food, level of service in the canteens). Along with this, proposals were put forward to improve the psychological climate of school life, return to the traditional five-point grading system, reduce the workload, put forward the problem of staff shortages of professional teachers, and increase their qualifications, including the level of communicative culture.

During the study, an analysis of indicators for self-examination used for the public report of the Russian municipal educational institution was made. This analytical report contains information and analysis of the work of the educational institution in the main areas of functioning and is intended for the public presentation of the results of the work to the founder, parents, and the public. The purpose of this analytical report is to describe the real situation at the moment, to attract recipients to its discussion and assessment, to express opinions, suggestions and recommendations for the development of the school. The effect of such a dialogue can be an update of the school development program, an increase in the resource support of the school, a change in its material and technical security, an expansion of the student population, and increased competitiveness.

The results of the self-examination of the activities of the gymnasium made it possible to establish that the vast majority of teachers have a fairly high level of satisfaction with the profession of a teacher (70% of all teachers of an educational institution), their position in the team and the gymnasium as a whole. This factor indicates a favorable atmosphere conducive to the professional development of teachers themselves, and, as a result, improving the quality of education in a general educational institution. At the same time, one cannot fail to note the fact that almost a third of the teaching staff of the gymnasium are either not completely satisfied with the chosen profession, or partially satisfied. At the same time, the number of teachers with a high level of creative potential in one of the most successful municipal educational institutions in Russia is only 18% (Figure 1). Another indicator that indirectly affects the quality of the educational process is the indicator of the participation of teachers in professional competitions, development of innovative projects and the

dissemination of pedagogical experience. The analysis of self-examination data indicates that the teachers of the gymnasium, which has a lot of professional regalia, do not use all the opportunities for generalizing and disseminating pedagogical experience. Measures are needed to stimulate educators in activities related to the dissemination of personal pedagogical experience. An oral survey of teachers made it possible to identify the following limiting factors for improving the quality of the educational process: the low motivation of individual gymnasium students to learn, the difficulty in implementing techniques and methods of individualization and differentiation of education; difficulties in intersubject integration; inability to build individual educational training routes for students and their tutoring, lack of preparedness for the implementation of the provisions of the system-activity approach in training; a large number of reporting documentation.

Thus, a study conducted on the basis of an experimental training ground showed that a high level of satisfaction with the quality of the educational process provided by the gymnasium prevails in the municipal educational institution (74% of the total number of respondents). The proportion of survey participants, which is characterized by an average level of satisfaction, was 22%. 4% of respondents are not satisfied with the quality of education. The greatest satisfaction of parents is associated with the socio-psychological climate of the institution, with its atmosphere of constructive interpersonal relationships that have developed in the educational environment. At the same time, students are dominated by a high level of satisfaction with the gymnasium as a whole, its authority in the city and the region, and involvement in the traditions of the gymnasium. The results of monitoring the level of satisfaction made it possible to identify cool teams that require a set of pedagogical measures of support and control, support for educational activities. The smallest values in terms of satisfaction with the quality of the educational process were determined in the position of the organizational side of the educational process for each category of respondents. The evaluation of this criterion includes the comfort of the premises in the school, the sufficiency of teaching aids for mastering subjects, and taking into account all the basic needs of students.

The data obtained during the study allow us to determine the main components of the model of the intraschool education quality management system and the system of requirements for them. So, we will consider the following components of the VSOKO model, which have received confirmation of their significance, as the main ones: 1) the conceptual block, which primarily includes the policy and goals of the general educational institutions in the field of quality, as well as goals, objectives and principles of internal assessment of the quality of education; 2) the legal framework as a basis for quality management, which will comprise, as previously indicated above, legal acts of the federal, regional and municipal levels, as well as local acts of a general educational organization; 3) the organizational unit, that is, the organizational structure of quality management.

The fundamental element of the organizational structure of the quality management of education of a municipal educational institution in Russia (Fig. 2), in our opinion, should be the scientific and methodological council of the school, which on a mandatory basis includes the head of the organization, the leaders of methodical associations. The leaders of methodological associations are usually the most experienced and qualified teachers, selected by the team and approved by order of the director. This composition is standard. In the context of the development of education, the scientific and methodological council may also include managers or representatives of individual projects, in accordance with the development program of the educational institution. Strategically significant from the point of view of designing the future development of the municipal educational institution is the inclusion in the above composition representatives of science, educational development institutions, the Center for Continuing Professional Development of Teachers and the Center for Assessing Professional Skills and Qualifications of Teachers. This management body develops diagnostic programs, monitors quality, provides regulatory and methodological support to participants in educational relations; analysis of the results and formulation of proposals to improve the quality of education.

Head of educational organization			
Level 1 Strategic Management

Level 3 Operational Management			
Board of Administration: Deputy Director	Board of students: self-government committees	Psychological service	

Figure 2: Organizational structure of education quality management of a municipal educational institution in Russia

Based on the complexity of the content of the concept of "quality of education", a municipal educational institution needs to create expert groups to evaluate it in three areas: quality of conditions, quality of content and process, quality of results. These groups can be created both due to the staffing table, and on a public basis; can work constantly or on demand. Competent members of the expert group should have experience in this particular area of quality assessment. When choosing experts, their personal interest in the decisions made should be excluded. Subject to the above conditions, objective decisions will be obtained, and the judgments of experts, in turn, will be appropriately accepted. The competencies of the Council of the school include: coordination of local acts on the assessment of the quality of education, participation in examination procedures and assessment of the quality of education in the selected areas, the adoption of a public report by the head of the educational organization based on the results of self-examination. The school council is a public, representative and elected body of school self-government. This governing body includes: representatives from the teaching staff of the school, from the parental community and high school students. Members of the School Council perform their duties on a voluntary basis. The information service is composed by the head of the press center, the site administrator and other involved persons, for example, technical specialists.

The organizational structure of education quality management, created on the basis of a specific municipal educational institution, is able to effectively implement the VSOKO model in practice that meets the requirements of consumers of educational services and Russian legislation in the field of education. The elements of the VSOKO model are designed to become elements of an effective management system of the municipal educational institution (Figure 3). Measures to implement the goals and objectives of the VSOKO should be included in the n-graph in which the respectively determined periodicity evaluation of certain parameters and responsible person. This schedule of the educational institution after an analysis of existing problems should be subjected to annual adjustment.

Figure 3: Elements of the VSOKO model in the management system of a municipal educational institution in Russia

The system of intra-school assessment of the quality of education in a general educational institution has a number of features: focus on assessing the individual progress of the student and teacher; the priority of self-assessment over external assessment, the inclusion in the system of education quality assessment of indicators consistent with the requirements of the Federal State Educational Standard and aimed at the emergence of new educational results. The main technologies for education quality management are problem-oriented analysis, marketing research of requests and satisfaction with the results obtained by consumers of educational services and participants in the educational process. No less important are the long-term goal-setting and decomposition of strategic goals for quality goals in the areas of educational activity; self-assessment of organizational management effectiveness.

Conclusion

The results of the study indicate the presence of a number of positive changes in the management of the quality of education in the municipal educational institutions of Russia: 1) the importance of creating an intra-school system for managing the quality of education is noted; 2) in certain regions, methodological recommendations have been developed that define the main components of the VSOKO; 3) self-examination is conducted on a mandatory basis in educational institutions, the results of which are open and published on the official websites of municipal educational institutions of Russia.

At the same time, there are a number of significant problems and limitations that do not allow ensuring the development of effective management decisions based on a reasonable assessment of the quality of education in municipal educational institutions. The organizational structure of the quality management of education, created on the basis of a particular municipal educational institution, is the guarantor of the effective implementation of the VSOKO model in the practice of the educational institution:

- the model should be adequate to the conditions and needs of a particular educational institution, since there is no single developed universal model of the VSOKO that could be applied in any educational institution;
- it is necessary to form a unified approach to the timing, levels, procedures of the VSOKO, which would ensure their continuity in the organization;
- the model should not ensure that the VSOKO is reduced only to monitoring the quality of education, since this is not the goal of introducing the model, it should be integrated into the process of effective management decision-making in the educational institution;

- reduced efforts to implement the model and accelerate processes are possible only in the context of digitalization of operations to collect and analyze the results of assessing the quality of education and ensuring timely access to the data of all bodies and employees interested in making management decisions.

Abstract

Timothy Besley and Robin Burgess (2004), based on the study of labor market in the Indian states, expressed an assumption that legislative regulation of labor market has a negative impact on economic development. The economic situation in Russia is a good confirmation of this assumption. Labor legislation of the Russian Federation imposes significant restrictions on the employer regarding the reduction of workers at enterprises and institutions. This allows to keep the unemployment rate in the country at a low level. However, this leads to significant negative consequences. Companies are cutting salaries, attracting hired professionals and moving salaries to the shadow sector of economy. This paper considers peculiarities of modern labor market in Russia in relation to the labor market, considered by Timothy Besley and Robin Burgess and in relation to the labor market in Western Europe. They showed that there is at least one significant difference - in Russian economy 45% of enterprises are enterprises with state participation. In addition, in Russia a significant part of population is employed in public sector. Thus, the state is able to limit the reduction of workers in a number of industries in order to maintain a low level of official unemployment. In particular, this confirms the "political" hypothesis on the issue of motives for regulating labor market. In Russia as in Western Europe there is an unfavorable demographic situation associated with an aging population. As in Europe, although to a lesser extent, there is a

problem of labor migration. However, these factors manifest themselves to a lesser extent in Russia which does not allow to use them as arguments for or against the assumption. under discussion.

Keywords: Labor Market Regulation, Unemployment, Hidden Unemployment, State Participation in The Economy

Introduction

Lack of flexibility in the labor market negatively affects output volume. This thesis is based on a number of works by various researchers and, first of all, on an empirical study by Timothy Besley and Robin Burgess (Besley T and Burgess R (2004)). Based on statistics from the Indian states for the period of 1958-1992, they showed that in states where workers are protected by law output and employment (as well as other indicators) are worse than in states where there is no such protection. This thesis has been repeatedly adopted as the basis for political decisions in India and a number of other countries and at present is considered generally accepted. We note, however, in the recent paper by Servaas Storm Storm S (2019), there is serious criticism of this position. His work shows that this result cannot be reproduced and is statistically unreasonable, which casts doubt on the methodology of Besley and Burgess. In the works of W. Siebert (Siebert 2003) the conclusion is not stated clear: "However, in terms of efficiency such regulation ... becomes a double-edged sword: some (working people) benefit from it at the expense of others (unemployed). Such a result cannot be called too effective. "

Thus, discussions about this thesis continue to this day.

In the previous work by Semenova A et al (2019), the author examined the thesis of Besley and Burgess in relation to Russian labor market. Russia has restrictions on labor market. It is shown that this leads to negative consequences. First of all, it is high hidden unemployment. In addition, this leads to moving salaries and wages to the shadow economy and to an increase in significant differences in salaries of top management and ordinary workers. The mechanisms of this phenomenon and the causes of it are considered.

According to the studies (2001), the reason for this state of affairs is laid down in the Labor Code - an employer has very high obligations to the employee (he must notify him of dismissal at least two months in advance, pay severance pay in the amount of three salaries, etc.). Therefore, an employer is forced to look for another way. One of the possibilities is wage reduction. This is due to the fact that in Russia a very significant part of wages are non-fixed payments. This leads to an increase in hidden unemployment. In countries with developed market economies the situation is the opposite - a fixed part of payments accounts for a large part of wages which makes it impossible to reduce wages. We note the following point: the reduction in wages will primarily concern highly paid specialists, since it is simply impossible to reduce wages of low-paid employees.

Thus, the Russian economy is a good confirmation of the thesis of Besley and Burgess. However, the question of similarity and difference of Russian labor market regulation in comparison with other countries remained unresolved. This study examines the main differences between Russian labor market and Asian and European labor markets.

Research Methods

Research sources for the study were the works by domestic and foreign scientists and economists on unemployment, the Federal State Statistics Service`s data, surveys` data and publications in scientific periodicals. The initial data for the analysis are taken from the reports of the Institute of Growth Economics named after Stolypin P.A. (2018) and Rosstat (the Federal State Statistics Service) for 2018-2019 (2019). The analysis of Russian labor market is based on the studies of Analytical Center under the Government of the Russian Federation (2001) as well as on the works by Siebert W.S. (2003).

Research Results and Discussion

There are two main aspects of regulation: establishment of acceptable working conditions and regulation of payments to employees.

The assessment of labor market regulation level is based on two indices - one of them concerns laws on protection of employment restricting the right to dismiss workers and the second concerns laws on protection of trade union rights. Russia is characterized by a high index of employment protection and a low index of protection of trade union rights. In this regard, Russia is closer to Greece and Portugal than to the United States and Great Britain. (Sources: OECD 2004, table 2.A2.4 (for the employment protection index); Botero et al, 2004 (for the union protection index)).

There are three main hypotheses about the causes of labor market regulation. According to one hypothesis regulation should compensate for the shortcomings of market regulation. According to another hypothesis labor market regulation is an expression of interests of some participants in the labor market. We also note the Botero hypothesis (Botero et al. 2004). According to Botero and his colleagues "regulatory methods in different countries are partly determined by their legal systems, and therefore, if a society regulates one particular area of activity, it will most likely regulate others as well" (Botero et al. 2004). Because of centuries of absolutism the powers of public administration are traditionally strong in Russia (as well as in continental Europe. Hayek (1960)). In this regard, Russia well confirms Botero`s hypothesis.

Currently economists are inclined to accept the view that labor market regulation is driven by political motives. An average voter stands for it (labor market regulation) viewing it as an instrument of income redistribution. Moreover, as shown in the work of St. Paul (Saint-Paul 1996), an average voter is a person who is employed.

Apparently, in Russia labor market regulation is also caused by political motives but the alignment of forces is somewhat different here.

According to experts, Russia has a very high level of state participation in the economy. According to the FAS Russia (Federal Antimonopoly Service, https://fas.gov.ru/documents/596439), the growth of the state's share in GDP from 2005 to 2014 rose from 35% to 70%. The IFF (International Finance Fund) in the 2019 report gives an estimate of 33% in 2016. According to experts of the RANEPA - 46% in 2016. Apparently a rating of 45% can be accepted as the most reliable. In particular, 28 companies of the 100 largest companies represented in the Expert RA ranking for 2017 are state-owned companies (the share of state participation is at least 25%), 5.5% of all people employed in Russian economy in 2017 work in them.

In addition, about half of the country's population (51.8%) (2019) is supported by the state: pensioners and people with disabilities (42.73 million people), officially unemployed (3.9 million people), officials and state employees (35, 22 million people), inactive population (30.15 million people). We will separately consider such group as officials and state employees. According to the study (2018), the sectors with the lowest level of value added generation per one workplace in 2017 were public administration (0.29 million rubles), education (0.37 million rubles), utilities and social services (0.39 million rubles) and healthcare (0.47 million rubles). As shown in our work by Semenova A et al (2019), based on the analysis of generation of value added per job during the crisis of 2014-2015, the decrease in output did not lead to an increase in unemployment. Instead, enterprises reduced wages of their employees. The same holds true for the above mentioned industries. Thus, here the hidden unemployment is even higher than in production.

The above mentioned facts allow us to put forward the following hypothesis. The objective functions of state-owned enterprises differs from commercial ones. If profit and economic efficiency are important for business then government policy is important for state-owned enterprises. The latter may be profit or efficiency, but it is not necessary. At the moment social peace is important to the government. Therefore, it is beneficial for the government to retain a lot of extra workers. Therefore,

high latent unemployment remains. This fully applies to officials and state employees. In enterprises with state participation this is, of course, not so clearly expressed but an influence of the state is still quite noticeable.

This confirms the point of view that labor market regulation is driven by political motives. The Russian labor market regulation system is the result of an informal agreement between workers, employers and the state that took shape in the 90s of the last century. For each of the interested parties this state of affairs is beneficial in its own way. This state of affairs is especially beneficial to the state since the state, as we saw above, is ready to put up with significant economic losses.

As for Botero's hypothesis, in our opinion, although the traditions of administrative management take place in Russia and the Russian system of labor market regulation, in a sense, they are a legacy of the Soviet past, this factor cannot be taken as determining.

Russia has similar problems in the labor market with Western Europe. This is a demographic situation and labor migration. As in Western Europe Russian labor market has faced the problem of an aging population. By raising the retirement age the government managed to hold back the labor force and skilled specialists in the economy for some time. Among the recent legislative initiativesm restrictions on the dismissal of workers of pre-retirement age can be noted here. The possibility of solving this problem through labor migration is also being considered.

To a lesser extent than in Western Europe but, nevertheless a migration problem is quite noticeable for the Russian labor market. Highly qualified specialists leave Russia and migration from the former Soviet republics results in low-skilled specialists. It also applies measures of state regulation of labor market. They mainly consist in the following: the host countries use the selective method in the regulating labor migration, the essence of which is that the state approves the entry of those categories of workers for which there is a demand in a given country, restricting the entry of all the rest. On this issue, there are also different opinions - the regulation procedure may become an incentive to increase the number of illegal migrants in the future and, in addition, undermines the foundations of existing legislative system. In particular, in real politics these views are held in countries such as Germany, Canada, Australia, Japan, Denmark and Norway. As for Russia, in our opinion, it is too early to draw any conclusions.

Conclusions

So, based on this study we draw the following conclusions. The main differences between the labor market examined by Timothy Besley and Robin Burgess and Russian labor market are the following: a) a high percentage of state participation in the economy, b) demographic problems, c) the influx of migrants. The last two factors also occur in Western Europe.

In our opinion, the fact that almost half of Russian enterprises are partially controlled by the state makes the mechanism of labor market regulation in Russia a unique phenomenon. This complicates the functioning of market laws and, thus, hinders Russian economy development. The Russian version of labor market regulation confirms the thesis that legislative regulation of labor market has a negative impact on economic development.

The assessment shows that in order to achieve the level of labor productivity in 2014, about 25 million of the 70 million workers must be freed. This is a difficult problem, what to do with this mass of unemployed. In this article we do not consider this issue.

The Russian system of labor market regulation is a balance of interests between workers, employers and the state. Each of the interested parties is happy with this state of affairs. However, it must be clearly recognized that this system has a negative impact on the economy as a whole. In society, however, there seems to be no clear understanding of this. Nevertheless, to improve the economy, it is necessary to change labor legislation in the direction of the laws of countries such as the United States, Germany and the United Kingdom.Список литературы/ References

Abstract

Currently, corporate social responsibility is developing both within the organization and in relations with society. Despite the development of state support for the agro-industrial complex, the socio-economic, technical, cultural, domestic, demographic and other problems of the village have recently intensified. The future of rural territories depends on in what way and how quickly these problems are resolved. In our opinion, their comprehensive solution is significantly determined by the activities of modern socially responsible organizations of the agro-industrial complex, since it is they who are interested in their own development and increasing profitability under conditions of stability.
Social and labor relations in the countryside are characterized by a low degree of satisfaction of demand for labor resources with its supply, which is confirmed by the constant outflow of the rural population to regional centers. The geopolitical and socio-economic situation forces our country to develop these areas as soon as possible. Despite this, the prestige of labor in agriculture does not actually increase. The citizens of our country have a negative opinion about life and work in the countryside. The labor market in rural areas, as a rule, is not represented by the abundance of employers, rural labor is associated with the seasonal nature of many types of agricultural work, therefore work in agriculture is characterized by a lower level of material incentives. In this regard, the social development of the village, due to agribusiness, needs state support with a perfect selection system for recipients. This article discusses corporate social responsibility as a factor in the development of rural areas. A system of state support for corporate social responsibility of agricultural enterprises is proposed.

Keywords: Corporate Responsibility, Social Responsibility, Agribusiness.

Materials and Methods

Social and labor relations in rural areas are characterized by a low degree of satisfaction of demand for labor resources with its supply, which is confirmed by the constant outflow of the rural population

to regional centers. Labor in the countryside is associated with the seasonal nature of many types of agricultural work. Work in agriculture is characterized by a lower level of material incentives (Table 1).
However, judging by the data in Table 1, there are positive changes in the ratio of the average salary in agriculture to the average for the economy, which over the past 7 years has increased from 56% to 69%. These facts confirm the need to develop corporate social responsibility in the agricultural sector for the well-being of rural areas.

According to E.M. Korotkov, corporate social responsibility is the realization of the interests of the enterprise by creating conditions for the social development of its staff and the active participation of the company in the development of society.

Corporate social responsibility in the agricultural sector provides for:

- responsible behavior with business partners;
- social responsibility to consumers of products, goods and services and to suppliers;
- social development of the economy - improving the business with the participation of employees of the enterprise;
- labor protection and health of the company personnel;
- responsible personnel policy, advanced training and professional retraining of personnel;
- reduction of the hazardous environmental impact;
- active work on interaction with public authorities and non-profit organizations to address social issues.

Table 1: The average monthly nominal accrued wages of employees of organizations of the Chuvash Republic for 2012-2018, rubles.

Indicators	Years						
	2012	2013	2014	2015	2016	2017	2018
Wholeeconomy	14896,3	17187,4	19387,5	20854,4	21369,4	22907,6	24529,8
Agriculture	8352,1	9595,1	10853,6	12800,1	14773,3	15974,2	16908,4
The ratio of the average salary in agriculture to the average for the economy,%	56,07	55,83	55,98	61,38	69,13	69,73	68,93

The social responsibility of agribusiness, in contrast to responsibility before the law, implies the presence of a voluntary desire by the management of the economy to finance the solution of social issues. We are talking about those activities, the conduct of which is not obligated by law or regulatory authorities. The social responsibility of the management of agricultural enterprises consists in constant interaction with authorities, which as a result increases the efficiency of enterprise management. And the result of such mutually beneficial cooperation is a steadily developing society in the countryside, where wealth is increasing.

Given the experience of social responsibility of foreign corporations, the management of domestic companies begins to perceive corporate social responsibility as the norm, without which stable development is impossible.

Fig. 1: Objects of social responsibility of agricultural enterprises

Figure 1 shows the main objects of corporate social responsibility of agricultural enterprises. These objects of development of society need, first of all, the economic support of agribusiness.

Social investments, depending on the objects and structure of the social responsibility of agricultural enterprises, can be directed both to the external and to the internal environment. Therefore, social investments can be both external and internal.

Depending on the direction of social responsibility and the costs associated with it, we can distinguish between external and internal social responsibility.

Let us consider in more detail the internal social responsibility of agribusiness, which is realized through investments directed inside the organization. In this case, social investments involve the allocation of financial, material, technical, technological and other resources to the implementation of social programs of the enterprise, and as a result of which in the future the company will receive some economic effect.

The manifestation of the internal social responsibility of owners and management should be felt by the employees of the agricultural enterprise. This implies the manifestation of not only mandatory liability prescribed by the legislation of the Russian Federation, but also additional responsibility, which is voluntary. Moreover, the latter may manifest itself to a greater extent.

Based on the foregoing, the following can be attributed to the directions of internal social responsibility of agricultural producers:

1. Social protection of company personnel;
2. Disclosure of the human potential of the company;
3. Making management decisions taking into account the interests of employees of the agricultural enterprise;
4. Socially responsible change in the structure of the enterprise.

The first area - the social protection of company personnel - involves the implementation of the following measures:
- the absence of discrimination on the basis of gender, age, national, racial and other grounds;

- ensuring the health and safety of workers in the workplace and assistance in difficult life situations. It is noteworthy that before the theory of corporate social responsibility appeared, only labor safety was implied. However, with the development of this theory, the scope of manifestations of measures to ensure the protection of the life and health of staff has expanded significantly. Studies of the development of human capital, taking into account the use of corporate social responsibility, have revealed an important trend: the negative consequences of excessive workload on employees, which leads to a deterioration in their health and performance, can be mitigated by company resources that are aimed at stimulating the organization's personnel;
- maintaining wages at a decent level and annual inflation indexing.

The second direction - the disclosure of the human potential of the company - should include training programs and professional retraining of personnel, which leads to increased competitiveness of employees in the labor market and to reduced dependence on one employer, and also saves the state budget funds aimed at promoting the employment of the population in case of dismissal of an employee. The disclosure of human potential is carried out in order to identify and stimulate talented highly qualified personnel. This area of internal social responsibility includes the use of modern mechanisms of employee motivation through remuneration and communication schemes.

The third area is the adoption of management decisions taking into account the interests of employees of the agricultural enterprise. It involves the adoption of key management decisions in accordance with the interests of company employees. This modern company development approach provides the involvement of employees in the company development process. Thus, due to corporate social responsibility, the effectiveness of personnel management is increased.

The fourth area - a socially responsible change in the structure of the enterprise - provides for the restructuring of the company in socially responsible ways.

Research Results and Discussion

For several years now, in Russia, with an eye on foreign experience, a socially responsible business has been developing. Domestic entrepreneurs have appreciated the benefits of doing business in a civilized way. It is worth saying that such changes are least noticeable in agriculture, and most noticeable in raw materials, energy, metallurgy, mechanical engineering, and the banking sector. This is confirmed by the rating data of the 100 most socially responsible enterprises of Russia, among which there are no agricultural enterprises.

Some people think that demanding changes in social management structures from agricultural enterprises is pointless, as they already have many unresolved problems. One can argue with this, since the development of the agro-industrial complex and rural territories today remains one of the most important areas of state support, especially in the framework of import substitution of food products.

The geopolitical situation and globalization processes increase the relevance of Russia's food security issues. But in fact, despite these changes, the image of labor in the agricultural sector has not increased in recent years. Russian people have a negative view of rural life and work in agricultural organizations.

Scientists of the Altai State Agrarian University Yu.A.Bugay, M.L. Akishina, A.A. Fannenstil believe that the main problem in the development of rural territories lies in a narrow-sector agricultural approach, and the fact that there are obstacles to the development of other types of production other than agricultural, despite their agricultural potential [1, p. 144]. Their publication, "The Impact of Corporate Social Responsibility of the Rural Business on the Employment of the Rural Population and the Development of Rural Areas," proves in detail that the social responsibility of agricultural enterprises is much higher than that of representatives of urban business. We agree with their opinion, according to which the rural population, unlike the urban population, significantly depends on one employer, who is the "locomotive" of life in the countryside.

For any enterprise, social costs in the short term will bring additional financial burden and subsequently a certain loss of competitiveness. Consequently:

1. Socially responsible business can be mastered, first of all, by the most profitable and financially sustainable agricultural enterprises with a sufficient margin of safety and significant competitive advantages.
2. The state and civil society should stimulate the spread of socially responsible behavior in the agricultural sector.
In this situation, with a competent approach, the implementation of the mechanism of social responsibility of agribusinessis able to solvemany problems of rural areas.This mechanism is designed to solve those problems that directly or indirectly concern both agricultural producers and rural residents. The practice of stimulating socially responsible business behavior is presented in table 2.

Table 2: Stimulation of socially responsible behavior

BytheState	**ByCivilSociety**
o Tax incentives; o Co-financing of socially significant projects; o Public–privatepartnership.	o Purchase of goods and use of services of socially responsible companies; o Investing funds in shares of socially responsible companies; o Work with a socially responsible employer.

The data in table 2 clearly show how the mechanism of socially responsible behavior contributes to the sustainable development of public life, takes into account the expectations of employees and those specialists whom the company expects to attract for work, as well as society, which directly or indirectly affects the enterprise.

In order for the concept of corporate social responsibility to be effectively implemented in agricultural enterprises, in our opinion, it is necessary:

1. To develop a system of indicators for assessing the social activity of agricultural enterprises, taking into account the areas of remuneration, staff development, health, safety, implementation of social programs and infrastructure of agricultural enterprises.
2. To conduct a prospective assessment of economic efficiency from the introduction of socially responsible practices.
3. To practically implement the proposed activities in agricultural enterprises of the Chuvash Republic.
4. To ensure the awareness of stakeholders about the implemented activities through the media and student information and advisory teams.
In order for these measures to be successfully implemented, the positive experience of voluntary social responsibility of the enterprises of the agro-industrial complex of Chuvashia is needed, aimed at improving the social and demographic indicators of the team, skill level, reducing the rate of staff turnover, improving the wage system, living and cultural conditions.

One of the most socially responsible companies in the Chuvash Republic is the Vurnarsky Mixed Products Plant (VZSP), a branch of the August Firm, JSC - the largest in Russia and the most specialized enterprise for the production of chemical plant protection products. This enterprise is the main production site of the August company, the largest domestic company for the production of chemical plant protection products. August is a socially responsible business. Today 750 people work at the Vurnarsky Mixed Products Plant, among which there are many highly qualified specialists with higher chemical and technical education. The August company regularly finances the training of employees at all levels, as well as the social support of plant employees and retirees. It is also important to note that the company allocates funds for the improvement of the village of

Vurnaryalong with local authorities. In recent years, the plant has built (or reconstructed) the following social facilities: a swimming pool (built in 2018, the construction cost of 240 million rubles), a fitness club, a sports complex, including a modern stadium, rope park, basketball and hockey courts, an amphitheater, leisure park and playground. Despite the prevailing stereotypes about the harmfulness of work at chemical industry enterprises, as well as the reduction in the population in the Vurnarsky district, the plant has no problems in selecting personnel due to many years of stability, sustainable development, attractive working conditions, prospects for professional growth, and social protection of employees. In addition, the company is one of the largest taxpayers of the republic.

In the agro-industrial complex of Chuvashia, the experience of JSC OldeevskayaAgrofirmis noteworthy - a producer of fresh environmentally friendly vegetables and milk, which pays special attention to labor protection. In order to improve working conditions, labor protection measures are carried out in the agricultural company. Occupational safety training and instruction is carried out constantly. When hiring, an introductory briefing on labor protection and an initial briefing on labor protection at the workplace are carried out as well as periodic medical examination of workers. All persons of the enterprise is provided with work clothes and other personal protective equipment in full in accordance with the standards. The agricultural company provides sanitary facilities: dressing rooms, showers, places for eating. According to the schedule, workstations are certified according to working conditions. Managers, specialists and authorized workers of the firm companies are being trained. The costs of conducting social policy for 2017-2018 are published on the website of the company. (table 3)

Table 3: Indicators of social costs of JSCOldeevskayaAgrofirmfor 2017-2018, thousand rubles

Indicators	2017	2018
1. Financial aid	548	449
2. Health resort and children's health camp vouchers	643	755
3. Corporateeventexpenses	624	730
4. Sponsorship	159	500
5. Vegetablesfortheholidays	206	250
6. Socially significant object maintenance	217	250
Total	2397	2934

As the data in table 3 shows, the agricultural company voluntarily allocated almost 3 million rubles for social needs in 2018, which is 22.4% more than in 2017.

For the successful implementation of the practice of voluntary social responsibility in agricultural organizations of the Chuvash Republic, a set of state support measures is required. According to the Ministry of Agriculture of the Chuvash Republic in 2019 2.2 billion rubles are provided for agricultural support, i.e. 11% more than in 2018. The list of government support measures is shown in table 4.

Table 4 : Measures of state support for agriculture of the Chuvash Republic

Name	Description
Singlesubsidy	1. Elite seed subsidies 2. Subsidies for laying and caring for perennial fruit and berry shrubs 3.Support oflivestockbreeding 4. Agriculturalinsurance

Unrelatedsupport	1. In the field of crop production 2. In the field of development of the production of seed potatoes and vegetable seeds
Dairycattleproductivityincrease	The amount of subsidy per 1 kg of milk sold depends on the productivity of cows
Softloans	Getting a loan at a preferential rate of up to 5% per annum in authorized banks
Smallbusinessforms	1.Support for novice farmers 2. Development of family livestock farms 3. Grants for the development of the material and technical base of agricultural consumer cooperatives
Capitalexpenditures	Subsidies for reimbursement of a portion of direct costs for the creation and modernization of agricultural facilities
Landreclamation	1. Landreclamation 2. Culturalequipment 3. Agroforestryreclamation
Hop production support	1.Subsidies for sold hops 2.Construction of hop trellis 3.Increased soilfertility 4. Technicalmodernization

According to table 4 among the existing measures there is no support for the social responsibility of agricultural enterprises. In our opinion, the existing support measures are insufficient, so they need to be supplemented with the following points:

1. Grants to agricultural enterprises for the implementation of internal social responsibility programs (to staff) on a competitive basis;
2. The provision of tax benefits to agricultural producers for the implementation of programs of external social responsibility (to the whole society).

As for the first point, you can use the experience of the club "Agro-100", which is engaged in the publication of the 100 best agricultural enterprises of the Chuvash Republic according to the results of work every year. When determining the winners, a set of indicators is assessed (revenue, sown area, salary, and others) - in accordance with the methodology for determining the members of the Agro-100 club, approved by a resolution of a joint meeting of the Government Commission of the Chuvash Republic on agricultural issues and the board of the Ministry of Agriculture of the Chuvash Republic February 13, 2008. This allows you to objectively approach the rating.

The enterprises - members of the Agro-100 club, invest in the technical renewal and modernization of the enterprise, increase the production of agricultural products, bear the social burden - the employment of workers is ensured.

To compile a rating of socially responsible agricultural producers for the subsequent allocation of grants for the implementation of social programs, it is necessary to use the criteria specified in table 5. We believe that in this way a general idea of the implementation of internal social responsibility in agribusiness can be formed. Agricultural producers will be able to direct the grant funds to the following social goals:

1. Remuneration;
2. Additional social guarantees for employees;
3. Further training and professional retraining of personnel;
4. Improving working conditions;
5. Medical care for employees;
6. Health resort service;
7. Sport and recreational activities.

Table 5: A system of indicators for assessing the social activity of agricultural enterprises

Labor Remuneration	Implementation of Social Programs	Staff Development	Healthand Safety
- the increase in the share of costs for the payment of wages in the total costs of the enterprise; - the ratio of the growth rate of the average wage to the growth rate of the company's revenue.	- the growth rate of social benefits per employee; -the growth rate of additional social benefits per employee; - the growth rate of social costs for own employees; - the ratio of the costs of environmental protection to the profit of the enterprise	- the proportion of employees who have undergone advanced training or professional retraining in the payroll number of employees; - the rate of increase in the costs of continuing education or professional retraining per employee.	- the growth rate of costs to improve working conditions per employee - an increase in the cost of medical care for staff per employee; - the rate of growth of expenses for the health and resort provision of staff; - The growth rate of expenses for sport and recreational activities.

The second paragraph of the proposed support measures provides for tax benefits to socially responsible agricultural producers implementing a policy of external corporate responsibility. These farms could finance the construction of social facilities such as kindergartens, first-aid posts, schools, roads, sports facilities, playgrounds, etc. and receive tax deductions commensurate with the funds spent for these purposes.

Conclusion

The implementation of the proposed measures will enhance the role of corporate social responsibility in the development of rural areas. On the one hand, this will make it possible to more rapidly increase the growth rate of agricultural production, and on the other hand, it will contribute to the return (in the form of tax revenues) of costs associated with state support for the development of social responsibility of agribusiness entities. Indeed, it is farmers and agricultural organizations that are more interested in social stability in the countryside, since the outflow of the rural population into cities has only increased in recent years. In such circumstances, the shortage of labor resources and especially qualified young professionals will increase. Thus, the effectiveness of stimulating socially responsible behavior of agricultural enterprises is expressed not only in the form of solving social problems in rural areas, but also in its social stability. The social responsibility of agricultural enterprises is much higher than that of representatives of urban business, since the rural population, unlike the urban population, depends significantly on one employer, who sets the pace of life in the countryside.

Abstract

The region is an important and largely determining part of the overall national socio-economic system, which has a complex internal structure, its elements form the interacting subsystems of business, government and society with direct and feedback connections.
When classifying subsystems, we highlighted a logical-structural diagram of the innovative potential formation of the region's socio-economic system, which allowed not only to analyze and evaluate the level of development, but also to identify priority directions for its increase, including the development of investment activity. The paper considers the issues of accumulation, analysis and development of innovative potential of the socio-economic system of the region. Rating estimates of the innovative potential of the regions of the Volga Federal District are given, their ranking and comparative assessment are carried out. Promising directions of development are identified, strategic directions of the state innovation policy are determined.

Keywords: Region's Economy, Innovations, Innovative Potential, Socio-Economic System Of The Region

Introduction

The dynamics of the development of relations of socio-economic systems at various levels becomes more informative and predictable if it is based not only on the study of traditional conditions and relationships, but also on the study of their innovative potential, patterns and characteristics of its

accumulation, implementation and development. Knowing the prerequisites, trends and the nature of the dynamics of the development of the innovative potential of regional socio-economic systems, provided they are adequately interpreted, gives ample opportunities for effective impact on spatial economic reality. Moreover, this approach in economic science can be regarded as the theoretical and methodological basis for the modernization of the regional economy (Haixiang G., 2017). One of the most relevant and difficult tasks of the research plan in this regard remains a qualitative assessment and forecasting of the innovatization of regional socio-economic processes, in which the specificity of the dynamic development and interaction of regional innovation systems is manifested.

The innovation of the socio-economic system of the region in the work refers to the opportunities and abilities of its business entities for creative activities aimed at obtaining a new form of income or some other kind of effect (Fernández-i-Marín X, 2015).

To date, economic science has developed certain methods and approaches to assessing patterns and trends in the accumulation, implementation, and development of the innovative potential of socio-economic processes in regional economies. However, none of them can be considered universal or sufficiently reliable, since it does not always ensure the coherence of estimates. The interconnectedness of research aimed at building a single forecast of the development of innovative potential of regional socio-economic systems will allow us to agree on existing methods for assessing and predicting the dynamics of the development of innovative economic processes that most fully characterize the state and prospects of development of the innovative potential of regional socio-economic systems.

The need to form an optimal integrated assessment and prognostic complex, combining in the best way various methods and approaches, in order to identify patterns of accumulation, implementation and development of innovative potential of regional socio-economic systems confirms the relevance of this study, its theoretical and practical relevance.

Materials and Methods

The study of the role of innovation, information and knowledge in socio-economic systems was based on the works of D. Bell, P. Drucker, M. Castells, M. Polanyi, J. Sapir, L. Thurow, F. von Hayek and others. Justification of the provisions of the systems theory and system concepts was implemented using the works of L. von Bertalanffy, R. Ackoff, L. Zadeh, R. Kalman, G. Klir, E. Laszlo, M. Mesarovich, A. Rappoport, D. Sornette, J. Takahara, A. Uemova, Yu. Urmantsev, B. Fleischmann, A. Hall, W. Ashby and others.

The problems of innovation-oriented development were considered on the basis of the works of P. Begidzhanov, N. Gazizullin, O. Gordeev, Yu. Zhiltsova, S. Makarov, V. Proskurin, I. Tukkel, E. Fakhrutdinov, R. Shakirov and others.

Certain aspects of modern scientific ideas about the structure and features of the functioning of regional socio-economic systems and the dynamics of the accumulation, implementation and development of their innovative potential are reflected in the economic, socio-humanitarian and natural-scientific literature, in particular in the works of N. Alekseeva, T. Bogatova, V. Gorfinkel, A. Granberg, L. Kornilova, Yu. Lapygin, N. Marenkov, B. Milner, A. Prilepsky, A. Sadriev, S. Timofeeva, S. Shigilcheva, etc.

The work used data from the Federal State Statistics Service; data of economic entities, ministries and departments; legislative and regulatory legal acts of the Russian Federation. When processing them, methods of system analysis were used; statistical data processing; financial and econometric analysis; general scientific methods of deduction, induction, analysis and synthesis, dialectical techniques and analogies.

Research Results and Discussion

Due to the fact that the socio-economic system of the region is a complex structure and consists of many different industry, functional, organizational, managerial and other subsystems, it is advisable to highlight their innovative potentials that can have different or identical transformation forces. Their implementation and development can be coordinated, therefore, more effective, or inconsistent, which means less effective, or even unprofitable (Medvedeva T.A., 2014).

Using the logical-structural scheme for assessing the existing and interacting in the regions of the Volga Federal District (VFD) innovative potentials of socio-economic subsystems (Fig. 1), differences in the level, direction of implementation and development of their innovative potentials, in particular production, reproduction and industrial structures potentials that positively and negatively affect the implementation of innovative economic policies of business, government and society, were identified.

Thus, the modern innovative industrial policy, which is a set of measures of state and legal regulation of the activities of economic entities, is determined by the fact that the existing structure of the economy of most regions tends to extensive reproduction, which leads to inefficient use of their production potential (Shigilcheva, 2018).

An analysis of the economic indicators of the Volga Federal District revealed that in 2018 the district produced 22.8% of Russia's industrial output. The highest growth rates in 2011–2018 occurred in the following regions of the Volga Federal District: Penza and Saratov regions, the Republic of Mordovia, The Mari El Republic, Republic of Bashkortostan and Republic of Tatarstan. A decrease in production potential was recorded in the Nizhny Novgorod and Orenburg regions.

Despite the decline in production, we can note that the economic potential of the Chuvash Republic currently has a sufficient impact on the socio-economic development of the Volga Federal District.

Fig. 1: Algorithm for evaluating the logical and structural diagram of the formation of innovative potential of the region's socio-economic system

Due to the limited resources of the regions, the most rational policy option to promote their economic growth is an unbalanced growth strategy aimed at supporting real and potentially competitive industries and enterprises; encouraging industries and enterprises supplying the market with fundamentally new and modernized goods (services) with improved consumer and operational characteristics, allowing them to expand their positions in existing product markets and conquer new ones. However, as experts indicate in their work, within the framework of this strategy, the revival of the entire industry is an extremely difficult task (Alekseeva, 2019).

Therefore, the strategy of unbalanced growth in the industry should be transformed into a policy of selective support for those industries and enterprises that are most promising for further progress of the region and could strengthen its innovative potential.

For the successful implementation of innovative industrial policy, we suggest using adequate tools for innovative industrial policy, shown in Fig. 2.

Fig. 2: Toolkit of innovative industrial policy of the region

We also note that in order to optimize the management of structural adjustment in the region, it is very important to achieve technological equilibrium of the sectors of the regional economy and to ensure the reprofiling of a number of industries on a differentiated basis (Rodríguez-Pose A., 2013). Enterprises subject to reprofiling can conditionally be divided into three groups:

a) producing unprofitable, uncompetitive products and bankrupt;
b) enterprises of conversion industries and enterprises focused on the creation of import-substituting industries;

c) enterprises with reserve capacities due to an objective decline in production (Miles D., 2017).
The innovative potential of the region's economic and social systems can be analyzed on the basis of our rating, the results of which are shown in table 1 (the calculation was made according to the official data of the Federal State Statistics Service) using the “distance method”, which allows, firstly, to establish the level of development of innovative potential in the region, secondly, to determine the dynamics of its change, and thirdly, to compare its innovative potential with potentials of other regions.

Table 1: Rating of the regions of the Volga Federal District in terms of the development of innovative potential for 2011-2018.

Region of the Volga Federal District	Years								
	2011	2012	2013	2014	2015	2016	2017	2018	
								Fact.	Diff.from 2000
1	2	3	4	5	6	7	8	9	10
Republic of Bashkortostan	1,866	1,817	1,903	1,752	1,798	1,723	1,750	1,622	- 0,244
Mari El Republic	2,378	2,400	2,410	2,370	2,363	2,379	2,408	2,200	- 0,178
Republic of Mordovia	2,333	2,221	2,139	2,123	2,223	2,257	2,262	1,973	- 0,360
Republic of Tatarstan	1,334	1,307	1,333	1,508	1,366	1,437	1,444	1,075	- 0,259
Udmurt Republic	1,818	1,862	1,774	2,028	2,150	2,120	2,109	1,888	0,070
Chuvash Republic	2,246	2,140	2,229	2,208	2,163	2,156	2,144	2,099	- 0,147
Perm Region	1,513	1,583	1,757	1,761	1,535	1,696	1,805	1,593	0,078
Kirov Region	2,286	2,338	2,208	2,338	2,311	2,338	2,309	2,218	- 0,068
Nizhny Novgorod Region	1,649	1,713	1,575	1,526	1,612	1,603	1,539	1,460	- 0,189
Orenburg Region	1,838	1,943	2,076	2,012	2,043	2,105	2,031	1,628	- 0,212
Penza Region	2,213	2,170	2,069	2,189	2,167	2,149	2,141	2,028	- 0,185
Samara Region	0,869	1,044	0,968	1,020	0,950	1,227	1,199	1,125	0,256
Saratov Region	2,085	2,114	2,042	2,079	2,114	2,100	1,959	1,890	- 0,195
Ulyanovsk Region	2,171	2,199	2,220	2,276	2,260	2,310	2,165	2,002	- 0,169

For each indicator, a “reference region" was formed, which has the greatest or optimal value of the indicator being studied. Then, based on the source data, standardized indicators were calculated using the formula (James H. (2017):

$$x_{ij} = \frac{a_{ij}}{opt_j a_{ij}} \qquad (1)$$

where x_{ij} are standardized indicators of the state of the j region;
a_{ij} is the value of the i indicator of the j region;
$opt_j\, a_{ij}$ - maximum (optimal) value of the i indicator
For each region, the rating value was determined by the formula (Newcomer K. E., 2015):

$$p_j = \sqrt{\sum_{i=1}^{n} (1 - x_{ij})^2} \qquad (2)$$

Regions were ranked in ascending order of rating, with the highest rating assigned to regions with a minimum rating value. The rating score and rating value of the regions are presented in table 2.

A compiled matrix of ranking the regions according to the level of development of innovative potential (high - up to 1,199, above average - from 1,2 to 1,499, average - from 1,5 to 1,799, below average - from 1,8 to 1,999, low - 2,0 and more) and the dynamics of its change (increasing, decreasing) shows that the Republic of Tatarstan and the Samara Region had the highest innovative potential in 2018. The indicated regions were characterized by large volumes of industrial production, construction, a low share of unprofitable organizations and a high standard of living of the population. It should also be noted that the Samara region is a leader in the Volga Federal District in terms of innovation and business activity, the volume of attracted foreign investment and the degree of development of small business. Therefore, it is the most promising in terms of strengthening the innovative potential of the region. At the same time, in the Samara region there is a tendency to decrease the level of innovative potential in 2018 compared to 2017.

Table 2: Grouping of the Volga Federal District Regions by the level of innovative potential and the dynamics of its change in 2011-2018

The level of development of innovative potential	Dynamics	
	Increase	**Decrease**
High	I. Republic of Tatarstan	II. Samara Region
Above average	III. Nizhny Novgorod Region	IV. -
Average	V. Orenburg Region, Republic of Bashkortostan	VI. Perm region
Below average	VII. Saratov region. Republic of Mordovia	VIII. Udmurt Republic
Low	IX. Penza Region, Kirov Region, Ulyanovsk Region, Chuvash Republic, Mari El Republic	X. -

The Chuvash Republic belongs to the group of regions with a low level of innovative potential. The competitiveness of this region is ensured by the presence of a developed construction complex, a low share of unprofitable organizations and a high share of innovative organizations. All this allows us to conclude that the use of an innovative approach to the development of the economy is especially relevant for the Republic, since it will contribute to changing the socio-economic situation in the region and increasing its competitiveness.

The strategic direction of the state innovation policy should be the formation and protection of the domestic market of scientific and technical products. Other scientists and economists of the region come to similar conclusions in their studies (I. Golyshev, 2016).

Specific measures of the strategy for the prospective development of innovative potentials of socio-economic systems and subsystems of the region should include the following set:

- formation of a catalog of innovative programs;
- introduction of competition between research institutes and universities of the Republic for the best indicators in the field of science and innovation;
- Republican competitions for the best innovative product, innovation process, the most progressive organizational and economic management;
- development and purchase of advanced technologies in the field of agriculture;
- reorientation of the state's structural policy to support the so-called "new" sectors of the economy (innovative and informational);
- conducting an audit, monitoring and audit of Republican programs for socio-economic development with a view to their compliance with the innovative development goals of the Republic;
- application of the indicative planning system for indicators of innovative development (for example, the share of innovative products in the total volume shipped, the share of research and development costs) at the micro- (enterprise), meso- (industries and complexes) and macro- (republic) levels;
- development of methods, tools and technologies of strategic planning and management at the Republican level.

Implementation of long-term goals related to the development of innovative potentials of socio-economic systems and subsystems and the achievement of competitiveness of regional economies should be accompanied by goals that have a socio-economic orientation in a strategic plan (OECD, 2017).

Chuvash Republic should set the following goals:

- achieving stable positions in relevant segments of the global market. These segments include mechanical engineering, electrical and instrument-making industry, chemical and light industry, electric power industry, construction industry;
- accelerated renewal of fixed assets (to date, depreciation of fixed assets in the main sectors of the economy of the Republic has reached 50%, which negatively affects the pace and quality of innovative growth);
- improving the environmental situation in the Republic and protecting information resources.

Medium- and short-term socio-economic goals are designed to ensure in the Chuvash Republic:
- alignment of the conditions for the implementation of innovative activities in the districts, between enterprises of various industries, forms of incorporation and legal forms;
- creating an attractive investment climate; optimization of resource consumption, primarily electricity and capital resources.

To achieve the above-mentioned goals in Chuvashia, it is advisable to carry out the following main tasks:

- intensive development of a public-private partnership system;
- formation of a strategy for future development, i.e. strategic goals will prevail over tactical ones to ensure long-term innovative growth and increase of the innovative potential of the Republic;
- implementation of targeted financing of innovative projects on a competitive basis;
- implementation of personnel policy in the field of innovation and high technology, contributing to the formation of innovatively receptive personnel;
- formation of innovative infrastructure as the material and technical basis of a continuous innovation process;
- accelerated development of innovative entrepreneurship, the most susceptible to market requirements;
- optimization of financing and stimulation of the innovation process in terms of regional competence;
- development of interregional cooperation and international exchange of high technologies and products;
- information support of innovative development.

Conclusion

The current state of innovative potentials of socio-economic systems and subsystems of the Volga Federal District regions is unbalanced, which negatively affects the effectiveness of its implementation.

When studying the innovative potentials of socio-economic systems and subsystems of the Volga Federal District regions, based on a comparative analysis of the characteristics of the analyzed region with the corresponding characteristics of competing regions, the Chuvash Republic and other regions of the Volga Federal District were selected as competing regions, due to their territorial proximity.

An assessment of the innovative potentials of socio-economic systems and subsystems of the regions of the Volga Federal District and their grouping based on the calculation of specialization coefficients and the construction of a rating of innovative activity showed that the Chuvash Republic belongs to the group of regions with a low level of innovative potential. The competitiveness of the Republic in relation to other regions with a low level of innovative potential is determined by the presence of a

developed construction complex, a low share of unprofitable organizations and a high share of innovative organizations. Thus, the use of a cluster approach to the development of the economy and its innovative potential, which will contribute to changing the socio-economic situation in the region and increasing its competitiveness, is especially relevant for the Republic.

The analysis shows that most regions of the Volga Federal District, including of Tatarstan and the Chuvash Republic, specialize in the chemical, construction industry and mechanical engineering. A high level of concentration of these industries, on the one hand, contributes to the development of competition, and on the other hand, creates conditions for production and cooperation innovative interaction between enterprises. All this allows us to conclude that these industries are the most promising in terms of increasing their innovative potential.

One of the relevant ways to increase the innovative potential of the region is public-private partnership. Creation and functioning of research and production bases and technology-innovative zones can prove to be effective. However, such a synergy between the state and innovative business requires special tools for each specific area of implementation and individual developments.

Goals and objectives of state regulation for the development of the innovative potential of the socio-economic system of the region are proposed, including auto-stabilization mechanisms and innovative approaches to modernizing the region's economy.

Abstract

The article considers the concept of a system and a system approach. The possibility of applying a systematic approach to accounting and control at the level of an economic entity is assessed. The definition of an integrated accounting and control system is given, its elements and approaches to their integration are considered.

Keywords: system, system approach, information integration, accounting, control, integrated accounting and control system.

Introduction

The concept of a system and the system approach formed on its basis is one of the key and universal scientific approaches. And if initially this concept and scientific approach was used exclusively in technical sciences (primarily in cybernetics), then in the future they acquire a universal character. Not surprisingly, this approach has also been widely applied in economics. Currently, the representation of the organization in the form of a system consisting of many interconnected elements is traditional and familiar. In accounting disciplines, however, this approach is ambiguous. There are scientists who advocate the presentation of accounting, analysis and control in the form of a single management information system. And scientists (most of them) consider accounting, analysis and control as separate, almost independent systems. Both approaches have the right to exist, however, isolation is convenient in the framework of scientific research, highlighting certain topical issues in the framework of separate scientific disciplines and directions. In practice, integration is determined by a number of significant socio-economic and technological factors.

The simplest factor lying on the surface is the technological one. The standards for creating and processing economic information over the past fifteen to twenty years have changed dramatically. Information that was originally created and processed manually or with the help of computer programs of limited functionality (accounting, marketing, analytical, and so on) is currently processed using management programs of complex automation (the so-called ERP systems). Within

the framework of such a software product, all management processes are interconnected, and it is practically impossible to consider them strictly separately, in the form of a closed information cycle. However, such a combination in practice is not limited to the program level and requires normative and methodological adaptation.

No less significant is the economic factor. The trend of recent years, in connection with a certain economic and political instability of the world community, is to reduce costs, primarily for the implementation of the managerial function. Part of this trend is the optimization of costs associated with accounting, analysis and control, without significant loss of their effectiveness. Integration theoretically can significantly reduce costs in the long run, but it is also a complex problem requiring economic justification.

Not so obvious, but nonetheless significant, is the social factor. Its influence is manifested in setting up new goals for the organization by the society and the state. If earlier its main goal was simply to make a profit, now it requires the organization to participate in the implementation of more global goals - such as ensuring food security, applying an innovative approach to carrying out activities and implementing management functions, attracting investments, solving social and environmental problems of the society and etc. The participation of any medium and especially large organization in the implementation of these global goals is strictly necessary and only in this way can it achieve sustainable and effective development in the long term. Effective integration of accounting and control can significantly improve the quality and variety of created accounting information, which will affect the efficiency and effectiveness of management decisions, which is important in the current socio-economic situation.

In such conditions, the integration of accounting and control into an integrated system based on a single software package seems to be the most effective solution. This will significantly increase both the quality of accounting information and the control functions carried out, and will significantly increase the efficiency of organizations.

Main Section

Materials and Methods

The direct object of research is the accounting system of both Russian and foreign organizations.

The main research methods are analysis and modeling.

First, let's analyze the main approaches of scientists to the key concepts of research. The basic concept is "system".

Despite the fact that the concept of “system” is developing as a scientific concept for quite a long time, it remains largely debatable and not completely formed. Each author working with this concept, to one degree or another, brings his point of view. Table 1 gives the definitions of the concept of "system" in the interpretation of some authors.

Table 1: Approaches to the Concept of the "System" of Various Scientists

№	Definition	Source
1.	System: a set of interconnected elements, each of which is connected directly or indirectly with each other, and any two subsets of this set cannot be independent.	Ackoff R., Emery F. (1974) On purposeful systems, Sov. Radio, Moscow
2.	The system is a holistic complex of interconnected elements that are in functional relationships and relationships with each other for a certain time.	Volkov Yu.G., Dobrenkov V.I., Nechipurenkr V.N., Popov A.V. (2000) Sociology, Gardariki, Moscow
3.	A system is a group of purposefully interacting elements.	Gaides M.A. (2005) General theory of systems (systems and systems analysis), GLOBUS-PRESS, Moscow
4.	A system is a collection of parts or components that are interconnected organizationally.	Gig J., van. (1981) Applied General Theory of Systems, Mir, Moscow
5.	A system is an object, phenomenon or process consisting of a qualitatively defined set of elements that are in mutual relationships and relations, form a single whole and are able to change their interaction with the external conditions of their existence structure.	Osipov G.V., Moskvichev L.N. (1996) Sociology. Fundamentals of the general theory, Aspect Press, Moscow
6.	A system is usually understood as a combination of interconnected elements, united by a unity of purpose and functional integrity. Moreover, the property of the system itself does not reduce to the sum of the properties of the constituent elements. Any system is formed as a result of the interaction of its constituent elements, and this interaction gives the system new properties that were absent from separately taken elements.	Prangishvili I.V. (2000) A systematic approach and system-wide patterns. Series "Management Systems and Problems", SINTEG, Moscow
7.	A system is a collection of interacting elements.	Bertalanffy L. von. (1968) General Systems theory. George Braziller, New York
8.	A system is an arbitrary thing when some of its relations satisfy a certain property (attributive definition). A system is an arbitrary thing, any properties of which satisfy a certain relation (relational definition). Both definitions fix a certain order of representing things in the form of a system.	TsofnasA.Yu. (1999) Theory of systems and the theory of knowledge, AstroPrint, Odessa
9.	A system is a separate part, a fragment of the world, of the universe, which has a special quality (emergence), relative self-sufficiency (thermodynamic isolation).	Atkins P. (1987) Order and disorder in nature, Moscow

The list of definitions carried out in the table allows us to conclude that they all differ in their content, but, in our opinion, the following points are common to them:

1. The definition of the system as a set of interconnected elements;

2. Mandatory presence of connections and interactions between elements;
3. Integrity.

Taking into account the general features, shortcomings and positive aspects of the above concepts of the concept of "system", we will try to formulate our own vision in relation to the topic of our study. A system is an integral set of interconnected elements united by a single goal to achieve a given useful result and interacting for its implementation. Our definition, in our opinion, does not contradict the system concepts discussed above, revealing a slightly different aspect of the concept of “system”, and therefore has some heuristic.

Based on the above concepts and the concept of the system we have given, we can conclude that the properties of the system are determined by:

- properties of its elements;
- properties of the structure of the system.

The generally accepted properties of the systems are shown in Figure 1.

Fig. 1: System Properties

In many ways, it is the concept of the system and its properties that are the basis of the system approach. It allows you to consider each object as a system consisting of a certain number of interconnected elements that have certain properties.

Using a systematic approach in accounting is currently quite common. In our opinion, the integration of accounting and control, in our opinion, is based on the following premises:

- the complication of the conditions of the organization and, as a result, the constant emergence of new information requests of users, the development of new types of accounting, analysis, control, as well as models of their interaction;

- development of information technologies and models of the information society and education, as a result of which new models and approaches in the field of automation of the organization, the development of electronic document management and data transfer;
- orientation of many organizations on the strategy of cost reduction, optimization of the organizational structure of the organization and the model for the implementation of its management and business processes.

Despite the fact that the integration of accounting and control into a single system is a fairly relevant and promising scientific direction, at the moment there is no optimal concept for such integration.

The question of creating an integrated accounting and control system can be divided into two problems: integration of accounting systems and integration of accounting and control.

The issue of integrating accounting systems in the past has become particularly relevant. At present, a lot of concepts have been developed for integrating accounting types into a single system. Consider the main ones.

According to Ya.V.Sokolova and V.F. Palia (1981) “an integrated system of economic accounting is a dialectical unity of various types of accounting in their essence”. Integration in their understanding should occur with the help of automated accounting systems and cover operational-technical, accounting and statistical accounting.

V.I. Tkach and M.V. Shumeiko (2012), within the framework of the engineering theory of accounting, suggests integrating accounting information through the use of a single information field and a structured chart of accounts.

I. A. Varpaeva (2014), within the framework of the integrated process-oriented accounting system model, offers to integrate financial management accounting based on the process-oriented approach and the application of information technologies.

A. A. Solonenko (2011), within the framework of the concept of an accounting system, proposes to integrate accounting information based on the allocation of common goals, objects, terminology and methodology.

According to I.V. Kalnitsky (2014) integration of components of the accounting and analytical system should be carried out depending on the management structure of the business entity and be organizational in nature.

Thus, we can distinguish programmatic, methodological, organizational, adaptive and mixed approaches to the integration of accounting systems (see Fig. 2).

Fig. 2: Approaches to the integration of accounting systems

The program approach involves the use of a single software product or a set of interconnected software products for the integration of accounting systems.

The methodological approach for the integration of accounting systems uses a single methodological base (a single chart of accounts, a single accounting policy, a single reporting system, and so on).
The organizational approach is based on the application of a process-oriented approach and the construction of an integrated accounting system in strict dependence on the management structure of the organization.

With an adaptive approach, the structure of the integrated accounting system is flexible and directly depends on changes in the external and internal environment of the organization.

In a mixed approach, several integration methods are used simultaneously when integrating accounting systems.

The second problem in the framework of creating an integrated accounting and control system is the integration of accounting and control systems.

On the one hand, in accordance with paragraph 1.2 of the Conceptual Framework for Presenting Financial Statements, the purpose of general financial reporting is to provide financial information about the reporting organization, which is useful to existing and potential investors, lenders and other lenders when they decide to provide this organization of resources. That is, we can conclude that accounting information is the basis for making management decisions, including for the implementation of the control function of management.

On the other hand, the control function is one of the main accounting functions. This postulate has a long history of scientific justification.

Among foreign scientists who identified the control function in accounting, one can name F. Best, F. Villa, J. Rhys, J. Rossi, B. Needles, R. Anthony. The founder of the doctrine of the control function of accounting is Leon Say.

Among Russian scientists we can name N.A. Blatova, Y.M. Halperin, L.I. Gomberg, M.I. Kuter, N.P. Kondrakov and others.

There are also a number of modern theories and paradigms that justify control as part of accounting.

Y.V.Sokolov (2004) highlighted the legal theory of accounting, according to which the subject of accounting is the control of the rights and obligations of persons involved in business processes.

S. Zeff, G. Miller, and M. Munitz (2014) substantiated the economic paradigm, according to which the goal of accounting is to control and evaluate economic indicators, ensuring conditions for achieving maximum production efficiency.

Based on the foregoing, we can conclude that the relationship of accounting and control is based on the following provisions:

- accounting forms the information base for monitoring;
- forms and methods of control directly depend on the organization and methods of accounting;
- an effective and rationally organized accounting system affects the effectiveness of control;
- control allows you to identify ways to improve and rationalize accounting.

The issue of integration of accounting and control is complicated primarily from a methodological point of view. It is currently impossible to combine them into a single process, as these are two different, albeit interdependent processes that are influenced by various factors. However, it is quite possible to bring together and increase the efficiency of such processes. Within the framework of an integrated accounting and control system, we assume close coordination and increased correlation between the accounting and control functions, leading to an increase in the efficiency of these processes.
Thus, the creation of an integrated accounting and control system is possible on the basis of various approaches, the most popular and simple of which is integration within the framework of a software product. All these approaches solve their problems, but are not universal.

However, in our opinion, the full integration of all types of accounting and control into a single process is impossible due to their different specifics, goals and methods. Individual objects of accounting and control need full integration, some partial, and individual objects can only be integrated at the program level. In this regard, we propose to use a flexible object-by-object approach when creating an integrated accounting and control system.

The concept of accounting and control objects is complex and debatable. The question is, what objects can be selected for integration? Let us consider this problem in detail.

In the field of accounting, the simplest is supposed to be based on generally accepted objects described in regulatory legal acts. For example, the document “Conceptual basis of financial reporting” in paragraph 4.1.defines five components of the reporting and, accordingly, accounting objects: asset, liability, equity, income and expenses. Despite the fact that this document is not a standard, the presented set of objects as a whole is generally accepted in the framework of financial accounting. However, tax and management accounting imply a slightly different detail of these objects, with each individual state (regarding tax accounting) and each author (regarding management accounting) offer their own approach.

The situation is similar in the framework of internal control - each author identifies his categories of objects. However, it is generally accepted, depending on the objectives of control, an orientation on two factors: features of activities and managerial decision-making in the organization, as well as features of the existing system of forming economic information.

In our opinion, within the framework of an integrated accounting and control system, the objects of internal control should depend on the accounting processes carried out within the framework of the system.

Based on the above, we will present a list of objects of an integrated accounting and control system:

1. Assets.
2. Obligations
3. Sources of financing
4. Income and expenses
5. Planning
6. Risk Management
7. Assessment of the quality of accounting information and the effectiveness of the accounting system

The above list of objects is of a general nature and can be clarified when applied in each specific organization, taking into account its industry and individual characteristics. We believe that the allocation of certain types of accounting objects (assets, liabilities, etc.) should be based on an assessment of their materiality for the organization. Moreover, the assessment, in our opinion, should be based on a combination of a quantitative and qualitative approach. Planning, risk management and assessment of the quality of accounting information, in our opinion, have already become standard for most organizations and require inclusion in the list.

Thus, we have considered the basic concepts of the study and can proceed to consider its results.

Results

The integration model of the presented facilities requires an integrated and flexible approach. We believe that their integration should be carried out at the following levels: method, reporting and software product (see Fig. 3).

Fig. 3: Levels of integration of accounting systems

At the method level, integration involves the use of a single base of methods for financial, tax and management accounting; single accounting policy; a single database of primary documents and

accounting registers, as well as a single chart of accounts with a multi-level system of analytical accounts to detail the most relevant information for users (about income, expenses, liabilities, etc.). Moreover, it is supposed to use both unified methods and documents for all elements of the system, and their partial combination - depending on the possibility and effectiveness of such a combination.

At the reporting level, it is planned to develop a unified system of interconnected reporting forms.

At the level of the software product, the formation of a single information space of the organization is supposed.

In our understanding, a single information space is a set of methods for collecting, storing, processing and protecting electronic information used by an organization. It should consist of the following elements:

- a single automated software package for all activities of the organization (in our opinion, the most effective solution in this case is to use a software product specially developed for the organization that takes into account its industry and individual characteristics);
- a single repository of the organization's management information in electronic form: primary documentation, accounting registers, internal and external reporting forms, analysis results and managerial decisions made with limited access for employees depending on their position (it is possible to implement both using local and server internal organization information network);
- a single information security policy (both a complex of antivirus programs and various instructions for employees to reduce information risk);
- A unified system of electronic document management organization.

An important point, in our opinion, is the installation of a requirements system, which must be met by an integrated accounting and control system. We propose highlighting the following requirements for an integrated accounting and control system (Fig. 4).

Fig. 4: The principles of an integrated accounting and control system

A single information space, as already noted, is the basis of an integrated accounting and control system. Without a specialized program for the comprehensive automation of the management process, combined with the use of electronic document management technology, an electronic repository of information essential for management decisions and an information security policy developed, integration is not technically possible.

The development of a single set of internal accounting and control standards will allow their integration, both at the method level and at the reporting level. In our opinion, it is necessary to highlight the following standards:

- a single policy of accounting and control;
- provision on a single information space and its components;
- provision on electronic document management;
- provision on an integrated accounting and control system and its constituent modules;
- the provision on a single system of interconnected reporting forms in the organization;
- provision on planning in the organization;
- provision on the target indicators of the organization, their planning and evaluation;
- provision on the assessment and management of the risks of the organization;
- provision on the assessment of the quality of accounting information and the effectiveness of an integrated accounting and control system;
- provision on consulting.

Integrality of the input information will significantly reduce the complexity of accounting and control by reducing the number of routine operations for entering data into the system: data will be entered only once in one software product and used by the entire system as a whole for various needs repeatedly.

The modular structure of the integrated accounting and control system will allow timely and effective adjustment of it, depending on changes in the needs of external and internal users of the organization. In relation to the topic of our study, by a module of an integrated accounting and control system we mean its element, which has a certain structure and allows, due to its change, to quickly change the quality of the module and the system as a whole.

In our opinion, the module of the system under consideration should have the following structure (Fig. 5):

The objectives of the module
Standards – Methods for Realizing Goals
Software product - a way to implement standards

Fig. 5: Module structure of an integrated accounting and control system

In the integrated accounting and control system, it seems to us appropriate to distinguish the following modules (Fig. 6):

Fig. 6: Structure of an integrated accounting and control system and an algorithm for the interaction of its elements

Let's characterize these modules.

The module of financial and tax accounting. Its main function is to collect, process and provide relevant information. The subsystems of financial and tax accounting included in this module, in our opinion, should perform the following functions:

- entry into the system and processing of primary documents;
- compilation of registers regarding financial and tax accounting;
- preparation and submission to users of accounting (financial) and tax reporting;
- preparation of accounting standards (with the participation in this process of the management accounting module, as well as the internal control module);
- full satisfaction of the needs of external users

Management and strategic accounting module. It, in our opinion, should perform the following functions:

- organization of management accounting in the organization;
- compilation of registers regarding management accounting;
- preparation of internal reporting (in close interconnection with the financial and tax accounting module);
- planning of current effective indicators (production volume, revenue, profit) based on the break-even point indicator;
- assistance in making tactical management decisions based on evaluating the effectiveness of each possible option;
- development of a long-term development strategy for the organization;
- assessment of factors of the external and internal environment;
- development of a system of indicators for evaluating strategic management decisions;
- risk assessment (both in the organization as a whole and within the framework of the accounting and control system) and the development of measures to reduce it;
- full satisfaction of the information needs of internal users.

Internal control module. It, in our opinion, should perform the following functions:

- the formation of a single accounting and control policy within the organization (with the participation of accounting modules in this process);
- development of standard internal accounting documents and corporate recommendations in the field of accounting and control (with the participation of accounting modules in this process);

- advising employees of accounting modules on accounting and control issues in order to develop common methodological approaches;
- monitoring and coordination of ongoing control procedures;
- assessment of the effectiveness of the integrated accounting and control system;
- assessment of the quality of accounting information;
- ensuring the safety of property and conducting audits and inventories on a regular basis (with the involvement of representatives of accounting modules);
- ensuring compliance with legal requirements;
- conducting an operational audit, compliance audit and audit of accounting (financial) statements;
- making recommendations on the results of the audit and monitoring their implementation.

The information module, in our opinion, should perform the following functions:

- implementation, maintenance and ensuring the smooth operation of a single software package for automation of the organization;
- creation, configuration and maintenance of a single data warehouse;
- introduction of a full cycle of electronic document management;
- ensuring information security;
- assessment of information risk and development of measures to minimize it;
- advising representatives of accounting and internal control modules on issues of effective work within the framework of a single information space and information security.

Based on the foregoing, the accounting and internal control process within the framework of the integrated accounting and control system will look as follows (see Fig. 7)

Fig. 7: Accounting and internal control process as part of an integrated accounting and control system

As can be seen in the above figure, the process of accounting and control within the framework of an integrated system of accounting and control remains unchanged. However, the methodology for accounting facilities, the contents of registers and reporting forms are changing significantly. The control technique also changes significantly due to a change in the approach to the definition of its objects.

Discussion

The presented research results are not absolutely universal. However, the proposed integration model allows to significantly optimize the information and control systems of the organization, which ultimately improves the quality of management decisions.

Conclusion

The proposed model of flexible objective integration allows to organize the operation of the systemin the most rational way, the modular principle provides a sufficient degree of flexibility, a strict delineation of the functions of the modules and implementation within a single information space will achieve maximum system efficiency. At the same time, it is quite universal and can be adapted based on the characteristics of the activity and the process of making managerial decisions of a particular organization. Further research suggests adapting the proposed model for organizations of various industries and territories of operation.

Abstract

In the context of the formation and further development of market relations in Russia, the informatization and digitalization of the society, fundamental changes are taking place in all spheres of life, making it necessary to introduce fundamental changes in the educational process. The article is devoted to the search for directions of improving the independent work of students, as the main way of forming knowledge, the present and future development of the individual. This question is especially complex, specific and interesting for the authors of this article who are engaged in the preparation of bachelors and masters in the field of "Accounting, analysis and audit".

Keywords: independent work of students (IWS), the educational process, types of IWS, types of IWS control, effective organization of IWS, principles of IWS organization.

Introduction

The modernization of Russian vocational education, its integration into the international educational space required a certain adjustment of approaches to its organization. Now much more attention should be paid to the independent work of students (IWS) - the basis of the formation of their knowledge, skills, and subsequent continuous self-education - the basis of personality development.

The development of informatization and the subsequent digitalization of the society necessitates continuing education. In modern society, you cannot learn once for life, this will lead to a crisis of competence. The only way to overcome this crisis is self-education - as a form of constant independent work on self-development and self-improvement, aimed at acquiring new knowledge. The student must master this ability to master the skills of independent work within the walls of the university, so that in the future to become self-fulfilled as a person and as a professional.

Research Results and Discussion

The educational process in universities is increasingly acquiring the character of independent educational work of students, organized and managed by teachers on the basis of the latest teaching methods and tools. In this regard, along with improving teaching methods, introducing new pedagogical and information technologies into the educational process, the most important tasks of universities are the rational organization, planning and monitoring of students' independent work, its further activation.

According to Abdykarimov B.A., Andasova B.Z. (2004) independent work of students is an integral part and the most important form of the educational process at the university, one of the main reserves for improving the quality of education and training of future specialists. The purpose of the IWS is the formation of the knowledge, skills and abilities of students aimed at independent creative solution of technical and scientific problems that arise in the practical activities of a future employee. Since independent work is both the goal and the means of obtaining education, the relevance of the search for methods and ways to effectively manage this process is undeniable. Fig. 1 clearly presents all possible types of independent work of students in the discipline "Financial accounting".

Figure 1: Types of independent work of students in the discipline "Financial accounting"

The role of independent work in the formation of bachelors and masters is extremely large, because it is in its process that the most important qualities, knowledge and skills, the ability to study new questions creatively, the criticality of the mind, and the ability to navigate the flow of information are brought up and developed. It is especially great and necessary in the study of the discipline "Financial Accounting" in the preparation of bachelors and masters in the profile "Accounting, Analysis and Audit".

In the context of the development of market relations in Russia, constant changes are taking place in the economy, legislation, and taxation. A lot of orders, orders of the RF Ministry of Finance, the Federal Tax Service, the Central Bank of the Russian Federation and other bodies, the constant introduction of amendments and additions to them, often their inconsistency and contradiction complicate and dement the work of accountants. They should spend a significant part of their time studying regulatory documents in order to keep abreast of all changes in accounting, to keep records correctly and, ultimately, to avoid various sanctions from the tax and other authorities.

In such difficult conditions, it is extremely difficult to prepare bachelors and masters in Economics, the profile of Accounting, Analysis and Audit, teach financial accounting, the procedures and rules of which, in contrast to management accounting, are determined by regulatory documents. The standard period for mastering the basic educational program of undergraduate studies in the field of Economics, the profile of Accounting, Analysis and Audit is 4 years, and its complexity in full-time education is 250 credits. By the time of graduation and the beginning of work, the knowledge given to students at the institute may become outdated. Sometimes this obsolescence occurs much earlier. Hence the constant obsolescence of educational and methodological literature - not a single textbook on accounting keeps pace with the constant changes in the legislation and new regulatory documents on accounting.

Therefore, now you can’t just teach students accounting, but you must first of all teach them to “learn creatively”, take any information critically, do not take textbooks as dogma, you need to educate and develop students' ability to navigate in the normative, reference and scientific flow information, the need for reading special periodicals. Only such training and education can form students' knowledge and skills inherent in a professional accountant.

Love, devotion, attachment to one’s profession, especially to the profession of an accountant, will not come immediately. They will appear only when knowledge and experience have accumulated, when you understand and master your business, when you are recognized as a specialist in this field, people will turn for advice, consultations, and you will be invited to work. Is it possible to achieve all this without working on yourself, without constant independent training? It is impossible,especially for the future accountant.

So how to organize students' independent work when studying accounting disciplines in difficult modern conditions?

First of all, it should be carefully and thoughtfully planned at the stage of development of work programs. When planning independent work it is necessary: to determine the full amount of information on the discipline, submitted for independent study; determine the optimal amount of information to be monitored; determine the frequency and timing of ongoing monitoring of independent work. In the work program of the discipline, it is necessary to clearly distinguish on each topic the questions submitted for independent study and the forms of control of students' independent work. It is also important that sufficient and latest regulatory, literary, reference sources are recommended.

In conditions of shortage of study time, undergraduate students will either have to separate topics of the discipline or separate questions from the students for independent study, but it is also necessary to establish proper control over the level of mastering the material. Here you can apply foreign experience, well represented in the movie "Legally Blonde". Its essence is that the lecturer gives students a lecture plan and a list of literary sources for self-study in advance. In the future, the lesson only discusses these issues, commenting on the answers (messages) of students. It is possible to conduct a lesson in combination: to devote only part of it to discussion of issues, and devote the rest of the time to practical work on the topic. All this will allow students to be not passive, but interested listeners and conduct lectures interactively.

Practical classes in Financial Accounting have always organically included elements of students' independent work. They were traditionally built according to the collection of tasks, covering all

areas of accounting work of the conditional organization and including the registration of facts of economic life with primary documents, maintaining accounting registers, preparation of accounting (financial) statements and tax returns. The whole complex of these works cannot be performed only in practical training, students must do part of the work at home on their own. And in the practical exercises themselves, a significant part of the work is performed by students independently under the guidance of a teacher. However, in modern conditions it is necessary to increase the proportion of students' independent work both in the practical classes themselves and outside the classroom. The teacher should skillfully organize and direct such work, clearly define the tasks for students, while it is desirable to individualize them and determine forms of control and encouragement.

The independent work of students is also based on the educational, four production practicesand undergraduate practice of students of the profile “Accounting, analysis and audit” (applied undergraduate). According to their results, students should write and protect reports on their own. At the same time, it is very important to teach and demand from students a critical assessment of the organization and accounting in practice objects, as well as the development of practical recommendations for eliminating identified deficiencies in accounting, proposals for evaluating the effectiveness of accounting policies, building or improving them.

An important role in teaching students to independently work on the study of “Financial Accounting” was played by the course “Fundamentals of Scientific Research”, which was studied in the third semester of undergraduate studies. Within its framework, students were taught the skills of self-education, the rational organization of independent scientific, educational, informational work. However, unfortunately, this discipline is no longer included in curricula.

One of the main places in the organization of independent work of students should be occupied by their research work. Students should be attracted to it throughout the training. For this, scientific student circles are created in the departments. Arousing students' interest in accounting problems, developing a research and creative spirit in them is the task not only of the head of the corresponding scientific student group, but also of each teacher - the scientific supervisor of student reports to student scientific conferences. The solution to this problem is also largely facilitated by the observance of the constancy in fixing one and the same teacher - the supervisor of studies and within the framework of the student’s scientific circle, both in the course work on the discipline and in the writing of the final qualifying work.

Among the interactive teaching methods combined with the independent work of students, one can distinguish scientific and practical research. So, at the Cheboksary Cooperative Institute (branch) of the Russian University of Cooperation V. Khristolyubovain 2008 made a similar reasearch, in which 5 teachers, 1 graduate student and 12 students were involved. The study was conducted on the materials of the Morgaushsky district consumer society of the Chuvash Republic, and was devoted to the organization of work of accounting. As a result of this study, an assessment of the accounting policy used in this organization was given, recommendations were developed for its improvement and organization of work of accountants, implementation of management accounting, etc. The results of the study were discussed at a round table with the participation of chief accountants of all cooperative organizations of the Chuvash Republic, to which all members of the scientific student group "Accounting in the market" led by the author were also invited. The results of the study were also published in the preprint of V. Khristolyubov and others (2009) “Organization of the work of the accounting department of the consumer society”: Cheboksary Cooperative Institute, Cheboksary.

Educational and methodological support is of great importance in the correct and rational organization of independent work of students is. All students, of all forms of training should be provided with basic textbooks and teaching aids, task books, guidelines for their solution. Moreover, all of them should be different for students of different courses, forms of training and are designed for “their own” volumes of time. The main direction at the same time is the creation of electronic libraries, which is already implemented in many universities. But for now it’s too early to talk about the sufficient supply of teaching and methodological materials for undergraduate and graduate

programs, which greatly facilitate the process of independent study of educational material for students.

The individual abilities of students are different. With these in mind, it is necessary to build independent work of students. Individual students who are better, well-trained and well-versed in accounting issues and, moreover, working in their specialty (which is often found not only among correspondent students, but also in the last courses of full-time education), should increase and complicate the volume of information for independent study, give independent practical tasks of individually defined complexity. The individual inclinations and abilities of students to study accounting disciplines for a teacher can be identified by testing or interviewing, as well as in the preparation of essays, scientific and practical reports, etc.

An important role in organizing the independent work of students is played by control. It should be systematic, both from the leading teacher and from the department. Monitoring the independent work of students in the discipline of "Financial Accounting" is advisable to carry out in various forms (Fig. 2).

Figure 2: Types of control of independent work of students in the discipline "Financial accounting"

The task of each teacher and the university as a whole is to ensure the effectiveness of independent work of students. This requires careful planning, systematic implementation, the use of its various forms and types, clear instruction of students on the order of implementation and presentation of the completed task, sufficient teaching and methodological support, the gradual complication of tasks, creative orientation, individual approach, control over deadlines, quality implementation, publicity and job promotion.

We single out the factors that determine the effectiveness of the organization of independent work of students in accounting profiles (Table 1):

Table 1: Factors of the effectiveness of the organization of the independent work of studentsof accounting profiles

№	Name of factor
1	The presence of carefully designed and approved educational and methodological complexes of all educational disciplines of undergraduate and graduate programs
2	The high level of the teaching staff not only in terms of scientific degree, but also pedagogical preparedness, experience, creativity, willingness to work “in a new way”
3	Adequate provision of the university library with educational and methodological literature, including electronic publications, as well as various guidelines for the organization of different types of independent work of students
4	Provision of classrooms, libraries with computer and telecommunication equipment. Use of innovative technologies by teachers and students
5	Availability of electronic tests not only in all disciplines, but also in all topics
6	The availability of equipped classrooms corresponding to the profile of student training (“Educational accounting”, “Analytical laboratory”, etc.)
7	The creation of branches of departments in organizations and enterprises on a contractual basis
8	Conclusion of community agreements and internships for students with organizations
9	Implementation of graduation qualification works by orders of organizations
10	Careful planning of independent work of students in the development of work programs with the definition of its types, forms, content, volumes, deadlines and control on each topic of the discipline and clear instruction of students on these issues
11	Possible individualization of tasks for each student or their small groups, based on the level of preparedness of students, self-awareness, responsibility, activity, etc.
12	Dosing of volumes of independent work of students, based on the total workload of students
13	The account of social conditions (life, work, rest)
14	Differentiated assessment and publicity of the results of the independent work of students, its promotion in various ways (additional points, etc.)

According to Kashina E.A. (1997), the informatization of education required the transformation of pedagogical processes through the introduction of new technologies in the educational process. Moreover, in the work of Nikulina T.V., Starichenko E.B. (2018) that despite the fact that the stage of informatization of Russian educational institutions has ended - they are equipped with computer technology; teachers have been trained and retrained on the use of information technology in the educational process, a lot of effort is still required to develop methodological and didactic materials, educational websites, educational software for various purposes, etc.

In the conditions of informatization and digitalization of education, the role of students' independent work increases significantly. The independent creative activity of a student in studies, on the one hand, acts as a quality of the process of cognition, on the other hand, as a quality of the personality itself. In this regard, further improvement of the educational process at the university should go along the path of increasing the volumes and complicating independent work while strengthening and improving the guiding and organizing functions of classroom lecture and practical classes.

A creative approach to the independent work of students requires its high-quality, systematic organization, skillful management. Independent work is both the goal and the means of education. Therefore, the search for ways and methods to effectively manage this process is relevant. In accounting disciplines, it can be carried out in the following areas (table. 2):

Table 2: Directions of the search for ways and methods of effective management of the independent work of students

№	Description of directions
1	The study and analysis of the budget of time and the complexity of students' independent work, the determination of actual time costs and its complexity in the discipline
2	Rationing of independent work, that is, the definition of the normative budget of students' time for independent work in general, for its individual types, for individual topics of the discipline; planning of independent work.
3	Organizational and methodological provision of students with textbooks, manuals, task books, guidelines, links to their sources. Appropriate organization of work of study rooms, laboratories, study accounting cabinet
4	Clear and effective control over students' independent work
5	Analysis of current performance and results of students' independent work control
6	Development and implementation of measures to further improve the educational process in general and independent work, in particular

We agree with the opinion of Pidkasisty P.I. (1980) that for the effective organization of independent work of students, a teacher of a higher school needs to know and observe the principles of its organization: the principle of systematicity and consistency; principle of activity; the principle of an individual approach; accessibility principle; principle of presentation; the principle of science-based calculation of time and dosage of homework. However, in our opinion, it is advisable to supplement this list of accounting disciplines (and not only) with such principles as the principle of regularity, the principle of control, the principle of organizational and methodological support, the principle of the connection of theory with practice, the principle of a gradual increase in the difficulties of tasks.

We will try to determine the features of the practical implementation of these principles in relation to the management of students' independent work in accounting disciplines and present them in table 3.

Table 3: Features of the practical implementation of the principles of organization of independent work of students in accounting disciplines

№	Content Features
1	Independent work should be focused. This is achieved by its clear wording.
2	Independent work should first be carried out under the guidance of a teacher, and then completely independently
3	The volume of work, the complexity of the tasks should be intense, but doable and grow from beginning to end of the study of discipline
4	Tasks for independent work should require the student to have knowledge of the discipline, study of legislative, regulatory, methodological, periodical literature
5	It is imperative to take an individual approach to students when organizing their independent work, as their abilities are different and each requires different tasks in complexity and different time to complete them
6	Orient students to complete assignments for independent work in individual cases on practical materials from specific economic entities (for course, graduate qualification, research work, a report to the conference). To teach students the skills of collecting such material and its processing

7	Tasks for independent work should not be routine, they should be interesting, new to students, but doable
8	Independent work of students should be systematic. It should be included in classroom and extracurricular activities.
9	Monitoring and evaluation of the results of independent work of students should be systematic

Conclusion

The independent work of students is not just a way of acquiring knowledge, but the fundamental principle of higher education, an integral part of the educational process regulated by the Federal State Educational Standard and the curriculum, in which as much time is spent on independent work as on classroom lessons. Therefore, the rational organization of students' independent work is the most important reserve for improving the quality of education and one of the priority and most effective directions for its development.

In the context of developing digitalization of education, the task of the university and teachers is to strive to master new technologies, opportunities to gain access to vast information resources and, on this basis, guide and individualize the educational process through rationalizing the organization of students' independent work.

Abstract

In recent years, Russian agriculture has received a new impetus for development through the implementation of the import substitution policy and the improvement of state support. At the same time, unresolved problems remain in the industry, and the degree of development of digital technologies is quite low. The need for digitalization in agriculture is determined by a large number of factors affecting the efficiency and productivity of processes including high labor intensity of production processes, staff shortages, high risks caused by climatic conditions, relatively low level of industrial engineering, increase in environmental pressure on ecosystems and others. These aspects determine the purpose of the study - to identify problems and factors hindering the transition of rural Russian economy to a digital model and the formation of a digital business. As a result it was found that the digital transformation of the industry depends, firstly, on the basic conditions, the formation of which is associated with the implementation of the economic, scientific and technical policy of the state; secondly, on the degree of activity and willingness of business and the population to use digital technologies to solve their problems. The limitations of business digitalization are: lack of own funds, insufficient maturity of business processes, lack of specialists in the field of IT technologies and insufficient development of digital competencies, low involvement of management and staff in the transformation, immature digital culture. The solution to these problems depends on both state policy and a change in the management paradigm at the corporate level.

Keywords: Digital Transformation, Digital Agriculture, State Policy.

Introduction

In modern conditions digitalization as a technological trend covers not only high-tech sectors of the economy but also penetrates deeper into other areas and sectors of the economy, digitizing the value chain, changing business models, forms and standards of interaction between transaction participants.

The influence of digital technologies on politics, economy, society is so great that in scientific circles this phenomenon is considered as a digital revolution. In the technological aspect its results depend on the degree of readiness and penetration into the practical economy of the so-called end-to-end technologies: big data and their analysis, autonomous robots, modeling, horizontal and vertical integration systems, additive technologies, the Internet of things, cloud solutions, cybersecurity, augmented and virtual reality. The main advantage of digital technology is the reduction in operating and transaction costs.

At the same time according to studies of international experts the digital transformation contains threats of deepening the differentiation and polarization of countries and sectors of the economy due to existing digital gaps. Among all sectors of the economy agriculture is the least advanced in using digital technologies and competencies. The results of the expert assessment of Rosatom State Corporation (2018) indicate that this situation is typical not only for Russia but also for developed countries - the USA, Europe (despite a higher level of readiness of countries for digitalization) as well as for developing countries.

In the context of globalization the need for digitalization of agriculture in Russia is determined by the following internal and external factors:

- ensuring food security of the country: population growth creates pressure on the demand for agricultural products while the production capabilities of producers are limited by the potential of ecosystems and applied technologies; in addition, the realization of the potential of import substitution also requires more radical transformations in agriculture with a focus on increasing production volumes, labor productivity, reducing costs, etc.;

- increased competition in the domestic and international food markets; in these conditions digital technologies can help increase the competitiveness of producers through lower costs and losses resulting in lower prices, higher product quality, the development of new competencies in the field of digital marketing, etc.;

- intensification of interindustry competition for alternative options for the use of agricultural raw materials, for example, for the production of biofuels;

- strengthening the process of urbanization and reducing the size of the rural population, the high complexity of operations and low attractiveness of the industry for young professionals which necessitates the introduction of labor-saving technologies and also stimulates the automation and robotization of production processes;

- aggravation of environmental problems among other things due to the growth of agricultural waste, food waste, etc.; waste management and recycling of raw materials can become additional sources of revenue growth and cost reduction;

- deterioration of land and need for comprehensive measures in the field of protection of natural and land resources;

- differentiation of countries and players in the global value chain, crowding out small players (farmers, small agribusiness enterprises); development of digital technologies and platforms creates a new environment for more effective interaction and cooperation of business of various sizes, opens up new niches and opportunities for using the economic and social potential of small business forms;

- creating conditions for the production of environmentally friendly products as the basis for ensuring and protecting human health and sanitary well-being; in recent years, the number of adherents of healthy eating has grown significantly, the demands of the population on food quality and safety have been increasing, digital technologies allow restructuring business processes in such a way as to take into account all consumer requirements for final products, etc.

Thus, the digitalization of agriculture is a sort of tool for achieving the goals and objectives of the Sustainable Development Concept. Digital technologies as inclusion contribute to achieving a balance of interests between all members of society, spheres of human life, improving the quality of life, solving the problem of intergenerational distribution of resources and ensuring environmental protection, etc.

Materials and Methods

The study was based on materials from an expert assessment of the state and development of the digital economy, agriculture and business, presented in the reports of the Food and Agriculture Organization of the United Nations, Rosatom State Corporation, legislative, regulatory and legal acts of the Russian Federation, reports and analytical information materials from the Ministry of Agriculture of the Russian Federation, data of the Federal State Statistics Service, etc.

Theoretical and methodological aspects of digitalization of agriculture are reflected in the scientific research of foreign and Russian scientists: N.M. Trendov, S. Varas, V. Zeng (2019), T.N. Astakhova (2019), I.A. Ganieva (2019), B.A. Voronin (2019), M.O. Kolbanev, N.I. Kuznetsov, V.N. Milovanov (2019), S.B. Ognivtsev (2019), A.V. Plotnikov (2019), S.A. Chernikova (2019), G.A. Shcherbina (2019) and others.

To achieve the objectives of the study general scientific methods were used: abstract-logical, monographic, analytical. The evidence for the conclusions of the study is provided by the use of systemic and statistical analysis.

Research Results and Discussion

Currently in the scientific literature there is no generally accepted concept of "digitalization". So many authors reduce digitalization to the "quintessence of automation and informatization". S.B. Ognivtsev (2019) notes that digital transformation is a representation of real objects and processes in digital images representing these objects in models and further interactions.

Applied to agriculture I.A. Ganieva (2019) defines digital transformation as “the transformation of economic activity in the industry through the introduction of digital tools - technologies and platform solutions designed to generate, process, deeply analyze and transmit analysis results in the form of numerical information about objects and subjects of the agricultural economy for the subsequent adoption of informed management decisions, providing a technological breakthrough in the agro-industrial complex ”. B.A. Voronin (2019) and others use the concept of "intellectual agriculture." This is agriculture based on the use of automated decision-making systems, integrated automation and production robotics, as well as ecosystem design and modeling technologies.

Thus, common to all definitions is the digitization of real objects, the use of digital technologies to solve production and managerial problems, and the interaction of stakeholders through the Internet.

According to FAO experts the conditions of two levels are necessary for the formation of a digital economy:

1) basic: a high level of development of the digital sector (communications, IT sector) and accessibility of infrastructure (mobile subscriptions, network coverage, Internet and electricity), the educational level of IT specialists, institutional support of the digitalization process (government policy, programs, support tools) ;

2) “activators” are factors of stimulation and promotion of digital technologies: the use of the Internet, mobile phones and social networks, digital skills of the population, entrepreneurial and innovative culture (talent development, incubators, programs).

In 2019, Rosatom State Corporation presented the results of the assessment of the National Index for the Development of the Digital Economy of the Russian Federation. International comparisons show

that in this rating Russia ranks 23rd with a total score of 0.458, which is below the average - 0.521. The profile of Russia is presented in Figure 1.

Fig. 1: International comparison of Russia on the digital economy development index

From the data in the figure we can conclude that Russia lags behind European countries in most of the basic conditions of the digital ecosystem, the exception is "cybersecurity", the parameter of which is above average, and "digital infrastructure", in which the value is quite close to average. As a result, low rates of application (demand) of digital technologies by the population and business as well as relatively low rates of digital impact. The problematic aspects include R&D / innovation (these are financing and commercialization issues) and the development of the digital sector.

As for the digital business, according to the results of a global study of the Digital Transformation Index (2018), conducted by DellTechnologies together with Intel, only 7% of the Russian companies surveyed are "leaders", 19% are "implementers", 36% are "evaluators", 37% are "led", 1% are "lagging behind". Thus, only 26% of company executives at the current stage see the potential of digital technologies and the possibility of their practical application for business purposes.

As noted by S. B. Ognivtsev (2019), for the digitalization not to become just another fashion trend it is necessary to aim the digital transformation, first of all, on the implementation of new economic models and fundamentally new control systems that would allow achieving the necessary efficiency and profitability.

In this context, in our opinion, the definition of the digital transformation of A. Prokhorov (2016) is relevant and most accurate. "Digital transformation is the process of the organization's transition to new ways of thinking and working through the use of social, mobile and other digital technologies. It includes changes in thinking, leadership style, a system of encouraging innovation and the adoption of new business models to improve the work of the organization's employees, its customers, suppliers and partners".

The digitalization level of agriculture and agribusiness is much lower than other sectors. Although information and analytical, other digital platforms exist at the state and business levels, business

management information systems for crop production and livestock production, satellite communications and navigation solutions (including for the purposes of safety and control of vehicles, fuel and lubricants costs)), enterprise management systems (ERP), accounting systems, electronic document management systems, personnel, asset and business process management systems, business analytics solutions, CRM systems, these technologies are fragmented and do not yet have a holistic solution. As a result, producers incur high transaction costs which negatively affects the level of financial accessibility of food for the population, the efficiency and profitability of agricultural producers themselves, their competitiveness in comparison with foreign companies. Some performance indicators of agricultural organizations in Russia are presented in Table 1.

Table 1: Performance indicators of agricultural organizations of the Russian Federation for 2013-2018

Indicators	Years						Change, (+,-)
	2013	2014	2015	2016	2017	2018	
Agricultural production index in comparable prices,%	105.1	104.1	102.1	104.8	102.9	99.8	-5.3
Index of physical volume of investments in fixed assets aimed at reconstruction and modernization,%	77.7	96.0	90.9	118.9	…	95.0	17.3
The share of investments aimed at reconstruction and modernization in the total volume of investments in fixed assets,%	8.7	8.4	8.6	8.9	10.3	9.2	0.5
The number of high-performance jobs, thousand units	333.8	368.2	318.2	335.1	365.8	431.9	98.1
Labor productivity index,%	106.2	103.3	103.6	103.0	105.9	99.9	-6.3
Labor capital ratio,%	103.6	103.3	103.7	104.0	106.7	107.1	3.5
Capital productivity index,%	102.8	100.0	101.1	101.6	97.3	93.2	-9.6
Energy ratio of labor: energy capacity per employee, hp	72	75	74	77	75	80	8
Energy ratio of agricultural organizations: energy capacities per 100 ha of sown area, hp	201	201	197	200	198	200	-1
Profitability index of agricultural organizations, taking into account state subsidies,%	7.3	16.1	20.3	16.4	12.0	12.5	5.2

An analysis of the data in Table 1 indicates that production volumes in the industry are unstable and in general there is a decrease in the indicator for the period under review. Among the reasons can be noted a decrease in labor productivity and capital productivity. Low rates of investment in fixed assets lead to a technical lag in agriculture. The share of investments in fixed assets aimed at reconstruction and modernization remains at about the same level of 9%. An increase in the number of high-performance jobs has been observed only in the last three years.

Innovative activity of agricultural organizations remains rather low for the industry. Share of organizations engaged in technological, organizational, marketing innovations for 2016-2018 is approximately: in crop production - 10% (the highest activity is observed for organizations growing seedlings, up to 20%), in livestock production - about 5%, in mixed agriculture the indicator increased from 2.7% in 2016 to 16.3% in 2018. The share of innovative products in 2018 was approximately 6%

in crop production, 2.1% in livestock and 1.4% in mixed agricultural organizations. The number of new crop technologies acquired by organizations has decreased from 635 units in 2017 up to 242 units in 2018, in livestock - from 526 units up to 188 units. The main reason is the rising cost of foreign technology. As a result, the livestock industry provides 93.5% of production by means of domestic reproduction animals.

As for the indicators of digitalization of agriculture, no statistics are currently being maintained, which is also a problem that needs to be addressed. According to the passport of the Digital Agriculture departmental project (2019), the share of investments for the purchase and implementation of digital products and technologies at the end of 2018 is 0.5% of the total investment of agricultural organizations; in agricultural organizations there are no specialists with digital competencies.

Thus, the growth in production volumes, crop yields and livestock productivity in the industry is ensured mainly by extensive factors, and the profitability index of agricultural organizations, even taking into account state support, remains low.

The current situation has determined the agenda for the digital transformation of agriculture - the creation of a digital ecosystem of the industry, combining knowledge bases, information resources, interactive communities, a network of business platforms, personnel capable of working with new technologies that provide solutions to systemic problems of the industry. To achieve this goal in 2018 the Federal Scientific and Technical Program for the Development of Agriculture for 2017-2025 was developed, and in 2019 the Ministry of Agriculture of the Russian Federation began to implement the Digital Agriculture departmental project, which includes five areas (Table 2).

Table 2: Directions for digitalization of agriculture in Russia

Digitalization direction	Opportunities	The benefits of agricultural producers
"Effective hectare" - the creation of the Unified Federal Information System on Agricultural Land	An intelligent system of automated collection, analysis, updating of information on the state of soil and land resources of the territory, developing recommendations on the optimal (landscape-adaptive) sowing of agricultural crops, cutting fields, planting crop rotation, agricultural cultivation technologies, assessing land plots (including cadastral value), control and monitoring of the functioning and effectiveness of land use systems and adaptive landscape agriculture, their impact on environment and rural areas	Profitability increase up to 50%
Creation of the Central Information and Analytical System of the Ministry of Agriculture of Russia	A single analytical base for monitoring the state of the agricultural sector and foreign markets, supporting management decisions by the Ministry of Agriculture of Russia and informing users	Government services and state support on the principle of "one window", saving time
Agroexport “from field to port”	A system for modeling export flows followed by linking forecast yields with the rolling stock of Russian Railways to break down bottlenecks	Entering foreign markets, reducing logistics costs
“Agro-solutions for agribusiness”: creating a single electronic trading platform, developing and scaling “smart farming”, “smart field”, “smart herd”, “smart greenhouse”, “smart processing”, “smart	Automation of all business processes (from interaction with consumers to waste disposal) based on digitalization: the creation of autonomous robotic agricultural facilities operating in an automated mode with minimal human participation.	In livestock business: - increase in milk production to 13 thousand liters per year; - decrease in the incidence of animals with mastitis by 70%; - improving the quality of dairy products by more than 40%; - product profitability of more than 40%;

warehouse", "smart agricultural office" solutions, individual business processes		In crop production: - reduction of crop losses up to 20%, increase in labor productivity by 30%; - increase in organic production up to 50%; - decrease in import dependence in the production of vegetables by more than 70%.
"Land of knowledge" - electronic educational environment	Agricultural specialists training	Advanced training of specialists in mastering digital skills, increasing labor productivity

According to the project developers through the Information system of digital services of the agricultural sector agricultural producers will also get access to a single electronic trading platform which will simplify their access to domestic and foreign markets.

Among the already launched projects it is worth mentioning Mercury Federal State Information System in veterinary medicine, which allows you to automatically compile veterinary accompanying documents, automatically take into account incoming and outgoing products at the enterprise, track the movement of consignments in the Russian Federation taking into account its fragmentation, forms a single centralized database of relevant information for subsequent reporting and analysis (obligatory for all who are involved in livestock).

The existing digital platforms include Seed Production FSIS which was created to build up-to-date databases in the field of seed production of agricultural plants and to inform agricultural producers and citizens about selection achievements, the availability and quality of seeds of agricultural plants produced in the Russian Federation as well as imported. A similar information resource is desirable for livestock breeding.

The digitalization of the economy and agriculture covers a range of important technological, as well as political, economic and social issues the solution of which is impossible at the level of an individual state. In this regard, the Government of the Russian Federation initiated joint projects with the EAEU member countries. The strategic areas for the implementation of the projects identified are: electronic customs, electronic commerce, electronic logistics, digitalization of industries, data economy, digital finance, IT standards, platform for digital integration of the EAEU countries. Achieving joint goals in digitalization involves: developing a single regulatory framework and harmonizing laws and regulations in this area, creating a single digital space and expanding the application of IT technologies, developing and implementing joint projects aimed at digital transformation of spheres, industries, markets and economies of the EAEU member countries as a whole.

Currently work is underway to create a unified information environment - a system of electronic veterinary certification, and subsequently it is planned to extend it to fish farming and fishing for marking eggs. The Ministry of Agriculture of Russia amended the law On Veterinary Medicine in the clause on labeling and registration of animals, according to which all animals born and imported into the territory of the Russian Federation from the list specified by law should be marked and registered so that each animal will receive a digital identification number. According to the legal act of the Russian Federal Service for Veterinary and Phytosanitary Surveillance electronic identification in 2018 became mandatory for all pedigree farms and since 2019 for all commodity farms including private household plots.

The digital transformation of agriculture aimed at creating a digital ecosystem of the industry should cover not only the processes of digitalization of public administration but, first of all, the formation of a modern digital business and the infrastructure necessary for its effective functioning, including financial and insurance sectors, logistics infrastructure, and educational and consulting services.

According to the International Independent Institute of Agricultural Policy (MNIAP) for 2012-2018 investment attractiveness of the industry remains quite high. Global investments in innovative start-ups in agriculture increased 7 times from $ 2.6 billion to $ 16.9 billion. The average transaction size ranges from $ 4.1 million in biotechnology to $ 1.5 million in online delivery restaurants. Priority areas for global investment are shown in Figure 2.

Fig. 2: Priority areas of global investment in digital agriculture for 2018,%

At present in Russia there is an uneven use of digital technologies among agricultural producers. Only large agricultural holdings can afford intensive investment in among other things digital technologies. As T.A. Shcherbina (2019) notes in his work the most attractive segment for investors is the production of fruits and vegetables. Of significant interest are investment projects in the processing of agricultural products (26% of projects), livestock (25%), poultry and crop production (16% each), greenhouses (15%), fish farming (12%). Feed production and veterinary medicine projects (3% each) are unattractive. At the same time there is a low involvement of farmers in the investment process. Domestic farms which lack significant financial resources and competencies in digital technologies use them primarily for interacting with consumers - advertising, taking orders via the Internet and delivering products.

It should be noted that the positive experience of implementing digital technologies in Russia is gaining momentum. In the regional section agricultural enterprises in Moscow, Lipetsk, Belgorod, Rostov, Sverdlovsk regions, Krasnodar Territory and some other regions are active. Among the technologies that have been tested it is possible to distinguish the following: design and creation of “smart farms”, geoinformation systems of fields, use of unmanned aerial vehicles and smart equipment, innovative accounting systems, etc.

However, in general, the level of agribusiness readiness for digital transformation remains low. Internal problems include: lack of equity and high cost of loans, as a result, low level of financing for innovations and digital technologies, insufficient maturity of business processes, lack of IT specialists and insufficient development of information competencies among other specialists, lack of vision and development strategies in the context of digitalization, low involvement of management and staff in changes, immature digital culture.

Accelerating digitalization is highly dependent on the availability of drivers. According to M.P. Galimova (2019) these include: human potential, technology and innovation, infrastructure, access to global trade and investment, sustainable resource support, domestic demand.

Private tools include

1) at the state level:

- expansion of interstate interaction and implementation of joint projects in the sphere of economy digitalization and assessment of the potential of digital technologies;

- formation of a regulatory framework governing the relations of entities in the digital economy;

- improving the information security of participants and the creation of mechanisms to suppress illegal behavior in the information and communication environment;

- increasing funding for the development of end-to-end technologies and promoting Russian information technologies on the world market;

- development of public-private partnerships in construction and expansion of digital infrastructure and stimulating the formation of a market for infrastructure services; increasing the availability of the Internet and mobile communications in rural areas;

- increasing the state order for IT specialists and encouraging the reform of the education system towards training specialists for the digital economy;

- development of a system to support and encourage the transition of business to digital technologies - subsidies, grants, preferential taxation, training programs for specialists;

2) at the industry level:

- creation of a single digital platform for agricultural management including regional and municipal level; development of standards for the interaction of participants in information exchange; development of systems for collecting, storing and analyzing data on agricultural facilities, as well as for statistical monitoring of the results of economic activities of agribusiness entities;

- formation of a basic set of business processes and methodology for the organization and management of digital agriculture;

- stimulating the creation of innovative farms as platforms for technology development and training; systematization and popularization of best practices;

- Development of a specialist education system for digital agriculture and agro-consulting on digitalization issues;

3) at the agribusiness level:

- development of a strategy for digital transformation of a business, assessment of the potential and possibilities of digitalization of business processes;

- study of best practices, design and development of domestic model of integrated digital enterprise;

- assessment of the marketing environment and external capabilities of digital interaction with stakeholders through cooperation;
- search for sources of financing for digitalization, including the possibility of state support;

- assessment and planning of human resources development taking into account the digitalization of agribusiness;

- creation of supporting systems: change management, innovation, solutions to non-standard problems, staff motivation and incentives, interaction with stakeholders, etc.

Conclusion

Assessing the prospects for the development of the digital agricultural economy in Russia it can be noted that Digital Economy of the Russian Federation state program, On the Strategy for the Development of the Information Society in the Russian Federation for 2017-2030 Decree of the President of the Russian Federation , the national plan for the development of competition in the commodity markets, as well as Digital Agriculture Departmental project of the Ministry of Agriculture of Russia form the prerequisites for the digital transformation of agriculture and determine the direction of its institutional infrastructure, financial and economic, resource support.

However, this process is at the initial stage when the goals and objectives of the digitalization of the industry are clear, and the mechanisms and tools for achieving them are so far blurred. Accelerating the process depends on the degree of readiness of end-to-end technologies and understanding of their commercial use. The winnings will be given to those countries, industries and business entities that are more open to cooperation and innovation.

Abstract

The development of mortgage activates various sectors of the country's economy, such as the construction industry, the real estate market, entrepreneurship, and creates the conditions for investing in the economy. In addition to the economic role, mortgage also performs important social functions, which are manifested in the possibility of improving housing conditions for certain segments of the population; in this regard, the issues of analysis and assessment of mortgage lending in the Russian Federation do not lose their relevance. The problem of mortgage lending is connected with a housing problem that 60% of Russian families have to confront. The problem is dissatisfaction with housing conditions, especially by young families with children. The growth of income and the increasing needs of the population in housing create favorable conditions for the effective solution of one of the most acute social problems in Russia - housing, as well as for increasing the volume of housing construction and raising funds in the housing sector due to the development of mortgage lending (Averin A.N., 2019). These provisions determined the following tasks of scientific research:
- to characterize the current state and trends in the functioning of the mortgage lending market in Russia, identifying factors that negatively affect the effectiveness of its development;
- to identify priority problems, the solution of which must be foreseen when forming the appropriate strategy for the development of the mortgage market in Russia;
- to offer the main directions for improving mortgage lending in modern economic conditions.

Keywords: Mortgage, Mortgage Lending, Mortgage Market, Analysis of The Mortgage Market**.**

Introduction

The study involved teachers of the Chuvash State Agricultural Academy and the Cheboksary branch of the Russian Presidential Academy of National Economy and Public Administration. The scientific problem was studied using data from the Bank of Russia, Sberbank of Russia PJSC as the largest bank in the banking system of the Russian Federation, and other banks that are leading at the federal and regional levels.

The role of mortgage lending in the total volume of lending market to individuals is increasing. The growth of the mortgage portfolio of the Russian banking sector reached 6.41 trillion rubles (the growth rate for 2018 was 124, %), which is explained by the growing demand for mortgages as the main way to improve housing conditions. In 2018, 1.47 million loans worth 3.01 trillion rubles were granted. (+35.4% in quantitative and +49% in monetary terms compared to 2017). The average mortgage loan amounted to 2.05 million rubles, an increase by 19.2% for 2016-2018. (Nasrulaeva Z.F., 2018).

The record growth in mortgage lending in recent years is largely due to a significant reduction in housing loan rates. The average rate on loans granted in 2018 amounted to 9.56% (-1.08 percentage points compared to 2017), including loans for apartments in new construction - 9.3% (-.11 percentage points), and for the purchase of finished housing in the secondary market - 9.67% (-1.09 percentage points). At the end of 2018, mortgage rates increased due to the growth of the key interest rate, and at the present stage they are at the level of 10-11%.

The main feature of the Russian mortgage market is the high degree of competition among market participants and among their offers to the consumer. Smaller players in the Russian mortgage market have to compete with state-owned commercial banks, whose share in the country exceeds 85%. Competition among banks leads to attractive conditions for customers, including existing ones. Mortgage refinancing procedure is being developed. A big number of mortgage programs in leading banks with favorable interest rates and refinancing programs, provision of state subsidies (mortgages with state support for families with children, military mortgages, etc.), loyal attitude and minimum requirements (no down payment or down payment starting from 10%) allow this type of lending to become more popular and increase housing affordability.

The problem of the development of mortgage relations is covered in the economic literature in different directions and from different positions. Some authors pay more attention to the theoretical side of the issue, others - consider practice in the field of mortgage lending, and others - focus on legal issues. The work of foreign economists is devoted to the analysis of certain theoretical aspects of mortgage lending: N. Almeida (2006), B. Amable (2000), B. Bernanke (1996), M. Campello (2006), J. Cook (1996), M. Gertler (1996), S. Gilchrist (1996), S. Liu (2006), P. Strike (1999) and others.
In domestic literature, the most complete analysis of the factors that impede the formation of mortgage-credit relations in modern Russia was carried out by A.N. Averin (2019), Z.F. Nasrulaeva (2018), N.K. Norets (2019), Ya.S. Pavlova (2018), S.V. Shchurina (2019), N.Kh. Shakirova (2018) and others.

However, in economic science there is a lack of comprehensive research. Little attention is paid to the connection of a mortgage loan with the real sector of the economy. Most studies are devoted to fragmented coverage of certain aspects of foreign experience in the field of mortgage lending.
Hence the need arises for the analysis of mortgage lending as one of the sources of investments that provide solutions to important social problems.

Materials and Research Methods

The theoretical and methodological basis of the study is provided by the results of fundamental and applied research of domestic and foreign scientists, materials of scientific conferences, regulatory and legal acts of the federal and regional levels.

The empirical base of the study is informational materials from foreign and domestic practice of the formation and development of the mortgage market, reference and statistical data of the Federal State

Statistics Service of the Russian Federation and territorial statistical bodies, legislative and regulatory acts of the Russian Federation, periodicals, and data from the global Internet.

In the process of research, methods of dialectics, a systematic approach, logical, structural, factorial, functional, comparative, economic analysis, statistical forecasting methods, as well as expert assessment and modeling methods are used.

Research Results and Discussion

Housing lending is beginning to occupy an increasing place in the volume of lending to individuals. According to the results of 2018, the share of mortgage lending in the total portfolio of loans to the population remained at the level of the end of 2017 and amounted to 44% (Fig. 1).

Fig. 1 : Dynamics and structure of the portfolio of loans to individuals in Russia, in trillion rubles.

As of 01.01.2019, the volume of the mortgage portfolio of banks reached 6.41 trillion rubles. (+ 23% compared to 01.01.2018). The mortgage market is growing, primarily due to new borrowers. The average mortgage loan amounted to 2.05 million rubles, an increase of 10.2% compared to 2017 and 19.2% compared to 2016.

Fig. 2: Dynamics of the average size of a mortgage loan in 2016-2018, in million rubles.

The growth of the mortgage portfolio of the banking sector reached 6.41 trillion rubles in 2018, the growth rate was 124%, which is explained by the growing demand for mortgages as the main way to improve housing conditions (Table 1).

Table 1: Dynamics of debt growth under housing loans to GDP in Russia,%

Date	GDP, billion rubles	Housing loans debt, million rubles	Share of housing loan debt to GDP,%
01.01.19	103 627	6 410 409	6,2
01.01.18	92 082	5 187 462	5,6
01.01.17	85 881	4 493 155	5,2
01.01.16	80 413	3 920 442	4,9
01.01.15	77 893	3 528 379	4,5
01.01.14	66 194	2 648 859	4,0
01.01.13	62 147	1 997 204	3,19
01.01.12	55 967	1 478 982	2,71
01.01.11	46 309	1 129 373	2,5

The share of housing loan debt to GDP in Russia is growing annually and in 2018 amounted to 6.2%. In general, this indicator is quite low compared to foreign countries: the USA - 73%, Hong Kong - 47%, Singapore - 54%, Mexico - 10%, India - 10%, China - 19.4%.

In the mortgage portfolio of banks 1.37 trillion rubles are housing loans granted upon the security of co-investment agreements for the acquisition of housing in the primary market (+ 22% compared to 01.01.2018).

The Russian mortgage market in 2018 experienced a real boom. In 2018, 1.47 million loans worth 3.01 trillion rubles were granted. (+ 35.4% in quantitative and +49% in monetary terms compared to 2017).

During 2016-2018 there was a decrease in the share of the primary market in the volume of loans issued, their share in 2018 amounted to 25% (Pavlova Y.S., 2018).

Analysis of the state of mortgage lending showed that the economic downturn of 2009 and 2014-2015 had an impact on the mortgage lending system. Many construction companies went bankrupt, citizens stopped trusting them, exchange-value of rouble dropped, inflation grew - all these factors affected the incomes of the population and the decrease in the volume of mortgage loans and contributed to the growth of overdue debts, especially in foreign currency mortgages.

Foreign currency mortgages granting is not widely-spread. In 2018, 12 mortgage loans in foreign currency worth 413 million rubles were granted, the average loan period amounted to 1.6 years. Since 01.01.2018 the volume of foreign currency debt decreased by 20% from 64.6 to 52 billion rubles (less than 1% of all mortgage debts) (Shchurina S.V., 2019).

According to the data provided in table 2 we can conclude that the volume of mortgage lending is growing during periods of economic stability and falling during periods of economic downturn.

Table 2: Quarterly Issued Housing Loans from 2008 to 2018, million rubles [7]

Year	I quarter	II quarter	III quarter	IV quarter	Total for the year	Annual growth rate,%
2018	582 049	727 400	761 424	942 242	3 013 115	148,9
2017	321 314	451 664	512 779	736 185	2 022 942	137,3
2016	323 664	341 213	362 506	445 958	1 473 341	128,9

2015	218 130	242 544	301 161	385 504	1 147 339	66,3
2014	334 817	434 836	452 217	540 661	1 762 523	130,2
2013	226 989	315 513	363 430	447 665	1 353 624	131,6
2012	180 950	248 434	269 185	330 378	1 028 947	143,5
2011	105 272	168 169	194 561	248 942	716 944	188,6
2010	48 947	84 415	100 716	145 981	380 061	by 2,5 times
2009	24 546	30 856	36 111	60 773	152 501	22,9
2008	150 759	188 424	198 280	118 345	655 808	117,8

In 2018, 368.3 thousand loans worth 0.87 trillion rubles were provided for the purchase of housing in the primary market. (+ 18% in quantitative and + 32% in monetary terms by 2017). This is 25% in quantitative and 29% in value terms of all mortgage loans issued in 2018.

The record growth in mortgage lending in recent years is largely due to a significant reduction in housing loan rates. Banks have been reducing rates steadily following a decrease in the key interest rate by the Bank of Russia.

The average rate on loans issued in 2018 amounted to 9.56% (-1.08 percentage points by 2017), including on loans for apartments in new construction - 9.3% (-1.11 percentage points), and for the purchase of finished housing in the secondary market - 9.67% (-1.09 percentage points) (Fig. 3)

Fig. 3: Weighted Average Mortgage Rates in Russia in 2016-2018, % per annum

In the first half of 2018, mortgage rates decreased steadily and reached 9.05% for new buildings (August 2018) and 9.51% for finished housing (October 2018). In the second half of 2018, mortgage rates shifted to growth following an increase in funding costs for the banking sector. Thus, the yield of 5-year federal loan bonds increased from 6.6% in early April 2018 to 8.25-8.5% in January 2019. The rate on loans issued in December amounted to 9.66%, increasing by 0.25 percentage points. compared to the minimum values. At the same time, the level of issuance rates in December 2018 is lower than last year's values (9.79 in December 2017). In December 2018, rates on loans for new buildings rose to 9.39% (+0.23 percentage points compared to October 2018), and for secondary housing - up to 9.75% (+0.24 percentage points by October 2018) (Schurina S.V., 2019).

The increase in rates is the result of a review by the main mortgage lenders of mortgage conditions since October 2018 due to an increase in the cost of funding. Taking into account the validity period of previously received approvals (on average - 3 months) and the time for obtaining a loan, these changes will still be reflected in the statistics on loans granted in January - March 2019.

In 2019, in the absence of new stresses in the economy, the mortgage market expects continued growth. The dynamics of mortgage rates will be determined by the length of the period of increased volatility in the financial markets. With the favorable situation in the market in the second half of 2019, rates can be reduced to 10% or lower. In the statistics of the Bank of Russia on mortgage issuance until the end of the first half of 2019, rates may continue to rise to about 10.5% - this is the result of processing loans approved in the first quarter.

Under the influence of the current rate hike, demand for mortgage products will be limited. So, for an average loan of 2 million rubles, raising rates from 9.5% to 10.5-11% means an increase in payment by 1.3 - 2 thousand rubles per month. This is only 2-3% of the income of an average family with 2 workers.

In general, the average mortgage rate in Russia is much higher than in the USA - 3.5%, China - 4-5%, Mexico - 9.5%, Hong Kong - 5.25%, Singapore -2.2%., which restrains the growth of mortgage lending in Russia. (Nasrulaeva Z.F., 2018).

The share of refinancing in loans granted in 2018 amounted to about 11.5% (about 350 billion rubles). About 170 thousand borrowers took advantage of the opportunity to refinance their loans.

The decrease in interest rates in 2017 by 3 pp to 10% and lower formed the demand for mortgage refinancing, which began to develop actively in the third quarter of 2017. Thus, the benefits of lowering rates are not only new, but also existing mortgage borrowers. Since the beginning of 2018, the share of refinancing has decreased by 2 times - from 16% in January to 8.1% in December 2018 (Fig. 4). A decrease in the share of refinancing is the first result of raising rates.

Fig. 4 : Dynamics of the share of mortgage refinancing in Russia in 2018, %

Mortgage refinancing will be facilitated by a dynamic reduction in interest rates and the growing popularity of refinancing among those borrowers who previously took loans at an average interest rate of 12% or higher.

With mortgage lending, credit organizations face the problem of overdue loans, which negatively affects the financial result of the credit institution. The share of loans with arrears over 90 days decreased to a historic low of 1.78%. Throughout 2014-2018 this indicator did not go beyond the recommended value in the economic literature - 3-5%. There are no prerequisites for the formation of a “bubble” in Russia (Norets N.K., 2019).

The Bank of Russia closely monitors the situation with the accumulation of risks in the field of mortgage lending in order to prevent the formation of a “bubble”. Since January 2018, risk-to-weight ratios for high-risk mortgage loans with a low down payment have been increased (for loans with a down payment of less than 10% - from 150 to 300%, with a down payment of less than 20% - from

100 to 150%). From 01.01.2019, the risk-weight ratios for mortgage loans with an initial payment of 10% to 20% (from 150 to 200%) were further increased. After the loan balance is reduced to less than 80% of the property value, a standard risk-weight ratio of 100% is applied to such loans.

Competition of banks leads to increasingly attractive conditions for customers, including existing customers. According to the ranking of the Rusipoteka Analytical Center, the top ten mortgage market leaders are headed by Sberbank PJSC (Table 3).

Table 3: Top 10 in the Russian mortgage lending market in 2017-2018. [7]

Results of 2018		Results of 2017	
Bank	**Volume, million rubles**	**Bank**	**Volume, million rubles**
1. Sberbank	1 560 204	1. Sberbank	1 082 413
2. VTB	672 292	2. VTB24	376 736
3. Gazprombank	149 408	3. Gazprombank	79 821
4. Russian Agricultural Bank	128 004	4. Russian Agricultural Bank	73 323
5. Delta Credit	74 643	5. Raiffeisen Bank	59 000
6. Raiffeisen Bank	63 441	6. Delta Credit	58 565
7. Absolut Bank	48 096	7. VTB Bank of Moscow	57 077
8. FC Otkritie	33 743	8. Absolut Bank	27 251
9. Alfa Bank	33 049	9. Uralsib	27 085
10. Uralsib	30 531	10. St. Petersburg	24 946

In 2018, the 15 largest mortgage lenders issued mortgage loans in the amount of 2.98 trillion rubles. According to DOM.RF and Frank RG, this is 50% more than in the same period in 2017. The market share of the largest creditor of Sberbank in 2018 amounted to 51.8% (- 1.7 percentage points for the year); VTB's share is 22.4% (+3.8 percentage points). The shares of Gazprombank (GPB) and Russian Agricultural Bank increased by 1.1 and 0.7 percentage points respectively, amounting to 5% and 4.3%. DOM.RF, taking into account the results of the work of the subsidiary Bank DOM.RF in 2018, took 5th place in the ranking in terms of the volume of granted mortgage loans, rising by 2 positions over the year. Foreign banks in the ranking – Delta Credit and Raiffeisen Bank - occupy 6th and 7th places, respectively (Averin A.N., 2019).

In the process of research, a number of problems were identified that hinder the development of mortgage lending in Russia:

- unstable economic situation complicates mortgage lending, which implies stable development for a long term;
- cost of mortgages is too high: the average mortgage rate in Russia is much higher than in the USA - 3.5%, China - 4-5%, Mexico - 9.5%, Hong Kong - 5.25%, Singapore -2,2%., which restrains the growth of mortgage lending in Russia;
- a decrease in the share of refinancing is the first result of raising rates;
- low level of solvency of the population. The ability of the population to use the borrowed funds of the bank directly depends on their financial situation, primarily on the level of income. For example, for residents of the Chuvash Republic, the recommended family income should be 64.8 thousand rubles per month in 2019, with an average salary in the region of 26.3 thousand rubles. It can be assumed that a mortgage is available to those who do not have an acute need for housing;
- increase in prices in the primary housing market, which will increase as a result of the transition from a shared to the project system for financing housing construction, will affect the increase in the credit burden on interest for developers and will affect the increase in the cost per square meter for the final buyer;

- high inflation rate is hindering factor in the dynamic development of mortgage lending in Russia, which does not allow the CBR to lower the key interest rate. In recent years, the inflation rate in the Russian Federation has decreased and amounted to 4.3% in 2018, but compared with the economies of other countries, it is still high - the United States -1.91%, the United Kingdom -2.1%, the Eurozone -1.57 %;
- low level of financial literacy of the population has a greater effect on the decision-making strategy in households than the size of the income of citizens, traditionally regarded as a key determinant of the financial behavior of the population;
- supply shortages in the housing market; existing secondary market cannot provide the basis for the development of mortgages.

The main factors in reducing mortgage rates are the systematic lowering of key rate by the Central Bank of the RF and low inflation rates, the programs of the Government of the Russian Federation to provide subsidies for the mortgage market, as well as the increase in the supply of economy class housing developers (Table 4).

Table 4: Factors for Reducing Mortgage Rates in the Russian Federation

Cause	Factor content
The policy of the Central Bank of the Russian Federation	Since 2016, the regulator has been systematically lowering the key rate for banks, which for the period from September 17 to December 16, 2018 was 7.5%. At the present stage – it amounts to 7.75%. The Central Bank of the Russian Federation plans to reduce the key interest rate for the future. If inflation rises, it will assess the feasibility of further raising of the key rate. The Central Bank of the Russian Federation predicts annual inflation in the range of 5.0–5.5% according to the results of 2019 with a return to 4%.
RF Government Policy	Decrease in the level of inflation indicators in recent years; subsidy program for the mortgage market, which will allow in the future to keep mortgage rates at an acceptable level.
Building companies Policy	Growth in the supply of economy class apartments

A consequence of lower mortgage rates may be an increase in the number of transactions in the primary and secondary real estate market. In order to combat the high cost of mortgages, the Central Bank of the Russian Federation set a goal to reduce mortgage rates in 2019 by 9%, and then by 8%. The market method of achieving the set target for the rate implies the resumption of the CBR rate reduction rate. However, the resumption of monetary easing will be possible no earlier than the second half of 2019, when inflation will stabilize after acceleration and will begin to decline again. And even in this case, the key rate is unlikely to drop from the current 7.75% below 7%. Consequently, a decrease in mortgage rates can occur up to a maximum of 9%. However, lowering mortgage rates will be able to stimulate the mortgage market, which, in turn, will spur demand for primary housing.

An increase in demand for mortgages depends not only on lower interest rates, but also on the solvency of borrowers. The macroeconomic indicators in the country are of great importance. If the cash incomes of the population are subject to stagnation, a decrease in mortgage interest rates will not lead to the desired result. Low-wage borrowers will not be able to pay mortgages (Nasrulaeva Z.F., 2018).

Thus, low solvency of the population is the main problem of the slow development of mortgages in the Russian Federation. Banks (credit institutions) grant loans, taking into account the income of citizens. It is this indicator (solvency) that is fundamental when granting a loan and, accordingly, the entire banking and credit system of the country. Banks issue loans if the monthly payment is not more than 40% of the borrower's family income. However, there are cases when borrowers, trying to get a loan, indicate higher incomes that are actually invalid. Thus, they make it difficult for themselves to pay interest on the loan. Given the real incomes of citizens, we can conclude that mortgage lending is not available to everyone (Shakirova N.Kh., 2018).

To increase the level of savings in incomes of the population, it is necessary to systematically carry out a number of important measures: implement a system of state measures to increase real cash incomes of the population, reduce inequality in incomes, continue the policy of lowering inflation, and monitor the savings process.

In addition to inflation, banks have the following difficulties:
- firstly, depositors seek to reduce monetary risk and therefore do not keep their funds on deposits;
- secondly, the income of future bank customers is growing much slower than the rate of inflation;
- thirdly, due to the small number of depositors, the level of mortgage lending services is decreasing.

Thus, the mortgage is developing as an offer for certain categories of citizens who own a high level of income.
The solution in this situation is the adoption of urgent measures to combat inflation, as well as raising the level of the economy as a whole.

Unstable economic situation. Mortgage -is a long-term loan. To offer a project of a strategic nature, i.e. for a long time, credit organizations require a certain guarantee of balance in the economy. Individuals and legal entities holding a loan also want to be sure that they can repay the loan over a long period. The country's economy directly depends on the economy in other countries, as well as the prices of resources in them. Currently, state and population incomes are fluctuating, as are under constant pressure from global sanctions and unstable prices for black gold. And therefore, our country has no guarantees of economic stability. Consequently, banks cannot issue loans to potentially insolvent populations. The way to solve this problem is to ensure the stability of the economic and political situation in the country.

The source of the high cost of mortgages, or, in other words, high interest rates is the high cost of attracting resources - the inflation rate should not exceed the interest on deposits, so that it would be profitable for depositors to keep their money in bank accounts. Following the interest rate on the deposit, the rate on housing loans will increase. Only a significant reduction in inflation in Russia will help to fully solve this problem.

At the same time, there is a shortage of offers on the mortgage market. The existing secondary market cannot provide the basis for the development of mortgages. Buying and selling in this market is often fraught with legal conflicts regarding ownership of housing. This is also due to the fact that the system of state registration of real estate transactions was developed much later than the Law of July 4, 1991 No. 1541-1 “On the privatization of the housing stock in the Russian Federation”.

With a high degree of probability it can be assumed that an increase in the solvent demand of the population due to mortgage lending without a corresponding development of the construction market will lead to a significant increase in prices caused by an acute shortage of offers in the primary housing market. The main obstacle to investment in housing is the high financial risks, which are more associated with risky financing schemes through shared housing construction.

The transition from a shared to a project system for financing housing construction will affect the increase in the credit burden on interest for developers and will affect the growth in the cost per square meter for the final buyer. In the Russian construction industry, there is a high cost of facilities under construction, which limits construction companies in the use of equity due to its insufficiency, since it is formed from net profit. Project finance can help small construction companies exit the market.

Russia has a long way to go in the struggle for stability in the economy and constancy in the mortgage market. Prospects for the availability of mortgages in the Russian Federation can be estimated based on the opinions of heads of departments and banks that have a direct impact on this process (Table 5)

Table 5: Predicted Positions of Mortgage Accessibility by the Government and Business in the Russian Federation

Source	Forecast
Bank of Russia	It is supposed to achieve mortgage rate indicators in the range from 9 to 10% with the key rate of the Central Bank of the Russian Federation at 6.5-7% and with annual inflation of 4% by 2020 (E. Nabiullina)
Government of the Russian Federation	The country has created all conditions for achieving a mortgage rate indicator of 6–7% (D. Medvedev)
Ministry of Economic Development of Russia	Mortgage rates will be 8–9% in 2019–2020. (M. Oreshkin)
Ministry of Construction of the Russian Federation	Proposals are being prepared to change the mortgage subsidy program in order to try to implement the ambitious plans that the President of the Russian Federation has set.
Sberbank	While maintaining the trend for lowering inflation, it is possible to achieve mortgage rate indicators in the value of 6–7% by 2020; as of November 2018, the mortgage rate of Sberbank is 8.99% (G. Gref)
Promsvyazbank	A mortgage rate of 8% will be reached by 2020 (D. Monastyrshin, chief analyst at Promsvyazbank)

Some experts predict a decrease in mortgage rates, which can reach record low values, while others, on the contrary, predict the formation of "financial bubbles" similar to those that had appeared in American mortgage market by 2008. The provision of cheap mortgage loans by American banks and the lack of proper solvency control of borrowers had become the causes of the global financial crisis.

In his annual Address to the Federal Assembly on February 20, 2019, the President, speaking about the support of mortgage lending, noted that it is necessary to consistently reduce mortgage rates to 9%, then to 8% and improve the effectiveness of preferential mortgage lending programs. For families with 2 or more children there is a preferential mortgage program at a rate of 6%. However, only 4.5 thousand families took advantage of the privilege. The rate is subsidized for only the first 3 or 5 years of the loan. It is proposed to establish a concession for the entire duration of the mortgage loan. This will require 7.6 billion rubles in 2019, 21.7 billion in 2020, and 30.6 billion in 2021. The program can reach 600 thousand families. 450 thousand rubles are given from the federal budget to the family with 2 or more children to pay for the mortgage loan. This will require an additional 26.2 billion in 2019, 28.6 billion in 2020, and 30.1 billion in 2021. It is necessary to provide the family with the opportunity not only to buy new housing, but to build their own home on their own land. Individual housing is not covered by the mortgage. Construction companies that transfer social facilities to the state and municipalities must be exempted from income tax and VAT.

Conclusion

Solving the problems of mortgage lending is a complex task that affects macroeconomics, social and political spheres, banking and construction sectors, and much more. It takes a long time to settle these elements and take mortgage lending to a new level.

The Government of the Russian Federation, with the help of various state mechanisms and social programs, is trying to make mortgage lending affordable for all the population. The Bank of Russia policy to combat inflation and the systematic reduction of the key rate has created favorable conditions for setting acceptable bank rates for mortgage loans, which has allowed over the past few years to significantly increase demand for mortgages. Russian commercial banks have lowered mortgage rates and offer refinancing of previously received mortgage loans, which testifies to the confidence of the banking sector in the state, the confidence of banks in maintaining stability in the economy at the macro level.

In the future, the main actions in stimulating the mortgage market by the state may be:
- ensure the stability of the economic and political situation in the country;
- implementation of measures to reduce the risks associated with long-term lending in order to increase the profitability and attractiveness of this type of lending for banks;
- reducing the administrative burden on developers, improving the regulatory framework and the procedure for regulating activities in the field of housing construction;
- taking additional measures to encourage the participation of banks in mortgage lending, for example, attracting banks to manage the funds of free grants provided to citizens for the construction and purchase of housing;
- providing support to families with low incomes when buying a home by providing them with subsidies to pay the down payment when using a mortgage loan;
- the introduction of the standard for responsible lending which is a standard that will be recommended to banks so that they familiarize customers with the procedure for paying a loan, and especially with those conditions when a security object could be withdrawn if the mortgage is not paid. The document describes options for pre-trial settlement of mortgage arrears, as well as options for helping if a person is in a difficult financial situation (T. Bogatova, 2016).

In our opinion, the main problem with mortgage lending for a young family in need of their own housing is no money for down payment, absence of a credit history, and lack of awareness of financial decisions. Therefore, in the study, we propose to open mortgage deposits in banks, which assume monthly payments, as with mortgage lending, only family funds will be received on a deposit account at an interest for a long period of time. 2-4 years savings, depending on the level of family income, will make it possible to form a down payment of 20-30%. A person will not be able to take away the savings before the expiration of the period indicated in the contract. At the end of the term, the citizen receives not only the deposited amount and interest, but also the opportunity to conclude a mortgage agreement at a preferential interest rate.

This practice will allow not only banks to evaluate the creditworthiness of a young family, but also for young people to realize their ability to pay a mortgage loan. If this load turns out to be exorbitant, the young family will always be able to refuse mortgage lending and will remain with their savings.

Abstract

The relevance of scientific research of the organizational culture of Russian enterprises is due to the changes that have occurred in the political, social and economic spheres. Changing the form of ownership and the status of enterprises stimulates the search for optimal ways to carry out business processes and the introduction of progressive forms of management.

In modern science, both domestic and foreign, there is no single concept of organizational (corporate) culture. There are several areas of research: some scientists consider corporate and organizational culture to be synonyms. Others formally believe that corporate culture is the culture of large corporations, and organizational culture is that of small organizations. There is a scientific opinion according to which corporate culture refers to specially created, externally formed values of an organization that contribute to its competitiveness, and the organizational culture develops by itself as a result of direct production and social interaction.

Keywords*:* organizational culture concepts, organizational culture assessment methods, organizational culture interpretation elements

Introduction

Researchers did not immediately come to understand the importance of organizational (corporate) culture but at a certain stage in the socio-economic development of society and management as a scientific discipline. The emergence, in particular, of new organization management methods is associated with certain market conditions.

In the modern theory of management there are three stages of progress towards the formation of a theory of organizational (corporate) culture, which are expressed in the following concepts: A. Fayol

"personnel management" and its basic principle of corporate spirit, E. Mayo and his human factor as a new type ofpersonnel labor assessment, A. Maslow "HR - human resource" and its human resource as the main object of management in the conditions of scientific production.

For most ordinary people organizational (corporate) culture as a business process was formed in the 1970s during the period of the so-called "Asian miracle" and the emergence of the Japanese management model where value orientations of entrepreneurial activity were called the main economic engine.

In the Russian Federation since the beginning of the 1990s there was a transition from a planned system of economic development to a market model of economic development. The American management model was chosen as an example of the development of entrepreneurial culture, which did not fully take into account all the features of Russian society and the realities of that time. In the 2000s during the formation of large business the concept of a valuable employee appeared as a carrier of the capital of a company requiring a more attentive attitude from the owner of the business. This situation in management entailed a number of problems that required the creation of working conditions that satisfied qualified personnel. Thus, the question arose of creating and maintaining a certain corporate (organizational) culture, methods for assessing it and choosing an interpretation for organizational and legal activities.

Materials and Methods

Teachers and staff of the Chuvash State Agricultural Academy have taken part in the study. The scientific problem was studied at the Chair of Economics, Management and Agricultural Consulting using available information resources including electronic library networks, information and reference systems, official Internet sites of government agencies of the Russian Federation and Russian enterprises. The objects of research were Russian business entities and business processes occurring in the management system. In the course of the work general scientific methods of dialectics, analysis, synthesis, induction, deduction, comparison, and analogy were used.

Research Results and Discussion

In order to deal with the problems of the theory of organizational (corporate) culture in the Russian model of management it is necessary to analyze three important components of the theory of organizational (corporate) culture:

- elements of organizational (corporate) culture and their interaction in the organization;
- the most acceptable interpretation of the phenomenon of organizational (corporate) culture taking into account the peculiarities of organizational and legal forms in the Russian Federation;
- themethodology most suitable for assessing organizational (corporate) culture.

Most domestic authors studying this issue agree that organizational (corporate) culture can be called a subjective element of organizational activity, which consists of a wide variety of complex assumptions unprovenly accepted and shared by members of a group or organization. To simplify the assessment procedures most authors propose to group elements of culture according to similar characteristics. At present it is customary to distinguish three such signs of classification - patterns, values and symbolism.

Many firms have special documents intended for staff which describe in detail their value orientations, called corporate codes. Using the general that is inherent in many definitions we can characterize organizational culture as follows:

Organizational (corporate) culture is a set of the most important assumptions accepted by members of the organization and expressed in the values declared by the organization giving people guidance on their behavior and actions.

These value orientations are transmitted to individuals through the symbolic means of the spiritual and material internal organizational environment. In Figure 1 you can clearly see many elements of organizational culture which are inscribed in the structure of all business processes in the organization.

The second no less important point is a different interpretation of the term organizational (corporate) culture. To date in various literary sources the concepts of "organizational culture" and "corporate culture" are identified and contrasted. How correctly and appropriately do these concepts compare and prioritize?

According to V.A. Spivak priority should be given to corporate culture as the basis for identifying personnel with a particular enterprise. By corporate culture the author understands the combination of material and spiritual values inherent in an individual organization, demonstrating its distinguishing features as an understanding of itself and others manifested in the behavior, interaction and evaluation of oneself and the outside world.

Fig. 1: Structure of interaction of elements of organizational (corporate) culture in an organization by S.S.Zhogova

His opinion is shared by V.V. Tomilov arguing that the culture of a corporation should be seen as an expression of core values in the organizational structure, management system, personnel policy exerting its influence on them.

According to E. Shane organizational culture as external adaptation and the unification of employees within the organization is of paramount importance.

According to A.A. Averyanovait's advisable to talk about corporate culture since it describes a system of values that is understood and taken lead from by employees of the organization. According to the author corporate culture consists of a set of rules adopted by employees of the organization expressed in the values required by a particular company which coordinate the norms of human behavior.

A.A. Maximenko and T.O. Solomandina believe that the difference between the terms organizational and corporate culture lies in the size of the enterprise. In their opinion the concept of organizational

culture is more appropriate for enterprises belonging to the category of small and medium-sized, while for large enterprises corporate culture is more suitable.

Some authors prefer to contrast the terms corporate and organizational. So A.E. Kapitonov and E.A. Kapitonov believe that organizational culture should include the qualitative characteristics of the assessment. The authors include the order of management and the degree of development of economic resources. According to them corporate culture includes rules within the company that is traditions and norms. The authors also substantiate the idea that organizational and corporate cultures have different tasks.

Another author N.N. Morgunova believes that corporate and organizational cultures are autonomous phenomena that have common components. Therefore there is no difference in these definitions.

In order to try to answer the question of the acceptability of the use of terminology organizational culture and corporate culture in the Russian management model it is advisable to compare the concepts included by the authors on the basis of the factors indicated by them.

Let us compare the concepts of "organization" and "corporation." In the Anglo-Saxon tradition “a corporation is a collection of people who have united to achieve common goals, carry out joint activities and form an independent subject of law - a legal entity”. "Organization" is a certain group of people whose activities are deliberately coordinated to achieve common goals. The Tax Code of the Russian Federation equates organizations with legal entities. A formal comparison shows that the concepts of "corporation" and "organization" are identical, they simply have different etymological roots. It should also be noted that enterprise is also an independent, organizationally separate business entity with the rights of a legal entity which produces and sells goods, and performs work and provides services. It can be created in any legal form from an individual enterprise to a joint-stock company or state corporation.

But it is necessary to clarify that enterprises are both commercial, where the main goal is to make a profit, and non-profit, where the goals are somewhat different.

Therefore, it is advisable to compare the concepts of "organization" and "enterprise".

1. An enterprise is a subject of market relations and is exclusively engaged in the production of goods and services. An organization, in addition to production, can engage in activities not related to it (politics, culture, sports, science);
2. An organization may be an informal group functioning according to its own rules and formed on the basis of friendly relations. An enterprise cannot be informal. All its activities are based on a legal basis;
3. The head of an organization may occupy his position on the basis of a legal act. In an informal organization a leader is determined by the will of its members; there may not be any documentary basis for this;
4. The effectiveness of the management of non-production organizations is determined by their bodies. Performance indicators for managing an informal organization, as a rule, do not exist. The effectiveness of enterprise management is determined by the parameters established by regulatory enactments.

Thus, we can conclude that organization, in the broadest sense, is a community of people united by mutual goals; this is a specific concept which can include both enterprises and corporations, therefore, in essence the concepts of “organizational” and “corporate” are synonymous, and denote the culture of a particular group of people.

With the increasing role of culture for organizations the need for its assessment increases. Therefore, the third, no less significant point for managers, is the choice of the most balanced methodology for assessing organizational (corporate) culture.

By“methodology for assessing organizational (corporate) culture”we shall mean a system of sequential actions aimed at researching the organizational culture to obtain information about the state of the company and identify its advantages and disadvantages.

In the process of studying and analyzing literary sources the currently existing methods for assessing organizational (corporate) culture were identified, which we combined according to the evaluation criteria into two groups - qualitative and quantitative.

Qualitative methods for assessing organizational (corporate) culture involve descriptive studies based on an analysis of the collected primary data about the company (survey, questionnaire, etc.) and private information (the opinion of employees about the company, its resources and development opportunities; level of motivation; suggestions to improve the work, internal conflicts, informal relationships) without quantitative expression (Table 1).

Table 1: Qualitative methods for assessing organizational culture

Methodology	Analyzedparameters
Typology of T.E. Dil and A.A. Kennedy	Employeeattitudetowards risk
Typology of R. Ackoff, Typology of M. Burke, Typology of C. Handy, Typology of W. Ouchi, Typology of G. Islam and M. Zipur, Methodology of E. Shane, Typology of R. Blake and J. S. Mouton	The relationship between the organization and employees
Typology of F. Klukholm and F.L. Stroberg, Methodology of C. J. (KawakitaGiro), Typology of M. Mark and K. Pearson, Typology of F.R. Manfred Ke de Vree and D. Miller, Typology of S. Medoc and D. Parkin, Methodology of F. Harris and R. Moran, Typology of Larry Constantine	Employeefeatures

Despite the fact that qualitative methods for assessing organizational (corporate) culture allow us to obtain a visual result of the study and identify the characteristics of culture at the same time they practically do not reveal the features of the organizational (corporate) culture of an individual organization (Table 2).

Quantitative methods for assessing organizational (corporate) culture involve conducting various surveys to obtain a numerical assessment of the state of the organization. These methods are used to obtain statistics about the organization under study.

Table 2: Quantitative Methods for Assessing Organizational Culture

Methodology /authors	Analyzedparameters
D. Denison model (DOCS), Methodology of G. Hofstede, Methodology of K. Cameron and R. Quinn (OCAI), Methodology of Van de Post and Koning, Methodology of N.V. Levkina	Taking into account the features of the internal and external environment of the company
O’Reilly, Chatman and Condwell Methodology (OCP), R. Cooke and J. Lafferty Methodology (OCI), C. Glaser and S.	The study of the internal environment of the company

Zamanou Methodology (OCS), Methodology of T.O. Solomandina, Method of I.D. Ladanova, Methodology of O.E. Steklova, Method of L.S. Savchenko	

When assessing organizational (corporate) culture, the greatest popularity in our country was gained by the methodology of K. Kemeron and R. Quinn (OCAI), which is explained by the ease of use and the universality of its application. In addition this technique was one of the first to be proposed by Russian specialists. Like most quantitative methods, the OCAI methodology involves questioning, mathematical calculation on a 100-point scale, interpretation of the results by typology, and construction of a framework design. The survey participant is offered six sets of questions, the results of which are used to build the entire diagnosis. This is a very subjective technique, where the error in the answers of the questionnaire is high and can vary depending on the circumstances. The second most popular use is the D. Denison Qualitative Assessment Methodology (DOCS). In comparison with the model of C. Kemeron and R. Quinn (OCAI), D. Denison's methodology (DOCS) includes a questionnaire of 60 statements rated on a five-point scale. The main disadvantage of this model is the complexity of the conduct, the advantage is a more accurate result compared to the OCAI methodology. The value of these methods lies in the fact that they both allow the management of the organization to catch the employees' mood for adherence to the existing organizational (corporate) culture or the desire to change it, being a valuable signal for the manager to take further actions.

Conclusion

Until recently the concepts of “corporate culture” and “organizational culture” were not clearly distinguished in Russian literary sources raising a lot of questions. To date no consensus has been formed on the correct use of these terms. The most common approach is that corporate and organizational cultures are identical concepts since the philosophy and ideology of the organization, value orientations, norms are accepted and shared by all members of the team. In addition, from the legal interpretation there are no significant differences in these terms. Therefore, both terms in most literary sources are commonly used together especially in educational literature. But no final decision on this issue has been made, which forms the process of transformation of the cultural space based on the following concepts:

The first concept is based on the fact that corporate and organizational cultures are independent phenomena. Organizational culture is a holistic view of the goals and values inherent in the organization, specific principles of behavior and ways of responding. Corporate culture is a set of assumptions accepted by all members of a particular organization, which defines the general framework of behavior accepted by most of the organization. The main difference between organizational culture and corporate culture is that the former is regarded as a theoretical model, and the latter for each particular organization is a set of types of organizational cultures.

The second concept is formed around an organization belonging to the category of small and large. It is worth noting that the separation by the size of the organization and type of business is not objective since a large enterprise may also have an informal internal structure, and relations in a small company may be official.

The third concept is based on the definition of a local industry organization and a multidisciplinary international corporation revealing the term "entrepreneurial culture", which refers to the culture of small enterprises. According to this theory corporate culture is part of organizational culture where the concept of "organizational culture" is broader than the concept of "corporate culture". So from the perspective of management the term “organizational culture” is more applicable.

The fourth concept considers the concept of corporate culture at the level of values and norms of a particular enterprise, suggesting that corporate culture as a concept covers norms and values at a wider level based on the social significance and responsibility of employees. From this point of view

an organizational culture can be formed as a result of long practical activities or the activities of a particular leader or by the formation of an organizational culture by specialists from outside. At the same time it can be developed to the corporate level, when the interests and actions of employees are maximally focused on the goals of the organization as a whole.

Building a certain organizational (corporate) culture for many managers is an integral part of the enterprise development strategy. Differences in goals, established patterns of behavior of employees of the enterprise can lead to conflicts, and therefore interfere with business. Therefore, the value-based way of management becomes the basis for the formation of organizational (corporate) culture. Thinking through the goals and values of the business creates a solid motivational environment for employees, forms a union of like-minded people. Also a strong organizational (corporate) culture motivates an employee to put much more effort into achieving the goals of the organization, to do it more actively and purposefully. In this aspect organizational (corporate) culture is an effective means of planning and implementing productive business ideas. It is important for an organization to consider this view of the essence of corporate culture especially at the stage of its formation.

In the formation of culture the head of the enterprise plays a paramount role. Strategically thinking leaders of successful enterprises use organizational culture as a strategic tool that makes it possible to direct employees to common goals and values, attract initiatives, maintain company loyalty, and optimize the communication environment.

The study of all aspects of organizational (corporate) culture creates scientific theories as a consequence of all previous research activities. All theories contain elements of empirical data accumulated in the initial stages of rational knowledge. Empiricism, hypotheses and laws in every scientific theory are its essential elements, which change during the development of the theory.

Theories of organizational (corporate) culture are currently under active development, both theoretical and empirical. The indisputable relevance and variety of existing concepts dictate the need to search for universal scientifically confirmed postulates, laws and principles of construction, methods of maintaining and developing the culture of an organisation.

It should be noted that in recent years the study of organizational culture generates intense interest. This is determined by the existence of a number of features of modern economic development, such as:

- transition to a new knowledge-based economy;
- change in the way of organization management (increasing the importance of human capital management);
- occurrence of significant changes in the process of interaction of organizations with the external environment;
- tendency to integrate the goods and services provided (the growing "complexity" of consumption and, accordingly, the promotion of products and services requiring effective interaction of organizations of various sizes representing different geographical areas, industries, patterns of ownership);
- aggravation of the problem of social responsibility and business ethics;
- demand for additional competitive potential of organization;
- need to expand the ability to predict the situation at the global, national, industry and organizational levels in the short and long run.

To summarize, we propose to interpret the organizational (corporate) culture as the social and spiritual life of a team consisting of beliefs, values and attitudes in which all employees of the enterprise participate. Corporate culture contributes to the achievement of tasks and the implementation of planned actions in the future.

Abstract

The article is relevant as the fuel and energy complex (FEC) ensures work and activities of Russia as a whole and the consolidation of its regions, formation of a significant part of budget revenues and foundations of innovative economic development. The purpose of the study is to identify priority areas for the development of the fuel and energy sectors based on a comprehensive analysis of the development of their innovation and investment activities. Research methods include dynamic, coefficient and comparative analysis, which allowed us to identify trends in the development of the Russian energy sector in 2008-2017. It is noted that the need for large-scale modernization of the fuel and energy complex, which will require significant investments and support from state authorities. A comprehensive study of the State Programs of Russia was conducted - "Energy Efficiency and Energy Development", "Development of the Nuclear Energy Industrial Complex", and Corporate Innovation Development Programs (PIR).
The results of the study identify priorities for innovative development in the electricity, oil, gas and coal industries of the fuel and energy complex. The conclusions formulated will allow for a more effective innovation policy in the fuel and energy sector.

Keywords: fuel and energy complex, innovation and investment processes, fuel and energy complex development programs

Introduction

The fuel and energy complex (FEC) is a combination of companies working in oil and gas production, oil refining, system for transporting and distributing gas, oil and its products, various types of power plants, and transmission and distribution network for heat and electric energy. Russia occupies a leading position in the world in terms of development of the fuel and energy complex and it is one of the most stably working sectors of the country's economy. The importance of the fuel and energy complex in the Russian economy is obvious as it fulfills the following functions: ensuring domestic demand for fuel and energy resources; formation of the needs of the budget system of the country. The development strategy of the fuel and energy complex should provide for the fiscal needs of the budget system, with a gradual redistribution of the tax burden and a decrease of the fuel and energy complex indicators in the structure of the country's economy. All this indicates that the fuel

and energy complex occupies a special place in the system of social production, is an important factor in ensuring the country's security and a guarantee of further economic progress.

Research Results and Discussion

In 2017, the share of fuel and energy complex in Russia's GDP was 22.6%, in export - 58.9%, in federal budget revenues - 39.6%, [2. 8]. Therefore, Russian practice is of interest to other countries that seek to accelerate the innovative development of the fuel and energy complex and increase its importance in the national economy.

The source of development of the fuel and energy complex is innovation, and the source of sustainable development is constant innovation process. Consequently, the sustainable development of the fuel and energy complex in the near future will be based on the formation and implementation of innovative policies aimed at developing effective solutions to meet the needs of society in energy in the conditions of exhaustion of the most common types of fuel in domestic practice.

Effective organization of the innovation process does not provide for the existence of a single mechanism for its financial support and depends on the type of economic activity, production specialization, development programs, innovation goals, the amount of necessary costs, the timing of receipt of financial resources, and interest rates on borrowed sources of financing. These factors together affect the choice of sources of fundraising and the formation of the resource base for financial support of innovative processes in the fuel and energy complex.

Modern studies prove the relationship of long-term economic growth with the level of development of technological innovations and their implementation. By supporting the innovative activities of energy companies, the state thereby has the opportunity to influence a significant part of the national economy. In the fuel and energy complex, the state owns a significant share of the complex, in accordance with which there is a high degree of participation in the activities of this complex. Through the adoption of long-term development programs, the state realizes its economic and social targets.

Thus, the State Program of the Russian Federation “Energy Efficiency and Energy Development”, developed to be implemented until 2020, is aimed at achieving the goals of the state: providing the country with highly reliable energy resources; increasing the efficiency of their use; reduction of environmental impact during their production and transportation.

The importance of the State Program “Development of the Nuclear Energy Industrial Complex” should be noted. The program was developed to be implemented until 2020 and aimed at the innovative development of the nuclear industry.

The adoption of programs testifies to the state’s interest in research and development, technological modernization using modern achievements of world practice. To identify promising areas of scientific research and technology development, the forecast of scientific and technological development of the Russian energy sector for the period up to 2035 was developed and approved in 2016 by the Ministry of Energy of Russia [5, 6]**.** To ensure the processes of scientific and technological development of the fuel and energy sectors, substantial investment is required. In general, the volume of investments in the fuel and energy sector of the Russian Federation in 2015 amounted to about 3.1 trillion. rubles, in 2016 - 3.7 trillion. rub. (equivalent to 25% of total investment in the economy), in 2017 - 3.5 trillion rubles. As shown in Figure 1, investments in the Russian energy sector in 2008-2016, according to the Federal State Statistics Service, have continuously increased at current prices, but investment growth has begun to decline since 2013 [2, 8].

At the present stage, the main increase in investment is observed in the oil and gas production sector and in the provision of services in this area. For 2008-2016 the volume of investments in oil and gas production grew by almost 2.4 times (taking into account nominal prices) and reached 2.4 trillion

rubles. in 2016, mainly due to the implementation of projects in the north and east of the country, as well as in the offshore areas. In 2015—2016 the volume of investments in the oil and gas industry decreased significantly due to lower oil prices, which caused a drop in total investment in the fuel and energy sector. According to the International Energy Agency, in 2016, the volume of investments in the fuel and energy complex amounted to about $80 billion, and the country ranked fourth in the world after China and the USA and India [3, 9].

According to the Ministry of Energy of Russia, in 2018 the level of depreciation of the equipment of power plants amounted to 36%, and that of the major equipment and power lines as a whole - 25%, which indicates "satisfactory" and "good" technical conditions respectively. However, the growth rate of capital investment in the electric power industry since 2011 has been lower than investment in the country's economy as a whole.

The reasons for underinvestment in the Russian fuel and energy complex is the use of own funds of business entities as the main source of investment. The industry is not sufficiently attracting large resources from the capital market. The instability of the regulatory framework and the imperfection of the institutional environment and market infrastructure also hinder raising funds for the energy sector. The presence of a large number of administrative barriers, direct state price and tariff regulation in the electric power and gas industries negatively affects the investment climate in the industry.

Currently, the fuel and energy complex faces structural changes in production, including the transition to the development of reserves of unconventional oil and oil, which lies at great depths in dense rocks, which will accordingly lead to an increase in production costs.

In 2011, the Innovation Development Strategy of the Russian Federation was adopted, on the basis of which the Corporate Innovation Development Programs (IDP) were developed. These are strategic planning programs that are developed for a period of 5-7 years. They contain a description of the set of measures necessary to introduce and bring to the market new innovative technologies, products and services, as well as measures to modernize existing capacities and technological development of oil and gas companies. Each IDP company is guided by its business development strategy taking into account the main trends in the market environment, as well as national priorities for the country's technological development in the state strategic planning system. Currently, IDP is implemented by more than 60 companies that provide about 20% of Russian GDP, including PJSC Gazprom and PJSC Rosneft [4, 5].

The country has a "road map", a set of tools to support the innovative development of energy companies has been formed. One of such tools is the selection and implementation of effective projects of national importance. In 2015-2017 20 national projects on the introduction of innovative technologies and modern materials in the fuel and energy complex were approved. The use of domestic technologies with the use of Russian materials, components and equipment will stimulate the development in the country of not only the fuel and energy complex, but also heavy oil engineering [1, 13].

In 2016, the "Energy Net" road map and the "Intelligent Energy System of Russia" concept were approved, which envisages the modernization of the entire electric power industry of Russia in the next 15–20 years in order to achieve leading positions of Russian companies in the high-tech world energy markets. The development of technologies and intelligent services will ensure the transformation of business models of organizations that will change the structure of the electric power industry and increase its reliability and safety.

The Ministry of Energy of Russia, having approved the "road map" for introducing innovative technologies, has created a mechanism to stimulate innovative activity and introduce modern technologies in the fuel and energy complex. The largest Russian energy companies are gradually introducing digital and "intelligent" technologies, including those made in Russia which corresponds to the advanced world trends [12, 13].

In the oil and gas sector, the most promising areas of innovative development include technologies for increasing oil recovery, developing hard-to-recover oil reserves, including in the offshore zone, as well as technologies for producing liquefied natural gas and its transportation. According to expert estimates, the technologies of "smart wells" and "digital fields" can reduce the cost of operating fields by about 20% [6, 7].

In the coal industry, the biggest priority is the development of high-performance tunneling complexes and the use of modern means of remote control and monitoring of downhole processes, the use of effective methods and technical means to reduce methane and dust emissions.

Currently, work is underway in the electric power industry to increase the reliability of the functioning of national energy systems, which will be facilitated by the development of technologies for actively adaptive electric networks, the technological concepts of Smart Grid and Energy Net, the introduction of automated protection and control systems for electrical substations ("digital substations"), and a new electrical and electronic equipment, the use of new structural materials, including composite materials, etc. [10, 11]

In atomic energy, the state-owned Rosatom corporation has created an advanced digital Multi-D project management system that allows you to effectively manage all stages of the nuclear power plant life cycle.

Such a large-scale modernization of the fuel and energy complex will require substantial investments and support from the state. The main sources of investment in innovation can be enterprises, large corporations, small innovative companies, investment funds, innovation development funds, etc.

Prospective financing of the fuel and energy sector involves an increase in the share of external sources (budget allocations to investment programs that have national priorities, bank loans, foreign investments), which are used to a much lesser extent. In 2016, own funds accounted for 67% of the production of fuel and energy minerals, and 50% of the total funding in the production and distribution of electricity.

It is expected that as a result of the implementation of innovative investment measures, by 2020 the energy intensity of GDP will be reduced by 9.41% compared to 2007, the oil refining depth will increase to 85% and the annual oil and condensate production will stabilize at 548 million tons.

Conclusion

Thus, the sustainable development of the fuel and energy complex is a process of constant search and implementation of solutions to achieve a new equilibrium between the changed environmental conditions and the capabilities of economic entities to realize their national economic mission in the new conditions. Sustainable development is based on the unity of the following components: effective investment policy; optimal composition and interaction of the participants in the complex to coordinate interests and areas of action; constant innovation process.

Abstract

The article identifies the problems of a comprehensive assessment of the results of managing innovative systems from the perspective of a systematic approach for the participants of the systems, describes the methodological approach to assessing the effectiveness of innovative systems from the perspective of the theory of human capital development, substantiates the possibility of achieving the goal - improving the quality of life of the population by increasing the quality of human capital. It is proposed in the article to use the resulting indicator - the quality of life of the population to assess the effectiveness of the innovation policy of the territories, an algorithm of the influence of innovation on the target indicators of the main components of the economic development of the territory with an expanded description of its stages is presented, factorial two- and three-dimensional models of the influence of the main components of the economic development of the territory on the quality of life of the population are developed, recommendations are given on the development of the innovative policy of territorial innovative systems.

Keywords*:* Innovation System, Human Capital, Quality Of Life Of The Population, Management Positioning Map.

Introduction

The modern model of socio-economic development, developed by the governments of the countries, is largely due to changes in the economic role of innovations, directions and mechanisms for the implementation of innovative processes laid down in official legislative documents and regulations for the sustainable growth of economies. Russia is objectively integrated into the global economy and the global scientific and technological space [Barro, R.J., 1996], [The Global Competitiveness

Report, 2018], [Fleurbaey, M., 2019]. But the level of this integration is not high enough yet. For the period 2010-2019, Russia, according to the Global Innovation Index, succeeded and rose from a place in the middle of the rating to a place in the first third of the rating of the countries observed. However, in 2010 Russia took 9th place in the ranking of the world economies of developed countries according to the UN data, by 2018 Russia's position fell to 11th, which indirectly confirms the long-term stagnation of the Russian national innovation system (NIS). Russia's GDP growth rate in 2018 amounted to 2.3%, with a global value of 3.0%. A peculiarity of managing the innovation sphere in Russia is predominant and insufficiently effective financing from the federal budget. Under the conditions of objective budgetary constraints, two interrelated tasks should be solved - actively attracting business funds to the field of science and innovation and increasing the profitability of relevant types of activities and sectors of the economy. All of the above does not provide impulses to the development of the Russian national innovation system (NIS) on the part of business. It should be noted that the Russian NIS is distinguished by the presence of gaps between science, education and business, a weak level of network cooperation as the basis for innovative growth in leading countries. The level of innovative activity of organizations oriented to international markets and directly determining the global competitiveness of the Russian economy is only 0.2 -0.3% from 2016 to 2018. According to the strategy of innovative development of the Russian Federation for the period until 2020, it was planned to increase this indicator to 2%. This task was set based on the high quality of human capital available in Russia, which is estimated to be higher than the general level of innovation activity (The Global Innovation Index) - 46th place, and in terms of the Global Qualified Professionals Index (The Hays Global Skills Index) - 27th place). All this testifies to the underutilization of the country's intellectual potential.

The aggregate indicator of the level of human development in the country according to the United Nations Development Program (UNDP) is the human development index, which is interpreted as a synonym for the concepts of "quality of life" or "standard of living". Between 2016 and 2019 Russia maintains a stable position in the international rating of human development at the level of 49-50 places among 188 countries. This situation indicates a stagnant state of the implementation of the state policy of socio-economic development of the country [Gokhberg, L, 2017] [Data on international ratings, 2020].

In recent years, a large number of regulatory documents have been developed in the Russian Federation aimed at achieving new qualitative and quantitative indicators of sustainable economic development. For example, the goal was set - to enter the top five leading economies in the world. Despite the fact that institutional conditions were created to achieve ambitious goals, this did not significantly change the competitiveness of the country's economy at the international level.

In this regard, the relevance of the research topic lies in the scientific and practical importance of the formation and development of technologies for managing innovative systems of various levels within the framework of the concept of competitiveness of territories, allowing for the long term to create conditions for sustainable economic growth, ensuring an increase in the quality of life of the population in all its aspects [Meissner, D., 2019]. In the world and domestic practice, with the abundance of available points of view regarding the problems of developing innovative systems, there is still no consensus on the categorical apparatus that would show all participants of these systems the importance of innovation as a necessary condition for improving the quality of life of the population.

In our opinion, ensuring the existing needs of participants in innovative systems interested in obtaining reliable information resources on the results of the effectiveness of applied technologies for managing innovative systems cannot be achieved for several reasons. They are associated with the lack of complete, reliable, timely, accessible statistical information in the context of objects of research; the lack of a methodology and a comprehensive assessment of the results of managing innovative systems from the perspective of a systematic approach; the lack of an approach to taking into account the influence of the level of innovative development of systems of various levels on the achievement of one of the national goals of the country - improving the quality of life of the population while maintaining macroeconomic stability.

Materials and Research Methods

The purpose of the study is the development of a methodological approach to assessing the effectiveness of innovative systems from the perspective of the theory of human capital development.

The object of research is the innovation system of the Russian Federation, which implements the state innovation policy.

The subject of the study is the factors of human capital development in the context of innovative systems of various levels within the framework of the concept of improving the quality of life of the region's population.

The methodology of work is based on foreign scientific works (G. Becker, I. Ansoff, P. Drucker, S. Kuznets, R. Nelson, D. North, R. Solow, C. Freeman, J. Schumpeter, S. Young and other authors) and domestic scientists (V.V. Ivanova, V.L. Makarov, G.G. Malinetsky, T.E. Kuznetsova, L.E. Mindeli, L. Gokhberg and other authors) dedicated to the formation and development of human capital, development of innovative systems and assessment of the effectiveness of their management to ensure innovative development and increase competitiveness of socio-economic systems.

The methodological basis of the study was a complex of general scientific and special methods of cognition. In the course of the study, such general scientific methods were used as: analysis, synthesis, generalization, historical, graphic method; special methods of cognition: formal-logical method and specific sociological.

Research Results and Discussion

An analysis of the definitions of "innovation system" proposed in scientific papers as applied to the research topic allows us to state that the innovation system can be considered as a set of subjects and objects of innovative activity that interact in the process of creating and selling innovative products and carry out their activities within the framework of the innovation policy pursued by the state. Given the current state innovation policy, it is assumed that all territories should be considered as innovation systems. The innovation system is characterized by a certain structure, its degree of orderliness and connections in accordance with the concept of open innovation. According to this concept, the innovation system is represented vertically as a three-level system (national, district, subject), and horizontally it is defined as an innovative platform that unites participants taking into account their mutual interests, within which innovation is synthesized using a dynamic and adaptive mechanism that generates, consuming and transforming innovation into innovative products.

In addition, the innovation system is influenced by environmental factors, which include market, infrastructure, cultural, knowledge and institutional conditions [Sveiby, K.E., 1997]. In these conditions of development of innovative systems, there is an objective need to study the specifics of innovative processes in the framework of the formation of the information society to justify their impact on the final result according to key indicators characterizing the achievement of the goals of the system. To assess the effectiveness of the innovation system, a level of competitiveness is used, which shows the degree of effectiveness of the creation, transfer and maintenance of customer value [Suvorova, A.P., 2017].

When exploring approaches to the formation of state innovation policy in the framework of the sustainable development model, it is necessary to proceed from the priority of the national goal - ensuring the quality of life of the population, which is determined by three aspects: the well-being of the population, the accumulation of human capital, and the level of human development. The well-being of the population is characterized by the achievement of a certain level of provision of the population with tangible and intangible goods. It is customary to distinguish three qualitative levels of well-being of the population: the first - sustainable satisfaction of the primary human needs, ensuring a normal level of life; the second is the achievement of material wealth, in which there is a saturation of primary needs; the third is the optimal, individually-oriented type of satisfying human

needs [Santalova, M.S., 2016]. The accumulation of human capital in terms of its ability to reproduce social capital, which can be characterized by the state of public health, educational, professional and cultural parameters [Rudenko, S.A., 2019]. The concept of "human development" as an indicator of the quality of life of the population is assessed in cross-country comparisons and is characterized by the possibility of fulfilment of a person through demographic, medical, environmental, and intellectual conditions of their existence and personal fullfillment, as well as the possibility of integrating individuals into society [Alimova, E.F., 2010].

The concept that combines the effectiveness of the innovation system with its results is the theory of intellectual capital. Despite a significant amount of research on intellectual capital, this theory is still considered to be undeveloped due to the lack of a unified understanding of the essence of this capital and approaches to its assessment. Researchers define different categories of human and intellectual capital [Novgorodov, P.A., 2017]. Most researchers interpret the category of intellectual capital as potential, which implies the possibility of obtaining a useful result through the use of this capital. Another fairly common approach to the essence of the category of intellectual capital is its understanding as a resource, and only a small part of researchers consider such capital as a result.

Moreover, all scientists engaged in research on the concept, essence and structure of intellectual capital are unanimous in their opinion that human capital is a structural element of intellectual capital.

In our opinion, the formation of intellectual capital as a result is preceded by the formation of resources, as well as capacity building and use (Figure 1). The resources should include human and labor resources as the physical presence of the population in a certain territory. The potential includes: firstly, the part of the population involved in the production of goods and services is economically active population; secondly, human capital, as a person's potential ability to generate income, which is ensured by an increase in the level of education, qualifications, employee health, and the formation of innovative skills and competencies. The result is intellectual capital, considered as qualifications, competencies, technologies, intellectual property, corporate culture and communication channels that can create added value and provide competitive advantages, high quality of human life. In the categories considered, a hierarchical vertical is clearly traced, the categories are interdependent, with each previous category being the basis for the next category. Each subsequent level of capital formation is formed by the increment of certain components, allowing you to go to the next stage of formation of intellectual capital [Sasani, Ali, 2012].

The basis of the hierarchy of constructing categories are human resources, as a set of qualities and characteristics of a person, which is the source of his ability to work of a certain kind. The scheme presented in Figure 1, in our opinion, combines all the categories we have examined into a single process of reproduction of this capital, which is reflected by the upward arrow from human resources to the top of the pyramid - intellectual capital. The reverse arrow in Figure 1 directly illustrates the process of reproduction of intellectual capital from resources.

Fig 1: The relationship of the categories that form the intellectual and human capital

For the intensive growth of the country's intellectual capital in order to ensure a high quality of life for the population, at each stage of the reproduction process, managerial innovative solutions are necessary within the framework of an innovation system of different levels [Suvorova, A.P., 2019]. Thus, since 2007, in accordance with Federal Law of December 29, 2006 No 256-FZ "On Additional Measures of State Support for Families with Children" [Federal Law, 2006], in order to create conditions providing families with children with decent life standards, they are building up human resources through increased fertility. At the stage of the formation of labor resources in Russia, for example, a migration policy is implemented that focuses on attracting highly qualified specialists and educational migrants [President of the Russian Federation, 2012]. The pension reform of 2019-2028, providing for a gradual increase in the retirement age, also contributes to an increase in the mass of labor resources [Federal Law, 2018]. All of the above measures of state policy allow us to form the resource base of intellectual capital.

The next stage of reproduction is related to capacity building based on the formed labor resources. The increase in the economically active population is facilitated by the implementation of state policy in the field of employment. However, it is human capital that is the fundamental potential of Russia's innovative growth through the formation of intellectual capital. The mechanisms that ensure the growth of competitiveness of the domestic national innovation system were laid down by the state in the Strategy for Innovative Development of the Russian Federation in 2012 [Government of the Russian Federation, 2011]. The state played a leading role in ensuring the implementation of innovation policy, creating an innovative field, using the development of the institutional environment and a system of tools and regulators, including support for the interaction of science and business, innovative infrastructure of universities, the creation of technological platforms, the development of innovative development programs for companies with state participation and others. Achieving the goal of the quality of life of the population is ensured by many factors (table 1), the main of which is improving the quality of human capital, which, in turn, is achieved through the sustainable development of institutions of the innovation system at various levels.

In order to implement the social functions of innovation and increase the degree of public involvement in the innovation process, improving the quality of human capital contributes to the formation of a creative class that, through the development of innovative thinking and culture through entrepreneurial initiatives, leads to the construction of a knowledge economy and a transition to the resulting level - intellectual capital. In Russia, it is possible to single out areas of the economy where

significant increments of intellectual capital have occurred: nuclear energy, space, and weapon technologies. The direct development of innovative systems in the given institutional conditions occurs through an increase in intellectual capital (Figure 2).

Fig. 2: Intellectual Capital Development Model

In order to identify the opportunities (potential) that allow ensuring the quality of human capital to meet the needs of the reproduction of innovative systems of different levels, it is necessary to determine the factors of the institutional environment for the development of innovative systems that determine the requirements for the quality of human capital and also affect the quality of human capital (table 1).

Table 1: Factors of the institutional environment for the development of innovative systems

Innovation system levels	Factors determining the requirements for the quality of human capital	Factors affecting the quality of human capital
National	Strategic national goals and development goals Current level of innovation development Level of technological development Legal regulation	Income and expense policy Health care system Education system Priorities for scientific and technological development Labor market Population policy Migration policy Pension system

		Living conditions Inequality and poverty Family, motherhood and childhood Criminality Level Ecology Partnership for sustainable development
District	District Development Strategy	Inequality and poverty Partnership for sustainable development
Subjective	Subject Development Strategy Level of technological development Features of institutional development	Income and expense policy Education system Priorities for scientific and technological development Population policy Entrepreneurship support Ecology Infrastructure development Partnership for sustainable development

Assessment of factors affecting the quality of human capital should be carried out: firstly, in order to study the impact of innovation on the possibility of ensuring an increase in the quality of life of the population of the territories; secondly, to determine the existing differences in the level of innovation within the framework of the concept of competitiveness of territories; thirdly, to justify the impact of innovation on the achievement of target indicators of the main components of the economic development of the territory.

Studying the impact of innovation on ensuring an increase in the quality of life of the population at each of the three levels is difficult due to objective reasons due to the lack of statistical information by factors. In accordance with the sustainable development goals of the countries, the Federal State Statistics Service (Rosstat) in the Russian Federation developed a project of the list of national indicators of sustainable development goals [Rosstat, 2020], [Sustainable Development Agenda, 2020]. Data collection on the levels of aggregation of official statistical information should be carried out according to national and subject innovation systems. In fact, the published collection "Sustainable Development Goals in the Russian Federation" [Rosstat, 2019] reflects information on indicators of achieving the sustainable development goals in the Russian Federation both for internal use (for the national innovation system) and international comparisons between countries. Data presented in the collection allow us to assess the current state of the dynamics of sustainable development of the country. It is not possible to compare the results of achieving the sustainable development goals with other CIS countries, BRICS and some OECD countries, since the point data for individual indicators are presented from 2015 to 2019.

In Russia, a number of national and federal projects (programs) have been developed and are being implemented in accordance with Decree of the President of the Russian Federation dated May 7, 2018 No. 204 "On National Goals and Strategic Tasks of the Development of the Russian Federation for the Period until 2024" [President of the Russian Federation, 2018]. Rosstat drew up a collection of methods for calculating indicators of national projects (programs), calculated as part of the implementation of this decree [Rosstat, 2018]. The study of this document allowed us to ascertain that the proposed indicators are calculated by industry ministries and Rosstat at the federal level as a whole for the Russian Federation on an annual basis. Thus, the problems of the methodology of statistical support for the adoption of managerial innovative decisions, which should form the invariance of all participants in the perception of innovative systems of different levels of the current state of innovative development and the quality of life of the population do not allow successfully implement public policy in this area.

The existing theory and practice of assessing the socio-economic development of territories of any level allows us to judge that in most cases the emphasis is on either the economic or social

component of economic development, thereby limiting the coverage of existing problems in these areas of development.

In our opinion, to justify the impact of innovation on the achievement of target indicators of the main components of the economic development of the territory, it can be represented by the following stages:

- assessment of the level of innovative development of territories;
- assessment of the quality of life of the population of the territory;
- assessment of the level of economic development of the territory;
- building a two-dimensional model “Quality of Life - Innovation”;
- building a three-dimensional model “Quality of life - Level of economic development - Innovation”;
- development of directions of strategic management decisions based on the analysis of the obtained model results.

In international practice, different approaches are used to assess the level of innovative development of territories. In practice, the index method is most often used, which allows you to calculate innovative indices by forming a system of indicators for the development of innovative processes and their regulation within the framework of regional innovation systems. In the practice of assessing the level of innovative development of the United States, the Portfolio innovation index (PII) technique is used [Statsamerica, 2009]. Based on the Portfolio innovation index, more than 3,000 areas within the United States are analyzed and five groups of territories are identified. With the aim of informing the innovation policy at the regional level, the European Commission applies the regional innovation development rating development model Regional Innovation Scoreboard (RIS) [Hollanders, H., 2019]. The structure of the Regional Innovation Scoreboard and Portfolio innovation indexes is such that they combine both innovation resources and their results.

In the domestic practice of assessing the level of innovative development of the territory, a methodological approach is applied, developed by the Association of Innovative Regions of Russia together with the Ministry of Economic Development of the Russian Federation in 2012 [AIRR, 2012]. The AIRR model includes a system of indicators grouped in 4 blocks: research and development, innovation, socio-economic conditions of innovation and innovation activity in the region. According to the authors of the approach, the rating reliably reflects changes in the innovative development of the economy of the constituent entities of the Russian Federation, since it is scientifically substantiated and built primarily on the basis of official statistics and is used as a tool for managing the regional innovation system. The results of assessing the level of innovative development of the territory allow the regional authorities to obtain the necessary information for making strategic decisions regarding the further development and improvement of innovative systems and the dynamics of changes in all directions reflected by indicators. One of the important components of the Association’s work is the exchange of regional experience in creating a favorable economic, social, legal, educational and creative environment for the development of innovations. In addition, the work of the Association contributes to the effective innovative development of its members, built on the recognition of various models of scientific and technological growth of the regions. Despite the practice-oriented nature of the AIRR methodology for assessing the level of innovative development of territories, the results of regional assessments are weakly related to the achievement of one of the national goals countries - improving the quality of life of the population.

To assess the quality of life of the population of the territory, data from the Russia Today International Information Agency, the largest Russian information provider for an international audience, are used. The agency draws up ratings of the constituent entities of the Russian Federation on various aspects of the country's socio-economic development and is one of the authoritative experts in this field [Agency "Russia Today", 2020].

Assessment of the level of economic development of the territory is carried out by the Federal State Statistics Service on a regular basis and can be used by researchers to assess different parties.

To assess the effectiveness of managing a regional innovation system aimed at achieving the national goal of improving the quality of life, by building an innovative institutional environment, a strategic toolkit — a management map — in the form of the matrix model "Quality of Life - Innovation" can be used. Such a model can be represented in the form of a coordinate system in which the X-axis shows the indicators of the rating of innovative development of regions, and the Y-axis shows the indicators of the quality of life of the population of the constituent entities of the Russian Federation, the factor sign is the innovativeness of the subject, and the resultant sign is the quality of life of the population.

As an information base for building the map, we used the ratings of innovative development of the AIRR regions for 2016-2018 and the ratings of the regions of the Russian Federation in terms of quality of life for 2016-2018 of MIA Russia Today. The object of the research is the innovative systems of the Central Federal District and the Siberian Federal District, since they are two types of development of the economic systems of the Russian Federation, namely, industrial and raw materials.

Management cards "Quality of Life - Innovation", based on data for 2016-2018, are presented in Figures 3, 4.

Fig 3. Map "Quality of life - Innovation" for the regions of the Central Federal District, 2016-2018

Fig 4. Map "Quality of life - Innovation" for the regions of the Siberian Federal District, 2016-2018.

The management card is designed on the basis of a systematic approach, which allows us to argue that any single problem - improving the quality of life - should be tied in conjunction with solutions to another problem - the level of innovative development of the region - focused on achieving the best socio-economic results, namely increasing the competitiveness of the region.

The position of the region on the management map allows us to assess the effectiveness of the innovation policy pursued by the regional authorities in dynamics and the competitiveness of the region in its impact on the quality of life of its population. The positioning of the region is determined by the minimum values on each coordinate axis, since the management map is based on rating estimates. Three authors zones of regional positioning: leading regions are "green", middle regions are "yellow" and weak regions are "red", which allows was visually assess the degree of success of the innovative development of the territory.

The approach used makes it possible to conclude that the innovation policy pursued by regional authorities has a significant impact on the level of innovative development of the territory with the ability to achieve the goal - to ensure a high quality of life for the population. Thus, the top 4 in terms of innovative development, through which a high standard of living of the population of the Central Federal District is ensured, is Moscow, Moscow Region, Voronezh Region and Kaluga Region. The green zone regions remain stable during the period under review. The arrows on the management map show the direction of the change in the position of the region from 2016-2018. For example, the

Tula region from the “yellow” zone in 2016 moved to the “green” in 2017-2018. However, improving the quality of life was provided not by increasing the innovative activity of the region, but by other factors. Note that for a full analysis of the effectiveness of the state innovation policy of the region, it is necessary to use additional factor attributes to analyze the socio-economic situation of the territory and study the assessment of their impact on the quality of life of the population. In the Central Federal District, the quality of life of the population in most regions for the period under review decreased, which indicates the insufficient attention of the authorities of this level to the issue of innovative development of the district.

An analysis of the positioning of the regions of the Siberian Federal District on the management map made it possible to conclude that none of the regions fell into the green zone, despite the presence of two large scientific and technical centers in the Tomsk and Novosibirsk regions and large reserves of natural raw materials. Note that in this district, the position of almost entities remains stable, maintaining positions in the "red" zone. The exception is the Krasnoyarsk Territory, which has improved its position in the ranking of innovative development of regions by 12 positions, but remained within the "yellow" zone. Presented on the two-dimensional matrix model “Quality of Life - Innovation”, the relationships and the mutual influence of the levels of innovation of the region and the quality of life of its population can be used by regional authorities to develop alternative options for strategic development.

In our opinion, the most complete idea of the possibility of strategic innovative development is provided by the construction of the three-dimensional model “Quality of Life - Level of Economic Development - Innovation”. The three-dimensional model includes the indicator "Gross Regional Product (GRP) per capita", which allows you to evaluate the economic component of socio-economic systems. In this model, the factor signs are “innovative development of the region” and “GRP per capita of the region”, and the resulting “quality of life of the region’s population”. By analogy with the two-dimensional model, three zones of regional positioning are distinguished: “green” - leaders, “yellow” - medium, “red” - weak.

The three-dimensional models “Quality of Life - Level of Economic Development - Innovation”, constructed for the Central Federal District and the Siberian Federal District for 2017, are presented in Figures 5 and 6.

1- Moscow, 2 - Belgorod region, 3 - Bryansk region, 4 - Vladimir region, 5 - Voronezh region, 6 - Ivanovo region, 7 - Kaluga region, 8 - Kostroma region, 9 - Kursk region, 10 - Lipetsk region 11 - Moscow region, 12 - Oryol region, 13 - Ryazan region, 14 - Smolensk region, 15 - Tambov region, 16 - Tver region, 17 - Tula region, 18 - Yaroslavl region

Fig. 5. Three-dimensional model “Quality of life - Level of economic development - Innovation” for the regions of the Central Federal District, 2017

1-Republic of Tuva, 2-Republic of Khakassia,
3-Altai Territory, 4-Krasnoyarsk Territory, 5-Irkutsk Oblast, 6-Kemerovo Oblast, 7-Novosibirsk Oblast, 8-Omsk Oblast, 9-Tomsk Oblast

Fig. 6. Three-dimensional model “Quality of life - Level of economic development - Innovation” for the regions of the Siberian Federal District, 2017

With the introduction of another factor in the model for the Central Federal District, only Moscow and the Moscow Region, Voronezh Region and Kaluga Region moved to the “yellow zone” as the leading regions. Thus, only Moscow and the Moscow Region provide high quality of life for the population of these territories with production volumes. If in the two-dimensional model only four

regions were represented in the “red” zone, then in the three-dimensional model their number increased to eight. The same trend continues for the regions of the Siberian Federal District.

So, a three-dimensional model using an indicator of the economic component of socio-economic systems allows a more objective assessment of the influence of model factors on the quality of life of the region’s population. This model, built over several years, allows us to analyze the dynamics of changes in the positioning of the region and, based on its results, allows us to develop alternative options for strategic management decisions by regional authorities. Of course, the factors of the model should be considered as opportunities for software solutions in the development of the territory and improving the quality of life of the population.

Communication and mutual influence of the level of economic development, the level of innovativeness of the region and the quality of life of its population, presented on two- and three-dimensional models, can be used in the development of managerial decisions within the framework of the development strategy of the region as a whole. Depending on the choice of management methods and models, managerial relations in the implementation of innovative activities and interaction mechanisms of participants in the innovation system, the regional leadership may generate solutions to the problems identified. For example, it is recommended to use information and institutional management methods to influence the awareness of participants in the innovation system; for choosing the direction of strategic changes in the region’s policy, it is necessary to determine the position of the region Compared with other regions - competitors and study the experience of the leading regions and closest competitors on the basis of benchmarking techniques.

Conclusion

The presented study reveals a relevant topic for the Russian Federation in the study of factors of development of human capital in the context of innovative systems to improve the quality of life of the population. The relevance of the topic is explained by the fact that the dynamics of the economic and innovative development of the country does not allow achieving the national goals declared by the state and the expected results of development strategies. One of the reasons for Russia's lagging behind the leading countries of the world is revealed - the underutilization of the country's intellectual potential.

The study of approaches to the formation of state innovation policy in the framework of the sustainable development model showed the inadequacy of a systematic study and full analysis of the process of reproduction of intellectual capital in order to increase it. In the work, a model for the development of intellectual capital in the conditions of innovative systems of different levels was proposed.

The factors of the institutional environment for the development of innovative systems have been identified that determine the requirements for the quality of human capital, as well as affect the quality of human capital in order to identify opportunities for moving to another level - intellectual capital.

It is proved that the assessment of factors affecting the quality of human capital cannot be fully realized due to the problem of the methodology of statistical support for making innovative management decisions. The classification of regions by positioning of regions in the innovation field is formed. The algorithm presented in this paper for assessing the impact of innovation on achieving the target indicators of the main components of the economic development of the territory will allow regional authorities to use the results in the development of managerial decisions in implementing the regional development strategy.

This problem is seen as a promising area of scientific and applied research.

Abstract

Accounting and internal control in organizations in the construction industry is one of the problem areas of modern control and accounting. The tasks of accounting in organizations in the field of construction include: the formation of complete and reliable information about an organization's activities, its property status, the provision of necessary information to internal and external users and the prevention of negative business results. Meanwhile, the possibility of high-quality and effective accounting and internal control of stocks depends on the presence or absence of methodological support in a construction organization.

This study develops the theory of methodological support of accounting and internal control of stocks in construction organizations. It interconnects the process of accounting and internal control of reserves in construction organizations, discloses the tasks and procedures of internal control, the measures of methodological, regulatory internal control of reserves, regulatory documents.

Keywords: Stock Accounting, Internal Control, Stocks, Accounting Methods, Accounting Records.

Introduction

The issues of accounting and control of activities have always been relevant not only at the level of managerial interaction but also at the legislative level, the process of organization and internal control of activities of construction organizations are very important and are considered in various aspects from the point of view of historical experience, practical activities in modern conditions and those trends that modern market dictates to us. The desire of a construction organization for stability, for reducing the possible risk draws special attention to the reliability of internal control and accounting systems all over the world. This issue is considered both in foreign studies and in the domestic system and has been developed in the works of many scientists and practitioners.

Materials and Methods

The object of the study is the practice of accounting and internal control of stocks in construction organizations of the region.

The subject of the study is the theory and methodology of accounting and internal control of stocks in construction organizations.

The results of studies that reveal the specifics of managing inventory are presented in the works of domestic scientists: Yu.A. Babaev, A.S. Bakaev, K. Drury, I.B. Laninai, S.A. Nikolaeva, Ya.V. Sokolov, O.V. Solovieva, and other authors.

Foreign authors such as A. Apcherch, E. Atkinson, J. Brimson, R. Garrison, C. Drury, D. Ryan, J. Foster made a significant contribution to the development of scientific methodological support for managerial accounting and internal control.

A significant contribution to the development and establishment of domestic audit, the study of the theory and methodology of its implementation, development and improvement of internal standards was made by Russian scientists and practitioners: Brovkina N. D., Burtsev V.V., Korotkova A.V., Marenkov N. L., Melnik M.V., Ovsiychuk M.F., Petrov V., Podolsky V.I., Pugachev V.V., Sheremet A.D.

More substantive issues of organization and conduct of internal control and internal audit are considered in the works of Andreev V. D., Bogomolov A. M., Burtsev V. V., Vasiliev N. E., Gordienko A. V., Labyntsev N. T. , Makalskaya A.K., Melnik M.V., Reutov V. Yu., SoninA.M., Sotnikova L.V., Shchadilov S.N., ShcherbakovV.V., Podolsky V.I., Sotnikova L.V., Savina N.V., Sokolov P.A., Kisilevich T.I., Khachemizova E.N. A large contribution to the theoretical and practical research and development in relation to the construction industry in terms of internal control and internal audit and accounting was made by: Avrova I.A., Adamov N.A., Artyomenko I.O., Baranovskaya, N.I., Danilov M.V., Zelenskaya T.M., Kasyanova, G.Yu., Kucherenko S.A., Ovsiychuk. M.F. Podolsky V.I., Sotnikova L.V.

At the same time, legal regulation of internal control in construction is not adequately covered in the scientific literature.

The methodological basis of the study is the principles and rules of accounting and internal audit of reserves, the works of domestic and foreign scientists on the theory and methodology of accounting and internal audit of reserves, the legislation of the Russian Federation and regulatory legal acts of accounting and internal audit of reserves.

Research Results and Discussion

In order to create an effective system of internal control, it is necessary to organize a system of accounting for reserves in accordance with applicable law and taking into account the specifics of economic activity. Assessment of the accounting system and internal control of construction organizations in the region showed the following problems:

- inventories of productive reserves and stocks are carried out formally, not always actual accounting data are recorded in the inventory sheets ;
- data on the movement of inventories are not reflected in a timely manner, which does not contribute to the high-quality planning of the purchase of productive reserves and sometimes leads to a halt in production;
- materially responsible persons do not always keep records of stocks in warehouses, material reports are compiled on the basis of accounting data, which can lead to fraudulent actions by both materially responsible persons and by accounting employees and managers;
- the workflow schedule is not observed while inventories are moving.

Without eliminating the above mentioned problems, it is impossible to establish effective systems of accounting for reserves and internal control in construction organizations. In this case, special attention should be paid to the methodological support of accounting and internal control of reserves.

The composition of the methodological support for accounting of inventories of construction organizations should include such basic units as: synthetic and analytical accounting, documenting and control of stock movements.

The main document governing the accounting of inventories in construction organizations is the accounting policy of an organization.

When forming the methodological section on inventory accounting in the accounting policy of a construction organization, special attention should be paid to the accounting methodology and the application of the chart of accounts.

The chart of accounts and Instructions for its application (approved by Order of the Ministry of Finance of the Russian Federation No. 94n of October 31, 2000) and PBU 5/01 "Accounting for material and production costs" established that the actual costs of acquiring material resources can be not only the amounts paid directly to the supplier, but also all other expenses that are directly related to the acquisition of material resources (information and consulting services, customs duties and fees, intermediary services, insurance, costs of maintenance of an organization`s supply unit, material interest for the use of borrowed funds charged before acceptance for accounting, the cost of bringing the inventories to a suitable for use state, etc. [3].

The indicated additional expenses for the acquisition of material resources can either be preliminarily collected on account 16 "Deviations in the value of material assets" or directly debited to account 10 "Materials" on direct grounds. One of these methods for all materials or for certain groups of material resources should be fixed in the accounting policies of the organization.

In addition, account 16 “Deviations in the value of material assets” can be used even in accounting for materials on account 10 “Materials” at actual cost to reflect difference in amount when paying for materials, the cost of which is expressed in conventional monetary units. In this case, account 16 takes into account only the total differences that arose prior to the adoption of material resources for accounting. This feature can also be taken into account when adopting accounting policies for accounting purposes.

To summarize information about the availability and movement of raw materials, other materials, fuel, spare parts, containers and the like belonging to the enterprise, account 10 “Materials” is intended.

Depending on the accounting organization adopted at the enterprise, the receipt of materials can be reflected either at planned (accounting) prices using accounts 15 “Procurement and procurement of materials”, 16 “Deviation in the cost of materials” or without their use, at actual costs of acquisition without value added tax and other recoverable taxes.

When choosing a method of accounting for tangible assets being on the way, you need to pay attention to the transfer of ownership of acquired tangible assets. The supply contract may provide for a different procedure for transferring ownership of material values. Depending on the procedure established by the contract, tangible assets belonging to the organization but not received by an enterprise may be taken for accounting for separate sub-accounts of account 10 “Material valuables in transit” in the valuation provided by the contract. At the moment of actual arrival of material assets to the warehouse, there is a “transfer” according to subaccounts and a cost adjustment in accordance with the actual data of settlement documents of material resources suppliers.

The accounting policy, as a rule, indicates that the procedure and terms of creation of primary accounting documents and their transfer for reflection in accounting are determined by the schedule (chart) of document circulation approved in the established manner. At the same time, it is advisable to separate the schedule (chart) of the workflow into a separate document and approve it as an application to the accounting policy of an organization for accounting purposes.

The actual workflow graph reflects the workflow system that has been developed in a construction organization.

The schedule includes a list of works on the creation, verification and processing of each of the primary documents, journals, books of records, consolidated documents, accounting registers and financial statements of a parent organization, separate structural units and an organization as a whole; departments (employees) responsible for this, indicating their relationship and timeliness of work.

Using a workflow schedule in enterprise management allows to reduce labor costs for processing documents at an enterprise due to:

- increasing the responsibility of performers for meeting deadlines for the preparation and processing of documents;
- identification and exclusion from the document flow of unused (redundant) documents (especially with regard to consolidated documents and accounting registers).

On the clarity of the scheduling of workflow to a large extent depends the timeliness of obtaining information for the needs of management of a construction organization.

The workflow schedule is the most important organizational regulation, ensuring the creation of a harmonious accounting organization system at an enterprise, a means of improving the quality of accounting service and, in general, financial and economic activities of a construction organization and a means of servicing the workplace.

As a means of servicing the workplace, the workflow schedule ensures the rhythm of the work of accounting workers at each workplace and the service as a whole, the performance of work within the established working day duration.

As a means of improving the quality of work of an accounting service and, in general, financial and economic activities of a construction organization it ensures the timely compilation and submission of accounting and statistical reports to established addresses, timely receipt of accounting information for the operational management of an organization.

The regulatory documents governing the organization of accounting workflow can be divided into the following groups:

- governing the general principles of accounting workflow organization;
- regulatory features of the workflow of primary accounting documentation regarding the application and filling out industry-standardized forms;
- regulatory features of the workflow of primary accounting documentation regarding the use and filling out unified forms (without industry);

The technology for processing accounting information to a great extent depends on the form of accounting independently selected by a construction organization. The selected form of accounting is fixed in the accounting policies of an organization for accounting purposes and is used continuously. A change in the form of accounting is formalized by making appropriate changes to the accounting policies of an organization.

Thus, the methodological support of inventory accounting in a construction organization is achieved by developing an accounting policy for the financial year and mandatory annexes to it (working chart of accounts, workflow schedule, provision for inventory of assets and liabilities, provision for internal control of a construction organization).

Construction organizations independently develop a procedure for organizing internal control in accordance with the requirements of current legislation and based on the features of functioning and requirements of managing an organization and sale of goods (works, services). When creating an internal audit service in an organization, its work is carried out in accordance with the regulation on this service, approved by the head of a construction organization.

In order to effectively organize internal control of reserves, it is necessary to ensure:

- accountability of some workers to others;
- internal checks and reconciliations of interrelated data on financial and economic activities of an organization, including the movement of stocks;
- regular inventory of stocks;
- continuous monitoring of the state of primary, analytical and synthetic inventory accounting;
- restriction of access to assets and records;
- monitoring of computer information systems and applications;
- regular operational analysis of stock movements.

The accountability of some workers to others is regulated by job descriptions based on professional standards, the structure of the construction organization and the regulation on internal control.

Internal audits and reconciliations of interrelated data on financial and economic activities of an organization, including movement of stocks, are regulated by the internal stock control program. We recommend the following program of internal control of stocks in construction organizations:

- correctness of registration of information on inventory and productive reserves and reflection of these results in the inventory accounting;
- validity of prices for purchased raw materials;
- accuracy of determining and writing off of the costs of used reserves;
- carrying out measures to calculate the limit standard for the volume of consumption of inventories per 1 ruble of the volume of sales of products (works, services), as well as a factor analysis of actual deviations from it;
- correctness of the synthetic and analytical accounting of inventories;
- conformity of the methods used by the Company for valuation of certain groups of material assets upon their disposal with the methods provided for by the accounting policy;
- correct procedure for writing off deviations of actual expenses for the acquisition of material assets from their accounting price (when using accounts 15 and 16);
- correctness of the write-off of the trade margin related to the goods sold.

Regular inventory of the stock contributes to the safety of the stocks of a construction organization. Inventory of stocks is carried out in accordance with the regulation on inventory of assets and liabilities and the inventory plan approved by the head of a construction organization.

Continuous monitoring of the state of primary, analytical and synthetic inventory accounting is achieved by conducting internal control procedures, which should be reflected in the analytical procedures. This is primarily a comparison of the data of primary documents with the data of accounting registers and indicators of financial statements.

When participating in the inventory of reserves of an internal controller, the following actions should be performed:

- request analytical accounting data for the MPZ in the context of the MOT, locations (units) with an indication of their types and cost;
- establish whether there are written instructions for conducting an inventory of stocks. If so, a copy of these instructions should be attached to the questionnaire;
- make sure that the requirements are reflected in the instructions for organizing an inventory of stocks, the order and control over its implementation comply with regulatory documents and the features of a construction organization;
- identify the responsible persons for the inventory;
- check the staff of permanent and working inventory commissions, a document on the commission composition (order, resolution, order);
- make sure that the materially responsible person is not included in the inventory

commission;

- familiarize yourself with the procedure adopted at an enterprise for assigning stockpile stock numbers;
- make sure that all materially responsible persons have concluded agreements on material liability;
- get a copy of the inventory for the internal control service;
- make sure that all members of the commission are present during the inventory;
- make sure that the inventory commission received, before the start of an audit, the latest at the time of the inventory receipt and expenditure documents or reports on the movement of material assets and whether receipts are collected from financially responsible persons, that all expenditure and receipt documents collected by the beginning of the property inventory are transferred to accounting;
- check the visas of the chairman of the inventory commission on all receipts and expenditures attached to the registers (reports), indicating "before the inventory on" ... "(date)", which should serve as a basis for accounting to determine the balance of property at the beginning of inventory data;
- check whether stocks (inventories, finished goods, goods, other stocks) entered the inventory documents for each item with an indication of the type, group, quantity and other necessary data (article, grade, etc.);
- get acquainted with the methods of calculation and types of devices during inventory of stocks (calculation, measurement, weighing, technical calculations) and their documentary reflection;
- make sure that the head of a construction organization has created conditions that ensure a complete and accurate verification of availability of property on time (provide manpower for re-weighing and moving goods, technically sound weighing facilities, measuring and control instruments and measuring containers);
- check whether measures are being taken to ensure that no inventory movement will take place at the time of the inventory;
- identify whether actions were taken by the commission to identify stocks unsuitable for production purposes;
- check the acceptance of documents, received during the inventory, by materially responsible persons in the presence of members of the inventory commission of stocks;
- check the presence of collation statements in the event of a discrepancy between the actual availability and accounting data;
- check that the amounts of surpluses and shortages of inventory in the collation statements are indicated in accordance with their assessment in accounting;
- in addition, when monitoring the inventory, it is necessary, on the basis of the sample formed during the test, to carry out control procedures for the selected inventories using the “from accounting to availability” method;
- at the same time form a sample for implementation of control procedures by the method of "from availability to accounting" and carry out these procedures;
- check the conformity of the name of the inventory values and objects, their number indicated in the inventory according to the nomenclature and in the units of measurement accepted in the accounting.

Based on the results of the inventory, the internal controller is obliged to express his opinion on the reliability and effectiveness of the measures taken during the inventory of stocks, paying particular attention to the availability of instructions for conducting an inventory of stocks, the correctness of instructions and correct presentation of inventory results.

In addition, the internal controller notes all identified inconsistencies, sets out his opinion on the inventory as an element of the internal control system in terms of its reliability.

As the main document regulating the internal control of compliance with restrictions on access to assets and records, computer information systems and applications we recommend a confidentiality provision with access regulation taking into account the job descriptions of each employee of a construction organization.

The internal controller may conduct regular operational analysis of stock movements based on material and production reports of materially responsible persons, accounting registers, taking into account traditional methods of stock movements.

Thus, all the described means of methodological support of accounting and internal control of stocks in construction organizations allow business entities to organize and maintain high-quality accounting of stocks and conduct effective internal control.

Conclusion

In recent years business activity in construction organization management and related activities has increased. In modern conditions, interest of owners and management of an organization in the effective and reliable functioning of internal control as a guarantee of timely analysis and improvement of activities of an organization is growing, since the improvement of an organization's management system is inextricably linked with the development of accounting, including inventory, which makes it possible to monitor and analyze the achievement of the goals set, to receive timely, reliable and objective information which is necessary in preparation and justification of management decisions at different levels.

Abstract

In medical circles, personal branding is important both from the point of view of doctors and patients – and here social media, with its accessibility and scope, can be a useful tool. The paper aims to provide an answer to the following research questions: Do medical doctors have a sense of being a brand, do they consider social media to be an appropriate tool for professional personal branding, and what benefits and risks do they perceive in social media in this regard? The presented diagnostic survey was carried out among 81 Polish medical doctors. The results show that a significant number of doctors who participated in the survey uses social media and considers it to be a good personal branding platform. Still, not many of them has accounts related to their profession. One of the reasons is that over half of the respondents do not see themselves as a brand, which results in a lack of conscious branding policy. Other reasons include risks associated with the use of social media, among which the respondents most often pointed to: loss of privacy, receiving judgemental posts about their private life, receiving requests for medical advice, and ethical dilemmas concerning doctor advertising.

Keywords: Social Media, Personal Branding, Medical Doctors

Introduction

People associate the concept of a brand mainly with big companies, manufacturers, and corporations. Prominent brands, such as Apple or Nike, embed themselves in people's awareness thanks to consistent communication, advertising campaigns, visual identity, and long-standing traditions. D. Aaker (1996) says that a brand can be both a product and a service, as well as an organisation, a person, or a symbol. J. Joseph (2013) goes a step further in holding a bold view that each person has a personal brand, shaped from the moment of their birth and being named by their parents. A personal brand is not based solely on one's profession or professional title. It allows to show why, for whom, and how one performs their job (Dalla-Camina, 2016). It is the way one is perceived by others, a created image which entails certain expectations (Peter, Gomez, 2019).

In medical circles, personal branding is important both from the point of view of doctors and patients. The strong image of a doctor affects his social capital, allowing him to be easily recognised by the patients, and strengthening his position in the professional environment, thus raising his confidence and increasing job satisfaction (Chu et al., 2018).

Social media, with its accessibility and scope, can be a useful personal-branding tool. It allows to shape one's image, reputation, and recognisability in the professional environment (Petrucă, 2016). Doctors can use it both to share their knowledge, experience, and discoveries, and to manage their professional profiles, which are a kind of business card, presenting the realities of their daily work and their interests. This increases chances for building a network of professional contacts and for finding new work possibilities. It also allows to keep in touch and interact with patients (Panahi et al., 2016), which may

be of key importance for doctors who want to build their personal brand due to the strict correlation between patient satisfaction and a specialist's image (Luca et al., 2015). This is why it is crucial to be aware of one's online presence and of its significance, and to thus be able to control one's own image and ensure consistency between online information and offline activities (Petrucă, 2016).

An analysis of literature shows that the issue of doctors building their personal brand on social media is new and rarely discussed. This paper aims to partly bridge this gap by providing an answer to the following research questions: Do medical doctors have a sense of being a brand, do they consider social media to be an appropriate tool for professional personal branding, and what benefits and risks do they perceive in social media in this regard? The presented diagnostic survey was carried out among 81 Polish medical doctors.

The paper opens with an introduction devoted to the presence of medical doctors on social media in the context of building their image and personal brand. Next, it describes the benefits of their activity on social media and the associated risks and challenges. The paper then presents the adopted research methodology and the results of the survey. It closes with a summary and conclusions.

Medical Doctors in Social Media

As social media becomes increasingly popular, the number of doctors using it also grows. This is why today personal branding and managing one's professional image via social media are especially important (Kalia et al., 2017). Patient platforms are constantly being developed which allow to find basic information about a particular doctor, such as the address of their office or telephone number. Some of them provide an option to submit an opinion about a given specialist. Doctors may not be aware of their presence on popular platform, where the quality of their worked is evaluated by patients. It is therefore very important to take control over one's image on social media and to consciously shape it (Kalia et al., 2017).

When deciding to be active on social media, it is important to carefully choose appropriate platforms and means of communication and interaction. The right choice positively affects brand recognisability and maximises the effects of the effort put in the branding process (Levy, 2013). Instead of creating many accounts on different platforms, it is much more effective to focus on specific platforms used daily by one's target group. When building an engaged community, regular and factual communication is of key importance (Kalia et al., 2017). When choosing a platform, it is worth paying attention to their purpose, type of published materials, popularity, users, as well as manner of communication and interaction (Table 1).

Table 1: most frequently used social media platforms and their main uses in personal branding

Name	Description
Facebook	• the largest and most used platform among adults • many configuration and interaction possibilities helpful in building a brand and an image • dedicated to those who want to build close relationships and engaged communities
Twitter	• real-time interactions • dynamically changing trending topics • source of up-to-date news and reports • dedicated to those who want to share the most recent news and get immediate feedback
LinkedIn	• created to facilitate establishing professional and business contacts • allows to build networks of professional contacts and exchange industry-specific information • provides a way to contact other companies • dedicated to those who want to build a professional brand
Instagram/Pinterest	• based mainly on images and photos, privacy concerns may limit their use among medical professionals • can be treated as complementary to the existing profiles on other platforms and used in order to reach a wider group of people
YouTube	• second largest search engine in the world, online video-sharing platform • used for uploading both amateur and professional videos • content of uploaded videos may be varied, from brand presentation to educational issues which emphasise brand quality and improve an expert's image

Source: Own elaboration based on: (Kalia et al., 2017).

Benefits of medical doctors' presence on social media

Social media profiles of medical doctors may be classified as personal or professional depending on the content they share. Personal profiles predominate, but more and more doctors choose the latter form of personal branding as well (Chretien et al., 2011). Their presence on social media benefits both themselves, and their patients.

The presence of doctors on social media provides patients with access to reliable information and improves their knowledge of issues concerning health and disease prevention. Moreover, it facilitates communication, and thus improves patient-doctor relationships, builds trust, and combats stereotypes (Kane, Sands, 1998). On the other hand, building a network of professional contacts allows doctors to promote their academic papers and practice, and to share their experience with their colleagues. They can talk about the difficulties of their daily work and discuss interesting medical cases with people who understand their point of view. Engaging in discussions about professional and ethical issues, current problems of the healthcare industry, career building, or healthcare management may inspire or guide less experiences colleagues or students (Chretien, Kind, 2013). And being able to get in touch with specialists from all over the world in real time allows to consult complicated cases regardless of physical distance (MacMillan, 2013).

According to sources, ca. 60% of doctors have a positive attitude towards relationships between medical professionals and patients established via social media. This concerns mainly doctors' engaging in educational initiatives, informing about drug administration instructions, as well as promoting a healthy lifestyle and a change of bad habits (Househ, 2013). Doctors' educational activities can take many forms on numerous different social media platforms, such as blogs, videos, or online forums. It has been observed that such activity is helpful in fight against obesity, motivates people to lead a more active lifestyle, and produces results in fight against cigarette smoking and risky sexual behaviour (Househ, 2013). According to research, communication with patients via social media contributes to better results of treatment and quality of care. The best results are achieved with treatment

of chronic diseases. Thanks to the established relationship, patients more strictly follow their doctors' instructions and are more satisfied with medical service they get (Farnan et al., 2013).

Risks and concerns associated with social media activity of doctors

The presence of medical doctors on social media has its benefits, but it is not free from risks. One risk results from the quality of published information, which may be unchecked, incomplete, unformal, or apply to individual cases only (Pirraglia, Kravitz, 2013). This is in contradiction to evidence-based medicine. Moreover, the authors are often unknown or unreliable. The interactive character of social media and freedom to publish any content exacerbates the problem (Moorhead et al., 2013).

Social media is a useful tool in building one's image, but its unskilful use may negatively affect one's personal brand. Information shared on social media profiles about one's values, ideas, or priorities shape other users' first impression. Moreover, the perception of a person is affected by photos they upload, websites they like, content they share and comment on, their posts, and even their online friends (Bernhardt et al., 2014). This is why it is recommended to make use of privacy settings which allow to decide what type of content is visible to people from one's contact list and to all users visiting one's profile. What is more, in order to maintain a professional image it is necessary to regularly search one's own name in an online search engine and check the available data – a so-called image audit (Ventola, 2014).

Another problematic issue is invasion of patients' privacy, i.a. by publishing comments, posts, videos, photos, or other materials concerning them. Thus, if one wants to discuss a medical case, name and other information about patients, specific dates and locations should be changed or left out, one should also not describe rare cases without the patient's consent (Ventola, 2014).

The presence of doctors on social media can also contribute to blurring the lines in the professional doctor-patient relationship. This occurs mainly due to communication in private messages, or requests to be added to the list of 'friends'. Doctors, too, by finding and making an inappropriate use of information about patients, such as their material situation, social status, or contacts, can violate these boundaries (Farnan et al., 2013).

The social media activity of doctors doubtless comes with its challenges and risks which, however, fade in comparison with its benefits. The very awareness of the existing dangers can make us avoid them or reduce them. Thus, it is important to consciously and carefully use social media as a tool for building one's brand, maintain relationships with patients, and develop one's image as a specialist in a given field.

Methodology and Sample

A voluntary, anonymous survey was carried out in July 2019 in Poland among doctors and dentists. The questionnaire was prepared as an interactive Google survey form. It was delivered electronically, directly to the respondents, through health care units and curtesy of the fanpage of "Okręgowa Izba Lekarska w Gdańsku – Młodzi Lekarze" on Facebook. The questionnaire was comprised of 24 questions, 5 of which were open-ended, and 19 closed-ended. Demographic data was also collected in a part of the questionnaire comprised of 6 questions.

81 respondents took part in the survey, among them doctors and dentists. 69.1% of the respondents were female, 30.9% were male, all between the ages of 25 and 52, among them over 80% aged 25–29 (44.4%) and 30–34 (39.5%). The most respondents (69.1%) lived in cities with over 250,000 inhabitants, and the fewest respondents (4.9%) lived in small cities with under 50,000 inhabitants and in villages. The sample was not tested for education due to the equivalence of a medical degree and an MA degree. However, it was tested for the level of professional development based on work experience and current function. The most respondents (59.3%) were doctors during specialty training, and the fewest respondents (6.2%) has no specialty. The average work experience was 5.3 years, with the most

respondents (64.2%) having worked for 1–5 years, and the fewest (25.9%) for 6–10 years. Average job satisfaction indicator on a scale from 1 (very poor) to 7 (very high) was 5.2.

Results

The sample was tested for social media activity. 98.8% of the respondents confirmed having a social media account, which shows the great popularity of such platforms.

The respondents were asked for their opinion about the chances of building a professional image among potential patients and other representatives of the medical profession with the use of social media. 77.8% of the respondents answered positively, 12.3% answered negatively, and 9.9% chose the answer "hard to say". These results show that there is high awareness of the potential of social media as a tool for building a professional image. Even so, very few respondents decided to have a strictly professional social media profile. Only 1.2% have a professional profile on Facebook, Instagram, or Twitter, or write a professional blog. For professional purposes, the most respondents (15%) use LinkedIn. Some respondents share both professional and private content on their profiles (Facebook 11.3%, Instagram 6.2%) or have two separate accounts, one professional and one private (Instagram 3.8%, Facebook 2.5%). However, most of them use their social media profiles for private purposes. The most popular platforms among the respondents were Facebook (83.3% private profiles), Instagram (48.8%), and YouTube (41.2%). Table 2 presents detailed figures.

Table 2: Social media profiles of medical professionals, by type

	Profile type				
Name of platform	**Private**	**Professional**	**Two separate profiles: private and professional**	**One profile with private and professional content**	**No profile**
Facebook	83.8%	1.2%	2.5%	11.3%	1.2%
Instagram	48.8%	1.2%	3.8%	6.2%	40%
LinkedIn	5%	15%	0%	0%	80%
Twitter	8.8%	1.2%	0%	1.2%	88.8%
Google plus	17.5%	0%	0%	0%	82.5%
YouTube	41.2%	0%	0%	0%	58.8%
Snapchat	15%	0%	0%	0%	85%
Blog, e.g. on WordPress	6.3%	1.2%	0%	1.2%	91.3%

Source: Own elaboration.

A certain reluctance to manage professional profiles on social media may result from a lack of sense of being a brand or from some difficulties in interpreting this concept and associating it with oneself. Asked whether they consider themselves a brand, doctors rarely gave definite answers. The results are therefore ambiguous, with many answers chosen by a similar number of respondents, with a slight predominance of positive answers (Figure 1).

Figure 1: Do medical professionals consider themselves a brand?

Source: Own elaboration

Moreover, this reluctance may result from a sense of danger and the awareness of potential consequences. The respondents were most often concerned about loss of privacy (61.7%), receiving judgemental posts about their private life (53.1%), receiving requests for medical advice (48.1%), and ethical dilemmas concerning doctor advertising. Figure 2 presents the most prevalent of those concerns.

Figure 2: Risks associated with social media activity of medical professionals

Source: Own elaboration.

Conclusions

A significant number of respondents use social media and consider it to be an appropriate means of building their image. Even so, not many of them have professional accounts. This may stem from a lack of sense of being a brand, which results in a lack of conscious branding policy, also on social media. Other reasons include certain risks, among which the respondents most often pointed to: loss of

privacy, receiving judgemental posts about their private life, receiving requests for medical advice, and ethical dilemmas concerning doctor advertising.

It is worth noting that ethical problems may emerge as a result of a lack of clear position of the medical profession and of guidelines about the use of social media by Polish doctors. Such recommendations have been made by, i.a., the American Medical Association (AMA), and cover issues concerning ethics, patient privacy, doctor-patient confidentiality, and informed consent. They also emphasise the need to control information published online and approve making a distinction between private and professional content.

In order to build and maintain a professional image, it is also important to perform regular image audits and use privacy settings offered by most popular social media platforms. The results of the survey also indicate the existence of a certain knowledge gap concerning the concept of a brand among the respondents, which may result in a lack of understanding of this concept and of a conviction about the advantages of engaging in professional communication and building one's own image.

In order to better illustrate the knowledge and awareness of medical professionals, broader studies should be conducted. This is especially important considering reports that in the future, lack of social media activity will negatively affect one's image, and therefore personal brand. This is connected with lack of control over one's image and loss of digital identity, which may result in loss of public trust (O'Hara et al., 2013).

A positive conclusion from the survey is that the respondents are aware of the potential of social media in the context of building an image, both among patients and medical professionals. It is now important to educate them about online security and privacy protection, and for medical associations to update the guidelines concerning ethics and professionalism. With the dynamic development of telemedicine and online consultations, this seems indispensable in order to ensure that medical professionals have freedom of action and can use social media to build their brand in the most professional manner possible.

Due to the methods of sampling, the obtained results cannot be generalised. However, they do provide a picture of how medical professionals perceive social media and can serve as an inspiration for further research in this area.

Heterodox Perspective on Sustainable Development in Economic Order – the Case of Poland

Wiktor SZYDLO

Wroclaw University of Economics and Business, Wroclaw, Poland
wiktor.szydlo@ue.wroc.pl

Abstract

Since 1990 Polish economy generally followed neoliberal path of growth. There was a chance that the new Constitution of 1997 would introduce and propagate broad and inclusive sustainable development paradigm. Unfortunately, this opportunity was missed in the 2000s. Some corrections of orthodoxy were made after the global financial crisis. The switch into the sustainable development path was only partial. The list of indicators in the economic pillar (or order) of sustainable development is still relatively narrow and not adequately popularised. Despite obvious weaknesses, the dominance of GDP and GDP per capita is practically intact.

Keywords: GDP, neoliberalism, sustainable development, Poland

Introduction

The aim of the article is to answer the question whether the experience of the recent global financial crisis and the overall experience of transformation translated into the adjustment of the socio-economic policy in Poland in accordance with the sustainable development (SD) paradigm. The paper also tries to assess whether the SD paradigm as defined by Polish Statistical Office (GUS) complies with heterodox lessons from the global financial crisis and earlier numerous crises in developing countries and emerging markets since 1980s. In particular, the set of SD indicators will be analysed on the basis of two publications by Polish Statistical Office: (GUS 2011) and (GUS 2015). Unfortunately, up till now Polish Statistical Office did not publish a continuation of the aforementioned studies of 2011 and 2015. To fill this gap time series of selected SD indicators of Poland were updated and contrasted with the figures describing other CEE countries. The discontinuation of GUS publications on this particular subject most probably springs from the fact that earlier model of SD – Millennium Development Goals agreed at the United Nations General Assembly in 2000 was scheduled for the period ending in 2015. On September 25, 2015 new SD strategy covering next 15 years: "Transforming our world: the 2030 Agenda for Sustainable Development" was adopted by 194 countries of the UN General Assembly. In consequence, GUS reports on the subject are replaced by the so-called voluntary review of the implementation of the 2030 Agenda at the national level. The 2018 National Report is the first document in this series.

The path of development in Poland – neoliberalism versus sustainable development

As the partially democratic Parliamentary elections in June 1989 marked the symbolic fall of communism in Poland, one can assume that Constitution of the Republic of Poland of 2nd April, 1997 manifested definitive break from the past legal system.

Paradoxically, the new constitution was implemented when the coalition of two-post communist parties (Alliance of Democratic Left – SLD and Polish Peasant Party - PSL) had the majority in the Parliament. At the same time, the President of the Republic of Poland who signed the constitution was Aleksander Kwaśniewski former senior member of the communist party which later transformed into Alliance of Democratic Left. This political constellation of the left wing party and peasant party enabled introduction of certain corrective elements to newly institutionalised neoliberal orthodoxy and the so-called Washington Consensus initiated by the Balcerowicz shock therapy (by some

economists also referred to as Balcerowicz-Sachs Program). One of critics of the shock therapy was Grzegorz W. Kołodko who was the Deputy Prime Minister and Minister of Finance since April 1994 till February 1997 in the governments formed by aforementioned two parties. Kołodko often dubs the Balcerowicz Plan a "shock without therapy".

In this context, it is hardly surprising that the Constitution of the Republic of Poland of 1997 attempted to rein back newly introduced turbo-capitalism as described by Szahaj (2017), Kowalik (2009) or Kieżun (2013). It would be a continuation of Kołodko's 'Strategy for Poland' which broke away from neoliberal dogma. Hence, transformation at that time was characterised by bustling and multidimensional activity of the state (Bałtowski 2019: 193). The introduction of the broad concept of sustainable development to the Constitution (in place of narrow and simplistic laissez-faire capitalism) could be understood as the confirmation of the new course in the socio-economic development.

The article 5 of the Constitution directly refers to sustainable development (SD) and states: 'The Republic of Poland shall (...) ensure the freedoms and rights of persons and citizens, the security of the citizens, safeguard the national heritage and shall ensure the protection of the natural environment pursuant to the principles of sustainable development.'

The article 74 also refers to sustainable development concept. This time rather indirectly: 'Public authorities shall pursue policies ensuring the ecological security of current and future generations. Protection of the environment shall be the duty of public authorities. Everyone shall have the right to be informed of the quality of the environment and its protection. Public authorities shall support the activities of citizens to protect and improve the quality of the environment.'

On the basis of these two articles, it may seem that the concept of sustainable development is narrowly defined by the Polish Constitution, i.e. the other pillars (orders) within SD concept are not adequately addressed. This remark might especially apply to the social order.

However, many other articles of the Constitution refer to social issues and social justice without mentioning the concept of sustainable development. In this context, it is worth quoting article 20: 'A social market economy, based on the freedom of economic activity, private ownership, and solidarity, dialogue and cooperation between social partners, shall be the basis of the economic system of the Republic of Poland.'

A number of other important rights are guaranteed by the Constitution of the Republic of Poland. Most of them are social rights which could constitute the social pillar of SD. For example, according to:

- *Article 24* – Work shall be protected by the Republic of Poland. The State shall exercise supervision over the conditions of work.
- *Article 59.1* – The freedom of association in trade unions, socio-occupational organizations of farmers, and in employers' organizations shall be ensured.
- *Article 65.5* – Public authorities shall pursue policies aiming at full, productive employment by implementing programmes to combat unemployment, including the organization of and support for occupational advice and training, as well as public works and economic intervention
- *Article 66.2* – An employee shall have the right to statutorily specified days free from work as well as annual paid holidays; the maximum permissible hours of work shall be specified by statute.
- *Article 67.2* – A citizen who is involuntarily without work and has no other means of support, shall have the right to social security, the scope of which shall be specified by statute.
- *Article 69* – Public authorities shall provide, in accordance with statute, aid to disabled persons to ensure their subsistence, adaptation to work and social communication.
- *Article 71.1* – The State, in its social and economic policy, shall take into account the good of the family. Families, finding themselves in difficult material and social circumstances -

particularly those with many children or a single parent - shall have the right to special assistance from public authorities.

- *Article 75* – Public authorities shall pursue policies conducive to satisfying the housing needs of citizens, in particular combating homelessness, promoting the development of low-income housing and supporting activities aimed at acquisition of a home by each citizen.

These noble rules and guarantees, however, were often breached in the course of rapid transformation and lack of concern by policymakers who focused either on speeding up GDP growth or fast disinflation (with rapid EMU membership as one of the aims). The improvements in other spheres (including social sphere) were supposed to be a consequence or a by-product of achieving the aforementioned two prime goals. Certainly, the policy which focuses on lowering inflation may exert negative effects on the social sphere, especially in the short-term. The pursuit of high GDP dynamics, in turn, does not pose such serious risks. Nonetheless, heterodox works on inequality prove that the marine metaphor according to which 'a tide lifts all boats', does not apply to current version of capitalism seriously affected by the process of monopolization and financialisation.

Therefore, the dignity of work was often forgotten in the Polish caricatured version of liberalism (rubbish liberalism) or turbo-capitalism (Szahaj 2017). T. Kowalik (2010), bitterly states that social justice is 'a fashionable subject, but not in Poland'. He also provides examples of senior and influential figures (for example, the President of the Constitutional Tribunal at that time) for whom 'social justice is only intuition'(Safjan 1999). The list of senior figures who are indifferent to the issue of division of national income is broad and includes L. Balcerowicz and his acolytes, liberal Henryka Bochniarz and conservative Ryszard Legutko. The last two persons expressed deep dissatisfaction when Amartya K. Sen won the Nobel Prize in economics in 1998 (Kowalik 2010). It is worth evoking another former President of Constitutional Tribunal, Andrzej Zoll. His stoic attitude towards the dramatic situation of the people working on short term contracts without any social protection is rather surprising. The professor of constitutional law maintains that: 'Prosperity originates out of work, savings and also exploitation. Being a realist, it is difficult not to see it. Injustice is unavoidable, especially during the period of such changes as in Poland'(Zoll 2017: 180-181). It is worth mentioning that according to article 208 of the Constitution 'The Commissioner for Citizens' Rights shall safeguard the freedoms and rights of persons and citizens specified in the Constitution and other normative acts.' Indeed, his views are startling given that he held the position of the Commissioner for Citizens' Rights between June 2000 and February 2006, i.e. at the time when the situation in the labour market in Poland was one of the most acute in Europe.

In this connection it is interesting to note that according to Józef Tischner – an influential Polish priest, first chaplain of 'Solidarity' and renowned philosopher, Leszek Balcerowicz was one of the three figures who formed the "ethic of solidarity" (the other two were Lech Wałęsa and Tadeusz Mazowiecki). Tischner (2018: 263) claimed that Balcerowicz 'bounded utopia of solidarity with Anglo-Saxon political economy'. The question remains to what extent his rather positive stance on economic transformation in Poland springs from the fact that he passed away in June 2000, i.e. shortly before dramatic increase of the registered unemployment rate to 20% in December 2002. Yet already in 1999 the unemployment rate was high and hovered above 11%. As Tischner was influenced by the book by D. Méda (1995) one cannot be sure that his views on the nature of unemployment would change. He might well continue to perceive hikes in joblessness as something unavoidable and therefore natural: 'Does political power has a power over dynamically developing technology? Is it not technology to 'blame' that smaller and smaller amount of human labour is necessary to produce increasingly bigger amount of wealth?'(Tischner 2018: 273). This way of thinking may evoke naturalism, historical determinism and neomalthusian approaches. At least in the short term, these predictions about the end of work by D. Méda and her followers proved premature as over 2 million usually young and educated Poles emigrated to more economically and technologically advanced West European countries in the 2000s. Less than 15 years later, history repeated itself when Polish employers started desperately seeking labour from East European countries.

In 1998 the composition of the parliament changed with Electoral Action Solidarity (AWS) and Freedom Union (UW) forming government with Leszek Balcerowicz from UW returning to the position of Deputy Prime Minister and Minister of Finance. The 'Strategy for Poland' was replaced by an ambitious plan to implement several major and expensive reforms (which included social security reform, i.e. its partial privatization) and subsequent cooling down policy. For a number of experts the economy was overcooled (i.e. the GDP growth was unnecessarily reduced to very low levels (Kołodko 2009; Woźniak 2017). The idea to build 'social market economy' according to sustainable development paradigm was put aside and the socio-economic policy returned to its neoliberal path with continuing financialization, less progressive tax system and mediocre condition and security of the labour force. Provenience of the ruling majority did not make much difference.

After nineteen years of turbulent, predominantly neoliberal transformation Poland (along with other post-communist CEE countries) was eventually hit by the global financial crisis that symbolically started with the collapse of the Lehman Brothers on September 15 2008. The viability of orthodoxy was questioned by scholars from various economic and philosophical schools: Belka (2015), Mączyńska (2019), Petru (2015), Szahaj (2017), Wilkin (2019), Woźniak (2019) and Żyżyński (2019). The sentiment of the general public also changed and culminated in reshuffling in the political scene. This major turnaround in 2015 was only partly the consequence of the increased positive sentiment towards conservative values. Even more so it sprang from the promise to strengthen neglected social sphere for example by the Family 500 Plus programme (monthly transfer of 500 PLN for each child up to the age of 18). Paradoxically (at least for Western public), this wholly left-wing socio-economic programme was introduced by a coalition of three conservative and right-wing parties. 'Several negative phenomena in economics were caused by neoliberal doctrine and the domination of neoclassical school which is characterised by market fundamentalism, i.e. the notion that market perfectly finds solution to everything, including ethics' (Mączyńska 2019).
Therefore, it is hardly surprising that such mistakes strongly affected social and political sphere in a number of developed countries, such as Greece, Italy, the USA and the UK – the Brexit. The question remains whether the global financial crisis will prompt necessary changes in the long term development strategy. The obvious recipe is to return to the sustainable development paradigm.

Selected sustainable development indicators in the economic order

SD is commonly referred to as meeting the needs of the present generation without compromising the ability of future generations to meet their own needs. The concept of sustainable development (SD) goes along with heterodox economics which prefers holistic, pluralistic and interdisciplinary approach. The concept takes into account time which is often neglected or trivialised by orthodoxy. It presupposes, unlike M. Thatcher, the existence of the society and even takes care of future generations. According to Wichaisri and Sopadang (2018) the concept of SD rests on three main pillars: economic growth, social inclusion and environmental protection. This model could be broadened. As noted by Fiedor et al (2002: 231) SD is a collection of four orders: environmental order, socio-demographic order, economic order and spatial order. This definition could be further extended by including institutional or institutional-political order.

Closer examination of economic pillar of SD seems particularly relevant in the case of the global financial crisis and the subsequent Great Recession (the most serious economic crisis since the Great Depression in the 1930s). It especially applies to heterodox perspective with its numerous studies on casino-capitalism, financialisation and monolopy-capitalism which greatly developed in the recent decades.

Economic order in Poland as discussed by two studies by Polish Statistical Office (GUS 2011) and (GUS 2015) comprises following five sub-orders (or sub-categories): Economic development, Employment, Innovativeness, Transportation, Model of production. From macroeconomic perspective the first two of these sub-orders, namely Economic development and Employment, require more detailed analysis. Innovativeness also requires, at least brief, analysis in the context of the aforementioned need to transform Polish economy towards high value added production.

Table 1: Selected* sustainable development indicators in Poland in sub-domain economic development within the economic domain (order or pillar)

	ECONOMIC DOMAIN	
	2011	**2015**
Economic development	Growth of Gross Domestic Product per capita	Growth of Gross Domestic Product per capita
	Investment outlays on fixed assets (Percentage of GDP)	Investment rate
	Dispersion of regional GDP per capita (NTS 3)	Regional dispersion of GDP per capita (PPP) at NTS 3 level
	Public debt (Percentage of GDP)	The debt of central and local government institutions (Percentage of GDP)
		Surplus/Deficit of central and local government institutions (Percentage of GDP)
		GDP per capita (PPP)
		Gross domestic savings rate (Percentage of GDP)

** The table does not include three indicators for the year 2011 and 2015: Water reception in the economy, water use of the economy and transport intensity in the relation to GDP.*
Source: Based on: GUS (2011) and GUS (2015).

The set of indicators in economic domain in 2015 was extended in comparison with 2011. At the same time, however, table 1 confirms the dominance of GDP (GDP per capita and GDP growth) as the leading macroeconomic indicator in the economic development sub-domain of the economic domain (pillar, order). Hence, two leading publications on SD in Poland (which were published during or shortly after the global financial crisis) to great extent mimic the hierarchy of goals powerfully advocated by the mainstream. Other sub-domains such as employment, innovation, transport and methods of production play rather minor role in the popular debate.

Heterodox approach, as it was already stated, is more holistic and interdisciplinary. Exhaustive analysis of the economic domain would require much more developed work (beyond the scope of this publication) and also cooperation with a host of experts in different domains. Hence, the analysis of economic domain will exclude several sub-domains such as "Employment", "Innovation", "Transport" and "Methods of production" which are described by 19 indicators. These sub-domains (with the exception of "Employment") do not belong to typical macroeconomic or microeconomic topics or problems. They are having their specific sectoral character. Undoubtedly, next studies should be more socially oriented and focus on the analysis of sub-domain "Employment" (described by 4 indicators) and selected elements of social domain which in the study by Polish Statistical Office (GUS 2015) is described by 31 indicators. For obvious reasons, the analysis of sub-order "Economic development" within the economic order should be of great interest for scholars. It applies both to mainstream economists and those with more alternative views (various heterodox schools).

The set of indicators describing the sub-order (sub-pillar) 'Economic development' fully confirms the dominance of GDP. According to GUS (2015: 139) 'GDP per capita is a very important indicator of the level of economic development and its long term growth constitutes the main goal of the state economic policy." Therefore, the growth of GDP per capita has a prime importance for policymakers.

Poland's performance measured by this indicator is impressive even in comparison with other Central and East European countries. Indeed, the country relatively quickly recovered from the transformational recession at the beginning of the 1990s and in subsequent decades recorded uninterrupted GDP growth. Poland growth performance seemed immune to numerous international

turbulent events that took place since the collapse of the iron curtain in 1989 such as the crises in the so-called Asian tigers in 1997, Brazil, Russia, Argentina, the bursting of the dot com bubble in 2000. The country also avoided the recession (often referred to as Great Recession) that followed the global financial crisis which symbolically started in September 2008 with the collapse of the Lehman Brothers. The same applies to long-term growth dynamics. According to GUS (2015: 140) 'average annual growth of GDP per capita amounted to 3.9% in Poland and 0.6% in the European Union (EU) in 2004-2014.' From this perspective, the stability of the economic growth in Poland is impressive. Little wonder that M. Piatkowski (2019) refers to Poland as "Europe's growth champion".

On the other hand, numerous studies confirm that GDP has its deficiencies even in comparison with Gross National Product (GNP) which used to be a standard measure of economic performance until 1990 when it was replaced by GDP (Stiglitz 2013: 231). Thanks to this change capital importing countries could boast fast economic growth (understood as GDP dynamics). At the same time, the leaders of developed countries (usually the exporters of capital) may portrait themselves as the promoters of more balanced economic development in the global scale. Poor countries catch up with more developed ones in terms of GDP per capita what automatically translates into rapid poverty alleviation in less-developed countries.

This rhetoric, however, blurs the real picture of country's socio-economic situation. GDP does not take into account net incomes which gain prominence in the era of globalization and financialisation (i.e. excessive growth of the financial sector at the expense of the real sphere).

As the calculation of net incomes could pose certain challenges to national statistical offices numerous mainstream economists or economic commentators make use of this fact and focus solely on GDP. Some experts do it deliberately others simply mimic the herd leaders. The change of prime economic indicator or indicators requires changes of the perspective in the influential mass media and government (with its numerous agencies such as national statistical office).

According to official figures the real gap between Poland and a number of West European countries is narrowing very rapidly. For example, according to recent Eurostat data (as of February 2020) Poland overtook Portugal in terms of GDP per capita. However, actual distance between Poland and a number of capital exporting advanced countries (such as the Netherlands, Germany, Japan) is not dwindling that fast.

It needs to be stressed that since the early 2000s the discrepancy between GDP and GNP (also referred to as Gross National Income – GNI) is widening in Poland.

GNI is the sum of GDP and foreign income (balance). While, "foreign income (balance) is the difference between the value of gross primary income (accounts receivable due from foreign entities to domestic entities) and the accounts payable of domestic entities to foreign entities or the sum balance of wages and salaries, income from direct and portfolio investments as well as other income and interest" (GUS 2019: 683).

In 2002 the discrepancy between GDP and GNI in Poland stayed below 0.5% GDP. Eight years later (i.e. in 2010) the foreign income balance amounted to -3.5% of GDP, while in 2017 the foreign income deficit exceeded 4 % of GDP. In absolute terms this figure amounted to 80.7 billion PLN. In other words, annual net outflow of income from Poland reached over 4% of GDP.

Fig. 1: GDP (current prices) minus GNI (current prices)

(i.e. -foreign income balance) (% of GDP) in Poland

Source: Own calculations based on GUS

GDP has a number of other disadvantages. This caveat also applies to GDP per capita. For example, it does not measure the actual distribution of income in the society. It needs to be stressed, that any serious economic analysis cannot be limited to a narrow set of indicators (not to mention single measure such as GDP). GDP is not and was never intended to be a measure of the quality of life (Coyle 2018: 80).

More recent report on sustainable development (SD) indicators of Poland (GUS 2015) introduced another indicator, namely „Gross Domestic Product per capita (in PPP)". Of course, it broadens the understanding of country's economic situation. However, it also proves that SD indicators in Poland were dominated by GDP. Historical comparisons of GDP per capita dynamics (calculated in PPP) show the success of transformation in Poland. The selection of the base year for calculations significantly influences the standing of Poland in comparison with other high-growth countries. Orthodox analyses have a tendency to shorten the time horizon. For example, they do not take into account that GDP per capita dynamics in Poland in the 1980s was one of the lowest among Central and East European communist countries. The distance between Poland and a number of capitalist countries also widened in the 1980s. Therefore, Poland had a lot to catch-up in the following decades. The country's good economic performance could be explained by the convergence (or catch-up theory) which states that the poorer or developing countries tend to have a faster income per capita growth than wealthy and developed countries.

Mainstream scholars also tend to select a base year that does not include all years of transformational recession (1990-1991 in the case of Poland). For example, when the base year is 1991 as in the case of the study by Balcerowicz (2016: 379) the economic growth in Poland was only slightly lower than in South Korea and was faster than in Chile and Malaysia. The gap widens significantly when the base year is set at 1989. Between 1989 and 2017 GDP per capita (measured in PPP) amounted to 141.2% in Poland, 235.5% in South Korea and 153% in Chile. It needs to be stressed, however, that during the same period the performance of many post-communist countries was far from spectacular. For example, the indicator increased by 81,1% in Romania, 50,1% in Hungary and only 39,1% in Bulgaria.

Proper assessment of long term growth performance requires taking into account the purchasing power of GDP. Purchasing Power Parity satisfies this requirement. PPP is the exchange rate at which GDP in all countries (measured in national currencies) is converted to the common currency such as Purchasing Power Standard (PPS). One needs to realise that calculations of this measure for

communist countries is rather difficult. This especially applies to countries which suffered from high inflation or hyperinflation (such as Poland). In consequence, the income collapsed even more than GDP. It needs to be stressed that cross-country comparisons could be affected by major exchange rate movements. For example, Poland significantly devalued its currency (zloty) in January 1990 (when the Balcerowicz Plan was introduced), but later till May 1991 the exchange rate against USD was fixed what led to real revaluation of zloty. Despite all these caveats, Poland's long term growth record (measured by GDP per capita in PPP) should be treated with due respect.

The indicator GDP per capita (PPP) is not particularly precise especially in countries with substantial population inflows and outflows. Poland became one of such countries especially after its fast transition to the market economy in the early 1990s. The economic performance after initial transformational recession in 1990-1991 was generally positive. New capitalist system offered many opportunities to young and educated people especially in big cities. Hence, emigration was rather subdued in the 1990s. Tertiary educational boom that started in mid-1990s prompted major transfer of young people from towns and villages to strong university and business centres such as Warsaw and several other big cities, such as Kraków (Cracow), Wrocław, Poznań and Gdańsk. It was an example of internal migration.

Economic condition dramatically changed at the turn of the century when the already mentioned cooling-down policy was introduced by the central bank. The situation in the labour market was further aggravated by the unfavourable demographic development, i.e. massive inflow of graduates from baby boom generation into the labour market. It is hardly surprising that emigration to West European countries was spectacular in the early 2000s. This trend even gained momentum after Poland's accession to the EU in May 2004).

Table 2: Estimated emigration from Poland for temporary stay* in the years 2004-2018 (thous.) (the number of persons staying abroad at the end of a year)

	2004	**2005**	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**
TOTAL	1000	1450	2000	2060	2130	2196	2320	2397	2515	2540	2455
including: the EU	750	1170	1607	1670	1720	1789	1901	1983	2096	2121	2031

** for years 2004-2005: over 2 months; for years 2010-2018: over 3 months,* *Source: GUS*

This spectacular development, however, is not particularly well documented in official demographic data (see figure 2). Several estimates point that actual emigration from Poland exceeded 2 million persons. This, in turn, could blur the GDP per capita (PPP) statistics. The proper GDP per capita figures were, in fact, higher than according to GUS or Eurostat. The actual gap between productivity and wage growth is even greater, i.e. the stake of labour force in GDP was diminishing.

The situation reversed in 2015-2019 with the massive inflow of labour from the East European countries (predominantly from Ukraine) to Poland. This phenomenon was mainly caused by the conflict in the East Ukraine which started in April 2014. The other factors include: the discrepancy in wages/salaries between the two countries, proximity (the countries are neighbours) and relatively similar languages.

Fig. 2: The number of work declarations registered by local employment agencies for eligible East European countries^ (including Ukraine) (thous.) in 2008-2019

Note: ^ Since 2014: BY, RU, UA, MD, GE, AM; In 2010-2013: BY, RU, UA, MD, GE; In 2009: BY, RU, UA, MD; In 2009: BY, RU, UA, MD.

Again, official population statistics does not take into account this massive inflow of people. Eurostat figures (see below) show even a population decline from 38.063 million in 2013 to 37.973 million in 2019. The underestimation of immigration (even though it is in most cases temporary) leads to the overestimation of GDP per capita in Poland in recent 4-5 years. It is even more the case with GDP per total employment indicator as immigrants are predominantly at the working age.

Fig. 3: Population in Poland (Millions)

Source: Eurostat.

The same problem is most probably present in other CEC countries (for example the Czech Republic) which also experienced influx of Ukrainian labour force.

It needs to be stressed that adequate assessment of immigration to Poland is not an easy task. The number of work declarations granted to aforementioned East European countries exceeds the number of persons applying for work (i.e. during one year two temporary permits could be granted to one person). On the other hand, Polish labour law offers several other forms of employment permits.

As noted by S. Izdebski Ukrainians could work in Poland on the basis of visa-free movement (for maximum 90 days) or visas in order to exercise work (for 6-12 months). After this period they have to return to Ukraine. Up to now (i.e. March-April 2020) the workplace emptied by these workers was granted to other workers with new permits and visas (Puls Biznesu 2020). Hence, temporary migrant workers were subject to constant rotation.

At the same time, there is a growing number of people possessing valid permits for long-term stay in Poland. The total figure increased by about 50 thousand annually in 2016-2019. On January 1 2020 as many as 423 thousand foreigners had such long-term valid permits. To put it into perspective on January 1 2019 and 2018 it amounted to 372 thousand and 325 thousand, respectively. Half of these people were Ukrainians. As of January 1 2020 the list of foreigners (i.e. 423 thousand) comprised (among others) the citizens of: Ukraine – 214.7 thous., Belarus – 25.6 thous., Germany – 21.3 thous., Russia – 12.5 thous., Wietnam – 12.1 thous., India – 9.9 thous., Italy – 8.5 thous., China – 8.5 thous., Great Britain – 6.3 thous., Spain – 5.9 thous., Georgia – 5.5 thous. and Moldova – 2.4 thousand (UDSC 2020). Almost 83% of all the foreigners possessing this document were at the age of 20-59. Thus, the majority were at the working age. The figures above do not take into account people whose temporary stay in Poland is based on visa or visa-free movement.

It is interesting to note that estimates by Ukrainian experts are higher than figures provided by Polish specialists. For example, according to Ukrainian Analytic Centre 1.2 million Ukrainians officially worked in Poland in 2016 (Solodko, Fitisova 2017). The same researchers also estimated that by the end of 2017 the number of Ukrainian workers would exceed 2 million people.

In the light of the above data, there is no doubt that the fifth recommendation of the so-called Warsaw Consensus (Piątkowski 2014; 2019), namely to open up to immigration, was very eagerly exercised by Polish authorities in the 2010s.

Crude comparisons of GDP per capita between countries do not take into account the amount of effort with which the GDP was produced. The OECD data clearly show that in developing countries this effort disproportionately rests on the labour force. Indeed, the discrepancies between the average hours actually worked (per capita paid employment) between countries are huge. In 2014 the figure in Mexico exceeded that in Poland by 15.9%. In contrast, in most West European countries it was much lower than in Poland, for example, by 12.8% in the UK, 16.3% in Sweden, 23.4% in France and 28.7% in Germany.

It is yet another proof that standard orthodox economic indicators such as GDP or GDP per capita do not adequately measure the level of sustainable development (not to mention quality of life). The gap between rich and poorer countries are simply more pronounced.

Finally, one should not overlook the fact that GDP is also used to measure spatial economic dispersion between regions in the economic order of SD. This fact, in turn, confirms GDP's hegemonic position. Interestingly, regional dispersion of GDP per capita (PPP) at NTS 3 level in former post-communist countries in most cases considerably exceeded the levels measured in affluent West European countries. The figure equals zero when the values of regional GDP per capita are the same in all regions. To illustrate the point, in 2011 the dispersion index amounted to: 45.5 in Bulgaria, 35 in Croatia, 42.1 in Estonia, 36.9 in Latvia, 40 in Romania, 35.2 in Slovakia, 44 in Hungary and 34.9 in Poland, while in Italy, Spain and France it amounted to only 25.2, 19.5 and 26.9, respectively (GUS 2015). The economic growth in most Central and East European countries was highly concentrated in several main regions or cities (especially the capital). This posed threat to territorial cohesion of Poland and many other CEE countries. This indicates that spatial order within the sustainable development is not adequately addressed. One of solutions is the ongoing development of longitudinal transportation projects aimed at intensification of trade and tourism between these countries.

Summary

The study by Polish Statistical Office significantly overestimates the information capacity of GDP by claiming that: „gross domestic product is a fundamental measure of economic development which in a concise form describes the fullest picture of national economy and the changes of economic structure" (GUS 2015: 139).

One has to agree with T. Sedláček and D. Orrell (2012: 60) who assert that GDP "pretends to be mathematics, but in reality it is not all about mathematics." To put it bluntly, this exaggerated

concentration on GDP masks deficiencies in many other spheres. Socio-economic development is a much broader concept than economic growth which is reduced to GDP dynamics. The sustainable development paradigm is also much broader than the concept of economic growth. Naturally, the criticism of GDP does not mean the outright discarding of this measure. It also should not lead to its replacement by any other "all encompassing" measure such as Gross National Happiness index as in the case of Bhutan for almost forty years. In many respects Bhutan differs from many other countries (also developing countries). It is a rather small kingdom with uncomplicated economy (Balasubramanian, Cashin 2019). Generally, the proper answer to neoliberal reductionism should be the broadening of socio-economic analysis.

Undoubtedly, the concept of sustainable development constitutes essential alternative to the dominant paradigm in economics. At the same time, it is much closer to heterodoxy which is a big advantage in the context of recent global financial crisis and subsequent Great Recession. However, the conducted analysis indicates gaps in the description of economic order of sustainable development paradigm. The list of indicators should be further extended and popularised in order to adequately evaluate monopolization, financialisation and the distribution of income.

Abstract

The important structural element of national higher education is the university. The level of specialists training in it is largely determined by the university management quality. This determines the importance of assessing of the university management quality. In practice, descriptive (verbal) assessments of the management quality (unsatisfactory, satisfactory, etc.) are often used. Therefore, the problem of validity of verbal assessment is important. The aim of this paper is to develop algorithms for quantitative assessment of the university management. The used database is information on the work of Russian universities. The research methodology is modeling and comparative analysis of empirical data on the activities of Russian universities. Conclusion: to improve the accuracy of the verbal assessment of the university management quality it is necessary to use quantitative estimates. The proposed model combines the construction of quantitative and verbal assessments of the management quality, which allows a more accurate verbal assessment of the quality of university management.

Keywords: Quantitative assessment of the university management quality, Verbal assessment of the university management quality, Algorithm s for assessing the university management quality

Introduction

The leadership of any university pursues the achievement of specific, predetermined strategic goals of its development and the solution of tasks that meet the achievement of these goals. These may be, for example, goals related to the development of university at all its levels — the entire university, faculty, specific educational program, or research project. At the same time, the management quality can be considered high only if these strategic goals and tasks are achieved and solved in a predetermined time frame and with the use of specified resources.

The problems of assessing the university management quality in scientific and practical literature are discussed quite actively (see, for example, Salmi (2009), Liman (2006), Rozovsky (2014), Achamer (2015), Vilgats & Heidmets (2011), Udam & Heidmets (2013), Biju & Nair (2017), Sima, Udam, Mattisenu and Lauri (2017)). However, most of the research is devoted to construction of descriptive

(verbal) assessments of the quality of university management. A specific feature of the research presented below is that it is devoted to the problems of building interrelated quantitative and verbal assessments of the quality of university management, and is a development of the authors' previous scientific works (Khalin, Chernova (2018), Belov, Chernova, Khalin, Kuznetsova (2018), Khalin V.G., Chernova G.V. (2019)).

The logic of the presented study, which determines the structure of the article, is as follows.

In the practice of university management, descriptive (verbal) assessments of the management quality are often used. As a rule, they require justification for the selection of their specific values. The reliability and accuracy of descriptive (verbal) quality assessments can be improved if the actual values of university activity indicators are used in determining their values.

That is why the article proposes the construction and use of quantitative assessments of the university management quality, on the one hand, calculated from the actual values of university activity indicators, and, on the other hand, linked to the values of verbal estimates of management quality.

The transition from a quantitative assessment of management quality to verbal is implemented on the algorithms developed and presented in the article. Through the proposed scaling procedure, algorithms, firstly, establish a mutual correspondence between the interval values of the quantitative assessment of the management quality and the specific values of the verbal evaluation. Secondly, they allow us to determine the specific meaning of the verbal assessment of the management quality based on the actual value of the quantitative assessment calculated on the real data basis.

The presented approach increases the reliability of the obtained verbal estimates, as they are ultimately determined by the actual quantitative values of university activity indicators.

The specific content of the algorithms for constructing quantitative and oral assessments which determine the quality of management depends on the level of the management problem.

Before an university management system for a certain period of time, different tasks can be posed, for example, achieving a certain value of a specific indicator of an university's activity, solving a certain management problem, or realizing some goal of university development.

Assessment of the university management quality for each of the management tasks has its own characteristics, the contents of which are taken into account in the proposed algorithms.

Realization of a specific goal of university development may include the solution of a number of specific management tasks, and the solution of any specific management task may suggest that some indicators of the university's activity should reach certain values.

This means a possible interconnection of the named management problems and, as a result, involves the complex simultaneous use of different algorithms, that confirms their interconnection.

So, when the management quality evaluating on the Realization of a specific goal of university development is, the algorithm of the management quality evaluating on solving a particular problem and the algorithm of the management quality evaluating on achieving by particular indicator of the university's activity of specific meaning can be used several times.

The contribution of this research is. First, the basis for constructing interconnected algorithms for quantifying the university management quality is the relationship of individual university activity indicators with the goals and objectives of university management. Secondly, the article proposes the options of establishing the correspondence of quantitative assessments with verbal. Thirdly, the article reveals the content of the proposed interconnected algorithms used to assess the university management quality on separate indicators, on solving specific tasks and on achieving certain strategic goals. Conclusion: the use of verbal assessments of the university management quality requires more

justification. Application of the proposed original quantitative approach allows to increase the reliability of the verbal evaluations, since the quantitative evaluations and verbal evaluations built on them are based on actual values of university performance indicators.

General Provisions

Need for Verbal and Quantitative Assessment of The Management Quality

The assessment of the university management quality can be verbal (poor, satisfactory and good) and quantitative, reflecting the degree (level) of achievement of the indicator value, solving the problem, achieving the goal.

The use of verbal assessment of the university management quality UMQ implies the possibility of applying of the different criteria for the selection of its specific value:

- expert opinion, determining the value of the verbal assessment of the University Management quality, formed on the basis of the experience of the experts themselves and analysis of the actual situation;
- values of the qualitative characteristics of various aspects of the university. So, if the university has the latest computer technology, then the quality of the University Management quality for solving such a task as providing technical equipment of the university can be assessed as good;
- quantitative assessment of the University Management quality, linked to different values of the verbal assessment of the quality of management. Its advantage is that it is based on the actual values of the performance indicators of the university, and therefore both estimates, quantitative and corresponding to verbal ones, are more accurate and objective.

The choice of the criterion for constructing a verbal evaluation remains for decision makers (DM). However, in view of the advantages of sharing quantitative and verbal assessments, we will dwell on this issue in more detail.

Options for the simultaneous use of verbal and quantitative assessments of the university management quality

Simultaneously, quantitative and verbal assessments can be used in assessing the quality of university management.

- on a separate indicator of its activities, for example, on an indicator of the average salary of university professors. It must be more than the average monthly wage calculated for the region, at least 2 times;
- on solving a specific management problem, for example, the task of creating a favorable system of academic contracts at the university requiring management of a number of indicators of its activities;
- to achieve the strategic goal set for a certain period, which involves solving a number of specific tasks. Such a strategic goal, for example, may be the creation of a favorable management system at a university aimed at attracting, retaining and developing any talents. Achieving this goal involves, inter alia, the solution of such tasks as the formation of a favorable system of hiring, work and academic contracts for professors; creation of favorable conditions for the admission of the most talented applicants, etc.

The above options for constructing estimates are related. Evaluation of the management quality to achieve the strategic goal involves the repeated construction of assessments of the management quality to solve all the problems (tasks) associated with the implementation of this goal. Assessment of the management quality on solving each of these tasks includes an assessment of the management quality to achieve a certain values of all indicators related to the corresponding task solution. This intercon-

nection of building assessments of the university management quality determines the interconnectedness of the algorithms used to solve them.

In general, a certain relationship should be established between verbal and quantitative assessments — the specific values of the quantitative assessment of the University Management quality must be matched to certain values of its verbal evaluation. It should be noted that the establishment of such compliance has its own characteristics, due to the variant of the task of assessing of the University Management quality: the management quality is evaluated on the achieving a certain value of its activity indicator; the management quality is evaluated on solving a specific management task or on achieving a certain strategic goal, which involves solving a number of management tasks.

Management Tasks and algorithms for assessing the quality of university management

Management Task 1 — Evaluation of the quality of university management to ensure a certain value of a specific indicator of its activities

It is carried out on the basis of the implementation of the simplest algorithm 1, applied to a specific indicator of the university's activities and including 2 stages.

Stage 1. *Construction scales of interval values of the studied indicator.* To solve the task of the university managing with respect to a separate indicator of its activity, it suffices to limit the construction of two interrelated scales that establish the relationship between the interval values of the indicator measured by natural (natural) units and verbal quality assessment. In tab. 1 presents an example 1 of building such scales for the indicator A.1 "Guaranteed amount of monetary reward for the month of the professor's work". In the table 1, compiled by the authors, an example 1 of constructing such scales for indicator A.1 "Guaranteed amount of cash compensation for the month of the professor's work" is presented.

Table 1: an example of interrelated scales in assessing the quality of management of indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work"

The scale of the values of the verbal quality assessment on the management of the indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work"	Quality of management is "bad"	Quality management is "Satisfactory"	Quality management is "good"
The scale of interval values of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by natural units	Less than twice of the average monthly salary in the region*	Not less than twice of the average monthly salary in the region, but less than four times the monthly average salary in the region*	More than four times of the average monthly salary in the region

**When establishing a scale of interval values of indicator A.1, linked to specific values of a verbal assessment of the management quality, here and in the future the authors took into account the requirements of the Decree of the President of Russia (Decree (2012)) and the real statistics of this indicator for the largest universities in St. Petersburg (Monitoring (2018).*

However, it should be noted that if these results are used to assess the quality of management of a university on solving a specific management problem to achieve a certain strategic goal, there is a problem of comparability, homogeneity of indicators measured by different natural (natural) units (rubles, hours, etc.) The comparability of such indicators can be provided by the transition from the values of the indicator, measured in natural units, to its values, measured in points (for example, on a 10-point system).

With further use of the analyzed indicator for the above cases, the scales construction involves the construction of not two, but three interrelated scales of interval values for each of the studied parameters.

Note that the conversion of the values of indicators measured in physical (natural) units to its point values, as well as the interrelated scales construction of interval values of indicators measured in natural and point units, require additional presentation and discussion. This is difficult to do because of the limited size of the article, and therefore is taken out of its limits.

In table 2 shows an example of building such scales for the indicator A.1 "Guaranteed amount of monetary remuneration for a month of a professor's work" for the case when it (this indicator) is used, for example, to solve such a problem of university management as creating favorable conditions of hiring, work and academic contracts university professors.

Table 2: example of interrelated scales construction when assessing the quality of management of indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work"

The scale of the values of the verbal quality assessment on the management of the indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work"	Quality of management is "bad"	Quality management is "Satisfactory"	Quality management is "good"
The scale of interval values of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by points*	From 0 to 5 [0; 5]	From more than 5 to 8 [5; 8]	From more than 8 to 10. (8; 10]
The scale of interval values of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by natural units	Less than twice of the average monthly salary in the region	Not less than twice of the average monthly salary in the region, but less than four times the monthly average salary in the region	More than four times of the average monthly salary in the region

** The boundaries of the scoring interval values of indicator A.1 here and in the future were established on the basis of expert opinion.*

Stage 2. *Evaluation of the university management quality based on the actual value of the studied indicator.* The actual value of an indicator measured in natural units is compared with its interval values, represented by natural units of measurement.

The hit of the actual value of the indicator in a certain interval of its values, measured in physical units, stage 1 determines

- the value of the corresponding verbal assessment of the management quality for this indicator, if it is a question of assessing the management quality only for this indicator,
- its assessment in points and the corresponding value of a verbal assessment, if it is a question of building more complex quality assessments.

Table 3 shows an example of the actual quality assessing of management at St. Petersburg State University by the indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work".

Table 3: an example of an assessment of the actual quality of management by indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work" (2017)

The scale of the values of the verbal quality assessment on the management of the indicator A.1 "Guaranteed amount of monetary remuneration for the month of the professor's work"	Quality of management is "bad"	Quality management is "Satisfactory"	Quality management is "good"
The scale of interval values of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by points	From 0 to 5 [0; 5]	From more than 5 to 8 [5; 8]	From more than 8 to 10. [8; 10]
The scale of interval values of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by natural units	Less than twice the average monthly salary in the region	More than twice the average monthly salary in the region, but not more than four times the average monthly salary in the region	More than four times the average monthly salary in the region
The actual value of the indicator A.1 "Guaranteed amount of monetary reward for the month of work of the professor", measured by natural units	53,094.96 r rubles [1]		

Based on the results of the application of the algorithm, the quality of university management to ensure the guaranteed size of the professor's monetary remuneration for a month of work is assessed as unsatisfactory.

Management Task 2 — Assessing the university management quality on solving a specific university management task

The quality of the solution of any problem is determined by the actual values of a number of indicators. Therefore, its assessment can be carried out on the basis of the implementation of algorithm 2, including the application of algorithm 1 inside it with respect to each of the indicators related to this task.

Stage 1. *The task formulation of the university managing, the quality of management on which will be evaluated.* It may be:

- attracting and retaining the best and most talented undergraduate and graduate students at the university,
- creation of favorable conditions for hiring, working and academic contracts of university professors etc.

For example, such a task will consider the creation at the university, for example, at the Faculty of Economics of St. Petersburg State University (SPbSU), favorable conditions for the hiring, work and academic contracts of professors. This task can be considered as one of those that must be solved in order to achieve such a strategic goal as the formation at the university of a constellation of talents — professors, researchers and students.

Stage 2. *Formation of a balanced scorecard used to assess the quality of university management on solving a specific management problem*. The development and adoption of any university management decision involves the use of certain information — those criteria and indicators that should describe the functioning of the university.

But it should include only the number of indicators that is necessary to describe the activities of the university and is sufficient for the management evaluation. The logic of the information formation used to assess the management quality for any object, including for a university, led to the introduction into scientific circulation of such a thing as "balanced scorecard".

In the general case, a balanced scorecard (SSP) is a system of indicators necessary for a complete and comprehensive description of the university management process, and sufficient for the assessment based on them to be reliable.

The originally balanced scorecard (BSC) was proposed by Robert S. Kaplan and David P. Norton as a system for measuring the performance of a financial company (Kaplan and Norton (1996).). Currently, the term "balanced scorecard (SSP)" is used both in a broad and narrow sense (see, for example, Balansed Scorecard (2018), Khalin, Chernova (2018b)).

Its use in a broad sense implies consideration of the BSC within the framework of the whole concept of development of a certain company, which unites the mission, strategic goals of development, the corresponding management system tasks, methods and ways to achieve them.

At the same time, only those of them that are necessary and sufficient to build an assessment of the company's development described by a certain concept are included in the BSC.

Leading foreign universities already have positive examples of actual use of BSC in a broad sense. Thus, management at the University of California[2] was aimed at achieving the goals and objectives arising from the concept of its development (Balansed Scorecard 2018).

The validity of the application for management and evaluation of its quality at the University of California of the balanced scorecard that meets the entire concept of its development (BSC in a broad sense) is confirmed by the leading positions of its member universities in authoritative world rankings. For example, in 2018, (UCLA (2018)), in the Top 100 of the Shanghai World University Rankings (ARWU), the University of California is represented by six out of 10 universities: University of California, Berkeley — 4th place; University of California, Los Angeles — 11th place; University of California, San Diego — 15th place; University of California, San Francisco — 21 place; University of California, Santa Barbara — 46th place; University of California, Davis — 96 place (UCLA 2018).

In the Russian higher education, the concept of BSC in a broad sense is not yet used, at least in relation to the strategic management and development of universities.

That is why this article offers options for applying this concept in the narrow sense — when the BSC does not cover the whole concept of the university’s strategic development, but is formed to assess the management quality to achieve a certain indicator value, to solve a specific task and to achieve a specific goal of university development.

For an example of stage 1 of this algorithm, i.e. to solve the task of creating favorable conditions of hiring, work and academic contracts for university teachers, indicators can be used

A.1 "Guaranteed remuneration for the month of the professor’s work",
A.2 "Guaranteed duration of the academic contract with a professor",
A.3 "The value of the classroom professor's load",
A.4 "The level of social support of professors ("social package")".

Stage 3. *Ranking of the BSC indicators used to assess the quality of university management in solving the named university management task.* The priority of indicators of BSC can be expressed by the values of weights. The indicators presented at stage 2 can be ranked as follows: the weighting coefficient 0.4 corresponds to indicator E.1; weighting coefficient 0.3 – to indicator E.2; weighting coefficient 0.2 – to indicator E.3; a weighting coefficient 0.1 – to indicator E.4.

Stage 4. Construction scale of interval *values of indicators expressed by natural units, interval point (score) values of these indicators and verbal assessment of the university management quality.* This stage assumes, for each of the indicators used to describe the task of the university managing (in our example for indicators A.1, A.2, A.3 and A.4), the use of stage 1 of algorithm 1 (example 2). Its result will be a collection of tables (by the number of indicators used), similar to Table 2 (Stage 1 of Algorithm 2, Example 2).

Stage 5. *Determination of the indicators' actual scoring (point) values used to assess the quality of university management in solving the specific managerial problem under consideration.* For each of the balanced indicators used to describe the task of managing the university, according to the actual value of the indicator, based on the results of the scaling of stage 5 of this algorithm, tables similar to table 3 are built (Step 1 of Algorithm 2, example 2).

They are determined by the actual point (score) value of the corresponding indicator. Since all indicators are expressed in points, they become comparable and comparable.

The result of this stage can be a table of final actual point values of indicators used to assess the management quality on solving a specific management problem.
In the presented example, they are given in table 4.

Table 4: actual values of indicators used to calculate the assessment of the university management quality on solving the task of creating favorable conditions for hiring, work and academic contracts for professors at the Faculty of Economics of St. Petersburg State University (2017)

Indicators	Actual values in natural units	Actual values of indicators in point units (A_i^B)	The actual verbal quality assessment of the management on the relevant indicator
A.1 "Guaranteed remuneration for the month of the professor's work"[3]	53,094.96 rubles	2	bad
A.2 "Guaranteed duration of the academic contract with a professor"	2 years	2	bad
A.3 "The value of the classroom professor's load"	8 aud. hours per week per lesson year	6	satisfactory
A.4 "The level of social support of professors ("social package") ".	5	5	satisfactory

Stage 6. *Calculation of a quantitative assessment of the university management quality on the solving a specific management problem.* This assessment can be used not only independently, but also to assess the university management quality in order to achieve a certain strategic goal of the university development, which implies, among other things, a solution to this task.

По этой причине назовем ее как субиндекс качества управления вузом (Index of University Management Quality — IUMQ) по решению рассматриваемой задачи, в то время как оценку качества управления вузом по достижению стратегической цели, предполагающей решение этой задачи, назовем как интегральный индекс качества Integral Index of University Management Quality (IIUMQ).

For this reason, we call this assessment as a subindex of university management quality (Index of University Management Quality — IUMQ), while the assessment of university management quality

on achieving the strategic goal, which involves solving this problem, we call as Integral Index of University Management Quality (IIUMQ).

The subindex IUMQ is calculated taking into account, firstly, the chosen method of convolution of all indicators used to solve the problem, and, secondly, taking into account the results of ranking of these indicators (stage 3 of the algorithm). For example, with a linear convolution of the indicators selected at stage 2 of the algorithm, but taking into account their ranking (stage 3 of the algorithm), the subindex will be calculated by the formula:

IUMQ = 2/5*A.1P + 3/10*A.2P +1/5*A.3P + 1/10*A.4P =

= 2/5*2 + 3/10*2 +1/5*6 + 1/10*5 = 3.1

where A.1P, A.2P, A.3P, A.4P — point actual values of indicators A.1, A.2, A.3, A.4.

Stage 7. Construction scale of verbal and quantitative assessments of the university management quality on solving a specific management problem. It involves the construction of two interrelated scales which establish the correspondence between the values intervals of the subindex in points and the verbal assessment of the university management quality on solving a specific management problem (Table 5).

Table 5: an example of interrelated quality management scales for a higher education institution for solving a specific management problem

Scale of values of the verbal assessment of the university management quality on solving a specific management problem	Quality of management is "bad"	Quality management is "Satisfactory"	Quality management is "good"
The scale of the point interval values subindex[4]	From 0 to 5 [0; 5]	From more than 5 to 8 [5; 8]	From more than 8 to 10 [8; 10]

Stage 8. *Verbal assessment of the university management quality on solving a specific management problem.* First of all, the scoring interval of the subindex is determined, into which the real value of the subindex falls (tab. 6). It (the actual value of the subindex) is calculated on the basis of the actual values of the indicators of university activities. The found scoring interval indicates the corresponding value of the verbal assessment of the quality of university management in solving the set task. Tab. 6 contains an example of establishing correspondence between a point and a verbal assessment of the quality of university management when the point grade, for example, is 6.

Table 6: an example of the value determining of a verbal assessment on the university management quality on solving a specific management problem

Scale of values of the verbal assessment of the university management quality on solving a specific management problem	Quality of management is "bad"	Quality management is "Satisfactory"	Quality management is "good"
The scale of the point interval values subindex субиндекса	From 0 to 5 [0; 5]	From more than 5 to 8 [5; 8]	From more than 8 to 10. [8; 10]
The actual value of the subindex		6	

The result of applying the algorithm is as follows. A quantitative assessment of the management quality for solving the specific problem of creating favorable conditions for the recruitment, work and academic contracts of university professors, found on the basis of specific values of its performance indicators, is 6 points. It meets the satisfactory quality of university management in solving this specific problem.

Management Task 3 — Assessing the university management quality on achievement of a specific strategic goal

Stage 1. *The formulation of the strategic goal of the university management system.* The quality of university management to achieve a certain strategic goal is determined by the solution of a number of specific tasks. Therefore, its assessment can be carried out on the basis of the implementation of Algorithm 3, including the application of Algorithm 2 in relation to each of the tasks being solved, and the application of Algorithm 1 in relation to each of the indicators characterizing all the tasks.

The strategic goals of university development can be very different. For example, it may be such a goal as attracting and retaining the best professors and teachers at the university. Such a goal, for example, is provided by the Salmi model (Salmi J. (2009)) for the formation of world-class universities.

Stage 2. *Formulation of university management tasks that need to be solved to achieve the goal.* Achieving a specific goal involves solving a number of university management tasks, including, for example, such as creating favorable conditions on hiringt, work, and academic contracts for university professors at a university (stage 1 of Algorithm 2).

Stage 3. *Ranking of tasks solved by the university to achieve the strategic goal of the university development.* The priority of these tasks can be expressed by the values of weights assigned to the tasks, taking into account, for example, the opinions of experts.

Stage 4. *Formation of a Balansed Scorecard,* used to assess the quality of university management for solving each of the tasks related to the achievement of the strategic goal of the university development. It should be noted that the process of forming the BSC can be carried out separately for each of the tasks to be solved, and can occur on the basis of target selection of indicators for each of the tasks from the general initial base of indicators characterizing all the activities of the university.

Stage 5. *Calculation of subindex* — assessments of the university management quality on solving each of the tasks that affect the achievement of the strategic goal of the university development. It is carried out for each of the tasks and involves the use of algorithm 1, taking into account the number of indicators used to solve each of these tasks.

Stage 6. *Calculation of the Integral Index of University Management Quality (IIUMQ)* — of the quantitative assessment of the university management quality on achieving the strategic goal of the university development. Suggests

- using the values of subindex found in step 5 for each of the tasks being solved,
- selection of the subindex convolution method (for example, the linear method),
- accounting of the ranking tasks.

It is implemented like step 6 of algorithm 2.

Stage 7. *Construction scaling of the verbal and quantitative assessments of the university management quality on achieving the strategic goal.* It involves the construction of two interrelated scales that establish the correspondence between the values intervals of the integral index in points and the verbal assessment of the university management quality on achieving the goal (similar to stage 7 of Algorithm 2).

Stage 8. *Verbal assessment of the university management quality on achieving the strategic goal.* It is conducted similarly to the content of stage 8 of Algorithm 2.

The result of the algorithm application will be a quantitative assessment of the university management quality to achieve a specific strategic goal. Found on the basis of specific indicators of the university's activities, it is the justification of the value of the generated verbal assessment of the university management quality to achieve this strategic goal.

Conclusion

The descriptive (verbal) assessments of the university management quality used in practice (the quality of management is poor, satisfactory, etc.) require serious justification for choosing their specific values.

To increase the justification of the choice of certain values of the verbal assessment of the management quality, the article proposes a model for determining the specific values of verbal estimates.

It is based on the construction of quantitative assessments of the university management quality, which (quantitative assessments) are based on actual values of university performance indicators.

The article proposes interconnected algorithms for the joint construction of quantitative and verbal assessments that are used to assess the quality of university management on a separate indicator of its activity (algorithm 1), on solving a specific problem of its management system (algorithm 2) and for achieving a specific strategic goal of university development (algorithm 3).

Algorithm 1 is used in Algorithm 2 as many times as many indicators describe the solution to a particular problem. Algorithm 2 is used in algorithm 3 as many times as many tasks must be solved to achieve the goal of university development.

The model proposed by the authors to determine the specific values of the verbal assessment of the university management quality at different levels, additionally involves solving the following issues disclosed in this article: the use of different systems of balanced indicators of the university activity, due to the difference in the content of different tasks of university management; the construction of scales of interval values of indicators, sub-indices and integral index associated with a verbal assessment of the management quality; the conversion of the indicators values expressed in natural units of measure into their scoring (point) values; determination of scoring (point) and descriptive (verbal) assessments of the university management quality when solving of management problems at different levels.

The proposed interconnected algorithms for determining the values of descriptive (verbal) assessments of the university management quality are based on quantitative estimates calculated on the basis of actual values of university activity indicators.

This ensures the validity and accuracy of the values verbal assessment of the university management quality on solving problems of the university management at different levels.

Corporate Social Responsibility as an Element of SME Management in Poland

Malgorzata KURAS
Czestochowa University of Technology, Czestochowa, Poland
malgorzata.kuras@pcz.pl

Abstract

The aim of the article is to present the concept of corporate social responsibility as one of the aspects of management in the sector of small and medium-sized enterprises operating in Poland. In the first part of the study, the nature of corporate social responsibility was presented and its role in business management was indicated. Subsequently, the state of knowledge on social responsibility in small and medium-sized enterprises and practices undertaken in this respect in key areas of CSR were analysed. On this basis, an attempt was made to assess the degree of SME involvement in the implementation of corporate social responsibility activities.

Keywords: corporate social responsibility (CSR), good practices, management, small and medium-sized enterprises.

Introduction

Corporate social responsibility (CSR) has been drawing constant attention already for several decades, becoming an integral part of the world of business and science. The belief that concentrating solely on economic effects is insufficient for the operation and development is becoming more and more common among entrepreneurs. Therefore, enterprises become increasingly actively involved in activities for the broadly understood social interests and ecology.

The complexity and multidimensionality of the CSR concept implies the emergence of its numerous definitions. The first of these was created as early as in the 1950s. of the 20th century and defines corporate social responsibility as a commitment of the entrepreneur to conduct policy, make decisions and conduct activities that will be consistent with the goals and values of the society (Bowen, 1953). Currently, one of the more frequently cited definitions presents CSR as a concept according to which enterprises voluntarily consider social and environmental problems both in their activities and in their interactions with stakeholders (Green Paper, 2001; Zafar and Farooq, 2014). Therefore, the above-mentioned definitions indicate that the concept of CSR covers the economic, social and environmental aspect (Castejón and López, 2016; Banasiak, 2014). The first of them is associated with the development of the enterprise based on ethical management, use of honest business practices and offering socially desirable, safe and good quality products of its operation. The social aspect refers to issues related to job creation, development of the staff, raising the standard of living of employees, ensuring health protection and safety at work, undertaking initiatives for the local community, avoiding discrimination and respecting human rights. In turn, the environmental aspect is related to the impact that enterprises exert on the environment through their activities and the measures taken to protect it.

To summarise, it should be noted that CSR defines a new framework for enterprise management that includes operation compliant with corporate ethics, respect for legal norms and human rights, as well as respect for the needs of stakeholders (Castejón and López, 2016; Banasiak, 2014). Hence the recommendation included in the international ISO 26000 standard dedicated to social responsibility, according to which CSR should be an inseparable part of the enterprise basic strategy (ISO 26000).

The implementation of the CSR concept is usually associated with large enterprises, because it is recognised that in the past it was mainly addressed to corporations. The reason may also be the ease

of access to data in large enterprises and the possibility of allocating significant financial resources to this purpose (Rojek-Nowosielska, 2008; Leoński, 2015). However, more and more often the benefits of applying the principles of social responsibility start to be noticed by enterprises belonging to the small and medium-sized enterprises (SME) sector (Ma, 2012). These mainly include: competitive advantage, greater commitment of the staff, better customer understanding and satisfaction, better reputation (Turyakira, Venter and Smith, 2014; Castejón and López, 2016; Ratajczak and Stawicka, 2008). Therefore, these entities should be interested in undertaking activities in this area. The implementation of CSR principles in small and medium-sized enterprises is also of great importance for the development of modern societies. These entities, due to the dominant advantage in terms of both size and employment, as well as their contribution to the creation of GDP, have a huge impact on the development of socio-economic conditions in the country (Zafar and Farooq, 2014; Lachiewicz and Matejun, 2012).

The aim of the article is a presentation of the concept of corporate social responsibility as one of the aspects of management in the sector of small and medium-sized enterprises operating in Poland and an attempt to assess the implementation of activities in the area of CSR. The state of knowledge on social responsibility in small and medium-sized enterprises and activities undertaken in this respect in key areas of CSR were analysed.

Materials and Methods

For the purpose of the present paper, the desk research technique, which consists in analysing already available data and information, was applied. Research activities included the analysis of data on the involvement of SMEs in activities for social responsibility and barriers inhibiting these initiatives. The data for this analysis was taken from the report entitled *CSR w MSP. Pod Lupą*, and they relate to 500 surveyed entities operating in Poland included in the sector of small and medium-sized enterprises. The study covered 200 micro-, 200 small and 100 medium-sized enterprises in the following industries: services (120), trade (110), production (100), construction (60), transport (50), hotels and gastronomy (40) as well as agriculture and processing (20).

Subsequently, research activities included analysis of data on the implementation of the so-called good practices in the area of responsible business undertaken by SMEs in Poland. The research was conducted on the basis of data contained in the reports "Responsible Business in Poland. Good practices" developed by the Responsible Business Forum association. They contain examples which, according to the authors of the report, best present the involvement of enterprises in implementing the principles of responsible business in Poland. Good practices are presented in key CSR areas which include: organizational order, human rights, work practices, environment, fair operating practices, consumer issues as well as social involvement and local community development. Examples of good practices contained in the publication come from notifications made by enterprises and concern the years 2012-2018. As part of the analysis, a comparison of changes in the number of activities (good practices) undertaken by SMEs in all CSR areas in individual years of the study period with respect to other enterprises included in the reports was made.

In the present study, statistical data from the annual report of the Statistics Poland (GUS) – "Działalność przedsiębiorstw niefinansowych w 2018" were also used. This publication presents information on the structure and economic results of non-financial enterprises conducting business activity in Poland in 2018. The data for the report were obtained from the following statistical forms: SP – Annual enterprise survey and SP-3 – Report on the business activity of enterprises.

Results and Discussion

The SME sector in Poland constitutes the largest group of business entities.[1] Their share in the structure of enterprises in 2018 was as much as 99.8%. Among them, the overwhelming majority

[1] This concerns non-financial enterprises, which are juridical persons, entities without legal personality and natural persons conducting business activity classified according to PKD 2007

were micro-enterprises, which were 2 million and constitute 96.7% of the total number. On the other hand, the percentage of small and medium-sized enterprises amounted to 2.4% (less than 53 thousand entities) and 0.7% (over 15 thousand entities), respectively. Large enterprises had the smallest percentage in the total number of business entities – only 0.2%, which corresponds to over 3.5 thousand enterprises. In addition to the dominant number of SMEs, they also have a significant impact on the generation of Polish GDP, constituting almost 50% of its value. Also in this case, micro-enterprises constitute the group with the largest share in creating its value, which is approximately 30%. In addition, approximately 68% of all people employed in enterprises were employed in the SME sector, while 40.8% of them were employed in micro-enterprises (Działalność..., 2019, pp. 19 and 21). The quoted data clearly indicate that the small and medium-sized enterprises sector is extremely important for the functioning of the entire socio-economic system. Therefore, it is reasonable to analyse the involvement of these entities in the implementation of CSR initiatives.

The first area of the analysis undertaken in this study will concern the issue of knowledge of the concept and the nature of corporate social responsibility among enterprises and the degree of implementation of initiatives they have declared in this respect (Table 1).

Table 1: Knowledge and implementation of CSR activities in SMEs

By place of business

** Y- yes, N- no, DK/DS – I do not know, Difficult to say.*

The data presented in Table 1 show that irrespective of the size of the locality in which the surveyed entities operate, as well as the turnover achieved by them, a very large percentage among them declare that they do not know the concept of corporate social responsibility. This percentage is slightly lower in enterprises operating in large cities and generating higher turnover, however it remains at a high level of 60-70%. In case of enterprises operating in villages or achieving lower turnover, this percentage reaches almost 80%. Therefore, the level of indications regarding the second examined aspect, which is the implementation of activities related to social responsibility is surprising. This is because It turns out that after learning about the definition and idea of CSR, respondents declare that such initiatives are implemented in the surveyed entities. The percentage of enterprises declaring such activities is at a high level, usually over 70%. In the case of the locality

(Polish Classification of Activities) in the following sections: B-J, L-N, P-S, excluding cultural institutions having legal personality, institutions of higher education, independent public health care institutions, activities of membership organizations.

size criterion, the highest level is demonstrated by those entities which operate in villages. Such results suggest that in case of SMEs, social responsibility initiatives are undertaken intuitively, unplannedly and most likely are a response to the immediate needs of the local society, which confirms the above-quoted remarks regarding the dependence of these enterprises and the local environment. Certainly, even such spontaneous activities should be considered in the most positive terms. Nevertheless, consciously undertaken initiatives have a chance to be more effective, because they can be properly planned, and it is possible to choose the best tools or be able to prevent potential difficulties in their implementation.

In turn, Table 2 presents various forms of CSR initiatives undertaken in three areas of activity significant for SMEs, namely: in relations with employees, business partners and the social environment.

Table 2: Activities undertaken in the field of CSR in SMEs

Undertaken activities*		Percentage of enterprises undertaking activities
Area of relations with employees	Providing conditions for professional development, training opportunities	58
	Activities aimed at facilitating the reconciliation of professional and family roles	57
	Adaptation of the work environment, machines and technical devices to the needs of employees and minimising the negative impact of workplace factors on employees' health	55
	Activities aimed at reducing occupational stress	47
	Activities promoting an active lifestyle	32
	Introducing solutions to facilitate the functioning of disadvantaged groups in the workplace	28
	Supporting pro-diversity activities	27
	Corporate volunteering	22
	Activities to promote a healthy diet	19
	No activity is is undertaken in this area	6
	Other activities	1
	I do not know, difficult to say	2
Area of relations with business partners	Transparent regulations for the sale of products/services	63
	Monitoring customer satisfaction with the quality of service	56
	Transparent information about the enterprise activities (e.g. on the level of salaries in the enterprise, profit margins)	41
	Introducing solutions enabling and/or facilitating cooperation with representatives of disadvantaged groups	33
	Determining and verifying ethical and legal requirements posed to business partners	21
	I do not conduct activities in this area	11
	Organising aid/volunteer events addressed to customers (e.g. food collection among people making purchase)	10
	I do not know, difficult to say	5
Area of relations with the social environment	Actions for the local natural environment (e.g. participation in the Clean Up the World action, planting trees around the enterprise)	39
	I do not conduct activities in this area	35
	Financial support for local non-profit organizations (NGOs)	32
	Material support for local non-profit organizations (NGOs)	23

**more than one activity could be indicated.*

Based on the analysis of the data contained in Table 2, it should be stated that significant activity of the surveyed entities occurs in the area of relations with employees and business partners. Lack of activity in these areas was very low – 6% and 11%, respectively.

In case of relations with employees, in two cases the percentage of enterprises undertaking CSR initiatives reached the level of almost 60% in very important issues: on the one hand ensuring appropriate conditions for professional development, and on the other hand – maintaining work-life balance . A significant percentage of enterprises also introduces health protection activities both in the context of preparing an appropriate workplace (55%) and caring for the psychological and physical condition of employees (reducing occupational stress – 47%, promoting an active lifestyle – 32% and healthy diet – 19%).

In turn, the area of relations with business partners was dominated by initiatives related to the application of transparent sale regulations (63%), monitoring customer satisfaction (56%) and informing about the enterprise activities (41%), which undoubtedly has a positive impact on its perception by this group of stakeholders.

The responses in the area of environmental protection are slightly different. Despite the fact that SMEs are indicated to be close to the local environment, as many as 35% of respondents declared that they did not undertake any activity in this respect. Only 39% of the surveyed enterprises undertake activities for the benefit of the local natural environment, while they are more involved in material or financial support of local non-profit organizations.

When analysing the activities of SMEs in the area of corporate social responsibility, one cannot ignore the issue of limitations hindering or preventing their undertaking (Table 3).

Table 3: Barriers to undertaking CSR activities in SMEs

Details*	What discourages my enterprise from activity (%)	What discourages other enterprises from activity (%)
Lack of knowledge how to implement such activities	71	70

**more than one indication could be made.*

According to respondents, the biggest barriers limiting undertaking activity in the area of social responsibility is the lack of knowledge concerning the method and possibility of the implementation of these activities, and the lack of funds to finance them. The reason for the formation of the first of these limitations may be the lack of knowledge on the concept and idea of CSR, as shown in the previous comparison. This ignorance, according to the author, may also have an impact on the emergence of limitation related to the lack of interest among employees in CSR activities, as well as the lack of conviction of the management about the benefits of implementing the principles of social responsibility for the operation of the enterprise.

Another source of data for the analysis undertaken in this study are the reports entitled *"Responsible business in Poland. Good practices"*. This is one of the most comprehensive reports presenting the activities undertaken as part of corporate social responsibility by entities operating in Poland. In Table 4, the data on the number of implemented CSR activities (so-called good practices) in small and medium-sized enterprises in comparison to other entities undertaking such activities, were summarised.

Table 4: Practices performed as part of CSR in SMEs in comparison to other entities

Details		2012	2013	2014	2015	2016	2017	2018	Total
Number of performed practices	Practices performed in SMEs	28	66	43	48	51	62	94	392
	practices performed in all entities	262	403	420	454	461	639	826	3465
	Percentage of practices performed in SMEs (%)	10.7	16.4	10.2	10.6	11.1	9.7	11.4	11.3

Source: own work based on Raport: Odpowiedzialny biznes w Polsce. Dobre praktyki for the years 2012-2018.

Based on the data presented in Table 4, it results that the total number of practices performed in the study period (by all entities included in the report) was 3,465, out of which only 392 were in the SME sector, which represents only slightly more than 11% of their total number. In case of the total number of practices, their annual increase throughout the entire study period is clear. Unfortunately, this trend does not occur in case of SMEs. A significant increase in their activities took place in 2013 compared to the previous one (by 38 practices) and in 2018 compared to 2017 (by 32 practices). The year 2013 was also the most significant in terms of the percentage of activities undertaken by SMEs in their total number (16.4%). In the remaining years, this percentage was approximately 10-11%. Certainly, such results cannot be considered as fully satisfactory. Nevertheless, taking into account the previous remarks regarding the insignificant awareness of the very idea of CSR among entities of the SME sector, it should be considered positive that despite all, the trend in the number of undertaken activities is growing. In the last year of the study period, 94 practices were reported, which constitutes over three times more activities compared to 2012.

A more detailed analysis of good practices undertaken in the group of small and medium-sized enterprises will concern particular key areas of CSR. Such a summary is presented in Table 5.

Table 5: Practices performed in key CSR areas by SMEs in Poland in 2012-2018

Year / Areas of CSR	2012	2013	2014	2015	2016	2017	2018	Total
Organizational order	1	3	4	1	2	5	9	25
Human rights	-	1	1	4	2	2	1	11
Work practices	4	9	5	4	3	8	17	50
Environment	6	9	6	5	8	7	14	55
Fair operating practices	2	5	7	5	6	4	4	33
Consumer issues	1	1	-	-	4	7	2	15
Social involvement and local community development.	14	38	20	29	26	29	47	203
Total number of practices for SMEs	28	66	43	48	51	62	94	392

Source: own work based on Raport: Odpowiedzialny biznes w Polsce. Dobre praktyki for the years 2012-2018.

Analysis of the data contained in Table 5 in terms of the frequency of application of practices in individual CSR areas clearly indicates that the largest number of them was implemented in the area of social involvement and local community development. Over the study period, as many as 203 activities in this area were undertaken, which represents almost 52% of all performed activities. The majority of initiatives undertaken in this area occurs in each year of the study period, and their number in the last year is more than three times greater than at the beginning (it should be noted that this increase does not occur successively from year to year). This phenomenon should be interpreted as a definitely positive one, especially because this area is an integral part of sustainable development. In addition, such numerous initiatives in this area seem to confirm the postulate about the significant relationships between entities of the SME sector and the local community. The reason why numerous activities are being undertaken in this area may also be the fact that they are usually of an individual nature and do not involve significant financial outlays, which, as mentioned earlier, is one of the major limitations in undertaking CSR initiatives.

A relatively large number of activities was also performed in the area of environmental practices (55) and work practices (50), which represent 14% and 12.8%, respectively of all undertaken initiatives. In the first of these areas, the number of introduced practices has more than doubled over the last year, which indicates that small and medium-sized enterprises are becoming increasingly involved in pro-environmental activities. In case of work practices, the year 2018 was also the one, in which the most initiatives were undertaken. This means that for SMEs employee-related matters are becoming one of the priority issues implemented as part of social responsibility, which would coincide with the previously quoted declarations of the surveyed entities.

Next, in terms of the number of undertaken activities, is the area of fair operating practices (8.4% of the total number of activities undertaken during the study period). Unfortunately, in this case within the last two years there has been a decrease in the number of introduced practices, especially compared to 2014 and 2016. Practices in this area mainly concern relations with suppliers, market education or dialogue with stakeholders. Therefore, enterprises should be very interested in their implementation for correct relations with broadly understood stakeholders, which undoubtedly affects the positive perception of enterprises by these stakeholders.

The area related to organizational order is very important from the point of view of implementing CSR activities. Because of the fact that it is a system that allows making and implementing decisions in an enterprise, it is a very important factor enabling integration of social responsibility with the operations strategy of the entity. Therefore, it is considered to have a significant impact on other areas implemented within CSR. As it results from the data presented in the table, 25 practices were

performed in this area in the entire analysed period, which constitutes over 6% of all undertaken activities. Most of them were performed in the last two years of the study period. This is not a significant number, however, because of the complexity and difficulty of the involved issues, it can be considered satisfactory. All the more so because a similar percentage of practices in this area was recorded in the same period in all entities included in the reports used for the analysis (Kuraś, 2019).

However, the smallest number of activities was performed in the area of human rights and consumer issues. In the area of human rights, only 1-2 practices were performed in individual years. In the second case, in 2014-2015 no activities were conducted in that area. According to the author, such a phenomenon may be the result of ignorance of more detailed issues falling within the scope of those areas.

Unfortunately, based on the analysis of all activities in all areas of CSR, it is difficult to notice a successive increase in their number. Performed practices seem rather immediate measures, there is no regularity in their implementation. The situation looks best in the area of social involvement and development of the local community, where, in addition to the largest number of undertaken activities, their successive growth and regularity can be observed. The fact that in the area of organizational order in the last two years of the study period there was a significant growth dynamics of performed activities is optimistic. This is all the more important as this area is crucial for the conscious management of activities in the area of social responsibility.

Conclusion

The considerations made in the article allow to draw the following conclusions:

1. In the SME sector, a very low level of knowledge of the concept and idea of corporate social responsibility is observed, while in enterprises operating in towns/cities it is slightly higher than in those operating in villages.

2. After learning about the definition and assumptions of CSR, a high percentage of surveyed enterprises declares the implementation of activities in this respect, but it is higher in case of enterprises operating in villages than those operating in towns/cities.

3. Because of the lack of knowledge about the concept of CSR, activities in this area are undertaken intuitively and accidentally, without a clear strategy in this respect.

4. The biggest barriers limiting undertaking activity in the area of social responsibility is the lack of knowledge concerning the method and possibility of the implementation of these activities, and the lack of funds to finance them.

5. Practices implemented as part of CSR by entities of the SME sector constitute a small percentage of activities undertaken by all enterprises, which is at the level of 10-11%.

6. Among the entities of the SME sector there is a slow increase in the number of so-called good practices in the field of social responsibility. Admittedly, the number of practices in individual areas does not increase successively from year to year and is irregular, however, it proves the increasing involvement of SMEs in the implementation of social responsibility initiatives.

7. The largest number of activities was undertaken in the area of “Social involvement and local community development”. The dominance of practices in this area occurred in each year of the examined period. According to the author, the intensity of activities in this area is the result of, on the one hand, strong relationships between these entities and the local community, on the other, the fact that activities undertaken in this area usually do not require high financial outlays.

8. Numerous practices were also undertaken in the areas of: "Environment" and "Work practices". According to the declarations of enterprises in the area of relations with employees, the activities concerned ensuring adequate development conditions and maintaining work-life balance.

Although a high percentage of enterprises from the SME sector declares that they undertake activities in the sphere of CSR, the analysis of the number of practices implemented by these entities in the study period indicates that they are not very numerous. According to the author, this is because of the fact that the practices included in the reports "Responsible business in Poland. Good practices" are reported by enterprises themselves, and because the majority of them implement the practices unconsciously, they are simply not included in the mentioned reports. However, it should be considered positive that the number of implemented practices is slowly increasing in most areas, which can be considered a slow increase in the involvement of SME sector enterprises in CSR activities.

It is very important to raise the level of knowledge about corporate social responsibility among SMEs, because it will allow for activities in this area in a non-accidental and orderly manner. It will increase the efficiency and number of undertaken activities and will enable appropriate tools to be prepared and optimal methods for their implementation to be used. Therefore, it will allow for better management of activities in the area of social responsibility in this group of enterprises.

Factors Influencing Employment in An AI Era

Simona NICOLAE

Politehnica University of Bucharest, Romania
nsim2005@yahoo.com

Abstract

Artificial intelligence (AI) is currently outsourcing the skills of the human resources to an extent to which it can transform them from an asset to an outsider of the labor market. Nowadays, more than ever, the human needs are increasingly met by using technology and artificial intelligence, polarizing the labor force in terms of its ability to adapt to change and progress. The paper aims to capture the perception of students from the final years of three master programs from Politehnica University of Bucharest about the impact of technology and artificial intelligence on jobs in order to demonstrate that higher education supports a proactive attitude in front of changes generates by AI on jobs. The methodology includes a quantitative analysis having a survey as a method of data collection based on a self-administered questionnaire comprising 12 factual and opinion questions from which 7 are closed-ended, 3 mixed and 2 open-ended. The survey is based on quota sampling, the sample size selected having 98 units, respectively all the students enrolled in second year of the three master's programs mentioned. Despite the fact that absolutely all participants are graduates of higher education, ISCED level 6, only a few (less than 1%) considered education as an important factor in adapting to the changes imposed by AI on their work.

Keywords: Employment, Human Resource, Labor Force, Technology, Artificial Intelligence (AI).

Introduction

The current stage of economic development is accompanied by the massive introduction of information and communication technologies in all spheres of human activity. Today the world is facing a new fourth industrial revolution, which is marked by the development of the digital economy based on the most advanced innovative technologies (Bataev et al, 2019)

Living and working in an environment marked by the impact of technology and Artificial Intelligence create the premises of such developments that can polarize the labor force in terms of adapting to change and progress. As a consequence of this situation, the artificial intelligence can play many roles varying from a device to a substitute for human work and having the most diverse influences on future developments of the human resources.

The jobs profile and the skills they involve often changes at a rate that goes beyond the possibilities of reaction of the labor force, adding both advantages and pressure to its working style. For an accountant, for example, studies have shown that it is necessary to have IT skills (Bigioi, 2017). The coexistence of generations on the labor market in general and within a company in particular makes the impact of technical progress very divers, facilitating the transformation of the labor force into human capital for the generation Y and generating fears, challenges and pressure for an important part of the generation X.

Working together in a friendly environment for one part of the human resources and challenging for the other part, can generate a wide range of phenomena at the labor force level, from satisfaction to burnout.

Besides, according to Lie and Mihăiță (2015), the main issue, among others, for burnout at a general level, taking into consideration employees from different fields, are long working hours and

workload. The use of artificial intelligence supports the efficiency of the work but, depending on the attitudes and the skills of the human resources, can lead to work overload.

People from all generations increasingly recognize that rapid technological change, while holding out the promise of valuable opportunities, also creates unforeseen impacts that can dramatically disrupt their careers and lead to massive changes in the composition of the workforce and the level of employment. Trends like these make workers anxious as many worries about their future livelihoods (Montealegre and Cascio, 2019). Excessive trust in new technologies can lead to large-scale or new forms of accidents. Global business networks will cause destruction of workers' biorhythms, some cancers, overwork, and task complexity. The social disconnection because of an independent work will be a risk for worker's mental health (Min et al, 2019). Attitude towards technical progress in general and artificial intelligence in particular, may in itself form a basis for a proactive or reactive behavior and can influence the adaptation to new technologies.

In this respect, we consider important to present the perception of human resources, who are at the end of a formal cycle of professional training, on the impact of artificial intelligence on human work. In this way we want to highlight the reactive or proactive behavior of the human resource towards AI but also the extent to which this is seen as a mean of progress or a source of fear for highly qualified labor resources.

The study certainly has its limits given by the small sample based only on qualified human resources and leaves the possibility of expanding it to other environments or areas. Education is an important factor in sustaining the adaptability of human resource in front of all sorts of challenges, especially in front of this generate by AI. The author considers the results of the study to be of importance for adapting the way in which it is build the attitude of the UPB graduates in front of the impact of AI on labor market.

Literature Review

Industries are changing and the number of robots delivered to the businesses across the world has risen from 100000 per year to 300000 in 2016. Adoption of industrial robots will lead on one hand to labor productivity growth, creation of new types of jobs, rising wages and making some of the jobs more pleasant to do. On the other hand, robots will make some jobs less and less important and some jobs will be expendable altogether (Chinoracky, and Corejova, 2019).

The rise of AI calls for a new human-machine symbiosis, which presents a shifting division of work between machines and humans. (...) In line with the vision of machine-humans symbiosis it is more meaningful to view AI as a tool of augmentation (extending human capabilities) rather than automation (replacing them) (Jarrahi, 2018). The digital revolution has provided significant productivity improvements for the back-office operations of firms and allowed consumers to buy goods and services online without having to physically go to a store or office. In the process it has eliminated a large number of repetitive mental tasks performed by people and shifted employment patterns (Makridakis, 2017).

In an era of rapid technological change there is widespread anxiety concerning the potential impacts of digital technologies across a vast range of industries. Policy responses to this changing employment landscape have tended to champion the necessity for growing ‘digital skills’ (Richardsona and Bissell, 2019). The trajectory towards increasing applications using AI has the potential to change many aspects of human lives and impacting society as a whole. The way forward is not clear and the potential roadmap is undefined. There are numerous benefits that could accrue from AI but there are also significant risks that swathes of society may be disenfranchised form the implementation of the technology. Decisions made within the next few years on the forward path for AI are likely to have an impact on all our lives and the lives of future generations (Dwivedi et al, (2019).

Methodology

The paper is based on a survey as a quantitative method of data collection and research using a self-administered questionnaire comprising 12 factual and opinion questions, 7, closed-ended, 3 mixed and 2 open-ended. The survey was attended by the students from the second year of three master programs from the Politehnica University of Bucharest: Quality of industrial products and services, Human Resources Engineering in industrial organizations and Economic Engineering in industrial activities. These programs are part of the nine master programs organized within Faculty of Entrepreneurship, Business Engineering and Management (FAIMA) from Politehnica University of Bucharest.

The sample size selected has 98 units, respectively all the students enrolled in second year of the three master's programs mentioned above. The stratification of the reference population was carried out on homogeneous layers, choosing only students of second year, the final year of long-term studies. Out of 98 students only 66 answered the questionnaire.

The hypothesis our study departs from is that the higher-educated labor resource, employed mainly in services, does not perceive AI as a threat to the workplace but as an opportunity for progress. The study is limited by the small sample, which, even if it is relevant for the profile of students enrolled in the Master's courses of FAIMA, does not provide valid results for the entire population with higher education.

The perception of students from Politehnica University of Bucharest upon the impact of artificial intelligence on jobs.

According to Verma and Sharma (2019), as world is approaching towards fourth industrial revolution one can't deny that automation is increasing at a very faster rate thereby creating an impact on labor markets in various countries. Some researchers have pointed out the positive impacts while others are of negative view point.

The purpose of this paper is to present the perception of students from the final years of three master programs from the Politehnica University of Bucharest on the impact of artificial intelligence on their jobs, both in terms of its content and its security. The study involved 66 students belonging predominantly to generation Y, 51 of them being between 24 and 39 years old.

Fig. 1: Number of participating students, depending on age

Out of a total of 66 students, 61 are employed and 45 have indefinite employment contracts. Jobs are mostly in the field of services and involve higher education training. Most of them works in areas such as logistics, accounting, banks, human resources, IT, sales.

Fig. 2: Employment status of the participants

In the analysis of students' perception of the impact of artificial intelligence on the labor market we considered to be of importance to highlight the type of activities that predominate in the participants' workplace. In this regard, students who have a job could choose between two major types of activities, namely, routine activities that involve physical and/or intellectual effort and creativity-based activities which may involve one, two or three types of skills: social skills communication skills and intuitive skills.

Among the CEE countries, a decline in routine cognitive jobs (…) occurred only in Hungary and Slovenia; while in Romania, Latvia, Lithuania, and Poland the average intensity of routine cognitive tasks increased sharply. These patterns are not a cause for concern, as they have largely been driven by sectoral shifts that are typical of economies in the process of converging with the most developed economies (Keister and Lewandowski, 2016). Most labor economists studying automation agree that the jobs most at risk consist of performing tasks that are routine. If the routine tasks are cognitive, they are easier to automate because programming raw data is simpler than programming movement (Holden, 2017). The question concerned two-time horizons, present and future and the answers are highlighted in figure 3.

Figure 3: The prevailing type of skills

As can be seen from the figure above, about 30% of the students want to give up the routine activities that involve intellectual effort, opting, especially in the future, for activities that involve social and communication skills.

These choices also support the logic of their answers to the following question: to what extent they fear the impact of technology on their jobs and their employment opportunities. On a scale from 1 to

10 where 1 means that there is no fear of AI and 10 means technophobia, more than half of the respondents were in the range 1-4.

Figure 4: Fear of human resources towards technology / AI

Moreover, 78% of the respondents use or have used in proportion of over 50% the AI at work, an important percentage of them, about 33%, using AI in proportion of over 80%. This shows that they have the opportunity to know directly how and if their professional activity are affected or not.

Figure 5: Use of AI in the workplace/current profession

Despite the massive use of artificial intelligence in the workplace respondents are not afraid of their replacement by AI. More than 50% consider that their work can be replaced in a proportion of 20% - 50%, 31% of the respondents considering that less than 20% or even none of the work they are currently doing can be replaced by Artificial Intelligence. The main argument the majority uses is supported by their answers to one of the open questions, respectively: what do you consider to be your main asset compared to the AI in the work you do (name only one element)? The strengths mentioned by them are very much found in the sphere of emotional communication or intuitive skills that are required by activities that, according to the research in the field, are not in danger of complete automation. Some of these strengths are: creativity (mentioned by 20% of respondents) passion, intuition, empathy, communication, the existence of feelings, dexterity etc.

In fact, about the same mentions were made when asked to answer the question: what do you think is the main weapon for mitigating the negative effects of the impact of AI on jobs? It was surprising that the education or training were not mentioned as a main weapons in counteracting the negative effects the AI has on jobs. According to Leustean et al (2016), studies have a very strong effect on what concerns personal values and beliefs and a strong effect on the economic level. Despite of the

fact that all respondents has higher education studies, only few of them consider education as a tool of harmonize the human resource-AI relation.

Figure 6: Impact of AI on work

As you can see from the figure above, very interesting are their answers to questions related to the impact of AI on their work over a time horizon of 5 and 10 years respectively. If for the time horizon of 5 years their perception is approximately the same as for the present time, when we refer to 10 years the situation changes. Those who believe that AI will affect the content of work and job security in a proportion of over 50% will increase from 21% for the next 5 years to 57% for the next 10 years. Also, those who believe that the impact on work in the next 10 years will be more than 70% increase from 1.5% in the next 5 years to 12.5% in the next 10 years.

Despite the large number of those who believe that AI will have a significant impact on work about 80% of respondents believe that AI means progress, 18% mean competition and less than 2% see AI as a threat.

Fig. 7: Impact of AI on future of work

Results

Out of a total of 98 students enrolled in three master's programs from Politehnica University of Bucharest, 66 responded to the self-administered questionnaire the research is based on. The participants in the survey are persons predominantly of generation Y (77%), with a level of education ISCED 6. 92% of them have jobs, of which 73% have work contracts for an indefinite period.

For about a third of the respondents more than 80% of their work involve artificial intelligence, only 5% considering that this is not necessary in their jobs. Also, 80% of respondents consider artificial intelligence as a factor of progress, while only 2% perceive it as a threat. Despite the fact that absolutely all participants in the survey are graduates of higher education, ISCED level 6, only a few

(less than 1%) considered education as an important factor in adapting to the changes imposed by AI on their work.

Conclusion

If five years ago we consider that, in economic terms, the people quality could make the difference between two competing companies (Ionescu, 2014), nowadays the impact of AI forces us to change the angle from which we look at economic and social efficiency.

There is evidence that digital technology and automation have already significantly affected work over and above the role of trade liberalization. This evidence shows that the use of digital technology in work is linked with increasing polarization of work between jobs mainly performed by workers with low levels of formal education ('low-educated') and jobs performed by high-educated workers (Frontier Economics, 2018). Artificial intelligence has already made a real revolution in many spheres of the economy. It is widely known that AI beat man in chess, go and many other games. Last year, the robot reached the final stage of the literary contest in Japan (population 130 million people). AI is already making films, writing music, painting and much more (Pavlov et al, 2019).

In these circumstances it is important to analyze the perception of human resources on the impact of digital technology and AI on the content of work and on the job security in order to meet the real training needs of students and to build proactive attitudes in the university environment. It is also necessary to increase the level of awareness about the role of education in rising the adaptability of the human resources since in Romania these calls for sources characterized by an inflation of the fragmented information, often incomplete and of poor quality extracted from the internet, social media, mass media, friends and other sources (Leustean et al, 2016).

The study revealed that the sampled persons approach the AI as a factor of progress and not as an anxiety-generating factor. The authors consider that the result of the study is the consequence both of higher education of the survey participants and of the fact that the majority belongs to generation Y, a generation by excellence formed together with AI. A proactive attitude towards the changes produced by AI in the labor market can only be built by increasing awareness of the role of education in this regard. Even if for the most participants in the study the AI means progress, the small share of those who are aware of the role of education in this relationship shows that their attitude is a positive one, of acceptance and trust, but not a proactive one, of pre-empting future developments that could affect their mode of living and working. The limitations of the study can be solved through future researches by expanding the types of labor resources included in the sample.

Analysis of the EU Security Architecture Confronting Terrorism and Bioterrorism in the COVID 19 Era

Mihail PADURARU

University of Economic Studies, Bucharest, Romania
mihail.paduraru@ccirom-tkm.ro

Abstract

Although the civilized world finds it difficult to accept, the terrorism phenomenon has become a reality with global implications, which is hard to prevent and manage. Many historical events were characterized by the use, or threat to use, of toxic substances and pathogens, presenting evidence which clearly demonstrates that certain individuals and terrorist groups have recently conducted research on biological agents or toxins, or tried to obtain these substances. Biological agents (such as bacteria, viruses and fungi) are easier to manipulate and transport than nuclear or conventional weapons and harder to detect as the symptoms of exposure can last from several hours to several days before occurring. A terrorist possessing chemical or radiological weapons could kill hundreds or even thousands of people. With a biological arsenal, he could kill hundreds of thousands of people.
In recent years, the European Union public debates and press agencies started raising questions on the implications of migration crisis, political extremism, terrorism and other forms of hybrid threats on the global supply chains. These debates demand from the European authorities countermeasures to prevent the tragedies and the loss of human life. The police, the military, border services and other security agencies of European Union countries seek to strengthen cooperation in order to address the present challenges and to deter immediate risks. At the same time, the terrorist phenomenon affects not only the internal order of a state, but also its relations with other states and, in order to be prepared, we must have a clearer understanding of the challenges facing the European Union and its security architecture.

Keywords*:* Security, Bioterrorism, Intelligence, European Union.

Introduction

The technological advances and rapid societal transformations characteristic of the 21st Century also meant that globalization has come to encompass most geographical areas and alter most human cultures. As such, for most state-players one of the main priorities became finding new solutions for ensuring national security within the new international framework. Moreover, another consequence was that states were practically compelled to join regional or international organizations, as this was the best option to meet the common objective of defending both global and national security.

Etymologically, the concept of security comes from the latin securitas, which means *"without care, serenity, peace of mind."* Traditionally, security has been associated with a state's military factor.

However, the concept underwent changes with a series of "paradigm" shifts since the end of the previous century. In terms of security, we encounter a shift from conventional threats - state actors, to asymmetric threats - non-state actors or state-sponsored irregular or hybrid aggressions.

Asymmetric threats differentiate from the classical approach, as the battlefield is transferred within the civil society. What does that mean for the individual?

In short, the emergence of a whole new set of threats to personal security, through the possible employment of biologic, chemical, cyber weapons created to alter normal life or to fuel a series of informational aggressions designed to erode the link between the citizen and his country by stimulating various feelings of mistrust in public authorities.

Thus, nowadays security has several components: political, economic, social, cultural, ecological and the individual component.

All these elements must be carefully considered when paying attention to security dimension.

EU in Counter-Terrorism Age

Terrorism is one of the most debated and controversial issues of the last decades, the most visible and most worrying manifestation of the hybrid threats to the security environment, an unconventional combat tactic threatening global peace.

International terrorism is the main threat to the states of the world, human society and democracy, both for the international structure and social cohesion frame, and for the national security of the states.
Thus, terrorism has two purposes, the first is to make life unbearable for the average citizen, and the second to create a destructive climate.

Under these conditions, terrorism can be considered one of the most serious threats to the European security, the European values and last but not least to the rights and freedoms of the citizens.

The United States Department of Defense defines terrorism in terms of identifiable elements as the calculated use of unlawful violence or threat of unlawful violence, to inculcate fear and to coerce, or to intimidate governments or societies in the pursuit of goals that are generally political, religious, or ideological (Department of Defence, 2010).

Following the terrorist attacks on the US (9/11) and some EU countries (Madrid, London, Paris, Brussels), it has become clear that the fight against international terrorism will not be short and that it will mobilize huge resources and capabilities especially after COVID-19 crisis, which may represent a previous frame of reference for future acts of bioterrorism.

The risk of terrorist attacks produced by means of biological agents is a major concern, keeping the attention of law enforcement services, governments and health authorities worldwide.

Bioterrorism means the deliberate release of biological agent or toxins in order to harm humans, animals or plants or to cause death, with the aim of intimidating a government or civilian population or compelling them to meet certain political or social objectives.

Threat of Bioterrorism in the E.U

Current terrorist techniques include suicide attacks, bomb use, narcoterrorism, bioterrorism, cyber-terrorism and even nuclear terrorism. Some terrorism analysts list latent terrorism among the modern terrorist techniques.

This new concept aims at replacing the actual use of terrorist means with terrorist threats at using them in order to achieve the goals targeted and aimed.

The same category of risk and serious threat to international peace, security and to fundamental human rights includes the proliferation of mass destruction weapons.

Associating it with terrorism, meaning the use of chemical, biological, radiological and nuclear weapons in terrorist actions (CBRN terrorism), it aggravates the threat facing humanity.

At any time there, exist the possibility that some terrorist groups will use weapons of mass destruction, not only as asymmetric responses, but also as extreme ways of implementing or imposing fundamentalist religious precepts, as a reaction to globalization, as a way of “punishing” populations, ethnicities, etc.

Thus, the proliferation of weapons of mass destruction represents probably the biggest threat to EU security.

Also, new developments in biological sciences may lead to an increased output of biological weapons in the coming years, chemical and radiological attacks are a very serious issue for Europe.

Biological agents (such as bacteria, viruses and fungi) are more easily manipulated and transported than nuclear or conventional weapons.

Moreover, they are difficult to detect, and symptoms of exposure can last from several hours to several days before the disease manifesting.

For many law enforcement agencies, the recent terrorist pattern shows an increased interest in using weapons of mass destruction and biological weapons.

It is relatively easy to purchase these type of agents, biological weapons representing an effective way to produce a generalized sense of fear among people.

Terrorist groups may use unconventional means such as biological weapons or materials which have the potential to infect thousands of people, contaminate soil, buildings and means of transport, destroy agriculture and infect animal populations and, ultimately, to affect food and feed at any stage of the food chain.

From a statistical point of view, the probability of a "bioterrorist" attack is very low, but with devastating consequences.

According to SARS-CoV-2 characteristics, this virus can be rated as lethal pathogen agent (or a natural outbreak of a disease) which was deliberate introduced in the EU or imported from a third country, and simultaneously affected severely, several member states like Italy, Spain, France and not only.

Also, the spread across EU borders had a considerable economic and social impact, especially as health services were overwhelmed with the number of patients requiring, laboratory tests, treatment and specialized medical equipment.

The use of biological agents and toxins as weapons is mainly characterized by the awareness of the effects and the advantage using the agent or toxin over potential enemies, human or animal.

The epidemiological evolution of SARS-CoV-2 is similar to a "mass" disease targeting the general population, raising questions on the probability of similar viruses being potentially spread on purpose in the future.

The characteristics of these types of agents (specific for weapons of mass destruction) are:

- Simple production technique, available to any nation with a pharmaceutical industry;
- Industrial production methods are to be found in making yoghurt, beer, even antibiotics or vaccines;
- Most equipment used in their production is "dual use" and is sold on the open market;
- The existence of previous pathogen crops, kept in certain specific facilities/warehouses;
- The ease of reaching the target, using even the weather;
- Increased efficiency: small quantities, with maximum effect;
- Large scale of contamination.

Biological agents are micro-organisms, including genetically modified micro-organisms, cell cultures and human endoparasites, which are likely to cause infection, allergy or poisoning.

The biological weapon, called *the nuclear bomb of the poor* or *the dirty bomb*, is an invisible weapon. It can be transported without being detected, even across borders, either in "culture" – to obtain the desired amount – either in quantities sufficient to commit a disaster.

Microorganisms can be released without noise and without causing immediate effects. The disease cannot be defined until the symptoms of the infection and the causative agent are known. If this one may easily spread from one person to another, such as smallpox, the number of victims can easily reach tens of thousands of cases.

According to their intentions, the terrorists will choose a biological agent, according to several characteristics:

- Easy acquisition/production;
- Easy use as a weapon;
- Easy transmission;
- Resistance to environmental factors;
- Terrorists' intention to kill or to cause a temporary disability;
- The countagiousness of the agent;
- The potential risk to the terrorists themselves.

The acquisition of biological agents is possible as a result of: a government's support; the diversion of substances during their transport; from natural sources; theft from universities, microbiology laboratories, veterinary laboratories and industrial companies.

From a technical point of view, producing various substances for terrorist purposes are not difficult to achieve.

A second-year or a third-year student in medicine or microbiology should have enough laboratory experience to be able to produce a biological agent, without exposing himself/herself to too many dangers.

As mentioned in the doctrine, bioterrorism agents could be utilized in various ways:

- Aerosols – spread either through conditioners or by an airplane or helicopter, or by a bomb scattering. Anthrax, tularemia, Q fever, typhus, smallpox and plague are likely to be spread by the respiratory route. Also, sarin gas and botulinum toxin could be spread in the same way.
- Water and food - it contains toxins, particularly ricin toxin and botulinum toxin, which mixed in large containers for beverage supplies could produce catastrophic consequences. It also the case of a large number of food bacteria: Escherichia coli and all food poisoning agents.
- Dermal route may be the source of infection for anthrax, tularaemia and smallpox.

Specialized publications reference over twenty cases of terrorist threats or attacks put into practice by the use of biological agents: cases of threats, apparently without consequences, whose authors said they could use such agents, but without providing evidence that they have indeed purchased them; cases when serious steps have been taken to purchase biological agents; cases in which certain quantities of agents were found on terrorists or persons suspected of having committed terrorist attacks.

They indicate a high number of threats (even actual attacks) on food contamination, but in most cases the reason was only financial and not political, and the authors were not considered terrorists.
Using ricin substance in several assassinations or assassination attempts is a worrying example of biological terrorism, as these attacks were attributed to intelligence services in some countries.

Bioterrorism risk raises many questions to law enforcement authorities, especially for those responsible to ensure security after the COVID 19 crisis will pass.

Terrorists have the ability to choose performers that are easy to manipulate in order to be sent to some certain locations to pose a threat to one person or to thousands of people.

This form of terror may have effects involving several jurisdictions or countries and it requires international cooperation at the level of sharing information and investigation.

The coronavirus crisis has highlighted the need to identify ways to strengthen the response capacity of E.U. bodies in charge of emergency situations when deal with such threats.

The threat that a terrorist group may acquire chemical, biological, radiological or nuclear materials (CBRN) requires governments and international organizations to adopt regulations and programs with significant impact, in order to protect populations against risks associated with this type of threats.

According to the general opinion during COVID-19 crisis, future risks of bioterrorism are so high which requires coordinated action in preventing, detecting and counter it as a top priority.

Most experts share the opinion that in order to "succeed" in producing such materials and use them as a weapon, terrorists have to overcome considerable difficulties. Therefore, the probability that such attacks occurring is small, but it is clear that no public authority can afford to ignore this threat after coronavirus crisis.

In order to avoid another crisis, ensuring security in the face of such threats must be a top priority on the list of E.U. leaders, given their negative consequences generated over the human, social, economic, financial and other segments of daily life.

There is also a general consensus among experts on the need to carefully consider the likelihood of a small-scale attack.

As the SARS-CoV-2 pathogen has already shown, the psychological, medical and economic effects generated by this virus had a significant impact on the population, and the use of a similar agent for terrorist purposes can be disastrous.

European Union Security Response

With regard to the terrorist threat, The European Union has developed a legal framework and a number of specialized bodies with the purpose to prevent and counter terrorism.

So considerable progress has been made on cooperation and exchange of intelligence between EU member states, but the terrorist attacks in Paris (7 January and 13 November 2015) indicated that the measures taken, were insufficient or even ineffective.

In addition to the issue of terrorism, the EU recently confronted and still faces a number of other crises, starting with the economic crisis of 2008, the crisis in Ukraine 2014 (including the annexation of Crimea by the Russian Federation), the crisis in Greece, the crisis of the refugees, Brexit and newly 2020 the CoVID-19 pandemic crisis.

All aspects stated above, indicates a number of important questions that need to be asked about the role and capacity of the EU to overcome these situations.
Moreover in the light of the economic and health crisis generated by SARS-CoV-2, there are voices questioning the EU's slow response and the lack of consensus among its members for a common approach.

Naturally, close cooperation between law enforcement agencies and institutions from the member states with competence tackling this type of problem is more than necessary.

With this aim, the EU encourages states to cooperate through its security institutions in order to ensure a coherent and cohesive response to future crises.

Security Institutions

Europol (The European Law Enforcement Agency), based in The Hague, is an important player in strengthening Europe's security for the benefit of its citizens. Europol manifests its authority in the fight against terrorism and organized crime by owning and managing databases and by initiating formats for cooperation between security agencies in the Member States.

On the issue of terrorism, Europol supports member states through analytical products such as reports, threat assessments and missing links for ongoing operations, exchanges of information and access to Europol databases, data exchange systems and through expertise of the Europol mobile office, which provides on-site assistance. Moreover, following the January 2015 attacks in Paris, with the support of the European Security Strategy, was created the ***European Counterterrorism Center***, a security priority designed to improve the Europol's counter-terrorism capabilities.

Thus, Europol has developed its expertise on terrorism issues and should be taken a step further bringing together its counter-terrorism capabilities, pooling resources and making the most of it.

Cooperation in Intelligence

Further in this presentation it should be emphasized that an important element of recruitment and radicalization in Europe is the terrorist and extremist activity on social media, and it was announced that a Europol-led intelligence police team across Europe is trying to detect and destroy this presence. A Special Function on EU Counter-Terrorism Policy is held by the **Counter-Terrorism Coordinator** (CTC). The CTC regularly reports to the European Council on, how existing counter-terrorism instruments, are being operating and implemented at EU level .

It closely monitors how EU Counter-Terrorism Strategy is implemented and presents specific policy recommendations based on security threats and special reports drawn up by INTCEN and Europol.

As well, another important player in EU security policy is the High Representative for Foreign Affairs and Security Policy (HRVP).

HRVP has several functions at the level of the EU institutions, but its main task is to coordinate and implement the EU's foreign and security policy.

In carrying out its work, HRVP is supported by the European External Action Service (EEAS), de facto the EU diplomatic service.

From a European security perspective, the EEAS coordinates the work of the EU Intelligence Analysis Center (INTCEN) and the EU Military Staff –(EUMS).

The EU Intelligence Analysis Center (INTCEN) is the only point of contact for civilian intelligence services in Member States across the EU institutions.

The Center has no operational capacity to collect information, however is based on the "products" received from the agencies from the Member States.

Within the The European Union Military Staff (EUMS) there is an Intelligence Directorate (IntDir), consisting of approximately forty officials from the member states' intelligence services, which also have the role to ensure the intelligence channel.

The role of IntDir is to provide early warning assessments and situation warnings, in order support the planning of the military operations. Thus, intelligence analysis became the response foundation for the crisis situations.

Moreover, in order to avoid discrepancies between civilian and military analytical products, but also to have an EU-wide cooperation mechanism, in 2007 was created the *Single Intelligence Analysis Capacity (SIAC).*

SIAC is a virtual format coordinated by the executives of INTCEN and EUMS IntDir, in order to synchronize the held known intelligence. So, within SIAC, both civilian and military contributions are used to produce all-source intelligence assessments.

For comprehensive documentation SIAC uses complex and diversified sources of information which include:

- The EU Satellite Center (SatCen), the national diplomatic missions and the EU in third countries;
- The EU civilian and military missions under the Common Security and Defense Policy (CSDP);
- As well as NATO and the OSCE as external partners of the EU.

Thus, in order to counter act the terrorist threats, multilateral cooperation between the competent authorities of the Member States is a absolutely necessary and mandatory solution.

Also, there are discussions on the extension of Europol's mandate which will be a significant progres in the law enforcement field.

Additionally, in the last years, the activity carried out by the Counter Terrorist Group (CTG),(a product of the Berne Club, which includes the twenty seven EU Member States, Switzerland and Norway), has brought a substantial contribution to the fight against terrorism.

The CTG has been described as a "parallel" intelligence-sharing network, where the intelligence agencies of the various member states participate on equal footing.

The Heads of the Member States intelligence services are the governing board of the CTG, and their meetings take place twice a year and generates thematic debates. Heads of Units meet four times a year, or more if needed to implement programs. Moreover, the UK does not plan to leave the CTG after Brexit, according to the head of MI5, who cited the importance of intelligence-sharing in the current climate.

It is necessary to mention that the establishmentof the SITCEN Anti-Terrorism Cell in fact meant its transfer from the CTG.

Thus, INTCEN, in collaboration with the CTG, draws up half-yearly assessments of the terrorist threat to Europe, a benchmark for analytical intelligence production at European level.

Conclusions

Among the root causes of most security crises, the deteriorating economic situation of one or more countries should be highlighted. This situation leads to increased poverty, unemployment, inflation, social insecurity, increasing virulence of criminal phenomena (organized crime, immigration, violent extremism), but also to insufficient structuring of institutions tasked with countering serious criminal phenomena.
Terrorism is a borderless threat and needs to be tackled at both national and international levels. Thus, EU states, through individual efforts, must constantly contribute to ensuring national and European security especially during unforeseen emergency situations such as the crisis caused by SARS-CoV-2.

Moreover, the EU has become a relevant player in the field of preventing and countering terrorism, and this status also entails the duty of the Member States to initiate a series of measures that will have the effect to improve security.

However, the nature of the measures taken, can became afuture matter of debate regarding citizens' freedom, especially in the context of the COVID 19 crisis.

The free movement of EU citizens is one of the most important achievements of the EU, but also indicates a possible vulnerability in the system.

The question to be asked is whether freedom is a security vulnerability? or if the relationship between them can be proportional?

It is clear that freedom would not be worthwhile if we were in an insecure environment without a sense of security, especially after the coronavirus crisis.

Consequently, the questions that need to be asked are whether freedom is a security vulnerability ? and also whether the relationship between freedom and security can be proportional ?

It is clear that freedom would not be worthwhile if we were in an insecure environment without a sense of security, especially after the coronavirus crisis.

The presence of a sense of security in the absence of freedoms is practically impossible. So we have to refer to these two concepts as two necessary conditions for prosperity. Rather, it can be said that security is a means to obtain freedom.

A more effective way to prevent potential crises in the future would be to initiate debates on giving up some freedoms in order to gain more security. This aspect has been strengthened by the social deterrence measures imposed by the authorities to prevent the spread of the pandemic caused by the pathogen SARS-CoV-2.

There must be a balance between security and freedom, and in the current context generated by the new hybrid threats, this balance must be based on security. People must to understand also that the process of strengthening security does not harm the freedom.

As well, it is imperative to mention that the limitation of certain rights for the sake of security should not be overestimated.

Giving up some freedom means that the state comes closer to the citizen, knows him better and understand his needs. It should not be seen as a violation of privacy.

Therefore the percentage of those who would give up some of their freedom to gain more security seems to be on the rise as a result of the COVID 19 pandemic crisis, that has spread terror and fear among the European community and beyond.

In a deeply interconnected world, no country can fight alone against global crises. Terrorist acts are more and more destructive every day and the bioterrorism threat creates unprecedented dangers. Thus, bioterrorism represents a fundamental challenge for the international community. That is why, at both community and national level, European states need to take flexible measures against this phenomenon.

Preventing, protection, tracking and responding are thus the four axes of the global approach to international terrorism which must be applied without delay in the case of the use of biological agents for destructive purposes, as a fundamental challenge for international security. The EU needs to insist on the prevention and repression of bioterrorist acts, as well as on the protection of its infrastructure and citizens.

Moreover, the EU has a duty to act with full power against the causes, means and capabilities of bioterrorism.

At the same time, increased attention should be given to the EU legal framework, in order to facilitate international cooperation and to ensure rapid response in case of bioterrorism, particularly by updating documents such as: Strategy to fight terrorism, Stepping up the fight against terrorism, Terrorist offenses, The Hague Program, European security strategy.

Also, a high-level political dialogue on the fight against terrorism must take place with each EU Council presidency and the strategy against terrorism should be complemented by an action plan that will contain concrete measures to be taken to prevent, protect, react and track biological pathogen agents.

Additionally given that prevention of bioterrorism is a top priority for NATO, the European Union should act in close cooperation with the North Atlantic Alliance in the fight against bioterrorism.

On one hand, the internal and external security challenges facing the EU and its member states, manifest itself as a complex, dynamic and open system. Their effects, favorable and unfavorable, are cumulative and with consequences of great diversity.

On the other hand, EU member states are each affected in a different way by the consequences of these effects, either in a positive or a negative sense. Therefore, their efforts will have different intensities, natures and directions.

In order to counteract the undesirable consequences generated by the new security challenges of the 21st Century, the European Union must to act coherently and focused both in terms of amplifying the positive effects and at the same time reducing and / or limiting the negative effects emanated from the system of security risks, dangers and threats against Member States.

The HRM Indicators Used in CSR Reporting in Various Sectors in Poland

Izabela TUREK

Faculty of Management, Czestochowa University of Technology, Czestochowa, Poland
izabela.turek@wz.pcz.pl

Abstract

The purpose of this paper is to explore which HRM indicators are used in CSR reporting in different sectors in Poland. The analysis relies on study of CSR reports of companies, which represent various sectors. The main goal of research in this article is answer the question: Are indicators which characterize HRM depended on the sector of entities' activity? The method used, analyse of chosen CSR reports, will based on reports which are clear for the author. It could cause that some valuable information from other reports will be omitted. Findings should show, which indicators of HRM are used to characterized the special conditions of human resource management depending on the sector of activity. The article assumes that the employment aspects presented in the reports can be identified as human resource management (HRM) reporting. There is abundant literature referring to a connection between HRM and CSR, but empirical research on groups of indicators characteristic for HRM in various sectors is hard to find. The development of this topic has generated the need to use a yardstick that indicates which indicators are sector-specific. Therefore, an indicator of reporting accuracy was constructed for the research and this is the main value of this paper.

Keywords: Corporate Social Responsibility (CSR), Human Resource Management (HRM), reporting.

Introduction

Corporate Social Responsibility (CSR) is a trend, that is being implemented by more and more companies (Lindgreen, at al., 2009). Human activity, both individual households and large corporations, affect the broadly understood environment. This environment should be understood as the market environment, the natural environment and society.

A lot of companies on the market are being aware of the effects of their activities, thus they take actions in order to limit or eliminate the negative effects of their activities and strengthen the positive ones. It is underlined, that in the long-term perspective, the care for social and environmental aspects should be just as important as striving for profits (Høgevold, 2014; Cramer *at al.*, 2006).

Both social pressure and the importance of CSR are reflected in reports published by companies. A lot of them publish CSR reports in a voluntary manner, but on some of them, operating in Poland, the reporting obligations were imposed through the legal regulations. In Poland, the obligation in CSR reporting has been introduced since 2017 by the provisions of the Accounting Act and concerns large companies. Thus, companies with major economic importance must formally describe their CSR activities. The CSR reports are not only a source of knowledge about the operations of a given company, but they can also be a means of promoting its image (Porter and Kramer, 2006). CSR is connected with ethics in business and the sustainable development. This ideas permeate each other.

The historical background of CSR in Poland is not long. It's because of fact, that to 1990 the Polish economy was dominated by centrally controlled system. This is the cause, that Polish research and publications on that area are not rich until 2000. For instance: the Polish base of scientific publications, named BAZEKON, includes only 2 publications with CSR subject, 6 about ethics in business and 4

about sustainable development of entity. In the following years more and more Polish scientists became interested in these issues. Hence the scientific achievements also increased significantly.

CSR reports pay attention on non-financial aspects of entities' activity, which are usually divided on areas: social, employment, environmental issues, respect for human rights and anticorruption. In this article consideration will be focused on employment aspects, which can be identified as the reporting about human resource management (HRM). The main goal of research in this article is answer the question: Are indicators which characterize HRM depended on the sector of entities' activity?

To answer that question, the research on non-financial information, connected with employment area, reported by enterprises assigned to two types of enterprises: production and nonproduction will undertaken. The reporting accuracy indicator proposed by the author of the article will also be used.

The coherence of HRM and CSR idea

From 1990s, worldwide companies began to issue their social reports. Two main reasons that contribute to this trend can be identified easily. The first one is the increasing pressure from various stakeholders, and the other one is that some companies have realized that reporting their social contribution is a useful way to benefit themselves (Gao, 2011).

A growing number of companies publish an annual social report, also referred to as a public-interest report (Malone and Roberts, 1996), values report, integrated report (Wallage, 2000), ethics report (Adams, 2002), integrity report (Kaptein and Wempe, 2002), sustainability report or triple-bottom-line (TBL) report (Elkington, 2001), to show their concern on social responsibilities.

Some authors underline, that organizational culture and corporate social responsibility share some common ground (Jaakson at al., 2012). Authors' question in the empirical literature is looking more closely at the lack of alignment between the practice of corporate responsibility and the reporting of corporate responsibility activities (Kujala *at al.*, 2013).

Corporate social responsibility can be as well referred to as business ethics because the strategy of the corporate social responsibility and the Code of Ethics or Conduct determines the attitude of the enterprise to its shareholders and stakeholders (Strautmanis, 2008).

CSR and sustainability has become an essential part of the international and global business activities of companies. It is the way of communication.

CSR reporting can be used to communicate with the environment of the entity, especially during the difficult situation. For example: "The period prior to and after the 2008 financial crisis represents a chain of events that led to the changes in beliefs regarding innovative financial products and banks' role in assuring the acceptable return on customers' investments as well as their role in rejecting loans to customers lacking loan-servicing capabilities. These concerns were further amplified by negative media attention. As legitimacy gaps can be overcome by communication, CSR disclosures (as one form of communication) could be used to repair banks' legitimacy both in the eyes of the Banks' CSR disclosures public as well as in the eyes of specific stakeholders. However, the impact of legitimacy repairing activities on disclosures depends on the strategy chosen" (Laidroo and Oobik, 2014). CSR has been considered by companies to be a useful tool to manage stakeholders or public relations, to enforce organizational or operational legitimacy and to build good reputation (Gao, 2011).

During the results of research by Skudiene and Auruskeviciene (2012) it is important to take into consideration today's economic situation. The research findings indicate that CSR is a very important tool that create benefits to organizations and go in accord with Hopkins (2007) observations that CSR leads to positive long-term affects and is a competitive strategic approach to managing a company.

The review of researches made by Gao (2011) proves that a growing body of evidence suggests that CSR is differently comprehended under different cultures and in different countries.

Human capital should be considered against the background of an intellectual capital in the context of a knowledge-based economy (Strautmanis, 2008; Lu et al., 2015; Obedgiu, 2017). The management of capital in the face of a new kind of an employee - the employee of the knowledge - needs the methods

which will conduct to greater emotional and intellectual involvement of employees in the enterprise (Soliman and Spooner, 2000). The management should also encourage employees to expand their knowledge constantly, as well as to expand their qualifications and competences (Chen and Huang, 2009).

Human capital should become a priority objective of investment in the enterprise. That is why, nowadays, human resources may be treated as intellectual capital resources, regardless the type of work performed by the employee or the position occupied (Szczygielska, 2009).

In practice, human resource is responsible for employee experience during the entire employment lifecycle. It is first charged with attracting the right employees through employer branding. It then must select the right employees through the recruitment process. Human resource manager brings on board new hires and oversees their training and development during their tenure with the organization. Human resource assesses talent through use of performance appraisals and then rewards them accordingly (Obedgiu, 2017).

Polish Law Background of CSR

Employees' issues are reflected in reports prepared by enterprises. In Poland reporting obligations are regularized by the Accounting Act according which financial, descriptive and non-financial data is expanded in proportion to the size of the entity. The Accounting Act in Poland introduced the obligation to draw up and publish a statement on non-financial information by the largest entities in terms of the number of employment and financial results, as well as by public trust institutions such as banks or insurance companies. Statements about non-financial information may be identified with CSR (Corporate Social Responsibility) reports and in this article, such naming will be used for simplicity. But, it should be underlined that in practice, reports which present aspects of social responsibility can take on different names - enterprises define themselves as social reports, CSR reports, sustainable development reports, and in the case of reports including financial information and non-financial information - integrated reports.

The way and the field of social activity reporting are supported by standards, norms, guidelines and recommendations. There are: international standard ISO 26000 Guidance on Social Responsibility, international norm Social Accountability 8000 (SA 8000), International Standard for Corporate AccountAbility 1000 (AA 1000), Global Reporting Initiative Guidelines GRI G4, Non-Financial Information Standard (SIN) for non-financial reporting in Poland (Bagieńska 2018). The key point mentioned in guidelines of The Accounting Act regarding the reporting of non-financial data is the ability for entities to use their own standards or indicators.

There is National Accounting Standard (Standard No 9) also, which is helpful to prepare the Report on the operations of the entity. It's not act of law, but the guide rather. It includes instructions how to prepare the report on non-financial information.

It should be mentioned that the employees' issues are regulated in the Labour Code in Poland and they are the base to establish relationships between the employer and the employee. These guidelines specify that: "the employer is obliged to respect the dignity and other personal rights of the employee. Employees have equal rights for the same fulfillment of the same obligations; this applies in particular to equal treatment of men and women in employment. Any discrimination in employment, direct or indirect, in particular on grounds of sex, age, disability, race, religion, nationality, political beliefs, trade union membership, ethnicity, religion, sexual orientation, as well as due to fixed-term employment or unspecified or in full or part time - is not allowed. (Labour Code, Art. 111, Art. 112, Art. 113). These guidelines are nothing more than diversity policy, which employers should use when hiring employees. It's nothing new in Polish law, but entities have not reported that aspects on the large scale.

Extended reporting obligations are imposed on larger entities, then the annual financial report is accompanied by a report on the entity's operations, if the obligation to prepare it results from the act or separate regulations. Report on the operations of the entity is mandatory for entities with a more complex legal and organizational structure and of greater economic importance.

The report on the entity's activity should include material information on the assets and financial condition of the entity, including an assessment of the effects obtained, an indication of risk factors and a description of the threats.

The unit's statement of activities should also include - if it is relevant for the assessment of the development, results and situation of the entity - at least:

- key financial performance indicators related to the entity's operations;
- key non-financial performance indicators related to the entity's operations as well as information on employee issues and the natural environment.

The aspects mentioned in the second point, related to employee and environmental issues, refer to reporting in the field of CSR.

The entities, considered the largest in the conditions of Polish economic realities, additionally include in the activity report - as a separate part of the statement on non-financial information.

When making a statement about non-financial information, an entity shall provide non-financial information to the extent necessary to evaluate the entity's development, results and standing and the impact of its operations on issues related to policies in relation to social, employment, environmental issues, respect for human rights and anti-corruption.

It is important from the point of view of the entities that the entity may use any rules, including its own rules, national, EU or international standards, standards or guidelines when drawing up a statement on non-financial information. In the statement, the unit contains information about the principles, standards, standards or guidelines applied.

The presented legal regulations in force in Poland show that the obligation to report CSR issues applies only to large entities, which does not mean that smaller entities cannot prepare such reports. In turn, although the obligation to draw up a statement on non-financial information is introduced in Poland with reference to financial statements prepared from the 2017 financial year, such reports have already been prepared and published by many entities. They took the form of separate CSR reports or were part of integrated reports.

Polish Experience in CSR

In the past non-financial reporting was a good practice of enterprises only. To increase consistency and comparability of non-financial information shown in the territory of the European Union, some of the big units should prepare a statement on non-financial information containing information on environmental, social and labor issues, respect for human rights, counteracting corruption and bribery (Directive No. 2014/95/EU). This regulation concerns approximately 6,000 large entities functioning within the EU area, including more than 300 Polish entities based on the estimations of the Minister of Finances (Krawczyk, 2019).

The CSR idea in business life is not long in Poland. The first steps taken in this direction by entrepreneurs took place in the late nineties of the twentieth century, although CSR, or even the promotion of business ethics were not common. A report conducted by the Business Ethics Center, citated in REPORT Responsible Business in Poland (2004), shows that 2/3 of the surveyed companies admit that they do not conduct any training on business ethics, and in nearly 80% of companies they recognize customary standards and no documents written to regulate these issues as ethical standards. The activity in ethics and CSR were rather intuitional.

The above trend was also highlighted in studies conducted by ICAN Institute, Crido Taxand and Employers RP. According this, 92% responders from Polish entities expect taking by managers activity connected with raising ethical culture in organization.

The employee area is important aspect in surveys in 2009 – 80% of surveyed say, that responsible company should “treat and care for employees well” – it shows, that social expectations are going in this direction.

In September 2011, CSRinfo, a communication and education platform, published CSR Reporting in Poland 2010, from which it followed that 29 companies had published CSR reports in 2010 (twice as many as in 2009). A further analysis demonstrated that apart from better transparency and reliability of data, there were many shortcomings, such as the tendency to exaggerate success and overlook challenges or problems, incomplete information, irregular reporting and poor advertising of reports. In summary, social reporting is developing in Poland but has a long way to go (Ćwik, 2009).

The subject connected with HRM is the management of age – in 2011 it was the one of the most important aspect, especially the employment of people over 50 years of age (Schimanek, 2011). This problem was continued in 2014, parallel with the management of the youngest workers, which are called the Generation Y (Millennials) (Leśnowolska, 2014).

The group of yang employees is very important take in point of view their interested in CSR activiti of corporation. The researches called "Millennial CSR Study" shows that people of 18-34 age, looking for work take into consideration social responsibility of potential employer – this is declarated by 82% respondents and 60% of them say, that they are ready to work for responsible employer for lowest salary (Gruszecka-Tieśluk, 2015).

The next important area, which should be take into account by CSR activity is the diversity. The formal form of this was implement in Poland in 2012 as the Diversity Charter. The Diversity Charter is a written commitment which is signed by organizations that oblige themselves to the introduction of equal treatment policy and diversity management, as well as active prevention of discrimination and mobbing in the workplace.

Diversity constitutes a fundamental value of the modern society. Nowadays 263 companies implemented the Diversity Charter in Poland and they become the signatory of Diversity Charter (data on 28 August 2019).

The very valuable researches were conducted in 2015 by Fundacja CentrumCSR.PL "Corporate Social Responsibility in Polish realities". During the research 227 the biggest firm representing 16 branches were monitored for 12 indicators. The conclusion of researches is, that information published in CSR reports is not specific, doesn't include clear declarations for future and doesn't include verifiable data (Gruszecka-Tieśluk, 2015). It's not positive image of CSR in Polish entities.

The research conducted by FOB in cooperation with PBS Institute and with Deloitte shows on the other hand, that 80% respondents realize the influence of CSR on Polish business activity. The most important conclusion is, that implementation of CSR actions effects not only the better reputation, but first of all impacts on ethics and involvement of employees.

Researches

As observed by Gao (2011): Various interests of employees are addressed by listed companies. The frequently addressed interests include "people oriented/centered (93.8 percent)", "salary and welfare (91.4 percent)", "education and training (86.4 percent)", "abiding by labour laws (85.2 percent)", "workplace safety and workers' health (81.5 percent)" and "employment policy (81.5 percent)".

The article will focus on reporting in these areas as key aspects of HRM. The main question is: Are indicators which characterize HRM depended on the sector of entities' activity?

In order to achieve the aim of the article, the research on non-financial information reported by enterprises assigned to two types of enterprises: production and nonproduction was undertaken.

The division into these two categories of enterprises was aimed at identifying groups of indicators in the scope of reporting HRM, characteristic for a given group of activities.

The survey covered 17 non-production entities and 17 production entities. They were selected from the list of companies submitted to the competition of social reports in 2018 and 2019. In fact, the audit was carried out on the basis of reports for 2017 or 2018, i.e. in the period in which large entities were covered by the non-financial reporting obligation. In the period under examination, a total of 73 reports were submitted to the competition, hence the research sample of 34 companies gives 47% of the total.

The similar statistics are achieved in the database CSRinfo. The types and number of entities in research groups are presented in the table 1.

Table 1: The types and number of entities in research groups

Nonproduction entities		Production entities	
Sector	**Quantity**	**Sector**	**Quantity**
Finances	11	Heavy industry	4
Trade	2	Chemical industry	3
Media	2	Construction industry	6
IT	1	Energetics	4
Hotel industry	1		
Total	**17**	**Total**	**17**

Source: own studies.

The division of the surveyed entities into two groups is justified by the different nature of the work performed by employees.

In production companies, employees are exposed to a higher degree of risk of physical injury, they are exposed to contact with dangerous substances or risky situations, such as breakdowns of machines, equipment at which they work, exposure to noise or changing weather conditions.

In non-production entities, workers come into contact with a different type of hazard, than in production companies. The direct threat to life or health is usually small, while greater emphasis is placed on the development of competence or the ability to cooperate with customers. An important aspect in the analysis of these issues is also the perception of certain types of professions as more "male" or "female".

The diversity of these groups of entities has contributed to the examination of whether their specificity is reflected in the applied non-financial HRM indicators.

The list of indicators has been conducted in the following groups:

- employment indicators,
- training (excluding health and safety training),
- benefits,
- health and safety indicators,
- salary indicators,
- periodic evaluation of employees,
- to survey employees' opinions.

The results of the obtained researches are presented in the table 2.

Table 2: Number of indicators used in individual enterprise groups

Indicator		Nonproduction entities	Production entities
Employment indicators	Age	11	12
	Sex	17	15
	Fixed-term contract or indefinite contract	14	13
	Full-time or part-time work	12	7
	Number of training hours	10	6

Training indicators	Average number of training hours per employee	12	11
Health and safety indicators	Frequency of accidents	7	10
	Number of accidents	13	16
	Severity of accidents	10	12
	Absence from work due to accident	10	11
Salary indicators	Women's to men's pay ratio	6	4
	Reference of wages to the minimum wage or average wage	4	2
Benefits		17	17
Periodic evaluation of employees		12	4
To survey employees' opinions		3	1

Source: own studies based on non-financial reports of 34 Polish entities.

Preliminary analysis of the data presented in the table 2, allows to observe general reporting trends, depending on the nature of the company's activity. We can see also, that some areas are characterized by several indicators and company choose that one, which are the most valuable for them.

In the case of nonproduction companies, a greater emphasis is placed on employee training, which is reflected in broader reporting on the subject. In production companies, on the other hand, the most important issue is occupational safety, which has been confirmed in the reporting. The analysis may be more detailed and deepened by examining the accuracy of reporting in particular areas. For this purpose, the reporting accuracy indicator proposed by the author of the article can be used.

This indicator measures the ratio of the number of indicators shown in the reports in the surveyed group of entities to the maximum number of indicators that could be used, assuming that each company will use all indicators selected in the survey.

The indicators of reporting accuracy in particular HRM areas are presented in table 3.

Table 3: Reporting accuracy indicator in nonproduction and production entities

Reporting accuracy indicator	Nonproduction entities	Production entities
Employment indicators	0,794	0,691
Training indicators	0,647	0,500
Health and safety indicators	0,588	0,720
Salary indicators	0,294	0,176

Source: own studies

The reporting accuracy indicators presented in the table 3, confirm certain reporting trends:

- a greater emphasis is placed on employee training in nonproduction entities,
- the most important issue is occupational safety in production companies.

These trends indicate that, depending on the nature of the company's business, other aspects are highlighted in non-financial HRM reports.

We can observe also, that aspect of wages is not the most exposed in the non-financial information reports, especially the women's to men's pay ratio.

In all the reports analysed, employers provide employees with additional non-wage benefits. The employee survey is not revealed in the reports to a small extent.

The analysis of the data in Table 2 gives grounds to claim, that the periodic evaluation of employees is an important element of HRM in non-productive entities – most of them perform employee evaluations.

It should be stressed that the proposed reporting accuracy indicator is not intended to assess the reliability of the report, but only to help identify which areas are particularly important for a given group of entities. It is also important to relate the reported indicators to data specific to the sector in which the company operates - only such a reference shows full information.

The reporting accuracy indicator can also be used to determine the accuracy of reporting in a given area in the context of an individual enterprise. It is then worth comparing the indicator to the average in a given sector or other selected indicator.

The review of non-financial reports of 34 companies shows that every of them report the diversity. This aspect is characterized by participation of women in management bodies as well as in the employment structure. Other indicators showing the application of diversity policy, such as the employment of disabled people or foreigners, are marginal.

Conclusions

This paper contains main findings from literature studies and research:

- the subject of CSR is very large and it can be characterized in many sections and in different shots,
- CSR has not long history in Polish practice and researches,
- aspects of employment reported by entities can be equated with HRM,
- the review of non-financial reports of 34 Polish companies shows that a greater emphasis is placed on employee training in nonproduction entities and the most important issue is occupational safety in production companies,
- diversity policy in Polish reports is not is not widely exposed,
- reporting accuracy indicator, proposed by author, can be useful to research how important is the reported area for the entities in sector or for the individual company.

It's difficult to avoid some limitations and it's not possible to accommodate every details of the subject. First of all, the research was based on review of 34 companies reports. The rationale is that these were the reports submitted for the competition, thus they were prepared carefully and information could be obtained from them more easily. In fact, the choice of companies to research was subjective but on the other hand they represented almost 50% entities which submitted reports to the competition in the examined period. Many threads require further and more detailed work, which will certainly be reflected in future researches.

Abstract

Indonesia is the third most populous country in the world, which will certainly have needs for housing. According to data from the Ministry of Public Works And Public Housing of Indonesia, it is known that the number of subsidized houses built in Indonesia in 2019 is a 74.6 percent. So, subsidized housing construction should be given greater attention in ensuring sustainable development. On the other hand, subsidized housing is a house that must be affordable by middle-low income people. So that environmental, social, economic aspects must be implement in harmony and affordable. This study aims to assess the sustainability management application in subsidized housing. The method uses the green neighborhood index in Indonesia, called Green Neighborhood GBCI. The location of this research is in Perumnas Parung Panjang. The data in the form of satellite photos, design master plan and the data from estate management system. The results of the green neighborhood index, then analyzed descriptively for the sustainability management discuss. Assessment in the Parung Panjang Perumnas gets 43 points according the GBCI Green Neighborhood Index. From the aspect of sustainability management, some input can be obtained for energy, water, material and culture aspects. If the input is carried out, the GBCI Green Neighborhood Index points will be 85 points so that sustainable development will be created in subsidized housing.

Keywords: Green Neighborhood, Sustainability, Management, Subsidized Housing, Indonesia

Introduction

United Nation said that in 2018 the total world population will be in urban areas reaching 55% and projected to continue to increase to 68% in 2050. Indonesia has a large population of 265 million in 2018 (BPS, 2019). The large population certainly has a high need also in terms of meeting the needs of the house, as a primary human need for life. The results of the construction of the Ministry of Public Works and Public Housing during 2019 were 1,257,852 housing units, with 938,405 units (74.6%) being subsidized houses, while 312,691 units (25.4%) were non-subsidized houses (PUPR, 2020). From these data it can be seen that the construction of subsidized houses is greater than non-subsidized houses, so attention to the quality of sustainability in subsidized housing is important to be studied.

Jakarta, as the capital city of Indonesia serves as business center and the center of government. Because of that, on the weekdays the numbers of workers as commuters reach up to 12 million people. Jakarta is to bear the process of rapid urbanization of the surrounding area, such as Tangerang, Bekasi, Bogor and Depok (Rahadi et al., 2015). Perumnas Parung Panjang as the case study of this research is located in Bogor, one of the urbanization regions that effect Jakarta. High population numbers and limited supply significantly increase housing prices (Rahadi et al., 2015). On the other hand, the government lacks control with firm policies, as a result housing prices grew out of control (Aswin Rahadi et al., 2016). Especially if it is related to sustainability, then there is still a view that the concept of sustainable housing means that prices are not affordable. Whereas price affordability is part of subsidized housing. One of the solutions to achieve sustainability in subsidized housing is estate management that applies a sustainable concept (Khamidi et al., 2010).

In a residential area, it is necessary to design a plan that must accommodate the concept of sustainable development. On the other hand, the residential area must also guarantee an estate management system that is sustainable and affordable (Khamidi et al., 2010). The maintenance of the environment after the planning and development period needs to be managed with sustainable estate management so that in the end it will create a comfortable, safe and livable housing environment for a better future and the quality of the best inhabitants.

Method

This study will use the Green Neighborhood GBCI (Green Building Council Indonesia) from Indonesia to conduct an assessment of the housing performance of Parung Panjang Perumnas in applying the concept of sustainable development. Then a descriptive analysis will be carried out using previous research to obtain input on post-development activities within the framework of the estate management system so that sustainable management will be achieved. This research will be conducted in the residential area of Parung Panjang Perumnas, Bogor Regency, West Java Province, Indonesia. Perumnas Parung Panjang area has an area of around 200 hectares, with the number of houses that have been built as many as 10,474 units. The location of the Parung Panjang Perumnas area can be seen in Figure 1.

Fig. 1: The location research in Perumnas Parung Panjang, Indonesia

The data used are observations of satellite photos, master plan planning data and data from the estate management system that has been implemented in the Parung Panjang Perumnas. Details of the data sources can be seen in Table 1. It is hoped that with this research step, the Parung Panjang Perumnas will be able to implement sustainable management and obtain a better assessment going forward.

Table 1: Data and source of the data

Data	Source
Satellite photos	Arc Map 4.0 base map, 2020
Master plan Data of Perumnas Parung Panjang	Perumnas (National Housing and Urban Development Company)
Estate Management Data of Perumnas Parung Panjang	Perumnas (National Housing and Urban Development Company)

This research will use the GBCI sustainability index assessment of residential areas (Green Building Council Indonesia, 2015). Then the level of conceptualization of sustainable concepts will be obtained in the case study. From these results, intervention steps can be identified to improve the application of

sustainable concepts in case studies. Intervention steps are obtained using the literature review and benchmark method from housing areas in other countries or regions.

Result and Discussion

An evaluation of the application of the concept of sustainable development has been carried out at the Perumnas Parung Panjang, Indonesia and has resulted in as many points as 43 points (Bronze Level). Details of the assessment results using the Green Neighborhood Index, GBCI can be seen in Table 2 below.

Table 2: Assessment point Green Neighborhood Index, GBCI result

Parameters	Maximum Point	Assessment Point
Land Ecological Enhancement	19	8
Movement and Connectivity	26	12
Water Management and Conservation	18	2
Solid Waste and Material	14	6
Community Wellbeing Strategy	16	8
Building and Energy	18	3
Innovation and Future Development	11	4
Total poin	122	43

Assessment result and improvement in estate management

The results of the assessment get Bronze levels in accordance with the provisions of the points level set by the GBCI (Green Building Council Indonesia, 2015). One of the steps to improve the application of the concept of sustainable development in housing that has been built, it needs to be improved by implementing several interventions in the area's estate management (Jones & Cooper, 2007), (Olanrewaju et al., 2015). Some steps that could be implemented in the Parung Panjang Perumnas depend on the parameters could be seen in Table 3.

Table 3: The Estate Management intervention to Perumnas Parung Panjang

Parameters	Improvement Point
Land Ecological Enhancement	Planting native trees Planting trees on green space Urban farming
Movement and Connectivity	Disability friendly Activate pedestrian Bicycle paths & parking lots Avoid on street parking
Water Management and Conservation	Alternative water sources Reduce runoff water Planting trees in a body of water Wastewater treatment facilities
Solid Waste and Material	Trash sorting socialization Waste treatment facilities B3 waste treatment facilities
Community Wellbeing Strategy	Satisfaction survey of area quality Promotion of sustainable lifestyles Sustainable living socialization program Local cultural preservation activities Local cultural education activities

	Simulation of disaster events
Building and Energy	Sound pollution reduction program
Innovation and Future Development	Involving regional greenship experts Create SOP for managing the area Sustainability innovation

Sustainable Housing Maintenance Management Model (SHMMM/ SHM3)

Some of the parameters that can be upgraded are then used as input to create the SHMMM. The process to build a conceptual of the SHMMM begins with the Planning stage, at this stage the vision of the subsidized housing area and the procurement strategy are carried out. Then the vision of the subsidized housing area and the parameters intervention was used as the basis in making Objective Estate Management, followed by being made the basis in making Estate Management Regulations and Standards. The Second Stage, Organization, at this stage the Estate Management Procedure was made, to be able to regulate the process of maintaining subsidized housing areas. Then followed by the Report Making and Report Submission process. The third stage, namely Directing, at this stage the development of Communication Patterns, work culture, and Division of Responsibility is carried out within a Sustainable Estate Management framework. The fourth stage is Implementation, at this stage the execution of all plans that have been made from the previous stages will be carried out. The fifth stage is Controlling, at this stage monitoring activities and re-checking of all activities that implement sustainable estate management will be carried out (Olanrewaju et al., 2015). Implementing estate management can influence the use of energy, water and materials in the area so that ultimately it will reduce the amount of emissions to the environment (Mustapha et al., 2017) which can be seen in Table 4.

The application of several things to the estate management of Parung Panjang Perumnas will affect the energy, water, material and culture aspects. The details can be seen in Table 4. By implementing the solution step then re-assessment by using the Green Neighborhood Index, GBCI, the value of applying the sustainable concept in the residential area becomes 85 points or Gold Level (Green Building Council Indonesia, 2015).

Table 4: The distribution of interventions in estate management based on the aspects affected (Mustapha et al., 2017)

Energy	Water	Material	Culture
Sound pollution reduction program,	Alternative water sources, Reduce runoff water, Planting trees in a body of water, Wastewater treatment facilities	Reuse development materials waste, trash sorting socialization, Waste treatment facilities, B3 waste treatment facilities	Planting native trees, Planting trees on green space, Urban farming, Disability friendly, Activate pedestrian, Bicycle paths & parking lots, Avoid on street parking, Satisfaction survey of area quality, Promotion of sustainable lifestyles, Sustainable living socialization program, Local cultural preservation activities, Local cultural education activities, Simulation of disaster events
Involving regional greenship experts, Create SOP for managing the area, and Sustainability innovation			

Benchmark improvement the sustainable estate management in affordable housing

Several concepts of improvement in the implementation of estate management can also be implemented in technical applications in residential areas. In the field of energy management: In Russia the construction of affordable housing has paid attention to energy efficiency that leads to a reduction in the cost. There are five management strategies C1 - C5. The C1 - C3 management strategies are for the middle low segment of Russian buyers, because there is not too much extra cost: C1 builds an installation of an automated heat supply unit, C2 provides an additional insulation of the building, and C3 builds an installation of wind and solar power plants. As for C4 and C5 management strategies are for the more affluent segment of Russian buyers: C4 build an installation of apartment ventilation systems with heat recovery, C5 provide an additional insulation of the building envelope with polystyrene (walls, roof), installation of an automated heat supply unit in the apartment block, using low-grade ground thermal energy in heat pump systems, installation of a solar system and installation of a wind and solar power plant (Baronin & Kulakov, 2015). In the field of water management: The housing complex in Cracow, Poland, soak ways, rain gardens, permeable surfaces and infiltration boxes are proposed. Some of this is done with the aim of limiting surface runoff, so that it can be reused and making savings on costs in accommodating surface runoff nationally. With the calculation of payback period (PP) and return on investment (ROI), it is obtained a potential savings of around 9% (rate of return) and investment return time is around 12 years (Godyn et al., 2020). In the field of material management software Building Information Model (BIM) can be used. The application of BIM software has several advantages, namely the precise amount of material needed, so that the waste of material can be reduced which in the end will reduce construction costs (Wei et al., 2017). In the field of culture improvement, a housing area needs to implement a Sustainable Green Management System (SGMS). SGMS is an integrated management system from several sustainability elements in the ISO standard. SGMS is useful for applying sustainable principles to existing facilities in an area with cost and time efficiency, so that productivity increases (Mustapha et al., 2017), (Gazea & Serbanoiu, 2018).

Conclusion

The application of sustainable concepts in housing that has been built can be done by intervening in the estate management. Sustainable estate management implementation will have a good impact on the environment, social and economic area. Estate management interventions in the housing area of Parung Panjang Perumnas, Indonesia were able to increase the concept of application points in accordance with the Green Neighborhood Index, GBCI in force in the country that gets 43 points (Bronze levels) that want to be upgraded to 85 (Gold levels).

Abstract

Increased population growth causes environmental problems, such as what happened in the capital city in Indonesia. If there is no systematic effort made, the environmental impact will occur to be significant. One of the ecological problems in the Capital City is the waste problem. The growth of waste every year continues to increase due to various human needs. Potential environmental pollution due to waste occurs accross multiple business sectors, both small and large scale. The office building is one of the contributors to the waste sector. The purpose of this study is to determine what factors are obstacles to waste management in an office building that can improve environmental performance. This research uses a qualitative approach, and the method used is a mixture of qualitative and quantitative through observation, interviews, and literature study. This research was conducted at a logistics company. Based on the results of the study showed that employee knowledge plays an essential role in the success of the waste Separating program in the Company. Limited knowledge makes it difficult for employees to distinguish and separate waste. It means that it is needed a way to increase understanding by socializing, providing clear information on the waste and easy access so that it can increase employee interest in Separating waste.

Keywords: Office Waste; Solid Waste; Sustainable; Segregation; Waste Management.

Introduction

Increased population growth causes environmental problems, such as what happened in the capital city in Indonesia. The issues faced by the capital city of Jakarta are getting heavier because day by day, the population is increasing, and the carrying capacity is also getting smaller (Sutiyoso, 2007). No systematic effort made, the environmental impact would occur to be significant. In principle, every human activity will affect on the environment. Moreover, there is no balance of environmental wisdom (Utomo, Sutriyono and Rizal, 2012). Wisdom on the environment needs to be done because the environment is a unit in which there is an abiotic environment (non-living things), and biotic (living things) (Chauhan, 2008). Therefore, humans must maintain and preserve the environment because environmental problems in the form of impacts on the environment will also affect human life itself.

One of the environmental problems in the Capital City is the waste problem. The growth of waste every year continues to increase due to various human needs (Mangarengi, Zubair and Abdurrahman, 2020), good clothing, food, shelter, and other needs are increasing (Utomo, Sutriyono and Rizal, 2012). Another thing is also due to population density, economic status, culture, even the size of a region that also affects the amount of waste (Kumar *et al.*, 2017). Various types of waste often accumulate everywhere, such as in households, markets, or other places. The amount of waste is due to various problems, according to Sutiyoso, (2007) waste is often not transported, so it piles up everywhere like on a roadside (Wulandhary *et al.*, 2019), most people still have the habit of littering,

making it very easy to find waste on the streets. This is also in line with research in India that the biggest challenges to the waste problem are the transportation of waste that is not maximally transported, handling, and disposal of waste (Kumar *et al.*, 2017). The bad impact of the large amount of waste is environmental pollution. Efforts to minimize waste from the source are needed because without realizing it in the future, problems will arise, such as public health (Tariq *et al.*, 2017) and environmental pollution. Environmental pollution is the addition of substances or materials into the environment which have detrimental effects (Utomo, Sutriyono and Rizal, 2012). Environmental pollution that occurs is like water pollution (Wulandhary *et al.*, 2019), and then air pollution that produces greenhouse gases (Balogun-Adeleye, Longe and Aiyesimoju, 2019).

Potential environmental pollution due to waste occurs in various business sectors, both small and large scale. The office building is one of the sectors contributing waste, according to the Indonesian National Standard (SNI) number 19-3983-1995 concerning the specification of waste generation for small cities and medium cities in Indonesia is 0.025-0.1 kg per employee/day (Nasional Standardization Body, 1995). The potential for waste is an average potential, which means that per employee or employee may be more than that generated per day. The lattest research conducted by Edjabou *et al.* (2015) found that waste generated by employees amounted to 0.08 ± 0.018 kg/employee/day. Office activities such as administrative activities that certainly use paper will produce potential paper waste, then food waste produced by employees, both organic and inorganic waste. Based on its composition, the generation of waste in offices is according to Wardiha *et al.* (2013) are food waste 26.43%, paper waste 18.55%, residue 16.83%, and organic waste 10.93%. With the considerable office waste potential, the company has conducted an environmental program related to waste management. This is because to improve environmental performance by placing two different types of waste bin facilities so as to make it easier for employees to separate waste according to type. Even though the company's program has been running, it does not mean that this program runs optimally in waste management because based on observations, it is often found that waste is mixed, so the purpose of this study is to find out what factors are obstacles to waste management in office buildings so as to improve environmental performance.

Methods

This research uses a qualitative approach, and the method used is a mixture of qualitative and quantitative through observation, interviews, and literature study. This research was conducted at a logistics company. The research was conducted at the company because the company was already ISO 14001-certified, so it must have run a clause that must be met so that environmental performance can continue to improve. This research involved cleaning staff that used to collect waste at the end of their work and involved the company's employees. The research activity began with observations made at all the waste facilities owned by the company and then continued with interviews. Interviews were conducted with selected informants, namely to Office cleaners and employees, for a period of 20-35 minutes to obtain the quality of answers desired by researchers comprehensively. Before conducting interviews with respondents, the researcher ensured that the respondent's profile was kept confidential, and the researcher gave a gift of souvenirs as a thank you for participating in this research.

Some of the questions carried out there are open questions so that they can be developed during interviews, and respondents can be free to answer without any sense of pressure. The research question can be seen below:

- What kind of waste is produced at this company during working day?
- What do you think about the waste Separating program that the company runs?
- What is missing from the waste Separating program so that it has not run optimally?

During the interview with the respondents, the researcher recorded every answer given by the respondent, and the researcher used a voice recorder so that the answers obtained from the respondents were not biased.

Result and Discussion

Waste management carried out by the company is to reduce waste from its source by placing separate waste bin facilities by type. Forms of handling carried out every day by way of waste collected every day at the end of operational office hours. The Office cleaners consist of people assigned to take out waste every day. Waste that is collected into plastic bags is always found waste that has been mixed even though the organization or company has provided two different types of waste, namely wet waste and dry waste. This program is part of the rules that have been issued by Nasional Standardization Body (2002), gathering, separating and processing at the source, then collection, transfer or separating and processing, transportation, and final disposal. The operational engineering scheme can be seen in Figure 1. below:

Figure 1: Operational techniques for waste management (Nasional Standardization Body, 2002)

Potential waste collected daily will be collected by the cleaners and will be dumped into a Temporary Waste Station (TPS) provided by the building management. According to research Shochib (2011), waste in offices, especially in the workspace, tends to be more inorganic waste such as paper, plastic, rubber, metal, glass, Styrofoam, and tissue, which is 90.69%, while organic waste is only 9.31%. This was confirmed by the Office cleaners. Based on the information from informant 1 explains that:

> *"According to the Office cleaners, there are very varied, especially in each location of waste placement. Waste bin facilities are placed in the area where food is more organic or wet bins compared to inorganic bins or dry bins. Meanwhile, there are more inorganic waste bins around the workspace. Waste can also always be found mixed with waste like waste in the workspace, and sometimes employees only see the waste can nearby, so it is likely that waste bin facilities is always mixed."*

This statement shows that there is inconsistency even though the organization or company has provided separate waste bin facilities. Lack of knowledge is one-factor, causing employees not to separate their waste. Based on the information from informant 2, the employee shows that:

> *"Waste is not placed in an appropriate place because they do not know what is meant by wet and dry waste. It may be added clearer information in the form of additional images making it easier for employees to dispose of waste. Placement of the point of the waste can also need to be considered so that no need to place each point placed two different waste bin facilities. Some employees still think that there is an Office cleaners who will separate it in the end, and it is not part of their job to separate waste.*

Employee participation needs to be done actively in running the company's program for waste management because it really determines the success of the implementation of a program. The level of employee concern is the key to a program that can run well. Employee concern for the environment lacks due to several things, one of which is the lack of environmental knowledge and the impact that will occur. Research founded by Handayani and Moersidik (2017) confirm that employees care about the environment is lacking because many employees have a perception that the waste management program is not part of their job because there are already Office cleaners who handle it. This is also confirmed research by Yulianto (2016) that many of them think to hand over the waste handling by the Office cleaners because they have already paid so that they do not need to participate in waste Separating.

Environmental knowledge is needed for employees to increase their awareness so that employees are more concerned about the environment. Increased knowledge can be from any activity, such as training. The positive impact of training activities will certainly increase knowledge, and if someone lacks knowledge about the environment, especially related to waste, it will be a challenge for an organization to controll the environment, especially the waste-handling program. (Kumar *et al.*, 2017). Therefore, to improve the environmental performance of an organization, it is necessary to educate employees (Susmono, 2017) so employees can behave friendly to the environment by helping in waste management (Nasional Standardization Body, 2002).

Education for employees can be in various ways, according to Xiao *et al.* (2017) by completing the waste bin facilities in the form of clear information, namely waste instructions according to the type. Clear information in the form of pictures or logos makes it easy for someone to participate in Separating waste (Xiao *et al.*, 2017). It is also confirmed by Sin-Yee and Sheau-Ting (2016) which states that the lack of clear information to separate waste becomes a barrier for someone to separate waste because clear instructions or information becomes vital. Even for someone who does not have limited knowledge related to separating waste, but the existence of clear information on the waste bin facilities can help someone to separate the waste (Sin-Yee and Sheau-Ting, 2016). Moreover, this information is given regularly and continuously will increase employees to participate in Separating waste (Edjabou *et al.*, 2015).

General advertisements such as posters that are easy to read and understand can also increase a person's knowledge so that they can participate in caring for the environment even though with this method, a person will not quickly change behavior (Xiao *et al.*, 2017). The conventional method that can be applied is through direct socialization because socialization is one of the two-way communication methods so that one cannot interact to ask something more in detail so that someone gets knowledge. Effective socialization is when there are questions and answers in it so that two-way communication occurs. The more people are socialized, the more their awareness increases, especially the awareness of the environment. According to research conducted Yulianto (2016), the more people who have not received good socialization, the lower the level of awareness and concern for waste segregation.

Effective waste management, one of which is to provide adequate waste bin facilities so that employees can easily dispose of waste in accordance with his office. Inadequate waste bin facilities will be a challenge for an organization in handling waste (Kumar *et al.*, 2017). Research conducted by Wulandhary *et al.* (2019) revealed that by providing adequate waste bin facilities, a person's

behavior can change and can optimize the program. The comfort factor and easy access to waste bin facilities are also an important part of increasing employee awareness to dispose of and then separate waste bin facilities can according to its type. These factors, according to Xiao *et al.* (2017), became one of the effective factors to increase participation in waste management. The easier accessibility to the waste bin facilities, the higher the likelihood of someone to practice waste separation behavior (Sin-Yee and Sheau-Ting, 2016). For example, the placement of inorganic waste bin facilities near locations that produce a lot of paper waste, this will increase one's ease of Separating waste (Armijo de Vega, Ojeda Benítez and Ramírez Barreto, 2008). Then the short distance also determines whether someone will participate in Separating waste or not. The results of the research conducted by Struk (2017) shows that someone's willingness to separate waste if the distance from the disposed of waste is not too far away.

Conclusion

Based on the results of the study showed that employee knowledge plays an important role in the success of the waste segregation program in the Company. Limited knowledge makes it difficult for employees to distinguish and separate waste. That means that it takes a way to increase knowledge with socialization, provide clear information on the waste and easy access so that it can increase employee interest in separating waste.

Abstract

In times of globalization the phenomenon of ethnocentrism is gaining interest among consumers who turn towards products produced and delivered by local producers. This phenomenon is particularly relevant to the food market. The main purpose of the paper is a to systemize major issues referring to the subject as well as to identify and analyze consumers' behaviors in the light of consumer ethnocentrism and to determine its impact on buying decision process. The paper presents partial results of the survey on ethnocentric attitudes of selected consumers with regard to Polish sweets market in a local perspective.

Keywords: Consumer Ethnocentrism, Buying Decision Making, Sweets Market

Introduction

The paper constitutes a brief theoretical and empirical study relating to selected aspects of consumer ethnocentrism. The paper was divided into two main parts: theoretical and empirical. The theoretical part completed the theoretical goal which was the critical review of the literature on consumer ethnocentrism phenomenon. The second part of the paper is of empirical nature. In this part the authors performed empirical goal which is the identification and analysis of consumers' behaviours. For this goal the survey method was used.

The main consumer's type of decision occurring the most often is purchase decision. Consumer is perceived as a target object of any enterprise's activity. That is why companies try at all costs encourage them for buying particular products. However, businesses do not have the only impact of consumer's purchase decision.

Consumer while making any buying decision pays particular attention to aspects such as price, quality, packaging, brand, advertisement, promotion or even atmosphere in a store. However, some psychological aspects like consumer ethnocentrism play significant role too.

Above mentioned notion refers to attitude concerning the purchase of only domestic products which is caused by duty to buy national goods and thus assisting local economy. Ethnocentrically oriented consumers treat their own group as the center of the world and classify others with the reference to it, usually they are seen as worse ones.

The basis for this research is the assumption that consumer ethnocentrism influences the purchase decision process in Polish sweet market.

The approach applied in the paper is of descriptive-empirical nature. The research methods involved in this paper are: induction, deduction, literature studies as well as survey and data analysis. The method of critical and comparative analysis was used in relation to the views presented in the literature.

The paper ends with a brief presentation of research findings which are of the preliminary nature and will be developed in further research.

Defining Ethnocentrism

Ethnocentrism notion was introduced and defined by G.W. Sumner as a belief that 'one's own group is the center of everything' in reference to which others are scaled and rated. (Sumner, 1906). Ethnocentrism creates the viewpoint that one's own group is better and more important that others groups in terms of language, behavior, customs and religion (Kowalczyk, 2016). The word ethnocentrism is composed of two expressions: 'ethnic' that stands for cultural heritage, and 'centrism' that stands for being in the center. The whole name refers to assessment of other groups while taking into consideration own cultural viewpoint (Barger, 2019).

Ethnocentrism is also understood as "*tendency for judging members of other groups and communities and also people of different lifestyles, on the basis of standards of own group or culture, where foreign groups are usually perceived as inferior to one's own group"* (Matsumoto & Juang, 2016).

Ethnocentric attitudes among persons composing a given society are being developed by all cultural systems. This means that they perceive their system of values, convictions and norms as better than others. Ethnocentrism thus may lead to intolerance, which causes conflicts and tensions (Hammond & Axelrod, 2006).

From the ethnocentrism's point of view, one's own group constitutes the center of the world, and others are assessed and classified with reference to it. Norms, value systems and behaviors characteristic for personal group are recognized as good, correct and appropriate. However, external groups' features that differ from one's own group are seen as bad, wrong and inappropriate. (Perreault & Bourhis, 1999). The phenomenon of ethnocentrism is widespread and deeply rooted in inter - environment relations. It is not only restricted to individual nations but also occurs within a much smaller social groups. It is also manifested in forms such as: nationalism, racial discrimination or religious prejudices (Watson & Wright, 2000).

Ethnocentrism is a natural consequence of socialization that took place in childhood. Its main purpose is to inculcate in child fundamental values, norms and roles appropriate for a particular society or community. In the early stages of socialization, ethnocentrism is treated as a positive phenomenon because it causes subordination to basic social norms binding all group members. It brings about also recognition of the system of values shared by all community members. As a result, an individual engages in behaviors that society benefits from and thus not only focuses on satisfying personal needs. However, while interacting with foreign cultures, ethnocentrism turns out to be dysfunctional: it leads to perceiving one's own group by its members as superior to others. As a result, a particular social group considers its system of values as universal and the only appropriate one. What is more, values shared by foreign groups (external) are being negated (Sharma, Shimp, & Shin, 1994).

Ethnocentrism favors the exaggeration of differences between groups and contributes to the lack of cooperation with members of other groups. This results also in disregard of authorities coming from foreign groups. However, from the other point of view, it contributes to a sense of community within own social group and the acceptance of authorities deriving from that group. In extreme cases, ethnocentrism manifests itself in the form of social distance, hostility toward certain nations, the lack of confidence toward 'foreigners' and blaming them for the failures and problems appearing within own group (Figiel, 2004).

Ethnocentric attitudes exist in many areas of human activity. These include among others: culture, politics, religion and economy. In each of these social areas ethnocentric behavior may be viewed as a feature of the way of thinking and acting with regard to individuals, social groups and even the whole society. Above mentioned behaviors may appear occasionally, temporarily or permanently (Fernández-Ferrín, et.al., 2017). Ethnocentrism in interpersonal relations, especially its aggressive form, is a

negative phenomenon and even sometimes a dangerous one. It can lead to fanaticism by causing serious problems and disputes.

Ethnocentrism helps group members to unite by sharing the same culture and also causes subordination to basic norms and rules present within a group (Fernández-Ferrín, Bande-Vilela, Klein & del Río-Araújo, 2015). That is why an individual is more interested in group's benefits rather than own ones. However, interacting with other foreign groups can lead to conflicts through exalting over them. It may be visible by prejudice, contempt and even violence (Josiassen, Assaf & Karpen, 2011),

Consumer ethnocentrism and buying decision process

Purchasing products usually engages putting special attention to standard factors, which include among others: quality, price, method of payment, delivery date, the possibility of discount, guarantee or possibility of return. However, contemporary marketing research concentrated on the analysis of consumer behavior, make use of the achievements of psychology. It examines the impact of factors that characterize emotional features of the buyer with regard to his/ her confidence in the company or product, reputation, as well as to general opinion about brand or country of origin (Watson & Wright, 2000).

Consumers, while buying any product, are generally driven by emotions and their choices are not always rational. Purchase decision of a specific brand is particularly difficult in the case of a large number of competing products. Consumers make the choice on the basis of own experience, knowledge or information received from a producer, family members or friends (Rudnicki, 2012). Consumer pays also special attention to promotional activities that shape his/ her view of reality, attitudes and references (Huddleston, Good & Stoel, 2001).

Each product can be identified according to certain characteristics, both physical and emotional ones. Origin of the product is treated as one of them. Consumer, due to information placed on the product or packaging, but also to specific symbolic labeling (bar code, national symbols of quality, name and address of the manufacturer, place of production, brand, language of product description) may assume where does the product come from (Rudnicki, 2012).

Nowadays, when the deepening internationalization of world trade is visible, the country of product origin is becoming crucial (Figiel, 2004). On its basis a consumer may assess a given country's product from the point of view of own preferences and stereotypes concerning that particular country. One glossary explains that country of origin depicts the impact of consumers' perception of a particular country on the assessment of products (or brands) originating in that country(Kowalczyk, 2016).

The phenomenon of consumer ethnocentrism is a specific variation of the effect of country of origin that consists in preferring the purchase of domestic products. The concept of consumer ethnocentrism was defined by Sharma, Shimp and Shin. According to these authors, consumer ethnocentrism may be defined as: "*a belief held by consumers on the appropriateness and indeed morality of purchasing domestic-made products. Consumer ethnocentrism implies the normative belief that purchasing domestic products is more beneficial than purchasing foreign goods"* (Sharma, Shimp & Shin, 1994).

Ethnocentric countries perceive other nations while taking into account two dimensions. On the one hand there is a concept of 'in-group' that strictly refers to home country. The second type, an 'out-group' touches overseas countries. Such division assumes that the first group is better than second one (Han, 1988).

From the ethnocentric consumers' point of view, the purchase of foreign origin products is improper because it weakens the domestic economy while causing an increase in unemployment. Due to that fact, products manufactured abroad are commonly rejected. Ethnocentrically focused customers, while buying products, are driven not only by economic or emotional reasons, but also by moral ones. However, non-ethnocentric purchasers do not notice such characteristics as the country of origin and while choosing the most adequate products they focus on other features of that commodity. In majority

of occurrences, buying decisions are more rational from the financial benefits viewpoint (Watson & Wright, 2000).

Consumer ethnocentrism has several attributes. First of all, it stems directly from the concern about own country and from the anxiety of losing control over the economy due to increased import. Secondly, it encourages to refrain from buying foreign origin products. Consumers with a significant level of ethnocentrism perceive the acquisition of foreign products not only in the economic context. It also creates problems with their morality. That moral engagement means that consumers in extreme cases purchase domestic products even though their quality is significantly than imported goods (Dyrda, 2010). Thirdly, it can be assumed that the level of consumer ethnocentrism is the sum of tendencies of particular individuals that compose a part of a given social group. Consumer ethnocentrism constitutes a form of economic patriotism in the consumption sphere and while being a social phenomenon it is the result of conscious and purposeful decisions (Han, 1988). Consumers' tendency to favor the purchase of domestic products, even when an entity is aware of product's inferiority to other commodities, results in several positive economic effects from the native country's point of view.

Summarizing, the consumer ethnocentrism's consequence is overestimation of domestic products, depreciation of the import significance and a sense of moral obligation for purchasing domestic products.

Economic activity is strictly based on the sale of products and services offered by any kind of an enterprise. (Rudnicki, 2012). It is known, therefore, that the target object is presented in the person of consumer that can be portrayed as an individual person who acquires and consumes goods or services for own use or ownership rather than for resale or use in manufacturing.

In order to obtain the largest possible number of customers, entrepreneurs need to be acquainted with specific consumers' behaviors their choices are directed by. It is crucial for developing the strategy that enables them to have an impact on consumer and his/ her behavior (Balabanis & Siamagka, 2017).
Nowadays, many definitions concerning consumer behavior may be enumerated. For instance, some authors introduce it as a field of research of cognitive processes and decision- making concerning the purchase and consumption of products and services (Falkowski & Tyszka, 2001). On the other hand it is defined as a set of consumer's actions and perceptions that contribute to preparation of decision on product selection, performance of a given choice and consuming. Moreover consumer behavior consists of three types of reactions: communicating, the purchase and consumption (Rudnicki, 2012).

Throughout the whole life, each person makes uncountable number of decisions. These include significant decisions that cause meaningful changes in human life and long - term consequences. There are also decisions of lower importance which do not cause any changes in human life and relate to everyday matters, such as selection of food, cosmetic brand or way of spending free afternoon.

Majority of decisions are taken immediately, in the heat of the moment and without any particular mental effort. However, some decisions constitute the result of long term analyses of all pros and cons as well as benefits and possible unpleasant consequences. Generally speaking, it is believed that the more important decision for a human is, the longer the period of reflection and extensive mental effort put in taking it is (Falkowski & Tyszka, 2001).

Decision in general may be defined as a conclusion reached after consideration of possible options. It is always associated with the necessity to make a choice. Making decisions relies on choosing a specific action from the set of possible actions.

The purchaser of particular goods is usually identified with the person that takes decision to acquire them. However, it is not always the same person. It is often very difficult to determine the decision - maker because decision making process may involve more than one person (Dyrda, 2010).

Selected Survey Results

The above-mentioned conditions are also typical for Polish consumers who are guided by similar behavioural patterns (Smyczek & Glowik, 2011). The Polish sweets market seems to be the relevant example as Polish sweet products are commonly perceived as of excellent quality. For the purposes of this work a survey was conducted which was an objective of the research. Its topic was to analyse the purchase behaviours of consumers. The following research questions were formulated:

1. Does a country of product's origin have an impact on the purchase decision?
2. Are consumers ethnocentrically oriented in terms of the purchase of sweets?

The survey was conducted on September - October 2019. The respondents were answering on the internet. There were 60 respondents involved with 57% of women and 43% men within the age range of 18 – 65 years who originated from Silesian region in southern Poland. They were chosen at random. The sample is justified by the region's population density and demographical structure which is reflected in it.

The first question related to the product's label. The results are presented in Figure 1. Results are based on a conducted survey.

Fig. 1: Particular attention to product's label

In the above mentioned question respondents had to decide whether a product's label has a piece of importance for them. Results show that major group usually scrutinizes labels (47%) while 25% of them always do it. Respondents who seldom look at labels constitute 23% of the surveyed group. Only 5% of questioned people never pay attention to product's label.

Generally speaking, it can be assumed that 72% of respondents check labels to a greater or lesser extent. In this question respondents were to determine whether the product's country of origin was important to them.

Fig. 2: Importance of product's country of origin

The question of country origin was presented in Figure 2. Results are based on a conducted survey. According to 40% of respondents, the country or origin has a piece of importance in the moment of purchase. Two groups of 30% surveyed answered that it is not important and defined it as difficult to say as well.

In following question respondents were to indicate whether they agree or disagree with the following statement: 'If there is a possibility to choose I prefer the purchase of foreign products instead of domestic ones'. Received answers were as follows and are presented in Figure 3.

Fig. 3: Consumers' preferences in terms of country of origin

.

The above question concerns preferences referring to the country of origin. 32% of respondents respond to not agree with mentioned sentence. The same percentage of surveyed perceived this enquiry as difficult to say. Remaining both groups of 18% of respondents neither disagree nor agree or agree with stated phrase. In the following question respondents were to indicate their preferences in terms of product's country of origin in terms of food.

Fig. 4: Consumer's preference of country of origin in terms of food.

While speaking about food products respondents absolutely prefer goods produced domestically (90%) which is illustrated in Figure number 4. Only 3% of surveyed favors products produced domestically but possessing foreign brands whereas 2% picks those produced abroad. For 5% on respondents country of origin is not important.

According to the greatest group of respondents, detergents and cosmetics produced abroad are most frequently chosen by 38%. 20% of surveyed picks produced domestically goods whereas 18% favors produced domestically but with foreign brands ones. The country of origin is not important for 23%. The next question concerns the perception of sweets produced in Poland which is presented in Figure number 5.

Fig. 5: Superiority of sweets produced in Poland over foreign ones

In above enquiry respondents were asked to present their point of view in terms of sweets produced in Poland. 25% of surveyed perceive them as rather better than foreign ones and 12% view them as definitely better ones. Poland's sweets are recognized as rather not better than foreign ones by 20% of respondents and as definitely not better by 3%. 40% of surveyed conclude that it is difficult to say.

It can be assumed that 37% of respondents in total treat sweets produced in Poland as better than those from abroad. In the next question respondents were declaring their preferences on the origin of sweets producers.

Fig. 6: The purchase of sweets coming from Polish producers only

The majority of respondents seems to be tolerant and buys both Polish and foreign brands sweets (57%). 22% of surveyed desire to buy sweets coming from Polish producers only whereas 2% purchases only foreign brands. 20% perceives this question as difficult to answer.

Results from this question, illustrated in Figure number 6, show that almost one-fourth of respondents are directed only for specific countries of origin: 22% of surveyed desire to purchase only Polish products whereas 2% looks for foreign brands only.

It can be also seen that over one-fifth of asked people (22%) may be perceived as ethnocentric consumers who value only national products and desire to assist only domestic economy. The following question relates to the better exposure of Polish brands of sweets in a store and is presented in Figure number 7.

Fig. 7: Indication of Polish brands in a store

In the last question respondents were asked to express their opinion on the improvement of Polish brands' visibility in a store. The major group answered that Polish sweets rather should be better indicated (37%). Additionally, 28% of surveyed claims that they should be definitely demonstrated in more visible way. According to 8% of respondents there should not rather be any improvement in that case whereas 2% definitely do not support this idea. One-fourth of surveyed perceives this question as difficult to say (25%).

Generally speaking, 65% of respondents manifest the urge for improved visibility of Polish brands in a store.

Conclusions

Summarizing the above findings the following observations based on the survey were made attempting to offer the answer to the research question on a consumers' ethnocentrism influence on the purchase decision process in Polish sweets market.

- 37% of respondents perceive Polish brands of sweets as superior to foreign ones whereas 40% of them perceive that question as difficult to answer. It assumes that over one-third of surveyed can be described as ethnocentrically oriented. A significant number of persons indicate uncertainty of purchased products quality what- as it can be visible after conducted research- was caused mainly by lack of knowledge concerning the recognition of Polish brands.
- Over one-fifth of respondents (precisely 22%) express the urge for the purchase of only Polish brands of sweets. The conviction regarding the purchase of domestic products in terms of duty for assisting national economy is visible here.

- 40% of respondents described country of product's origin as important factor of purchase decision whereas 30% of surveyed do not pay particular attention for that aspect. 30% view question no 5 as difficult to answer.
- 37% of respondents perceive Polish sweets as superior to foreign ones. However, 22% of surveyed expresses the urge for the purchase of only domestic brands. It assumes that over one-fifth of society wants to buy sweets only domestically what can be treated as a symptom of consumer ethnocentrism. This phenomenon in some way encourages to the purchase of local products.

More detailed research in this area is required, however preliminary simplified results confirm the assumption that ethnocentrism is of key importance in consumer choices in Poland and the sweets market is a good example of this phenomenon.

Abstract

Corporate social responsibility (CSR) and sustainability efforts are of increasing importance to consumers when making purchasing decisions. The telecommunications industry is one of the most heavily regulated industries in the DACH countries (Germany, Austria, Switzerland and Liechtenstein), with only a few participating companies generating the highest revenues. This example will be used to examine the dynamics of CSR practice in an oligopolistic market. Despite its increasing importance, there are hardly any studies on the CSR practices of mobile network operators (MNO) in the DACH countries. Therefore, their CSR strategies and activities shall be analysed for similarities, differences and trends. First, a literature review was conducted to identify research on the topic, and all MNO in the DACH countries were identified. Subsequently, the reporting of the individual companies' CSR activities since 2017 was analysed. MNO in the DACH countries take their social responsibility seriously and practise diverse and comprehensive CSR strategies. Health and mobile radiation exposure is an essential element in all CSR strategies. Furthermore, the topics of sustainability, energy efficiency, climate and environmental protection, infrastructure development, diversity, occupational safety and health, data protection and security, protection of children and minors and digital literacy and inclusion are essential elements of CSR in MNO. The mobile communication industry in the DACH countries shows exemplarily the dynamics of how CSR practice in an oligopolistic market works.

Keywords: MNO, CSR, Strategic Management, Mobile Communication

Introduction

The social responsibility and sustainability efforts of mobile network operators (MNO) are becoming increasingly important for consumers when making purchasing decisions (Lee et al., 2015). Corporate social responsibility (CSR) communication, especially sustainability reporting, is an essential tool for highlighting and disseminating initiatives and steps to support sustainable development. The Global Reporting Initiative's (GRI) sustainability reporting framework is in the process of becoming the world's most widely used standard for CSR reporting in large corporations (Blasco & King, 2017) In the DACH countries (Germany, Austria, Switzerland and Liechtenstein), the telecommunications industry is one of the most heavily regulated industries. Only a few companies operating on the market achieve the highest revenues – the MNO can, therefore, be seen as an oligopoly in the DACH countries. Although more and more MNO are reporting separately on CSR initiatives and the achievement of their social and environmental goals, the information is often not detailed enough to be of value (Bhandarkar & Alvarez-Rivero, 2007). Standardised and consistent reporting is essential if CSR activities in MNO are to be monitored and managed (Bowrey & Clements, 2019). Accordingly, the market considered in this paper presents the mobile communication industry – specifically the MNO market – in the umbrella countries on the basis of their sustainability reporting. Despite the increasing importance of CSR in the practice of MNO, hardly any research exists in this area. There is an especially small amount of literature available on the question of how mobile services can be made more sustainable, fair and transparent.

Therefore, this study aims to analyse the application and implementation of CSR strategies of MNO providers in the DACH countries and to qualitatively analyse them for similarities, differences and trends. Furthermore, this example will be used to examine findings on strategic corporate management and dynamics of CSR in an oligopolistic market. The obtained results are intended to provide meaningful insight into business practices and extend the existing literature. First, the study carried out a literature review. It then identified all MNO in the DACH countries and analysed their sustainability and their reporting of CSR activities since 2017.

Literature Review

In the DACH countries, the mobile communications market is characterised by different players and different sub-markets. These can be divided into MNO and mobile virtual network operators (MVNOs). MNO are companies that operate and manage the infrastructure (e.g. cable connections, switching stations, the core network and network management systems) to provide mobile services, and thus they act as the market's network operators. MNO, therefore, have access to all network capacities, which they license to MVNOs in addition to their core business through a cooperation strategy, thus making their mobile network services available to other companies (Luber & Donner, 2019). Accordingly, MVNOs do not have their own networks, and they act as resellers by cost-effectively marketing mobile services under their product and brand names. An MVNO is thus characterised by a strategy of cost leadership (Nollau, 2017). In the DACH market under review, the MNO players are divided as follows. The German mobile communications market is made up of three MNO providers: Telekom Deutschland GmbH, Vodafone GmbH and Telefónica Germany GmbH & Co. OHG (Bundesnetzagentur, 2020). The Austrian mobile communications market also consists of three MNO providers: T-Mobile Austria GmbH, Telekom Austria AG and Drei Austria GmbH (ICT Kommunikation, 2020). The Swiss mobile communications market subsumes the companies Swisscom AG, Sunrise Communications AG and Salt Mobile SA under the term MNO (BAKOM, 2020). The mobile communications market in Liechtenstein comprises a total of three MNO, each with its own infrastructure: Telecom Liechtenstein AG, Swisscom (Schweiz) AG and Salt (Liechtenstein) AG (Amt für Kommunikation, 2020).

There is currently little knowledge on the subject of CSR in mobile communications companies. Although more and more mobile communications companies are reporting on their CSR initiatives and the achievement of their social and ecological goals, the information is often not detailed enough to be meaningful (Bhandarkar & Alvarez-Rivero, 2007). There is little literature available, especially on how to make services in the mobile communications industry more sustainable, fair and transparent (Wang et al., 2016). With reference to this, numerous research deficits are explicitly seen in the areas of 'climate protection', 'fairness and transparency' and 'data protection' (WEtell, 2019).

In the modern global economy, behaving appropriately socially responsibly is now seen as a social necessity (Marsden & Andriof, 1998). Accordingly, customers are increasingly demanding that mobile communications companies also assume social responsibilities (Lee et al., 2015). Standardised and consistent reporting is essential if CSR activities are to be monitored and managed (Bowrey & Clements, 2019). The question for MNO is no longer whether CSR activities should be carried out, but rather how they should be carried out (Smith, 2003). In line with this, CSR has also gained importance in management research (Schneider, 2015). Accordingly, CSR must not only be understood as a business management process but must also be professionally integrated into the area of strategic corporate management (Maignan & Ferrell, 2004). Indeed, international standards and a wide range of instruments (e.g. certification, corporate mission statements and sustainability reporting) or comprehensive management systems are available for modelling CSR in mobile communications companies (European Commission, 2004). In return, sustainability and social concerns can be significantly promoted through their inclusion in CSR frameworks and standards as companies must take these concerns into account in their CSR reporting (Miethlich, 2019). However, so far, there is little knowledge about the implementation of specific CSR activities (Peloza & Shang, 2011; Wang et al., 2016). Therefore, the acquisition of profound knowledge of how CSR activities affect mobile communications customers – in terms of their overall impression of the company and its benefits –

remains of great importance for strategic corporate management (Chen et al., 2018; Peloza & Shang, 2011).

Increased competition in oligopolistic markets – such as the mobile communications market – leads to increased adaptation and activity of CSR (Hawn & Kang, 2018) and can lead to a sustainable competitive advantage (Lambertini & Tampieri, 2015). In oligopolies, strategic market considerations seem to be the primary reason for a company's implementing of CSR (Lambertini & Tampieri, 2015; Wirl, 2014). Companies operating in an oligopolistic market play a pioneering role here, which other companies adopt. This 'rat race', therefore, explains the rapid adaptation and the great growth of CSR in oligopolistic markets (Wirl, 2014). On the positive side, the presence of companies with CSR can be seen as effective self-regulation of an oligopolistic market (Lambertini & Tampieri, 2015). For example, one of the few existing studies on CSR in the mobile communications market, which uses the South Korean mobile communications market as an example, showed that CSR is a key factor for competitive success. A positive correlation was found between CSR and customer satisfaction and the decision to choose a provider (Lee et al., 2015).

This anchoring of CSR is particularly elementary in the area of strategic management with regard to the achievement of sustainable competitive advantages in the mobile sector. Only through this can mobile communications companies achieve and maintain a competitive position in the market (Bea & Haas, 2016). However, CSR activities can only give mobile communications companies a real competitive advantage if they succeed in generating or expanding actual customer benefits (Papulova & Papulova, 2006). Sustainability reporting, therefore, plays an important role in mobile communications companies' generation of competitive advantages from their CSR activities. Only through customer awareness of their commitments can advantages for the company be created (Peloza & Shang, 2011). The method for achieving and securing a lasting competitive advantage is referred to in the specialist literature under the term 'competitive strategies' (Kerth et al., 2015). Porter (2008) discusses competitive strategies, and Baumgartner and Ebner (2010) discuss the classification of CSR strategies, dividing them into conservative, visionary, introverted and extroverted strategies. According to Porter (2008), the basic strategic options for gaining a competitive advantage are differentiated into two types: the strategy of cost leadership and the strategy of differentiation. Porter posits that a competitive advantage can only be achieved if entrepreneurial action is taken by focusing on one of the two main strategic directions: either the most favourable cost structure (strategy of cost leadership) or differentiation (strategy of differentiation). For this reason, these strategy options are also known as generic competitive strategies (Porter, 2008). Within these generic strategies, there is a third option concerning the cultivation of the market area: the strategy of concentration on focal points. In this case, the concentration takes place in a sub-market – e.g. an industry or a target group – that has a certain structure of needs (Bea & Haas, 2016). The validity of the respective generic competitive strategies is industrywide, whereas, in the strategic approach of concentration on focal points, it is only specific to the respective segment (Porter, 2008). Accordingly, the market to be addressed is defined by focusing on a niche of the respective industry (Kerth et al., 2015).

The prerequisite for gaining a sustainable competitive advantage in the mobile communications sector is profound knowledge and a clear understanding of customers' needs. Only if customer needs are met profitably, effectively, consistently and better than by competitors can a real competitive advantage be created (Papulova & Papulova, 2006). In this respect, CSR activities are very suitable as a means of developing differentiation strategy methods in the mobile communications market (Chen et al., 2018). Within this strategic sub-area, decisions on services are considered a market-related problem. The respective components of the differentiation strategy represent intangible (and tangible) problem solutions in line with customer needs (Brockhoff, 1999). Satisfying customer needs through a service programme geared to those needs can ensure that strategic marketing and corporate goals are achieved (Meffert et al., 2015). These aspects thus make a sustainable contribution to the corporate success and viability of mobile communications companies in the DACH market.

Methods

First, all MNO in the DACH countries were identified. Then, the CSR, sustainability and annual reports from 2017 to 2019 were examined with regard to CSR activities. The identified MNO were asked by email to provide any missing information, such as the year for which the first CSR or sustainability report was published. Furthermore, the GRI database (GRI, 2020) was used for complementary information. The scientific publication databases Web of Science and Scopus were also searched for research on the topic using the following query: *('CSR' OR 'social responsibil*') AND ('MNO' OR 'mobile network operator' OR 'telecom*' OR 'MNO') AND ('German*' OR 'Austria*' OR 'Switzerland' OR 'Swiss' OR 'DACH' OR 'Liechtenstein')*. Three publications were found in the Web of Science database and 10 were found in the Scopus database, of which only two articles at least partially dealt with the CSR practice of MNO or telecommunications providers in the DACH countries.

Results

The literature research carried had only revealed an investigation into the CSR of a Swiss MNO and a further article on an Austrian MNO. No additional literature on the subject exists. Sachs et al. (2006) examined the organisational and strategic implementation of CSR at Orange SA, a Swiss MNO and predecessor of Salt Mobile SA, and pointed out variants for interaction with stakeholders. Szőcs et al. (2014) investigated the Austrian mobile communication market and demonstrated a positive correlation between CSR and corporate reputation. There are no studies on the CSR practices of MNO or the telecommunications industry in general in the DACH countries. On this basis, the CSR and sustainability reporting and annual reports of the companies identified were examined concerning their CSR activities. The identified MNO in the DACH countries are listed in Table 1, and the form of CSR reporting is described.

Table 1: Overview of sustainability/CSR reporting by MNO.

Country	MNO	Sustainability/CSR reporting
Germany (D)	Telekom Deutschland GmbH	1996: first reports on sustainability activities in various publications* From 2003, combined personnel and sustainability reports* From 2004, also reports according to GRI standard* From 2008, separate CSR report* Annual reporting to date
	Telefónica Germany GmbH & Co. OHG (O2, E-Plus)	2006: first CSR report? From 2009, GRI Standard Separate CSR reports Annual reporting to date
	Vodafone GmbH	2001: first CSR report* Separate CSR report From 2009, GRI Standard Parent company maintains international CSR reports Annual reporting to date
Austria (A)	Telekom Austria AG (A1)	2005: first CSR report? CSR report integrated into the annual report From 2005, GRI Standard Annual reporting to date
	T-Mobile Austria GmbH (Magenta)	2010: first CSR report? Separate CSR report From 2011, GRI Standard

		Annual reporting to date
	Drei Austria GmbH (3)	No dedicated CSR reporting; the superordinate, international holding company maintains CSR reports Annual reporting to date
Switzerland (CH)	Swisscom AG (formerly Schweizer Telecom)	1997: first CSR report* Separate CSR report From 2009, GRI Standard* Annual reporting to date
	Sunrise Communications AG	2015: first CSR report* Separate CSR report Annual reporting to date
	Salt Mobile SA (formerly Orange SA)	No CSR reporting* Only keywords on the website, no specific reports or further information about them (Orange SA had CSR reports already from 2001, according to GRI)
Liechtenstein (FI)	Telecom Liechtenstein AG (FL1)	No dedicated CSR reporting References to individual CSR activities integrated into the annual report
	Salt (Liechtenstein) AG (7acht)	No dedicated CSR reporting
	Swisscom (Schweiz) AG	No dedicated CSR reporting

*Sources: Company websites, *provided by the company by email.*

Most MNO in the DACH countries carry out regular annual CSR or sustainability reporting. The first reports date back to 1996 in Germany and 1997 in Switzerland, and CSR was, therefore, a strategic issue in both countries at a very early stage, much more rapid than in other sectors. The CSR reports are mostly published separately and are based on the GRI standard. There are also a few mobile communication companies that have recently stopped publishing CSR reports, but have previously done so for more than a decade. This applies, for example, to the Swiss MNO Salt Mobile SA. It is noticeable that no MNO in Liechtenstein carries out dedicated CSR reporting.

The CSR and sustainability reporting, as well as the annual reports of the identified MNO, were examined for their CSR activities. The only criterion was that the activities had to go beyond the legal minimum. The activities found were assigned generalised terms, which are listed in Table 2 for each company.

Table 2: Overview of MNO' CSR activities in the DACH countries.

Country	MNO	CSR activities (cumulative)
D	Telekom Deutschland GmbH	Digital literacy, Digital inclusion, Health and mobile radiation exposure (EMF), Occupational safety and health, Infrastructure development (network quality and reliability, service for all), Climate and environmental protection, Cultural and sports sponsoring, Sustainability (products, services, operations and supply chain), Cyber security, Consumer protection and security, Protection of children and minors, Diversity, Equal opportunities
	Telefónica Germany GmbH & Co. OHG	Data protection and security, Digital inclusion, Health and mobile radiation exposure (EMF), Occupational safety and health, Good employer, Protection of children and minors, Sustainability (products, services, operations and supply chain), Climate and environmental protection
	Vodafone GmbH	Supply chain integrity and safety (working conditions and sustainability), Health and mobile radiation exposure (EMF), Digital literacy, Diversity, Social inclusion, Energy efficiency, Sustainability (products, services, operations and supply chain), Data protection and security
A	Telekom Austria AG	Digital literacy, Digital inclusion, Products with social added value, Sustainability (products, services, operations and supply chain), Climate and environmental protection, Energy efficiency, Infrastructure development (network quality and reliability, service for all), Data protection and security, Health and mobile radiation exposure (EMF), Diversity, Occupational safety and health, Good employer
	T-Mobile Austria GmbH	Diversity, Protection of children and minors, Data protection and security, Digital inclusion, Accessibility/being barrier-free (in shops, website, services etc.), Infrastructure development (network quality and reliability, service for all), Sustainability (products, services, operations and supply chain), Climate and environmental protection, Energy efficiency, Good employer, Health and mobile radiation exposure (EMF), Occupational safety and health, Equal opportunities
CH	Swisscom AG	Digital literacy, Data protection and security, Protection of children and minors, Sustainability (products, services, operations and supply chain), Accessibility/being barrier-free (in shops, website, services etc.), Good employer, Supply chain integrity and safety (working conditions and sustainability), Climate and environmental protection, Energy efficiency, Health and mobile radiation exposure (EMF), Energy efficiency, Occupational safety and health, Diversity, Equal opportunities
	Sunrise Communications AG	Energy efficiency, Climate and environmental protection, Sustainability (products, services, operations and supply chain), Diversity, Cyber security, Data protection and security, Infrastructure development (network quality and reliability, service for all), Good employer, Occupational safety and health, Health and mobile radiation exposure (EMF), Digital literacy, Corporate volunteering, Support of domestic social initiatives

	Salt Mobile SA	Health and mobile radiation exposure (EMF), support of recycling initiatives, support of public health projects
FL	Telecom Liechtenstein AG	Sustainable management and development, Health and mobile radiation exposure (EMF), Good employer

Source: Sustainability and annual reports from 2017.

The CSR activities of companies are generally very comprehensive and diverse. Health and mobile radiation exposure was named by all MNO as an important CSR activity, with information included in reports on radiation as well as on the limits and their radiation levels, which are all below the legal limits. Sustainability is also a central issue for almost all MNO (i.e. achieving sustainability in their products, services and supply chain). For most companies, this also includes the topic of energy efficiency, in the sense of reducing energy consumption and purchasing from sustainable sources. Climate and environmental protection is, therefore, an aspect of CSR for almost all companies. At the same time, the expansion of infrastructure to achieve the broadest, most reliable and best possible coverage is also a topic in the context of CSR. Social CSR activities refer in particular to occupational safety and health and diversity in the workforce, as well as the fact that MNO themselves want to be good employers. Furthermore, digital literacy, data protection and security, protection of children and minors, digital inclusion and accessibility/being barrier-free (in shops, websites, services etc.) are further aspects of CSR.

Conclusion

CSR has become increasingly important in management research in general and is fundamental in the mobile sector's achievement of sustainable competitive advantages. Mobile communications companies in particular succeed in achieving and maintaining a competitive position in their saturated markets through product differentiation. However, CSR activities can only give companies a real competitive advantage if they succeed in generating or expanding actual customer benefits. Despite the increasing importance, there are hardly any studies on the CSR practice of MNO in the DACH countries. Therefore, this study has analysed their CSR strategies and activities and examined them for similarities, differences and trends.

MNO in the DACH countries take their social responsibility seriously and practise diverse and comprehensive CSR strategies. MNO started sustainability and CSR reporting at an early stage: Deutsche Telekom reported publicly on its CSR activities as early as 1996, and Schweizer Telecom began one year later, in 1997. Health and mobile radiation exposure is an essential element in all CSR strategies. Moreover, the topics of sustainability, energy efficiency, climate and environmental protection, infrastructure development, diversity, occupational safety and health, data protection and security, protection of children and minors, digital literacy and digital inclusion are important elements of CSR in MNO.

The analysis also showed that some MNO, such as Salt Mobile SA, no longer maintain or publish CSR reporting. This aspect serves as an indicator that CSR in the DACH countries is not always influential on the purchase decisions of customers. This circumstance may also be because the MNO sector has been making CSR efforts and reporting on it from early on – for decades. For this reason, CSR is taken for granted by customers and is less effective as a means of product differentiation. This can also be seen as an indication of the characteristics of an oligopolistic market: at first, companies adapt each other's product differentiation strategies quickly and comprehensively, but after the strategy has been exhausted, they slowly abandon it, one by one. It also appears that in the case of MNO, the transformation of the international CSR strategy to the regional level is not working sufficiently.

In summary, it can be said that CSR activities in the DACH countries are comprehensive and diverse. In Germany, this aspect is strongly pronounced in all MNO. In both Switzerland and Austria, on the other hand, there is one MNO that hardly conducts any CSR activities (or simply does not report on

them). In Liechtenstein, CSR, or at least CSR or sustainability reporting, still seems to be of no significance for MNO.

The mobile communications industry in the DACH countries is an example of how the dynamics of CSR practice work in an oligopolistic market. The study has comprehensively shown the current situation of CSR practice of MNO in the DACH countries. A further area in need of research is the analysis of the strategic contribution of CSR to business success in the mobile communications market (as an oligopolistic market).

Abstract

This work is articulated in the context of our research which is big data and mental health, we will talk about big data, its chronology, its characteristics and its relationship with business intelligence, then we will present the relationship between big data and mental health and finally a literature review on nomophobia one of the mental health disorders. We are also interested in this work, to introduce machine learning, its different algorithms, its applications as well as its relationship with big data, and finally part of this chapter is devoted to the use of supervised learning methods for classification of the state of nomophobia in students. The main objective of our project is to study the psychology of university students and to know their nomophobia state which has consequences on the physical and psychological health of the individual. In general, the recommendations we will work on involve activating the program and rendering it in the form of an information system that will always be accompanied by its owner. The system will be converted into an application which will be downloaded to a smartphone. It will also be equipped with information and tests which will be accessible offline without the presence of the Internet.

Keywords: Machine learning; Big Data; Business intelligence; Psychology; Consciousness; Intelligent system.

Introduction

Nowadays, scientific research in the field of psychology and its relationships with technology are becoming more dynamic. This fact has led researchers to offer products that help booming humanity by combining a range of fields such as medicine, psychology, sociology, education and technology. There are still many constraints on the mental health sector such as new technologies: smartphones which are the source of several diseases such as nomophobia. The challenge for mental health specialists is to ensure quality care for their patients while minimizing costs. When data access and information analysis functions are available at all levels of a mental health business, it has multiple benefits: can monitor effective treatments and optimize results so that effective decisions can be made. In addition, precise information helps companies in this sector to identify the most efficient service and workflow practices. In this work, we tried to facilitate the task of descriptive analysis of our data by the use of the technologies and the most known tools in this field. The quantitative explosion of digital data has forced researchers to find new ways to see and analyze the world. It is about discovering new orders of magnitude concerning the capture, research, sharing, storage, analysis and presentation of data. Thus, was born the « ***Big Data*** ». It is a concept for storing an unspeakable number of information on a digital basis. According to the archives of the digital library of the Association for Computing Machinery (or ACM) in scientific articles concerning the technological challenges to be met in order to visualize « large data sets», this designation appeared in October 1997. Literally, these terms mean big data. They denote a very large set of data that no conventional database or information management tool can really work. Indeed, we procreate about 2.5 trillion bytes of data every day. Its information from everywhere: messages we send to ourselves,

videos we publish, climate information, GPS signals, transactional recordings of online purchases and much more. This data is called Big Data or massive volumes of data. The web giants, at the forefront of which Yahoo (but also Facebook and Google), were the very first to deploy this type of technology. However, no precise or universal definition can be given to Big Data. Being a complex polymorphic object, its definition varies according to the communities which are interested in it as a user or service provider. A transdisciplinary approach makes it possible to apprehend the behavior of the various actors: the designers and suppliers of tools (computer scientists)[1], the categories of users (managers, business managers, political decision-makers, researchers), health actors and users. Big data does not derive from the rules of all technologies; it is also a dual technical system. Indeed, it brings benefits but can also generate disadvantages**.** Thus, it is used by speculators on the financial markets, independently with, at the end, the creation of hypothetical bubbles.

The arrival of Big Data is now presented by many articles as a new industrial revolution similar to the discovery of steam (early 19th century) of electricity (late 19th century) [2] [3] and computers (late 20th century)**.**Others, a little more measured, qualify this phenomenon as being the last stage of the third industrial revolution, which is in fact that of "information". In any case, Big Data is seen as a source of profound upheaval in society. Big Data issues and challenges are far from new. If we look at the chronology of the events that created Big Data as we know it today, we can see that this genesis goes back quite a long time and that idea had to convince and that the solutions mature in order to get there (see table 1).

Table 1 : Chronology of BIG DATA

Date	Events
1997	First appearance of the term Big Data (NASA) to designate the challenge of working with large volumes of unstructured data
1998	First NoSQL database (and use of the term) by Carlo Strozzi
2000	Neo4j (NoSQL database oriented graphs)
2001	First definition of Big Data (Volume / Variety / Velocity) by Gartner
2005	Birth of Hadoop
2005	Birth of CouchDB (NoSQL document-oriented database)
2006	Google BigTable publication
2007	HBase birth (document-oriented database)
2007	MongoDB database (document-orienteddatabase)
2008	Birth of Cassandra (partitioned NoSQL database)
2008	Creation of Cloudera company
2009	Birth of Spark (data analysis)
2010	Creation of DataStax (Cassandra)
2011	Creation of the company Hortonworks
2014	Spark breaks the record "Terabyte releases Benchmark"

Here is a list of the sources and nature of the most common data in Big Data:
Sources

- Business data,
- History of use of your services by users,
- Customer files (Customer Relationship Management (CRM))
- Data provided by partners
- Social media
- Call centers ...

Nature

- Transactions (e-commerce)
- Geolocation
- Social media
- Emails/documents
- Internet of Things (sensors, ...)
- Pictures
- Audio

Big Data and Mental Health

Mental health (including addiction) is the fifth contributing factor to the global burden of the disease, with an economic cost estimated at 2.5 trillion US dollars in 2010, which is expected to double by 2030. Developing information systems to support and strengthen mental health at the population level health surveillance is an essential element of the World Health Organization's Global Action Plan 2013-2020.

The widespread use of social media, combined with the rapid development of IT infrastructures for efficient processing of "Big Data" and above all, the maturation of natural language processing (NLL) and machine learning (ML) technologies offers interesting opportunities for improving health at the population and individual levels.

The use of “big data” social media for health applications - health applications in particular for the public - is a rapidly growing field of research, variously called infoveillance, digital epidemiology, and digital disease detection. Mental health has been a subject of research for NLP researchers since the beginning of the discipline, as evidenced by the interactive psychotherapist program ELIZA Rogerian by *Weizenbaum* (1966) and the "paranoid" conversation agent by Colby, PARRY (1972). As you would expect, the domain has evolved a lot since the development of these first chatbots [4]. Recent work uses sophisticated NLP and ML methods to, for example:

- Predict the risk of suicide of active duty military personnel using data from the electronic medical record.
- *Choudhury et al.* describes the creation of a dataset on Twitter using participatory sources from Twitter users with depression scores indicative of CES-D (*Center for Epidemiological Studies-Depression*). This data set was then used to form an ML statistical algorithm capable of identifying tweets indicative of depression, and then applied to geocoded Twitter data derived from 50 American states, the results being closely correlated with depression data from the United States Centers for Disease Control.
- Automatic personality assessment via social media language: Researchers used data from users of my Personality, a Facebook application designed to measure personality variables (including "Big 5" variables). The researchers used a sample of 71,556 participants who had both completed the online personality questionnaire and granted access to status updates on Facebook.

Recent technological advances have considerable potential for understanding and improving mental health, both at the individual and population levels. However, risks in particular for privacy remain for example nomophobia.

Nomophobia, The Evil of Generation Z

Nomophobia, by definition, is a phobia linked to the anxiety of not having your mobile phone at hand. Nomophobia for no mobile phone phobia is a new kind of disorder linked to our new digital consumption. Being permanently connected to your smartphone via our applications and our social

networks has become a real reflex. To the point where you can sometimes feel completely lost if you don't have your phone with you all the time.

- ***Technology, Towards Nomophobia***

Nomophobia has the negative consequence of increasing anxiety, even anxiety attacks that can result in chest tightness; lumpy sensations in the throat and stomach, nausea and vomiting, abdominal pain. Behavioral symptoms may also develop. The most frequent is the avoidance of situations where the nomophobia person could be deprived of his mobile [5]. An individual suffering from such dependence thus risks reducing his range of possibilities. For example, he will refuse to go to places where he could find himself cut off from the network.This addiction to the mobile phone is sometimes, especially in young people, correlated with personality disorders, or disorders such as obsessive-compulsive disorder or social interaction anxiety.

- ***The causes of nomophobia***

Nomophobia has been booming since the appearance of smartphones, making it possible to be permanently connected to the world through the Internet and social networks. For nomophobes, the anxiety of being deprived of their smartphone rather symbolizes the fear of being isolated, cut off from the world. Boredom can also be a possible cause of addiction to cell phones and nomophobia (the subject is playing more and more on his cell phone to pass the time) [7].

- ***The consequences of nomophobia***

This phenomenon has many consequences, both socially and on the health of smartphone users. On **the social level**, we observe social isolation. The user cuts himself off from the outside world, leaving his loved ones behind his phone, even in public places. In the bus, the train, at home, in front of the television, in the bedroom and even in the toilet, the smartphone has invaded all spaces. We also observe a trivialization of the language through coded writing. The user will write a large number of text messages in which the words will be shortened, abbreviated and phonetically written. These coded messages popularized by the younger generation are sometimes incomprehensible for an older generation.

In terms of health, especially in children and adolescents, there are difficulty concentrating, insomnia or poor quality sleep due to electromagnetic waves emitted by the telephone, brain tumors, neck pain , dysfunction in the hand and wrist in the most addicted.

- ***The impact of nomophobia on human psychology***

Nomophobia causes psychological disorders resulting in an excessive, uncontrollable or even obsessive need to use a telephone to the point of spending so much time and energy, that the object and its use end up negatively interfering with the daily, professional or emotional life of the subject who may develop anxiety, sometimes phobic and / or depression which will also indirectly affect those around him. Many users have become slaves to their smartphones, to the point where they can be panic attack, their breathing may become short, nausea, tremors or an accelerated heart rate.

Figure 1: The French and the Smartphone in 2016

Result

The analysis of key indicators collected from officials of the Ministry of Health will be carried out according to different axes of analysis. These were developed according to the needs of managers and also according to the availability of data.

Following the needs analysis that we conducted, it was necessary to plan the creation of the following dimensions:

- Age.
- Level of study
- Gender
- Response

This phase places us in the seventh step of the "Dashboard system" work conduct methodology. We took a bottom-up approach to building our data warehouse. « *This approach called "Bottom-Up" consists in going from the bottom up, in other words, starting by designing the datamarts and grouping them thereafter until obtaining the datawarehouse* ». In our case, it is the construction of the two datamarts of consultations and treatments.

Choice Of Multidimensional Model

We presented in the second chapter the different diagrams of a DWH: star and snowflake. In our case we opted for the star model, which is the classic model. It is considered to be the simplest model and one that offers great ease of navigation.

We chose this model for several reasons to cite:

- Queries are faster on a star schema.
- The adaptability of this model to 1-n cardinalities between the fact table and the dimension tables, which is the case for the relationships between the facts and the dimensions that we have noted.
- ETL is simpler with a star diagram.

- The space occupied by the dimension tables is negligible compared to that of the fact table; indeed the majority of the dimension tables that we have collected are not large.
- Performance: Limited number of joins, management of sparse data [8].

Although the star model has some drawbacks such as redundancy in dimensions, especially in dimensions that have a hierarchy, but it is the most suitable model for our case.

The design of a remote psychotherapy application« E-psychotherapy»

We have previously seen the importance of machine learning algorithms for classifying the state of nomophobia for students. In the same spirit, we thought of implementing a design of a mobile psychotherapy application that allows each user to pass psychological tests:

- ***Personality test:*** from a set of questions see **appendix 5**, the test allows to assign a score for each user and from this score we can know the personality of the user, for this fact we can base on a code programmed in C language see **appendix 4.**
- ***Nomophobia test***: this test allows to know the state of the user towards nomophobia, in other words it allows to classify the user in 3 classes : « *nomophobic, risk of being nomophobic, is not nomophobic* »

In addition, the application allows the user to chat with an online psychologist, this allows users who refuse to visit a psychologist to be in contact with one and share their problems.
The fact table "consultation_fact" contains information about students, such as age, gender, level of study, and their responses regarding psychology. Data used as analysis axes is entered as foreign keys referring to dimension tables which contain the data integrity of each dimension. The figure 2 represents the multidimensional model of this datamart. On the other hand, we built the multidimensional model of Datamart "nomophobia" using a fact table connected to dimension tables. (see Figure 3)

The fact table called "*nomophobia fact*" contains data which come from different different source tables; they make it possible to calculate the indicators relating to nomophobia.
The fact table "*fact nomophobia*" contains the primary keys of all the dimension tables with which it is linked.

Use cases represent the services that the system to be developed must provide according to the needs of each actor. In this section we present the use cases of our application. The figure 4 illustrates the structure of the major departments needed with supervisors and subjects. Besides, the figure 5 represents the class diagram of the system. The class diagram describes the classes that the system uses.

Figure 2 : Datamart E-psychotherapy

Figure 3 : Datamart Nomophobie

Figure 4: Identification of use cases

Figure 5: Class diagram

Discussion

Psychologists agree that this addiction to Smartphones is most often the result of a deficiency. Social networks for example meet three human needs: attachment, group membership and recognition. If one of these needs is not met, creating a virtual and ideal "me" can be a way to compensate. The fashion of the selfie testifies to this narcissism assumed by the users. They need to exist permanently. Another psychological impact, users no longer accept being frustrated. With smartphones they have everything right now. Older users have lived without smartphones and are therefore less affected by this phenomenon. But young adults, those born with a smartphone in their hands, do not experience this feeling of frustration. Or little. The problem is that successive developments have not helped users to mitigate the impact of smartphones on their daily lives. Manufacturers are making ever more efficient devices and operators are offering ever cheaper plans with ever greater data volumes. And we don't even talk about connected objects. So yes, psychologically, a lot of users have become completely addicted. So much so that they favor virtual relationships over real relationships. Their virtual "me" has taken over their real "me". All observers note that human relations have deteriorated since the emergence of the smartphone.

In this part, we tried to make a general design of our application in which we presented some models (mockups) using an online software called **CREATELY** which is a tool for creating diagrams online. (see figure 6)

Figure 6: Creately interface

At the first level, the application allows the user to display the start page. This is the door to the main window. This interface contains the logo of the application as well as a "connection" button which allows the user to connect to the application (see figure 7). In the interface illustrated in figure 8, the user enters his login and password to connect to the application, and if it is a new user "new user" redirects him to the registration interface. Then, the redirection to the next page which contains the different tests.

This is the interface that allows the addition of a new user. In this window he enters his login, password, profession and age. Once done correctly, the "Validate" button allows you to go to the home window. (see figure 9)

In this home window, the user has three options to choose from:

- **Consultation**: to consult a psychologist
- **Test**: to do tests like personality test and nomophobia test.
- **Statistique**: to view statistics for users of this application.

This interface allows the user to choose the test that suits him among the proposed tests

- Personality test: this test allows the user to know his personality type.
- Nomophobia test: this test gives the user his nomophobia state.

Conclusion

Big data is accumulating in a multitude of fields and offers new research possibilities. The role of these resources in mental health surveys remains relatively unexplored. Big Data is positioned as a powerful tool to increase understanding of human behavior. Its ability to aggregate and correlate large volumes of data from various sources allows a quick overview of a patient's behavior, which was previously complicated and time consuming.

Internet has intrigued new modalities of psychotherapy treatment. Electronic psychotherapy uses the power and convenience of the Internet to enable simultaneous (synchronous) and deferred (asynchronous) psychological therapy between individuals and professionals. The term electronic psychotherapy is defined as a professional mental health care service via Internet technology, such as email, online chat technology, multimedia interaction, or any combination thereof. This work, allowed us to define the functionalities of our application, which led us to start the design phase (technical and graphic) to ensure a good implementation of a functional system meeting the cited needs.

The design phase was important in order to be able to visualize the functioning of our application in an abstract way, and from which we can move on to the implementation phase.

Abstract

The notoriety of Blockchain innovation and the wide extent of its application brings about a great deal of progressing research in various pragmatic and scientific fields. Albeit still new and in the exploratory stage, Blockchain is viewed as a progressive arrangement, reacting to present-day innovative concerns, for instance, decentralization, trust, identity, data possession, and data-driven decisions. Simultaneously, the world is confronting an extension in the amount and a decent variety of computerized information created by clients and gadgets. During the dynamic quest for the most ideal approach to save, arrange, and process Big Data, Blockchain technology makes a significant contribution. Its suggested answers for decentralizing, credible, transparent, and data security management, have significantly affected the quality of analysis reports regarding this data. This paper considers and suggests a Blockchain-based arrangement related to the exemplary Big Data process that can reinforce and enhance the performance of this area.

Keywords:Blockchain, Consensus, Big Data, Smart Contract

Introduction

The emergence of the Blockchain was in 1991 by a team of researchers (Haber and Stornetta, n.d.) who needed to make a PC device to timestamp computerized files so that they can never be backdated or edited. Nonetheless, this technology immediately faded into obscurity in 1992 with the emergence of the "Merkle tree" protocol, which had the option of collecting a few documents in one block. Furthermore, in 2008, the innovation returned in another, increasingly strong edition designed by an unidentified individual introducing himself under the pseudonym "Satoshi Nakamoto", the maker of Bitcoin, the original application founded on the Blockchain(Nakamoto, n.d.).There is no centralized or ranked framework when we discuss the Blockchain. The fundamental qualities of this innovation depend on decentralization, transparency, and security. This innovation incorporates three fundamental components: a chain founded on the timestamp of the blocks, the circulated stockpiling instrument in regard to a shared network, and a consensus system relying on the shared nodes.Blockchain technology provides three categories that adjust to the requirements of clients. There are public Blockchain, the semi-private Blockchain, and the private Blockchain(Nofer et al., 2017). As long as public Blockchain is available to everybody; any individual, element, or body can take part and assume the job of validator or verifier (digger); this is the situation of the "Bitcoin" Blockchain. In contrast, there is the semi-private Blockchain or a Blockchain with authorization, in this engineering, the nodes which control the network must acknowledge other new partakers as indicated by specific rules. Overall, this sort of Blockchain is available in the banking and insurance sectors. The Ripple is a case of a Blockchain with an authorization that connects global banks and which plans to substitute the SWIFT framework. The third category of this technology is the private Blockchain, the usage of whichconcerns closed entities. For instance, a university administration, which would prepare every one of its faculties to make an inward Blockchain for its own needs.Compared to the emerging Blockchain technology, enterprise information systems have made great strides in recent decades, aimed at providing business decision-makers with the data they need. The technology behind these

systems, including data warehouses, common database systems, and Big Data, has matured and established a good position in the market.However, in the era of the explosion of Big Data, new challenges have emerged, namely: the risks of data circulation, the trust of data sources, and the ineffectiveness of data management and analysis have gradually attracted the attention of researchers.Furthermore, to address these challenges to strengthen data security, high availability, and credibility, numerous studies have been conducted. In the case of secure data distribution and management of solutions, research proposes the use of a decentralized blockchain-based solution for Big Data supporting key functions and discussing its implications for the management and sustainability of Digital archives (García-Barriocanal et al., 2017). Other researchers propose a system that can manage client data in a secure and distributed way using cryptographic primitives as well as a keyword search service(Jiang et al., 2020). Another proposal, stresses the importance of trust in the field of Big data and presents a secure data sharing system, based on Blockchain (Yue et al., 2017). In collaboration with a German bank, a group of researchers is following scientific research methods in design to design, implementing, and evaluating Blockchain prototypes used to manage the workflow between organizations. The results are encouraging and demonstrate the potential of Blockchain as an inter-organizational workflow management infrastructure (Fridgen et al., N. D.).In the next section, we will examine the qualities of the Blockchain which can modify the present version of the collection and manage monstrous quantities of data. After that, we will examine the significant difficulties of the Big Data sector and the way its combination with Blockchain technology can be a superior answer to tackle these difficulties that despite everything influence the quality of Big Data analysis outcome. Lastly, we will introduce a Big Data model dependent on Blockchain architecture.

Litterature Review

➢ *Characteristics of Blockchain*

Blockchain is a circulated "peer-to-peer" system, every node in the network has the chance of recording and saving operations (Chen et al., 2017). In theory, the data is shared by default and circulated between the nodes with no middle person or outsider mediation. In this decentralized structure, the nodes are active to participate in tasks and operations. In contrast to the centralized structure of traditional mechanisms, decentralization is a peculiar attribute of the Blockchain which increases its performance (Gao et al., 2018). Furthermore, the Blockchain data is in general transparent as anybody can view and question the data hereunder, just by utilizing the block explorer. All members have similar approvals and permits, so information and operations are open and solid (Nofer et al., 2017), but the exchange of data between the nodes does not dictate common trust between the partakers (Gao et al., 2018). This innovation depends on the standards of shared system conventions utilizing decentralized structures or a halfway focus structure which shapes a relationship of trust between network nodes and appropriated framework structures. Assurance is a significant factor that distresses trading partakers. However, partakers don't have to deal with common trust connections in the Blockchain framework since it utilizes hash capacities and the consensus protocol to take care of this issue.One of the major objectives of Blockchain-based systems is to guarantee the irreversibility of transactions. It is impossible to cancel the block containing the transaction (the data) because this requires significant computational power, making it highly improbable that the hypothesis of a longer chain development may not contain this block. Thus, once the chain is long enough, it makes it technically impossible to go back.Transactions can be considered, de facto, as irreversible; they cannot be modified or deleted, and all the histories are accessible and searchable.This guarantees the traceability of data (Wang et al., 2018).

➢ *Security of Blockchain*

- ***Cryptography***

Blockchain transactions are valid and reliable due to complex calculations and cryptographic evidence between the parties involved.Each block in the Blockchain is composed of its data, its nonce (an arbitrary number), the hash of the previous block and its hash calculated with the SHA256 algorithm,

then a large proof of work algorithm is executed to find the smallest value starting with 000 for the block to be signed. So, if we change anything in a block, this block and the following blocks lose their signatures, and given the complexity and the computing power, this is not possible(Gao et al., 2018).

- ***Integrity Control***

A digital signature, thus, ensures the integrity and authenticity of the data (the data comes from reliable sources). Integrity control is ensured by calculating a hash of a given by a hash function. A safe hash function (SHA-256 for example), always generates two distinct fingerprints for two distinct data (this is not the case for MD5). Furthermore, the authenticity of a signed data follows from the fact that only the owner of the private key can carry out the signature. Since the public key is accessible to everyone, a means is needed to attest to the link between it and its owner(Shrier et al., 2016). The digital or electronic certificate answers this problem and is issued by a certification authority. Digital time-stamping consists of affixing to any type of digital document (text, image, video, sound, etc.), a time and a date that are legally authentic in the form of an electronic seal. The electronic signature is the set consisting of the digital signature and the digital time stamp. A block recently added to the blockchain includes the electronic signatures of the previous blocks. For example, in the figure below, Block 2 contains theelectronic signature of Block 1. Therefore, to falsify Block 2, you must first falsify Block 1 (see Figure 1).

To falsify a digitally signed block, it would be necessary, firstly, to generate the same footprint for two separate blocks, which is impossible to achieve. Also, we should keep in mindthat the hash functions provide data integrity control.Additionally, the private key with which the signature is made should be available. Moreover, to calculate a private key of 128 bits length, it is necessary to carry out 2128 possible tests (with a powerful computer executing 10.51 x 1015 instructions per second, which will take approximately 1018 years). As a result, Blockchain security increases as more blocks are added to it. Logically, the more blocks you add to the Blockchain, the more fingerprints and keys will have to be calculated to falsify the blocks (Shrier et al., 2016). Consequently, the security of the Blockchain increases as more blocks are added to it.

Fig. 1.Digital Signature of a Block

- ***Peer-to-Peer Network***

Peer-to-peer networks offer better security than traditional server-client networks. Distributing the Blockchain across many entities (nodes) is providedwith immunity to Denial of Service (DoS) attacks that strike many systems. Therefore, the distributed peer-to-peer network, in combination with the consensus protocol, gives Blockchains a high degree of resistance to malicious attempts.

- ***Smart Contract***

A Smart Contract or a smart contract is simply a script that runs automatically, and which has offered a very powerful code execution capacity to integrate business logic on the Blockchain; since the founders of Ethereum kept Nick Szabo's idea of a smart contract more than 20 years ago in mind.

These scripts are executed by all the nodes of the Blockchain, and the result is validated via the consensus protocol before being accepted(Clack et al., 2017). The execution of this code and its result are validated and verified by the entire network, which is not possible on a computer program hosted on a single server or even in the Cloud. The latter, consequently, ensures the resistance of smart contracts against any malicious attempt at falsification or mishandling. The smart contract has many advantages.It particularly facilitates the transaction for the transfer of assets other than value or cryptocurrency.It also provides an application framework for the application domain, for example, considering a request home mortgage loan. Additionally, it could integrate all the business logic and the intelligence of the rules and regulations, to allow the automatic calculation and the start of the operations, with high transparency.These operations are registered in the Blockchain, and the user can directly access the system without any intermediary or a trusted third party. An intelligent protocol integrated into the contract has been proposed to validate trust in a PKI (Public Key Infrastructure) ecosystem, which will be transparent and automatic. Furthermore, some research has described the ability to assess the effectiveness, scalability, and feasibility of smart contracts. More specifically, BDD (behavior-based development) and TDD (test-driven development) are two useful alternatives for validating and estimating the accuracy of intelligent contracts programmed with the Solidity language; which is an object-oriented language, and which has been influenced by C ++, Python and JavaScript, designed specifically to target the Ethereum Virtual Machine (EVM). It is a static-type language, which supports inheritance, libraries, and user-defined complex types.

The Blockchain' Impact On The Big Data

Security and Management

Information is the lethal weapon of the 21st century. Whoever has the information has the power. Big Data aims to be able to take advantage of new data produced within the framework of the five rules often described by 5V: Volume, Speed, Variety, Veracity, and Value (see Figure 2).

The impact of Blockchain is evident on several levels:

In the Big Data sector, three problems are frequently encountered in the use of generated data: Data reliability, data security, and data management.

- ***Veracity***

The veracity of the data represents one of the major challenges of the exploitation of the data whose analysis accuracy is affected. With this Big Data (see Figure 3), quality and accuracy are less verifiable, and the lack of quality and accuracy often results from large volumes and less efficient analysis reports. However, the combination of Blockchain and Big Data could be a better solution to face this challenge which always damages the quality of Big Data analysis results. Blockchain is a distributed data system, secure and inviolable, which is based on consensus algorithms. It will also be a repository of data verified and written by the members of this federated ecosystem while maintaining its consistency and integrity.

The ecosystem records all events as the identity holder goes through different stages and provides each authorized entity with a verifiable history. Thus, the register can be enriched and verified without limit, as well as the Blockchain keeps track of each recorded action, which will eliminate the first exhausting but essential phase in the traditional Big Data infrastructure: Data cleaning.

- ***Security***

The integration of Blockchain into the Big Data management structure solves the problem of security via mathematically verifiable cryptographic signatures. Additionally, thanks to the use of the Merkle tree, the Blockchain is immutable, so once the data is added to the Blockchain, it cannot be changed. This immutability property makes Blockchain derive data very reliably. Also, the transparency feature in the Blockchain aligns with the trendy trend of Open Data, on two aspects: Legal openness which

means that access to data is legal, just like the exploitation and sharing. Then, there is Technical openness which means that there must be no technical barrier to the use of data. In general, Open Data is only non-personal data (Zyskind et al., 2015). Simply put, these data do not include any information on individuals, for obvious reasons of respect for privacy. Moreover, the integration of the Blockchain guarantees this rule, since it is based on anonymity and since each node in this system is represented by an address.

- ***Management***

Blockchain's ability to securely, transparently, and immutable store public data eliminates the possibility of falsification or manipulation by bad actors while promoting the protection and continuous availability of data since the concept of Blockchain does not represent the Single Point Of Failure (SPOF) problem (Lee, 2017).

Fig. 3.Classic Architecture of Big Data

Big Data Model of Security Sharing Based on Blockchain

There is a model of Big Data based on Blockchain and smart contracts that were proposed by a group of researchers(Yue et al., 2017), which aim to improve the security performance of Big Data. As shown in Fig. 4, the system designs three major parts, namely, data producers, Blockchain network, and data users.

- The data producers are divided into school, government, and business. With the school collecting student's data, the government collecting the citizen's data, and the enterprise collecting the user's data. These three parties will collect the massive data through the smart contract to store in the Blockchain, for the use of data sharing.
- The smart contract code runs on the contract layer of Blockchain, which provides the authority to control the system. Each data producer corresponds to deploy a smart contract on the Blockchain and storing the data through it.
- The data consumers are also divided into individuals who need data assets or organizations that research Big Data. They can initiate a data transaction request, which requests the data producer to provide data usage rights and obtain an authorized data set from the Blockchain through a smart contract. A smart contract is designed to accept only two types of requests: one is to store data requests, and the other is the query data request.
-

Fig. 4.Model of Big Data Based on Blockchain and Smart Contracts (Yue et al., 2017)

This model ensures three major aims:

Secured Data Storage:Parties with data sources use the blockchain as a data storage system and place the data in a specific way to link it to the blocks. The timestamp server, encryption algorithm, and working evidence can guarantee security, confidentiality, and credibility of the data. Moreover, the data source is stored in the blockchain, which is a distributed data registry shared by each node. Transaction information and authentication information in the block is transparent. So,if hackers alter block data, the network consensus model (Proof of work) will ensure that other nodes reject the wrong nodes. This model withstands all attacks against traditional data storage models. Thus, data information is encrypted and stored by the private key and can be accessed and authorized by the data owner. Miners use specific hash algorithms and MPT operations to encapsulate transaction data and codes received in a certain amount of time in data blocks with timestamps. The irreversibility of time and the unidirectionality of the hash value ensure the authority of the data.

Safe Sharing:Gathering the owners of the main data sources to create a blockchain network, then each blockchain acts as a network node that maintains the content of the nodes. Accordingly, Blockchain information is synchronized between nodes and ensures data sharing is secure.The data sharing blockchain network is designed using a data flow protocol driven by smart contracts, which is used to call the data storage and authorization management interface. Furthermore, the structure of the traffic protocol is as follows: When a data producer joins the Big Data blockchain network, they automatically launch a contract creation transaction. The address of this contract corresponds to the address of the data producer.The latter can store the data in the Blockchain by calling the storage interface. Next, the data requester submits a data authorization request to the contract holder via the contract address and the "ABI call query interface". The data owner authorizes the data via the "AddAuthorize (address user)" function. As a result, the data circulation protocol built through smart contracts ensures secure data sharing.

Authority Management:The data owner authorizes the data to the data requester. Automated execution of the smart contract ensures the entire process to be open and transparent.

Blockchain Consensus Algorithms

Consensus algorithms play a crucial role in maintaining the security and efficiency of the Blockchain. Using a good algorithm can lead to a significant increase in the performance of the Blockchain application(Mingxiao et al., 2017).

PoW (Proof of work)

PoW is the consensus algorithm used in bitcoin. Its central idea is to allocate accounting rights and rewards through hash power competition between nodes. Based on the information in the previous block, the different nodes calculate the specific solution of a mathematical problem. It is difficult to solve a mathematical problem, though. The first node that solves this math problem can create the next block and get some Bitcoin reward. Satoshi Nakamoto used HashCash to design this math problem in bitcoin (Nakamoto, n.d.).

The specific calculation steps are as follows:

- Getting the difficulty: after the production of all the 2016 blocks, the bitcoin exploration algorithm will dynamically adjust the difficulty value according to the hash rate of the whole network.
- Collecting transactions: collecting all pending transactions on the network after the production of the last block. Then calculating the Merkle root of these transactions and filling in the block version number, the 256-bit hash value of the previous block, the current target hash value, the Nonce random number, and other information.

- Calculation: Browse the Nonce from 0 to 232 and calculate the SHA256 double hash value in step 2. If the hash value is less than or equal to the target value, the block can be broadcasted. Then, complete the accounting of the node after checking the other nodes.
- Restart: if the node cannot determine the hash value at a certain time, it repeats step two. If another node finishes the calculation, it restarts from the first step.

The PoW takes the workload as a backup. The newly created block is linked to the blocks in front of it. The length of the chain is proportional to the workload. All nodes trust the longest chain. If someone wants to tamper with the Blockchain, they have to control more than 50% of the world's hashing power to ensure that they can become the first to generate the last block and master the longest chain. The gains from falsification can be far greater than the cost. Thus, PoW can effectively guarantee the security of the Blockchain (Cachin and Vukolić, 2017).

PoS (Proof-of-stake)

PoS was mentioned in the first Bitcoin project, but it was not used due to robustness and other reasons. The first application of PoS is PPCoin. In PoS, the digital currency has the concept of the coinage. Therefore,the age of a coin is its value multiplied by the period after its creation. The more parts a node has, the more rights it can get on the network. Consequently, coin holders will also receive a certain reward based on the age of the coin.

In the design of PPCoin, mining is also necessary to obtain accounting rights. The formula is proofhash<target room age *>(Mingxiao et al., 2017). The proofhash is a hash value made up of the weight factor, the unspent output value, and the fuzzy sum of the current time. However, PoS limits the hashing power of each node.

While the difficulty of mining is inversely proportional to the age of the coin, PoS encourages coin holders to increase detention time. Nowadays, with the concept of the age of the coin, the Blockchain is no longer entirely based on proof of work. This effectively solves the problem of wasting resources in PoW. Thereby, the security of the Blockchain using PoS improves with the increase of value in the Blockchain. Thenattackers must accumulate a large number of coins and hold them long enough to attack the Blockchain.

This also greatly increases the difficulty of attacks. Including PPCoin, there are also many other coins using PoS such as Nxt and BlackCion. But they take into account the rights of the nodes and use a random algorithm to allocate the accounting rights.

DPoS (Delegated proof of stake)

In the initial bitcoin design phase, Satoshi Nakamoto hoped that all participants could use the CPU to extract it. Thus, the power of hachage can correspond to the nodes and each node has the possibility of participating in the decision-making of the Blockchain. With the development of technology and the appreciation of bitcoin, machines specially designed for mining are invented. Also, the hash power is grouped in the participants who have a large number of extraction machines. Ordinary miners rarely have the opportunity to create a block. BitShares is an example of DPoS(Gao et al., 2018).

In the Blockchain with DPoS, each node can select the witnesses according to its stake. Across the network, the first N witnesses who take part in the campaign and obtain the most votes have the right to count. The number N of witnesses is defined in such a way that at least 50% of the voting stakeholders believe that decentralization is sufficient. Furthermore, elected witnesses create new blocks one by one as shown and get rewards; whereas,cookies must guarantee adequate online time.If a witness is unable to create their assigned block, the activity of this block will be moved to the next block and the stakeholders will vote for a new witness to replace it. The Blockchain using DPoS is more efficient and more energy-efficient than PoW and PoS (Mingxiao et al., 2017).

PBFT(Practical Byzantine Fault Tolerance)

In distributed systems, Byzantine fault tolerance can be a good method for resolving transmission errors. However, the first Byzantine system requires exponential operations. Until 1999, the PBFT (Practical Byzantine Fault Tolerance) system was proposed, and the complexity of the algorithm was reduced to a polynomial level, which significantly improved efficiency (Baliga, 2017). The PBFT consists of five states:

- Request: the client sends a request to the master server node. After that, the master node gives the request a time stamp.
- Prior preparation: the master server node records the request message and gives it an order number. Then, the master node broadcasts a pre-preparation message to the other following server nodes. The other server nodes initially determine whether to or not accept the request.
- Prepare: if a server node chooses to accept the request, it broadcasts a preparation message to all the other server nodes and receives the preparation messages from other nodes. The transfer of RAFT states after collecting 2f + 1 messages, if a majority of nodes choose to accept the request, then it will enter the validation state.
- Validation: each node in the validation state sends a validation message to all the other nodes of the server. At the same time, if a server node receives 2f + 1 validation messages, it might believe that most nodes reach a consensus to accept the request. Then the node executes the instructions in the request message.
- Respond: the server nodes respond to the client. If the client does not receive a response due to the network delay, the request is returned to the server nodes. If the request has been executed, the server nodes only have to send the response message several times.

Raft

After the problem of the Byzantine generals was raised, Lamport proposed the Paxos algorithm to resolve the problem of consistency under certain conditions in 1990(Baliga, 2017). Nevertheless, since the content of the article was difficult to understand, it was not accepted. Lamport republished the article in 1998, and Paxos was briefly reintroduced in 2001. Paxos then occupied the dominant position in the field of the coherence algorithm; from which many other algorithms are derived.However, the Paxos algorithm is too theoretical thatpeople have a lot of trouble understanding it and implementing engineering.

In 2013, Ongaro from Stanford and others published the article and proposed the Raft algorithm (Xiao et al., 2020). Raft achieves the same effect as Paxos and is more practical in the implementation and understanding of engineering. The Raft cluster typically contains five server nodes. Up to two nodes are allowed to plant at the same time. The server node has three states: leader, follower, and candidate. There is only one leader in a mandate, and the leader is responsible for handling all client requests.

Result And Discussion

The model above is partially approaching our proposal.Based on the fact of the combination between Blockchain and Big Data, its efficiency will be considerably increased following the adoption of the points below:The model proposed above is based on the consensus mechanism Proof of work (POW). The effectiveness of the consensus mechanism is generally assessed according to three main criteria; termination (activity): all operational nodes participating in the consensus must eventually produce value. Confidentiality/consistency (security): all operational nodes must agree in real-time on one of the values proposed by one of the nodes, this value must be valid according to the rules defined by the mechanism. Fault tolerance: even if one or more nodes fail, the mechanism must be able to operate. Unfortunately, in asynchronous systems such as distributed node networks, no deterministic consensus algorithm can guarantee these three properties at the same time (FLP is impossible) (Fischer, Lynch, and Patterson 1985). Fault tolerance is indeed absolutely crucial in a network of distributed nodes, and

the consensus mechanism must choose between security and termination based on the requirements of the application that designed the distributed platform. However, functional and non-functional considerations must be taken before ensuring the appropriateness of an appropriate consensus mechanism, i.e.: Performance objectives (especially the number of transactions per second), power consumption, scalability, size of nodes, and the expected relationship between different participants: users and verification nodes.This important point has not been taken into account in previous research. Our proposal will take into account the requirements of the designed system, such as transaction throughput, energy consumption, as well as the scalability of the network; given the massive data to be processed.

Fig. 5.A Big Data-sharing Model Based on The Blockchain Using DPoS Algorithm and Smart Contracts

A synthetic comparison of consensus mechanisms showed that the delegated proof of stake (DPoS) (explained in a previous section) is more efficient at the level of security, scalability, decentralization, and more efficient at the level of energy consumption (Xiao et al., 2020). On the other hand, our proposal is based on Blockchain in the flow of data between the different entities that own the data sets (Smart Contracts). It is also based on the process of collecting information (Blockchain private consortium) whose interest is seen through the volume of data generated by the Internet of things as an example (see figure 5). Moreover, it explodes about the volumes generated by other data sources while representing several problems namely: the heterogeneity of IoT systems and security flaws such as exploiting the weaknesses of a device that could allow access and modify highly sensitive data such as personal or health information. The aggregation of the Blockchain and this important source of data solves firstly the problem of heterogeneity since IoT data will be converted, processed, extracted, compressed, and finally stored in the Blockchain. Secondly, it guarantees the security of the data. The integration of smart contracts can help to secure an agreement between nodes, automate the data transfer, payment between data-driven and minimize or even eliminate the risk of unpaid payments and mainly reduce intermediate costs in the preparation and monitoring of a contract.

Conclusion

This article quickly sums up how Blockchain innovation and its characteristics in collaboration with Big Data work emphasize the pertinence of these advancements and how they are firmly identified with one another. We gave Big Data stage dependent on the blockchain: an idea that can emphatically impact Big Data to locate an increasingly secure information arrangement in a circulated manner on a P2P network and to guarantee the security, the management, and veracity of the information to guarantee its worth. A few difficulties remain, for instance, consensus models, computation expenses, and time. Moreover, Blockchain applications are arrangements that require significant changes or the total substitution of existing frameworks. This makes the progress troublesome and moderate. The Blockchain is still in its beginning times of improvement, and these obstructions will eventually be survived, opening the path for some fascinating prospects. In the future project, we will attempt to suggest an entire platform Big Data-based Blockchain by taking into account a custom consensus algorithm that will address our issues while diminishing the expense of computation, time of treatment, and the expense of substitution of existing systems.

Abstract

This article presents, from a bibliographical study, an andragogical model allowing setting up a learning situation for adults in a state of literacy. Because we see that the majority of people stop their studies at an early age. For this reason, literacy can only be truly effective if it fits into larger visions and makes it more sustainable. The reason why our model is based on modern andragogical approaches using information and communication technologies (ICT), online training logistics, is that these later become tools of citizenship and take on a lot of importance.

Keywords Andragogical, Modeling, Online Training Logistics

Introduction

This article is based on the results of an integration needs analysis information and communication technologies (ICT) to fight against illiteracy in Morocco, The project is part of the partnership agreement between the Agency National Anti-Illiteracy Network (ANALN) and Abdelmalek Essaadi University of Tetwan (UAE) which aims at the contribution of the UAE to the development of the project RAMAA II (Research Action Tailored Learning for Recipients of literacy programs) initiated by UIL (the UNESCO Institute for Learning throughout life).

This research also aims at the contribution of the UAE to the development of the project of the integration of ICT into the training and learning in literacy and post-literacy initiated by the DVV, while using didactic materials with andragogical approaches according to the needs of the beneficiaries. Because Morocco counts improve its Human Development Index (HDI) ranking, this using didactic materials with andragogical approaches according to beneficiaries' needs.

The National Agency for the Fight Against Illiteracy (ANALN), created in 2014, wants accelerate the pace of enrollment in the program to combat illiteracy to reach 1.2 million registered annually by 2024. This is done by developing a guide with television program to strengthen teaching, particularly in active population. According to UNESCO, an estimated 759 million young people and 15 years and older) in the world today are illiterate, and about 153 million in Africa, two-thirds of whom are still unable to read or write. These figures remind us that we must make further efforts why every year since 2002, UNESCO publishes a world report education for all (EFA) monitoring; so the 2006 report looked at literacy emphasizing that this is an international issue.

From here RAMMA sees day because it is part of the perspective, initiated by UNESCO for lifelong learning

(ULL) at the request of the countries; The first generation was conducted from 2011 to 2014 in five countries in French-speaking Africa: Burkina-Faso, Mali, Morocco, Niger, and Senegal during this first phase (RAMAA I), which was based on the objective of measuring the level of knowledge and

skills in reading and writing mathematical reasoning of young people and adults aged 15 and over .since 2016, seven other countries have joined the project, representing a total of twelve countries, all committed to the implementation of the second phase RAMAA II (RAMAA II) to achieve target 4.6 of Sustainable Development Goal 4 (SDG4) on education, which demands that "by 2030 all young people and one considerable proportion of adults know how to read, write and count ", as well as a support program for interuniversity training, the aim is to bring together postgraduate students (Masters, PhDs) with research projects in the field to promote exchanges scientists and intellectuals, and to open fields for applied scientific research.

In Morocco the number of postgraduate students with research projects in the literacy field is 9 PhD students and 30 masters (according to the survey conducted by ULL.

With the help of DVV International, which has been running a national office in Rabat since 2008, it has been able to create a network of educators working in the field of illiteracy, using technology to ensure learning throughout life.

In the context of development within the Moroccan university and among the axes of the development of research at the digital level aimed at literacy and post-literacy, Morocco has already developed a project "Alpha Nour" dedicated to training in distance in the field of the fight against illiteracy.

For what to choose such as subject of thesis? There is a need for interactive digital resources for adults in literacy, but there are several questions among them: How? Which model? What purpose? Which public?

The goal of this paper is to propose digital model resources by relying on a mortgage-deductive approach while taking into consideration the andragogical circumstances (phases of conceptualization).

The Theoretical Framework

A. Adaptive Hypermedia

Adaptive hypermedia systems are hypermedia systems that reflect some characteristics of the user in a user model and use this model by adapting different aspects of the system to the user [1].

The goal of these hypermedia systems is to adapt the presentation of the knowledge and help the learner to move in relevance. As a result, in a hypermedia we must be able to modify both the content of the pages and the links between different pages [1].

The architecture of adaptive hypermedia relies mainly on two models: the domain model and the learner model. They are characterized by the relationship between the domain model and the media used to present the concept to the learner.

Adaptive hypermedia represents a significant step towards classic hypermedia. Indeed, the different techniques used allow learners to be guided in their learning, and to better teachers structure their knowledge. Likewise, distinguishing between knowledge of tools that allow presenting it clarifies the work of the teacher. The latter can then better structure his work, thinking first of all about the organization of knowledge, and then how to expose them. However, some problems persist because the adaptation of the content has often been put aside. First of all, you have to adapt the content to guide the learner in his progress.

The role of hypermedia in the process Teaching/Learning:

According to the definition given to the hypermedia above, we can deduce that hypermedia plays an important and effective role in teaching learning. hypermedia remains a flexible and flexible tool in which we can integrate links, images, sounds ... the principle of hypermedia is based on the

navigation between the objects the latter allows us an interactivity. Digital information the opposite of written information can be hidden to the screen only at the request of the user.

The importance of online training logistics

Online andragogical learning requires adequate logistics and materials for excellent online training. we must understand the logistics used to train online individuals reaching a certain age and responsible maturity. In order to properly follow the training and especially the workshops or online and instant exercises, the training logistics must be constantly monitored, whether for IT equipment or the online Internet network. There is therefore a logistics cloud that includes three important logistics components, namely the infrastructure, the platform and the application.

CSCL (Computer-supported collaborative learning) systems born from the emergence of Web 2.0, takes shape in the training of adults who want to continue their studies. Distance learning logistics will bring together information and communication technologies for education (ICT), which are digital tools and products that can be used in the context of education and teaching for adults.

An online learning platform (Learning Management System) becomes necessary. This involves setting up a website that hosts didactic content and facilitates the implementation of andragogical strategies. As an essential logistical tool for trainers is the interactive whiteboard (IWB) which is a device combining the advantages of a touch screen and video projection. A white touch screen is connected to a computer via a cable (usually USB). The computer is capable of transmitting various information to the whiteboard, including the new position of the mouse cursor. A video projector is responsible for displaying the computer screen on the whiteboard. Thus the trainer can easily move around and better transmit knowledge and knowledge to people who follow the training at a distance.

Basic models for design

The Learner Model

Knowing that our goal is not to innovate in the field, but to seek a model to achieve the goals set because until now a good representation of the learner model remains essential.

The model we decided to use, described by Nicaud [2] and Balacheff [3], consisting of two sub-models: an epistemic model and a behavioral model.

The Epistemic Model

The epistemic model is the component that allows the system to know this that the learner is supposed to know or not to know, it also makes it possible to reason on the knowledge of other agents.

A. So far, teaching systems use three types of weighting [4]. It can be binary (know or not know the concept), discrete, by defining categories of learner (e.g. novice, average or expert) or continuous (the values belong to an interval). It's this last technique that we decided to use because we think it is the more able to represent the knowledge of the learner. Moreover, she is the only which allows to take into consideration the time, parameter that we also have decided to use.

Indeed, in order to improve our epistemic model we introduce time as variable of a function of forgetfulness, because anyone who does not regularly review a particular knowledge, risk forgetting partially or completely.

And we also introduce the motivational variable because adults are not children; the rate of their motives is different; every adult is sensitive to external motivations (promotions, best jobs, etc ...)

The Behavioral Model

Our adaptive system is very close to the learner, which means that it has to take into account its preferences, objectives and capabilities natural.

The preferences of the learner will have an impact on the organization of the situations problems.

The learner's goals will also influence the behavior of the learner. The system will have to be more or less flexible, flexible to adopt a point view of the organization of knowledge.

The abilities of the learner will be taken into account in detailed ways.

Learning Styles

We cannot teach adults like teaching children; traditionally children are seen as a blank page in which children teachers can pour knowledge.

Why trainers cannot control adults by the same way. Because children have little experience in the real world unlike adults who have a lot of accumulated experience and who can enrich their education; our life experiences can be considered as a reservoir of information.

In recent years researchers in the field of adults education and their learning processes find that the experience contributes to the intellectual faculties and therefore to learning.

Understand and use Learning Styles

Researchers propose different definitions of learning styles and they classify each one in their own way. For example, Reuchlin [5] defines the cognitive style as “the organization and the general operating procedures of the by which each subject acquires and elaborates information about his environment”. Individuals are more effective when they learn in a personal way.

Usually, there are different and many views on styles learning depend on types of learners (three types of learners). Well that most people can learn using one of these styles; most people prefer one [6].

Visual learners: Visual learners are those who generally think in photos. They often prefer to see things written in a document, a text, on a slide or a PowerPoint slide. These maps, graphics, diagrams and other highly effective visual learning tools.

- Auditory learners: Hearing learners are those who learn generally better by listening. They usually like to learn through lectures, discussions, and read aloud. they remember best in hearing or saying things out loud.
- Kinesthetic Learners:Kinesthetics, also called tactile, are learners who learn best by touching, feeling and experimenting what they are trying to learn. they remember best by writing or physically manipulate the information [6].

An overview of the literature quickly highlights the plurality and diversity of learning style templates. These different models are grouped in three typologies [7]:

- Grasha and Reichmann [8]: models of learning style that interested in preferences for teaching conditions and learning.
- Kagan, Rosman, Day, Alpert and Phillips [9]; Myers [10]; Witkin and al. [11]: learning style models that deal with the personality of the learner. Honey and Mumford's model: learning style models that rely on practices and experiments to assimilate and concretize theoretical concepts. Experiential learning is organized in four phases: concrete experience, thoughtful observation, conceptualization abstract and active experimentation.
- Gregorc [12]; Honey and Mumford [13]; Kolb [14]: style models who are interested in how the learner deals with information, in terms of privileged means.

David Kolb's research contributes to our field the latter studied learning and noticed that anyone who finds in learning situation goes through a four-phase cycle.

1. Concrete experience of an action / idea.

2. Observation in a thoughtful and attentive way.
3. Abstract and theoretical conceptualization.
4. Implementation of the idea / action based on the initial experience.

Kolb gave a name to the different types of learners, depending on the phase of the learning cycle.

The divergent:	Learn through specific experiences is better in situations who solicit ideas. The divergent is interested in people and emotions. It makes sense of observation; is adept at perceiving an object or a problem under different angles. Enjoys innovative activities, he has a fertile imagination and interests varied. He is interested in people and values feelings. But he does not check his theories and he lacks depth.
The assimilator:	The assimilators like create theoretical models and are less interested than others in people and practical applications of knowledge. It logically reorganizes information, juggle with ideas and theories. This type appreciates the theoretical courses and they are able to take a lot of information and put it in a specific order and logic.
The convergent:	Take the time to observe and reflect, compare experiences with knowledge. The convergent type like to be practical than emotional. Plus, they prefer to deal with things rather than people. They prefer to solve problems so the solution is unique. And they learn by memorization rather than reasoning.
The accommodator:	Learn by error they like to take risks. The accommodator adapts easily to new experiences and tends to find solutions. He learns by manipulation, performing the tasks. They likes to be involved in the planning and carrying out activities; They tends to trust the reflections of the 10 others rather than his own analysis he is sensitive to the reactions and opinions of others, and He enjoys small group exercises.

Andragogy

B.a. Who is the adult?

In the agreed definitions, the adult is defined as the person who has ceased to go to school, and who has reached the age equal to maturity (from 16 to 21) depending on the country.

In normative definitions, we find that the adult is the person who is reasonable, responsible and autonomous. These notions make it difficult for adults to express his needs for help then the learning process at this. The category of society must first and foremost help him to express his needs. The adult means to be responsible, then the learning process must also empower the adult throughout the course.

B.c. Definition of andragogy:

The term Andragogy appears for the first time by Alexander Kapp in Germany in 1833.the term "andragogy" is an existing concept from ancient times it is formed from two Greek words andros which means "man", and agogos who wants say "the guide". So, by andragogy science and practice of education adults. (Larousse), or the set of techniques likely to lead to knowledge, educate, train apprentices, workers. (Wikipedia).

Then Thorndike [15] will be one of the first to investigate in the field of adult education by broadening the knowledge of the adult learner.

For his part, Lindeman [16] also mentions that adult education must be seen as a new approach to learning that can be also essential for an illiterate worker. Lindeman states that the education of adults should be considered from a situation perspective.

In 1980 UNESCO adopted the concept of andragogy to designate continuing education adults.

The term andragogy then evolved into a theory of adult education with Eugen Rosenstock-Huessy, who writes andragogy as a true means by which adults maintain a relationship of intelligence with the modern world.

For Roger Mucchielli you have to take into account certain characteristics of the adult in his learning. Understand that for adults, the real thing is their life with their current and future professional responsibilities. No way for him to return the adult to the school system: memorizing or being judged will rather need training that starts with the analysis of his situation to meet its immediate objectives by putting people into situations referring to his own experiences.

Finally, the term will be popularized by the American humanist Malcolm Knowles [17] who was looking for a coherent and comprehensive theory of learning the latter will draw a clear opinion that the which the adult finds must be comfortable. in 1984 Knowles will define andragogy like the art and science of helping adults learn and it will suggest 4 principles of base of andragogy:

- The learner's self concept (autonomy, self-diagnosis, self-evaluation)
- The adult learns from his experience and his mistakes.
- Learning is related to developmental tasks (motivation is extrinsic).

The immediate application of learning because adults are more interested in learning things that have an immediate impact in their personal or professional life.

From here Knowles will define Andragogy as “the art and science of helping adults to learn” [17].

To learn effectively Knowles [18] has created a learning model in adults based on:

- The need to know: Adults need to know why they have to learn, so you have to make them feel that need to be able to to join a formation.
- The concept of self in the learner: Adults are aware of their own decisions and their lives. They need to be seen and treated as individuals able to self-manage.
- The role of the learner's experience: the adult accumulates a reservoir of experience Adults come to training with experiences they are not a blank sheet.
- The will to learn: adults have a desire to learn if people knowledge and new skills allow them to better cope with new real situations.
- The orientation of learning: With maturity adults orient their learning around life or a problem they are investing energy for learn if they feel it will help them cope with this situation.
- Motivation: adults are sensitive to external motivations (better jobs, promotions, etc ...) but most of all, they are sensitive to pressure interior (desire, self-esteem, etc ...).

B.d Andragogical models that integrate the characteristics of adults:

The Muchielli Rogers model:

For Muchielli [19] adults, aware of their potentialities and possibilities realization that can offer them the learning; their motivation is one function of their characteristics and the social or educational situation in which they evolve. Generally for the adules the real is their life with their responsibilities current and future professionals. Then adult education cannot be done by the school system or the university system, since in adults:

- There is resistance to return to school, not only because adult risk of recovering attitudes or blockages, but because this system is a threat of evaluation.

- Adults feel that academic-academic knowledge is not do not serve much in everyday life.

Bernice Mccarthy's model:

Based on the characteristics of the learner adult Bernice Mccarthy [20] finds that adult education must take into account some requirements:

- It is necessary to start from lived situations, problems or difficulties to emphasize the need for knowledge.
- It is necessary to adapt to the learning styles of adults.
- It is necessary to ensure understanding of the themes after each stage of teaching.

The model of Knowles:

The andragogical approach presented by Knowles [17 and 18] is marked by the contemporary humanist, according to this philosophy the human being is basically a trustworthy organization, able to assess the situation that he observes, to understand himself, to make the choice and to act accordingly.

The model of self-training:

The self-training model focuses on the subject, the person and his / her life experience, more than on the environment. So that the person can be autonomous in learning, it must master metacognitive strategies, that is, to say strategies that refer to knowledge about his activity cognitive and on the control of the task in which she is engaged.

Autonomy in learning also means that the person is mature emotionally that she is confident in her ability to learn. This assumes that the educational environment is reassuring.

B. From the andragogical model to the content model

Illiteracy is not an isolated phenomenon, it is both a particular problem, and a symptom of an economic, political, social and cultural situation. This plague has a direct impact on our life and on our society by causing a strong isolation and low self-esteem among the category of people involved.

C.a. Being an illiterate what is it?

Being an illiterate means:

- Do not have the ability to write and express thoughts in an organized manner.
- Not having the power to communicate with family, friends, neighbors, his banker and even with the teachers of his children.14
- Not be able to do basic calculations - such as addition, subtraction, multiplication and division.
- Not being able to solve a simple situation in real life such as paying bills.
- Can not understand the signs and symbols he faces every day in his life.
    - Bus: know the bus routes in his city or buy his ticket?
    - Health: understand simple notices.
    - Vote: Know where to register to vote in an election ...

What can be deduced?

Adults usually know their needs, their motivations, their interests, their capabilities and goals. So why not integrate them into a approach that will allow them to express their thoughts, to solve their problems, to process new information and to better understand the world that surround them?

C.b. Modeled problem solving problem

Every day in our real life the adult learner is confronted with situations problems (learning situations) that he has to solve, at home, at school, in the street, at the supermarket, at work ... In the sphere of cognitive psychology, the problem situation concept developed at the end of seventies within the educational movements of New Education. Cognitive psychology studies the mental strategies of individuals in the interpretation of a given situation and the resolution of problems encountered. Starting from the premise that "learning is understanding", she states that knowledge is acquired through a problem-solving process implement a dynamics of questioning. Faced with an obstacle, the individual summon his knowledge and abilities to break the deadlock.

Fig. 1. Solving problem model

Through the exercise of its potentialities, but also by the exchange with others on the complexity of the situation, he is building new skills. The reason why our model was based on the notion of problem situation is that the adult learner combines several concepts to solve a problem in real life (fig.1).

- Mental representation: Mental representation is very much related to acquired knowledge, if the concept is an object already facing the screen, the concept construction uses knowledge stored in memory (term-term / long-term memory) and / or elements from environment to analyze the situation and make sense of the situation encountered.
- Cognitive conflict: In a situation where the representations of an individual are perceived as incompatible because it is a confrontation between what he believes he knows about the situation (his representation) and what he sees reality). This observation forces the individual to deconstruct the initial representation in order to build a new one while integrating new knowledge.
- Socio-cognitive conflict: develops when an individual becomes contradiction or incompatibility between ideas, representations actions ... here the individuals makes a cure to another person because usually the last does not learn alone but he learns in interaction with other individuals.
- The situation-problem: We can say that each learning situation will be resolved by following a difficult process because in the first place a situation problem is a situation to build with care. Its objective remains to establish a imbalance, a conflict, a discrepancy between what the learner thinks he / she knows about problem posed (his initial representations) and what he finds in reality. This which will provoke a question which will lead to give several hypotheses.

C.c. How to build a problem situation?

"We just learn to learn" does not learn, on the contrary it must get as close as possible to problems, obstacles and real situations to ensure a good level of learning. We must formulate the situation-problem so as to take into account every little detail.

A problem situation must:

- To convey functional knowledge.
- To convey a functional know-how.
- Be built with an interactive didactic approach.
- Take into account the learning styles of adults.
- Be framed by objectives and skills.

C.d. Model to set up a learning situation at adults.

The heart of our model is the situation problem in order to solve it we confront two variables (fig.2):

Fig. 2. Model for setting up a learning situation in adults

Fig. 3. The learner model: it is necessary to place the learner in good receiving conditions by giving meaning to the proposed learning activity. According to [21], a model of the learner is born from the desire to adapt the interaction tutor / learner according to each learner. This author defines model learning as a "set of learner-specific information. This information is most often about the knowledge and know-how that the system attributes to the learner in view of his behavior, for [22] the learner model is central to an adaptive learning system since it reflects the understanding of the learner (and possibly others aspects such as goals, learning preferences, motivations, etc.).

Fig. 4. The content model: the content put in place must be around the situation to solve, the adult learner will not learn anything but on the contrary he will learn new information that will have a direct relationship with the situation problem. Some other variables impact our model such as:

Fig. 5. The choice of the problem: Every adult learner with particulate problems then the problem must be motivating.

Fig. 6. The interactions: The back and forth between the data of the memory and the data of the problem situation will impact according to the age of the learner.

Fig. 7. Storage in the memory: It is necessary to structure the knowledge in the memory so that the learner does not give up the training.

Conclusion

Several researches have focused on adaptive hypermedia most are destined for formal training, based on pedagogical principles, but very can who are interested in the educational field.

Really one can understand that without literacy, one cannot be neither a independent person or an independent person. Literacy represents for anyone illiterate - the freedom to go, to move forward and to achieve those goals in life without being afraid [23]

According to my studies I found that andragogy was used in several domains but very little research that has focused on illiterate adults because this category of people remains very complex which makes it very difficult to generate a fixed model, but apparently one must think of a flexible model that takes into consideration of the target audience. So when it comes to learners in situation for post-literacy literacy, which andragogies should be followed to what digital resources? What about adult literacy?

Abstract

This article discusses a new form of interaction between the taxpayer and tax authorities tax monitoring. It is noted that tax monitoring is used for the largest taxpayers as a pilot project. The features of this form are: on-line monitoring, voluntary nature and the availability of selection criteria for the implementation of the procedure and regulation of interaction between the taxpayer and the tax authority. In total, in 2017, 14 taxpayers used tax monitoring, while the transition to the procedure uses the qualitative and quantitative criteria considered in the article. The main positive aspect of applying tax monitoring is the cancellation of field and office tax audits with respect to the taxpayer. Moreover, like any new project, tax monitoring has 4 main problems when implementing, the main of which is not the complete abolition of tax audits, which reduces the attractiveness for taxpayers. Moreover, as measures to improve the process, it is proposed: the development of common standards and formats for information interaction, as well as formalization of approaches to checking the effectiveness of the Taxpayer Internal Control System for taxes and further development of a risk-based approach to tax audits. The article notes that the central element is the internal control system of the business unit, and an expert assessment of the internal control system is proposed in the work.

Keywords: Tax Control, Tax Monitoring, Internal Control System, Efficiency.

Introduction

The tax monitoring procedure has been introduced in the Russian Federation since 01.01.2015. The Federal Tax Service of Russia continues to implement a mechanism for enhanced interaction between taxpayers and tax authorities. Federal Tax Service of Russia clearly formulated objective of the introduction of the tax monitoring institute - formation of optimal P model institution prior tax

clarification on the basis of this analysis, increasing the transparency of enforcement of the Russian Federation tax legislation, a significant improvement in investor perceptions of the business climate. According to the Federal Tax Service of Russia, about 2,000 taxpayers fall under the law. In 2016, out of the submitted applications for participation in tax monitoring, seven participants were approved, then in 2017 the number of applications increased significantly, and the decision to conduct tax monitoring was made with respect to 14 new participants.In 2017, participants in tax monitoring will be organizations operating in the field of:oil production and production of petroleum products (members of the group of PJSC Rosneft, LLC Zapolyarnneft);

•natural gas production (members of the Novatek group);
•production and trade (LLC Russol, LLC Unilever Rus);
•production and transmission of electric energy and thermal energy (PJSC InterRAO);
•the provision of communication, broadcasting and television services (PJSC Megafon, PJSC MTS);
•financial activities (JSC National Clearing Center Bank, LLC HSBC Bank (RR). In a research study by Boboshko Diana Y.. (2020)

According to the tax authorities, the institute of tax monitoring will solve the following problems: increase the predictability of tax payments; timely identify gaps and conflicts in the legislation on taxes and fees; reduce the costs of tax audits, legal costs in connection with the reduction of tax disputes, as well as provide an increase in the level of legal culture of taxpayers; reduce the number of field tax audits, as well as the taxpayer will comply fully with tax laws. The subject of tax monitoring is formulated for two categories of taxpayers:

1. For all categories of taxpayers, tax agents, payers of fees and insurance premiums, except for members of a consolidated group of taxpayers -the correct calculation (withholding), completeness and timeliness of payment (transfer) of taxes, fees, insurance contributions, the obligation to pay (transfer) which in accordance with Tax Code of the Russian Federation assigned to the taxpayer (payer of the fee, payer of insurance premiums, tax agent) - organization;
2. For participants in a consolidated group of taxpayers - the correct determination of the income received and the expenses incurred for the purposes of calculating and paying corporate income tax.

When conducting tax control, it is necessary to comply with a number of principles, the most important is the observance of the legal procedure, since tax legislation contains a clear mechanism for the implementation of tax control, requirements for the execution of procedural documents drawn up during the events. Failure to comply with procedural requirements is the basis for the cancellation of decisions of the tax authority. In a research study by Eliseeva E.N. (2017) The main principles of tax monitoring in Russia include:

• voluntary participation in tax monitoring is a right, and not a taxpayer obligation, as provided for in a desk and field tax audit. Tax monitoring is the first form of tax control, which is declarative and voluntary in nature (article 105.27 of the Tax Code of the Russian Federation .;
• limited participation - not all taxpayers can participate in the procedure, only those that meet quantitative and qualitative requirements;
• expansion of information exchange between taxpayers and tax authorities;
• exemption from other forms of tax control;
• the possibility of obtaining clarifications from the tax authorities on tax-complicated transactions in the organization.

The first question that arises when mentioning tax monitoring is which organizations can use it. The Tax Code of the Russian Federation provides for quantitative criteria that enable the transition to the use of tax monitoring:

1.The amount of taxes (VAT on internal operations, excise taxes on internal operations, corporate income tax, mineral extraction tax) for the calendar year preceding the year in which the application for tax monitoring is submitted is at least 300 million rubles .;
2.The total amount of income received according to the annual accounting (financial) statements of the organization for the calendar year preceding the year in which the tax monitoring application is submitted is at least 3 billion rubles .;
3.The total value of assets according to the accounting (financial) statements of the organization as of December 31 of the calendar year preceding the year in which the tax monitoring application is submitted is at least 3 billion rubles.

Thus, quantitative criteria are very relevant for tax monitoring and allow you to constantly monitor the largest payers of taxes, fees and contributions to the budget. At the same time, the principle of increasing the effectiveness of tax control is implemented. Currently, the goal of tax authorities is to reduce the cost of tax control measures and improve its quality and effectiveness. At the same time, it can be assumed that the Pareto principle is implemented here, the essence of which is 20% of the effort gives 80 % of the result, and the remaining 80 % of the effort is only 20 % of the result.

The quality indicators include the mismatch:

• regulations for information interaction in the established form and requirements for regulations for information interaction;
• internal control systems to the established requirements for the organization of the internal control system.

The period for which tax monitoring is carried out is a calendar year (article 105.26, clause 4 of the Tax Code of the Russian Federation), and the period is January 1 of the year of the specified period and ends on October 1 of the year following the specified period. For example, the taxpayer filed an application for tax monitoring in 2016 and the tax authorities made a positive decision, therefore this procedure will be valid from 01.01.2017 to 01.10.2018.

The main advantage of using tax monitoring by a taxpayer is the cancellation of field and desk tax audits against him. However, there are exceptions to any rule.

The second advantage of using tax monitoring by an organization can be attributed to the fact that when conducting tax monitoring, the tax authority is not entitled to send a motivated opinion to the organization on issues related to monitoring compliance of prices applied by the organization in controlled transactions to market prices.

In addition, we can highlight a number of positive aspects of applying tax monitoring for a taxpayer:

1. Tax risk reduction;
2. Decrease in interpretation uncertainty of tax legislation;
3. The opportunity to get a free consultation with a tax specialist.
However, tax relations are not only taxpayers, but also tax authorities. The positive aspects of applying the tax monitoring procedure for tax authorities include:
1. Permanent tax control of the largest taxpayers, who are the main payers of taxes to the budget of the Russian Federation;
2. Enhancing the transparency of law enforcement of the legislation of the Russian Federation on taxes and fees;
3. Significant improvement in investor perception of the business climate;
4. Simplification of the tax audit process;
5. Reducing the risk of taxpayers using illegal tax evasion schemes;

6. Ensuring the timeliness and completeness of reflection of tax obligations of taxpayers;
7. Reduced costs of tax audits, legal costs in connection with the reduction of tax disputes.

Tax monitoring is a new stage in the relationship between the taxpayer and tax authorities, many points have not yet been finalized and the mechanisms have not been debugged, but it is undeniable that the introduction of the tax monitoring procedure will positively affect the volume of tax revenues to the budget.in book by Hanlon, M. (2014)
The main problems of applying tax monitoring include:

1.The inability to apply monitoring by medium and small enterprises. At the same time, the mechanical transfer of the mechanism of tax monitoring of large enterprises to medium and small enterprises is impossible, adaptation is necessary for new conditions;
2. Not used to control compliance with market prices;
3. Incomplete cancellation of tax audits;
4. Security risks are not regulated when examining the taxpayer information base. In a research study by Kostygova L.A., Sidorova E.Yu (2019)
Thus, in the future until 2020, the authors propose the following:
1. Development of common standards and formats for information interaction. In the tax monitoring mode, the taxpayer can choose between two possible formats of information interaction - to provide the tax authority with direct access to its information system or to submit information in electronic form. Both options provide for the possibility of organizing various methods of transferring information to the tax authority and using a variety of electronic formats (xls, doc, pdf, jpg, etc.) and their combinations. In international practice, the standardized structure and format for transferring data to tax authorities is widely used - the so-called standard tax audit file (StandardAuditFileforTax, or SAFT-file). The structure and content of the information in the SAFT file allows the tax authority to obtain the information necessary for effective tax audits, complete analytical procedures and minimize additional document requests. The specified standard has already been adopted as mandatory for use in a number of OECD countries (for example, in Portugal, France). In addition, it is supposed to be used for organizing the international exchange of information between tax authorities of OECD countries. Given the latest trends in the development of international tax information exchange, it is impossible to exclude the use of a similar standard for building information interaction in the framework of tax monitoring in Russia. In a research study by OECD (2008)/

2. Development and formalization of approaches to checking the effectiveness of the taxpayer internal control system for taxes. Using the results of the internal control system, so as the development and development of practical experience in applying the principles of evaluating the internal control system during tax audits, unified methodology and approaches to assessing the effectiveness of these systems will be developed based on the results of pilot projects and international standards (COSO, etc.), already operating in a number of countries.

The use of statistical methods in tax audits. The regulation of information interaction on tax monitoring provides the opportunity for the organization to independently determine the volume, principles for selecting information and documents for the tax authority, provided that information about its internal control system is disclosed. In development of this principle in the international practice of tax administration, methods of statistical analysis of taxpayer data have become widespread. Such methods allow tax authorities to significantly reduce the amount of requested and verified information, limiting verification procedures by spot testing areas of high risk. Statistical methods, as a rule, are used in automated tax control systems that allow for the efficient processing and testing of significant amounts of tax information. In a research study by OECD. (2010)

3. Further development of a risk-based approach to tax audits. The practice of applying tax monitoring should give impetus to the study by tax authorities of key business processes of taxpayers in the main

sectors of the economy at a qualitatively new level and, as a result, lead to a significant reduction in the number of questions examined as part of the audit and the further development of a risk-based approach to planning and implementation tax audits. As a result, we can expect a general decrease in the number of tax disputes and litigation, labor and other expenses of tax authorities and taxpayers on tax administration, the establishment of a constant and constructive dialogue between them, and mutual trust.
One of the methodologically unsolved problems is the question of evaluating the effectiveness of the internal control system. As a hypothesis of the study, it was proposed that the RF Tax Code provides for quantitative and qualitative criteria that allow the transition to the use of tax monitoring. Quantitative criteria are very relevant for tax monitoring and allow you to constantly monitor the largest payers of taxes, fees and contributions to the budget. At the same time, the principle of increasing the effectiveness of tax control is implemented. Currently, the goal of tax authorities is to reduce the cost of tax control measures and improve its quality and effectiveness. At the same time, it can be assumed that the Pareto principle is implemented here, the essence of which is 20% of the effort gives 80% of the result, and the remaining 80% of the effort is only 20% of the result.

The quality indicators include the mismatch:

• regulations for information interaction in the established form and requirements for regulations for information interaction;
• internal control systems to the established requirements for the organization of the internal control system.
In order to solve this problem, the article will use the expert method in developing an assessment of the organization's internal control system that applies tax monitoring.
In the framework of the study of foreign experience in building an internal control system, the following can be noted. The Belgian Tax Administration Division of Large Enterprises (hereinafter referred to as the Division) announced the launch of a two-year pilot project on joint tax compliance. The program aims to transform the traditional approach of subsequent tax investigations into a system of effective, real and constructive dialogue on corporate tax matters. The joint compliance program will cover corporate income taxes, VAT, taxes equivalent to income taxes, and other taxes administered by the Division. However, the collection and collection of taxes will be excluded. It is assumed that the program will spell out certain elements of the corporate internal control system.

The pilot program will be open to very large enterprises. Participation is voluntary. The following thresholds are expected to apply:

- revenue of 750 million euros or more;
- overall balance of 1.5 billion . Euro or more;
- staff more than 1000;
- subject to corporate income tax in Belgium.
It is still unclear whether the sum of the threshold values or the passage of only one of the criteria gives access to the joint compliance program (when other conditions are met). The mandatory principle of " All - in " or " All - out " will apply to Belgian organizations and group affiliates based on association rules.
To gain access to the joint compliance program, taxpayers must also:
• have been timely filed tax returns in the past;
• have been to pay all taxes;
• Create a robust tax control system ("TCF") . Moreover, here we have in mind an analogue of the Russian system of internal control and:

• may not have been involved in tax evasion;
• may not have violated tax laws and have not shown serious setbacks over the past 3 years. In a research study by Sidorova E.Yu (2019)

Participation in the Joint Compliance Program does not mean that taxpayers will receive a more favorable tax regime. All rights and obligations based on national and international law remain fully applicable. Although the goal of the Program is to reduce the number of disputes through a constructive dialogue in real time, businesses and the Division may agree to disagree with the Program. In this context, in-depth tax audits are still possible.

At the same time, joint ventures participating in the Program can expect to receive a lower risk profile with a corresponding impact on the degree of audit. From a procedural point of view, it is not yet clear how an active and widespread exchange of information between enterprises affects or interacts with international (automatic) mechanisms for the exchange of information.

One of the main advantages offered for the Program is the most prompt feedback on tax positions (statuses). It is currently unclear whether the Program's dialogue will provide the same level of legal certainty regarding tax positions as formal preliminary decisions (resolutions) or preliminary pricing agreements.

This pilot project will start at the end of 2018. Successful preliminary discussions with taxpayers will lead to a more formal acceptance process if both the enterprise and the Department consider that the Program will bear fruit. The most important part of the admission process will be related to the review of the Tax Control System (a Russian analogue of the internal control system) , as well as to the basic concepts of the Program. It is assumed that the duration of the admission process will vary from 6 months to 1 year. . In a research study by Muradov I (2019)

The approval procedure for the use of tax monitoring is regulated by two main documents:

1. The Tax Code of the Russian Federation, part one;
2. Letter No. ED-4-15 / 12378 of the Federal Tax Service of Russia dated June 28, 2017 "On the direction of the procedure for assessing the completeness of information specified by an organization in a tax monitoring application and documents (information)" (hereinafter - the Letter).

At the same time, the Letter regulates the methodology for checking qualitative and quantitative indicators. In this case, two approaches are used during verification: formalized and high-quality, but this does not allow an objective assessment of the submitted documents; it is proposed to use a quantitative approach to verify individual points.

Thus, initially a formal approach was taken to verify information about the organization, then the Federal Tax Service of Russia will examine additional information about appealing the tax authority in pre-trial procedure. Let us dwell on this in more detail, as a second appendix on assessing the completeness of the information specified by the organization in the application for tax monitoring, and the documents (information) submitted in accordance with paragraph 2 of Article 105.27 of the Tax Code of the Russian Federation are examined with reference to appeal against decisions of the tax authority in pre-trial the procedure , in particular, analyzes the types of inspections, the period being checked, taxes as an object of verification, the amount of additional charges and the stage of consideration. The reasons for the appearance of this application is understandable:
•evaluate taxpayer compliance
•assess the degree of readiness of the taxpayer to recognize the arguments of the tax authority and agree with its decision. This conclusion can be drawn from the fact that the table contains the column "Consideration (stage) of consideration", in this column there can be 3 formulations: I agree with the decision, it is aimed at pre-trial settlement, the case is in court;
•evaluate the effectiveness of the implementation of tax monitoring, as it is necessary to correlate the amount of costs of the audits and tax monitoring. In a research study by Vinogradova E.V et al (2019)

However, these goals cannot be fully realized with the help of this application, since it is necessary to understand the entire volume of inspections carried out by the Federal Tax Service of Russia with respect to the taxpayer, it is possible that there are inspections that did not reveal offenses.

At the same time, an analysis of foreign practice confirms the fact that for a number of countries taxpayer compliance is one of the main criteria for allowing the use of tax monitoring, for example, Germany, where only law-abiding taxpayers can use tax monitoring.

Further, in the continuation of the above information, the tax authorities examine the information on the consideration of tax disputes in the courts , however, the presence of this application is very controversial, since the information contained in it is fully correlated with Appendix 2 and the column on the results of consideration is present in two applications.

The formal approach is implemented in Appendix 4, “Assessing the Legality of Handling a Tax Monitoring Application , ” where quantitative criteria for tax monitoring are checked and the check is symmetrical, namely, the taxpayer’s information is checked with the tax authority.

At the same time, qualitative indicators are tested , using two approaches and formal quality. In this audit, it is necessary to implement an additional methodological approach to assessing the internal control system, however, this does not allow an objective assessment of the submitted documents; it is proposed to use a quantitative approach to verify individual points. So in Appendix 7 for prices of the Regulation on the internal control system and documents governing the internal control system formally verifies the presence or absence of indicators in accordance with Order of the Federal Tax Service of Russia dated 16.06.2017 No. MMV-7-15 / 509 @ "On Approving the Requirements for the Organization of an Internal Control System", then a reference is made to the document and description, in this case there is the problem of a fair assessment of the quality of the system. We propose to apply an expert approach to the assessment of the internal control system (table 1). It should also be noted that Appendix 7 gives a classification of the levels of organization of the internal control system and gives a qualitative description of each level, which, together with the quantitative method, will allow tax authorities and taxpayers to more accurately determine the quality of the internal control system used.

Table 1 - the System of expert assessments of the internal control system of the organization that applies tax monitoring

Indicator	The importance of the indicator, Ki	Expert Score , Oi	Consolidated Index Jn
1.Control environment	0.08		
Compliance with professional, ethical and behavioral standards	0.05		
The participation of the head of the organization	0.01		
Organizational structure, distribution (differentiation) of powers and responsibilities	0.01		
Competencies and staff development	0.01		

2. Risk Management	0.55		
Identification by the organization of risks associated with the distortion of the accounting (financial), tax and other statements of the organization for tax monitoring purposes	0.2		
An organization's assessment of the risks associated with the distortion of the accounting (financial), tax and other statements of an organization for tax monitoring purposes	0.2		
Documentation of risks by the organization associated with the distortion of the accounting (financial), tax and other statements of the organization for tax monitoring	0.15		
3. Control procedures	0.13		
Description of organization control procedures	0.05		
Documentation of organization control procedures	0.05		
Evaluation of the effectiveness of control procedures of the organization	0.01		
Organization automated control procedures	0.01		
The ratio of automated and manual control procedures of the organization	0.01		
4. Information systems	0.09		
Internal and external audit of organization information systems	0.01		
Availability of protection against unauthorized access to source data	0.05		
Organization information systems for the organization of accounting and tax accounting	0.01		

Organization information systems used to control the correctness of the calculation (withholding) of taxes, fees, insurance premiums and to prepare the accounting (financial), tax and other statements of the organization	0.01		
Real-time controls	0.01		
5. Monitoring and evaluation of the effectiveness of the internal control system	0.15		
Monitoring and evaluation by the organization of the organization's internal control system	0.1		
Measures to improve the organization's internal control system	0.02		
Internal and external audit	0,03		

The calculation of the composite competitiveness index for each group of factors will be performed according to the formula:

Jn = Oi * Ki ,
where: Jn is the composite competitiveness index of the group of factors of each block;
Oi is the value of expert assessments of the indicators of each group of competitive factors within the block;
Ki - the importance of the indicator of a specific competitiveness factor in the overall structure of the block.

There are four levels in total:

initial (1) level - 0 - 20 points;
certain (2) level - 21 - 40 points;
controlled (3) level - 41 - 60 points;
managed (4) level - 61 - 80 points;
improving (5) level - 81 - 100 points.
These percentages are the benchmark for pricing and experts, Oi Moreover, as the characteristics of each level, it is necessary to use the descriptions given in Appendix 7 of the Requirements for the organization of the internal control system
The " Control environment " section in the weight equivalent is 0.08, the statistics are based on the insignificance of this section in the overall assessment system of the internal control system, and these sections are more formal than semantic.

The " Risk Management " section in the weight equivalent is 0.45, the statistics are based on the significance of this section in the overall assessment system of the internal control system and these sections are semantic.

The “ Control Procedures ” section in the weight equivalent is 0.22, the statistical data are based on the partial significance of this section in the overall assessment system of the internal control system and these sections are semantic, while the most difficult question is about the effectiveness of control procedures of the organization .

The “ Information Systems ” section in the weight equivalent is 0.09, statistics are based on the fact that this section is of a technical nature and is developed before submitting an application for tax monitoring and is worked out before the start of tax monitoring.

The section “Monitoring and evaluating the effectiveness of the internal control system ” in the weight equivalent is 0.15, statistics are based on the fact that this section can be debugged as standard business processes that will have minimal errors.

Thus, the use of the methodology given in table 1 gives a clear quantitative assessment of the organization’s internal control system and allows two tax-monitoring entities to diagnose it by levels. The mechanism of applying the internal control system will allow using the risk-based approach to obtain the most favored nation treatment for bona fide taxpayers. A company may, due to the system, be less often subject to audits, which should be first subject to the activities of those taxpayers for whom cases of violation of tax laws were previously identified: this can be as a failure to pay tax payments, evading interest and fines, using various types of withdrawal schemes from taxation. In this regard, the system provides high-quality interaction until the fact of verification.

Detecting The Cross-Points In Laser Generated Lattice Using Hessian Eigenvalues And Mathematical Morphology

Sebastian IWASZENKO

Central Mining Institute, Plac Gwarków 1, 40-166 Katowice, Poland

siwaszenko@gig.eu

Abstract

Many of the industrial activities are connected with threats caused both to the employees and the infrastructure. It is especially true in the case of deep mining industry, where the seismic threats are counted among the most dangerous ones. Risk management in such a case requires the knowledge of the current conditions, which can be obtained by the use of computerized monitoring systems. In the article, a detailed part of such a system is presented. The monitoring of rock mass tension is performed by analyzing the deformations of conical borehole made in the draft sidewall. The article presents the method for discovering a set of points formed by the crossing of the laser-generated lattice on the conical borehole surface. The methods of noise reduction methods are presented. The discrimination of the lattice lines by use of the Hessian matrix as well as the detection of its crossings are described. The developed algorithm was tested on the images gathered in the laboratory stand simulating industrial conditions with satisfactory results.

Keywords: Information systems issues, knowledge discovery, image analysis, image processing

Introduction

Information technology is playing a crucial role in many aspects of nowadays industry. The information systems are used widely in different branches of industry, influencing not only the productivity but also the organizational culture and safety. The last is especially true in case of inherently tough industrial activities such as raw materials excavations. Though many aspects of safety factors can be mentioned here, it is out of doubt, that the seismic ones, especially in deep mines are of most importance. The most effective way to improve safety in the case of these threats is prevention associated with continuous monitoring of the state of stress prevailing in the rock mass. The information gathered during the monitoring process can be used in the estimation of the rock mass condition and assess the potential of severe consequences. One of the most important parameters is the tension appearing in the rock mass. However, its determination is not easy and requires constant monitoring. One of the methods bases on the determination of shape changes of the geometry of the borehole drilled in the sidewall. The borehole is usually about 8m long, but its most important part is the conical shape at the end. The deformations of the cone in time are caused by the influence of rock mass and depict the stress in it. It is important that the determination of the shape of the cone is performed in the way which does not influence the tension field. Therefore, the optical methods were considered as they allow assessment of the shape without the necessity to touch the measured surface in any way.

The determination of the shape using optical methods can be performed using structured light, stereoscopy, or laser distance scanning. When the structured light is used, the known geometric pattern is projected onto the surface (Geng, 2011; Wang, Zhou and Shuang, 2020). The analysis of the deformations of the projected shape gives the information about the surface shape. The knowledge about it is discovered by calculating the difference between the placement of known elements of the pattern on the surface and their placement on the plane. The usage of stereoscopy takes advantage of observing the scene, the investigated surface, by two (or more cameras). The corresponding points are identified in the images gathered by the cameras. The displacement of the points reveals the knowledge about the analyzed shape (Koch, 1995). The last-mentioned method uses a laser beam for the direct measurement of the distance between the laser source and the surface. The distance is measured in a

set of selected points (the surface is scanned) and the measurements inform of the shape of the analyzed surface.

In the article, the method using both structural light and stereoscopy is considered. The source of light, the laser projector, display a rectangular grid on the surface of the cone. The first step and the crucial difficulty in the shape assessment process is the detection of the grid lines and precise detection of the key points formed by lines crossing.

Image processing and analysis were widely used in the many branches of industry (Yu and MacGregor, 2004; Honkanen, Eloranta and Saarenrinne, 2010). It is also true for the mining industry. The image analysis was used for the raw materials enrichment process (Kistner, Jemwa and Aldrich, 2013; Fu and Aldrich, 2019), assessment of mineral resource quality (Yaghoobi *et al.*, 2019; Iwaszenko and Smoliński, 2020), or the monitoring of people's behavior (Fang *et al.*, 2020). One of the applications is a determination of the bulk rock materials granulometry. In the article, a method for enhancement of the gathered image quality is presented as well as the method for displayed rectangular grid lines cross-sections. The presented methods use Hessian matrix eigenvalues analysis for the linear structure discrimination (Sato *et al.*, 1998). The method uses the 'vesselness' parameter (Frangi *et al.*, 1998) as a discriminative quality. Once the grid lines are extracted from the image, the morphology operations are utilized for grid cross-sections determination. The method was implemented and used in the equipment for the rock stress monitoring developed in Central Mining Institute (Kabiesz *et al.*, no date).

Materials and Methods

Image Acquisition

The images for the experiment were collected using RGB cameras mounted on the cylindrical metal-plastic chasse. The chasse has diameter 76mm and the length 160mm and can be inserted into the drilled borehole when necessary. The lattice pattern was generated by a laser projector placed along the chasse axis. The two cameras were placed on both sides of the laser projector. The scheme of the cameras and the laser projector montage is presented in Fig. **1** and the frontal view of the equipment is shown in Fig. **2**.

All images were gathered at the laboratory stand consisting of the rock block (233mm x 180mm x 350mm) with centrally drilled cone borehole on the biggest side. The cameras and the projector focus was set at 120mm, which resulted from the laboratory stand geometry. There were 12 series of pictures taken. Each series consisted of 5 images. The images had a resolution of 2592x1944 and were registered with 24-bit RGB color depth (8 bit for each channel). The laser projector (red) was the only source of light during the experiment. The example image taken during the experiment is depicted in Fig. **3**. All images, due to hardware limitations, were saved as jpg files.

Fig. 1:The schema of the image acquiring equipment

Fig. 2:Frontal view of imaging equipment

Fig. 3:The example of input image

Image Preprocessing

The 'raw' images registered during the experiment suffer from a few drawbacks:

- the images are distorted by the camera optics,
- the framing is not perfect,
- the noise, reflections, and 'false' curves make the image hard to analyze.

Therefore, the images have to be preprocessed before any other analysis steps are taken. The two first drawbacks can be corrected relatively easily. The distortion can be eliminated using camera intrinsic matrix and distortion coefficients (Zhang, 1999). Because the scene observed by the cameras is steady and there are no significant movements in the field of observation, the cropping parameters can be determined once in the beginning (even manually) and applied consecutively to all registered images. The last problem, however, needs more attention.

The first step in images preprocessing wast to switch from the three-channel, color RGB image into the one-channel grey level. The transformation was motivated by the fact, that the illumination used is monochromatic and the only important information contained in the image has geometric nature – the placement of grid lines and lines cross-sections. The images were converted to HSV color space, and only the V (value) channel was used for further processing. The preliminary noise elimination on the images consisted of two phases. It was assumed, upon inspection of the noisy region of images, that its nature is probabilistic and caused by poor light conditions during image acquisitions (which is the inherent feature of the conditions inside the borehole). It implies, that the noise levels in each pixel will vary in the images taken within the series. Fortunately, there are no changes to the laser projected grid at the same time. Therefore, summing up the images taken during the same series will result in significantly higher amplification of the region containing the lattice lines, and a relatively low increase of values of pixels in dark areas. In other words, the same pixels on the lattice on different images have similar values, but the pixels in the noisy parts of the images, have different values on each image. All images taken during one series were added, and the result was normalized to a standard 8-bit color range. As a second phase for noise reduction, a 5x5 median filter was used.

Gridlines Discrimination

The grid lines discrimination method uses the 'vesselness' feature, proposed in (Frangi *et al.*, 1998) and previously used for discrimination of linear structures (e.g. vessels) on computer tomography (CT) images. The method was successfully utilized in the linear structures discriminations on images (Fabijańska, 2017; Sebastian Iwaszenko and Karolina Nurzynska, 2019). The method utilizes the comparison of eigenvalues of the Hessian matrix. The Hessian matrix is composed of second-order partial derivatives of the function. Treating the image as the function of two variables, the Hessian can be written as follows:

$$H = \begin{bmatrix} I_{xx} & I_{xy} \\ I_{yx} & I_{yy} \end{bmatrix} \tag{1}$$

where $I_{ij} = \frac{\partial I(i,j)}{\partial i \partial j}$, and I is the image. The eigenvalues and eigenvectors of the matrix hold the information about the intensity and directions of function values changes. In the case of the considered image, the values are simply the image gray level. The discrimination of the linear structures on the image requires finding all the pixels for which the first eigenvalue, λ_1 is much greater than the second one. Moreover, in the case of discriminating the bright lines, the λ_1 should be close to zero while λ_2 should be negative. Such a combination reflects the situation when there is almost no change in color in direction of the first eigenvector and there is a huge drop in the color value in the direction of the second eigenvector. The (Frangi *et al.*, 1998) propose calculation of the feature which value depicts the chance, that the given point is placed at the linear structure:

$$v_\sigma = \begin{cases} 0 \; for \; \lambda_2 > 0 \\ e^{-\frac{\mathcal{R}_B^2}{2\beta^2}} \left(1 - e^{-\frac{S^2}{2c^2}}\right) \end{cases} \tag{2}$$

where S is a Frobenius norm of H matrix, $S = \sqrt{\lambda_1^2 + \lambda_2^2}$. The β and c are the parameters. The $\mathcal{R}_B$ parameter measures the "blobness" of the pixel's vicinity and is calculated as follows:

$$\mathcal{R}_B = \frac{\lambda_1}{\lambda_2} \tag{3}$$

As the linear structures observed in the image can manifest at a different scale, the v_σ is calculated for the image blurred by Gaussian filter with standard deviation σ. The complete algorithm for enhancing and discriminating linear structures uses a series of different, increasing values of σ_i. The image is blurred using the values, and for each pixel a v_σ is calculated. The result consists of the highest detected v_σ values between all scales used. The β value was equal to 0.5 and c was equal to half of the maximum Frobenius norm at a given scale.

Morphological Transformations For Grid Cross Points Identification

The linear structures discriminating algorithm allow discovering the laser grid among disturbances and noises present in the image. The determination of the crossings of the lattice lines was performed using morphological operations.

The proposed solution uses the erosion operator with two cross-shaped structuring elements, one being the negative of the other. Before the application of erosion was performed, the histogram of the input image was equalized. This operation improved overall quality and positively influenced the results. Then two images were obtained, one after erosion by the cross-shaped element, and one by the erosion using the negative of it. The last image was subtracted from the first one, and the result was binarized using threshold operation. Such operation can be interpreted as a kind of hit-or-miss morphological operation (Dougherty and Zhao, 1992). After performing the operations, the resulting image should

contain mostly the pixels placed in the regions of line structures crossing. The proposed operation is straightforward and can be effectively performed.

Results and Discussion

The images used for testing the proposed methodology were gathered using the laboratory stand. There was a total of 10 pictures taken in each of the 12 series. The images were taken by two cameras, yielding 5 pictures per camera per series. The typical raw image is presented in Fig. **3**. The conversion to HSV color space as well as morphological operations and image arithmetics were done using the OpenCV library. The improvement in image quality due to proposed preprocessing can be noticed in Fig. **4**. The obtained result shows noticeable noise reduction. However, the image is still problematic in a direct investigation, therefore further steps had to be taken. The calculation of the multiscale vesselness parameter requires defining the range of the σ parameter used for images blurring. The range depends mainly on the size (thickness) of the linear structures, which are supposed to be detected on the image. For laser lattice images, the set of experiments was performed varying the starting σ value from 0.2 to 5 and the ending value from 2 to 30. The parameter was changed with steps 0.1, 0.2, and 0.5. It was observed that the lattice is well discriminated against on the pictures with σ varying from 0.5 to 5 with step 0.2. The wider intervals did not change the observed discrimination of the lattice significantly, though the highest values resulted in very long calculations times. The typical result of used linear structures discriminations is presented in Fig. **5**.

Fig. 4: The image after applied preprocessing - the significant noise reduction can be observed.

Fig. 5:The image after linear structures discrimination and normalization. The lines of projected laser grid ara clearly visible.

The application of morphological transformations resulted in the images similar to the one presented in Fig. **6**. The detected cross points can easily be spotted. Their segmentation, however, lacks precision. There is rather a cluster of pixels present, where one can expect a single point. The reason for that is connected with the spatial dimension of the lattice itself. The thickness of the lines is as high as 8 pixels. This is the cause, that the crossing contains a group of pixels instead of the one. These clusters can be refined to the single-pixel by calculation of its centroid. There is also another problem, which can be observed in the image. As the conical hole is drilled, the few circular scratches on its surface are made. The scratches are clearly visible when lit by the laser light as the parts of circles, disturbing the view of the lattice. They were not eliminated nor by the preprocessing nor by the linear structures discriminations. They are still visible on the final picture, but at this time, that rather cause the pixel clusters on the lines crossing are bigger than in the other places. Though it is still possible to reasonably detect the crossing, it is not as precise as in the other places. Fortunately, the problems occur only in very limited numbers of crossing and therefore can be neglected in most applications. The presented method proved its robustness when applied to every test image and can be used as the method of knowledge discovery from image information.

Fig. 6: The image after morphological transformation and thresholding. Lines cross points are visible as 'dots' (pixels' clusters)

Conclusions

The method for discovering the knowledge of the set of characteristic points upon the image information was presented. The characteristic points are formed at the crossing of lines of the laser-generated grid. The knowledge of point's locations is crucial in determining the shape of monitoring borehole used for the determination of the stress field in the rock mass. The presented method is able to reduce the noise level at input images, discover the linear structures, and identify the crossing of the grid lines. Though the method proved its usefulness, there still is a place for improvements, e.g. its effectiveness (calculation times can be long) and the ability to eliminate false signals from the scratches on the borehole surface. The improvements will be elaborated during further method development.

Acknowledgments

The research presented in the paper has been supported by the statutory activity of the Central Mining Institute: Classification of objects based on video information for a selected set of mineral fractions – No. GIG: 11126019-172.

Socially Responsible Investments and Investment Policy Evidence from Listed Companies in Poland

Prof. Marzena REMLEIN, Ph.D.

Poznan University of Economics and Business, Poland
marzena.remlein@ue.poznan.pl

Abstract

The subject of the considerations is the investment policy, the concept of socially responsible investments and their disclosure in the reports of listed companies in Poland. The research problem of the paper boils down to examining the investment policy of listed companies in Poland in the field of socially responsible investing. The purpose of the paper is to evaluate the investments made by companies listed on the Warsaw Stock Exchange and to assess disclosure of information about SRI in the company reports. The research methods used are financial analysis method, content analysis method, descriptive statistics using the IBM SPSS 24 program and the MS Excell spreadsheet.
The examined period covers the years 2011-2018. The results of the research prove that listed companies in Poland have a significant percentage of investments in their assets, and the results obtained from investing activities largely contribute to the financial success of the company. In addition, the surveyed companies show good quality information about SRI (89.5% in 2018). The analysis over the period 2011-2018 shows that the disclosure quality about SRI is steadily increasing. The results of the research increase knowledge in the field of making and reporting information on socially responsible investments.

Introduction

Investments mean economic expenditures for increasing or restoring assets that will bring positive effects in the future. Investments understood in this way include expenditures on creating new production capacities by constructing new facilities or expanding existing ones, as well as investing free cash in a way that will generate increased income in the future. Currently, when making decisions about investing free financial resources, investors take into account not only economic factors (rate of return on invested capital and risk), but also social, environmental, ecological and ethical ones. In such a situation, Socially Responsible Investing (SRI) becomes an alternative to traditional forms of investing, understood as the result of the investment strategy adopted by the company, which equally strives to maximize profit as to achieving specific social goals and taking into account the needs develop sustainably.

The research problem of the paper boils down to examining the investment policy of listed companies in Poland in the field of socially responsible investing.

The purpose of the paper is to evaluate the investments made by companies listed on the Warsaw Stock Exchange and to assess disclosure of information about SRI in the company reports.

The paper is organised as follows. The introduction builds up the motivation for the paper and states its purpose. The second chapter provides an overview of the investment literature, especially SRI. The third one shows dataset and research methodology. Next chapter reports and discuss the main results of an empirical research. The final chapter summarises the main findings.

Literature Review

The term “investments” is particularly important in a market economy, where investing is a fundamental factor for economic growth and development. J. Hirschleifer (1965, p. 509) defined investments as current renunciation of future benefits. The present is relatively well known, while the

future is always a secret. This means that the investment is a renunciation of certainty for the expected benefit.

There have been many attempts in the literature to define the concept of investment (e.g. Baumol, Blinder, 1991; Beherens, Hawranek, 1993; Dydycz, Wrzosek 2000; Dziworska 1993, 1996; Francis 2000; K. Jajuga, T. Jajuga, 2006; Leszczyński, Skowronek-Mielczarek 2004; Relly, Norton, 2006; Walica, 2004; R.J. Wonnacott, P. Wonncott, 1990; etc.) . However, in most cases they are based on the definition of J. Hirschleifer.

Investments are most often understood either as monetary expenditure that is to bring income to the investor (financial aspect) or as a process in which cash is transformed into other goods (material aspect) (Różański, 2006, p. 13). Initially, the scope of the investment was narrowed to material goods, so a material approach was widely recognized. The development of technology and technology caused that investments in intangible assets are made and the development of capital markets caused an increase in capital investments.

There are two basic trends in defining the concept of investment:

- the monetary (financial) trend, treating the investment as cash flows, while a direct connection with obtaining the effect in a material form is not necessary,
- material (economic) trend, where the investment is perceived as a movement of goods, it is therefore necessary to obtain a material effect.

Currently, when defining the concept of investment, the emphasis is on their financial side. The adoption of the monetary (financial) option results from the immanent, natural relationship between finance and investment.

The author understands investments as a current commitment of financial resources to acquire specific assets, both material and immaterial, thanks to which the investor expects to achieve benefits. Investing is a process of engaging financial resources in order to obtain benefits, assuming that these benefits from the investment will be greater than the funds involved.

Recently, we can observe an increase in financial investments in accordance with the concept of sustainable development. This is indicated by the growing number of assets on the global financial market managed in accordance with this concept (Janik, 2014, p. 8). This means seeking a balance between the economic, ecological and social aspects of the enterprise. Economic policy cannot be detached from social policy or environmental policy. Achieving this goal in practice requires that economic development supported social progress and respected the need to protect the environment, social policy strengthened economic results and environmental policy was economically effective (Gasparski, 2003, p. 54). The investments that take into account both economic, social and environmental factors are referred to as socially responsible investments (SRI).

The field of SRI has been characterised by debate (Bruyn, 1987; Hylton, 1992) or lack of consensus about definitions (Cooper, Schlegelmilch, 1993; Frankel, 1984). Even the terminology is not settled. Thus broadly similar or related terms which appear in the literature include social (Bruyn, 1987; McGill, 1984), divergent (Schotland, 1980), creative (Powers, 1971), green (Simpson, 1991), targeted, development and strategic (Wokutch et al., 1984) investing or investment. However, the two most common terms are socially responsible investment and ethical investment (Sparkes, Cowton, 2004, p.46).

Socially Responsible Investing is a kind of philosophy and at the same time a practice of making strategic investment decisions, in which traditional financial criteria, i.e. the rate of return and risk, are extended and supplemented with non-financial factors, including social and environmental aspects, and those related to corporate governance (Urban 2011, p . 496). According to R. Sparkes (2002, p. 22), SRI is an investment philosophy combining both financial and non-financial criteria.
The review of the literature on socially responsible investing (Klasen, Röder, 2009; Marcinek, 2016; Pasewark, Riley, 2010) demonstrated that, when making decisions to invest their own funds in

accordance with the SRI concept, the investors focus primarily on four areas: economic (business), social (sociological), environmental (ecological) and ethical (moral). Research on socially responsible investing can be divided into two main groups. The first group includes literature studies on the SRI concept itself, and the second group concerns research on effectiveness of investments taking the ESG factors into account.

The development of market for socially responsible investments has led to research verifying their effectiveness. However, the researchers' opinions on this issue are divided.

Skeptics of the SRI concept believe that limiting the investment portfolio to socially responsible investments must lead to a decrease in its efficiency by reducing the achieved profit or increasing the risk incurred (Jedynak, 2011, Geczy, Stambaugh, Levin, 2003). Supporters of the SRI concept quote the results of indexes of socially responsible companies and the funds that declare to pursue SRI in the long term (Statman, 2005; Schroder, 2007; Jedynak, 2012; Kubińska, 2014). Positive results of research on the effectiveness of SRIs are also cited by the 2016 report by Deloitte, on the impact and scale of including ESG factors in the process of making investment decisions.

The development of the SRI concept and its positive impact on the results of business operations justify the need for research on disclosing information about SRI in company reports.

Data and Methodology

The research problem of the paper boils down to examining the investment policy of listed companies in Poland in the field of socially responsible investing.

The source of data for research are the financial statements of companies listed on the Warsaw Stock Exchange, operating as part of the RESPECT Index project framework[1].

In order to select the research sample, the following assumptions were made:

1) the survey covered companies of the RESPECT Index at 27 December 2018
2) the examined period covers the years 2011-2018,
3) due to the nature of the operation and various accounting and financial reporting rules, banks, insurance companies and entities operating on the basis of securities trading regulations as well as regulations on investment funds and investment fund management were excluded from the research sample,
4) the companies that did not publish financial statements for all the years covered by the research were excluded.

Out of 31 listed companies, 12 companies were excluded due to:

- 9 companies - specifics of their operations and different accounting and financial reporting principles,
- 3 companies - lack of financial statements for all years covered by our survey.

The sample consists of companies that operate in the industry:

- construction industry, energy industry and fuel industry –3 companies in every industry,
- raw materials – 2 companies,
- other industries (chemical industry, electrical machinery industry, hotels and restaurants, media, retail, telecommunication, timber industry and wholesale – 1 company in each industry.

Of the 19 companies accepted for the research, we included 8 companies listed in the WIG20 index (contains 20 largest companies), 8 companies that were part of the mWIG40 index (includes 40

[1] RESPECT Index is the first index of responsible companies in Central and Eastern Europe introduced on the GPW Warsaw Stock Exchange in 2009. The main goal of the project is to promote the highest standards of responsible management.

medium-sized companies), and further 3 of the mWIG80 index (comprises 80 small companies). Taking companies of various sizes into the study makes the research sample more representative.

Considering the 8-year period, 152 reports published by companies were subject to observation.

The research methods used are financial and content analysis, descriptive statistics using the IBM SPSS 24 program and the MS Excell spreadsheet.

H: The value of investments on the Polish capital market improves over time, but this is not reflected in socially responsible investments.

Results and Discussion

Value of Investments

The research problem boils down to examining the value of investments disclosed in the financial statements of the surveyed companies.

A preliminary analysis of the individual financial statements of the analyzed companies allowed to conclude that in the period of 2011-2018 all of the surveyed companies invested their free funds. This proves how important an asset group the investments are for the companies. The descriptive statistics are presented in Tab. 1.

Tab. 1 : Descriptive statistics – Total investments

Statistical measures	2011	2012	2013	2014	2015	2016	2017	2018
mean	4 254 481	4 530 106	5 441 915	5 314 844	5 695 980	5 673 548	5 523 919	5 651 437
median	384 302	767 419	662 025	636 998	660 536	686 083	517 999	499 506
max	22 903 348	22 657 054	23 166 290	25 611 801	29 049 000	29 515 000	30 040 000	32 868 000
min	38 633	40 649	40 275	40 627	39 967	64 005	68 969	66 497

Source: Author's calculation

Fig. 1 : Disclosure Index of Total investments over period 2011-2018

The average value of total investments measured by its mean (blue colour) is PLN 4.25 million in 2011 and it rises steadily up to PLN 5.65 million in 2018. The improvement can be identified in 2013. If the median (red colour) is taken into account, it produces a higher level than the average value. At the beginning of the examined period only one company had investments over PLN 20 million. It was company which operate in energy industry. At the end of the period, 2 companies (both companies in the energy industry) had investments worth over PLN 20 million. The largest value of investments is over PLN 32 million.

The next step in the study is the analysis of relative values - investment share in total assets.

Tab. 2: Descriptive statistics – Investment share in total assets (%)

Statistical measures	2011	2012	2013	2014	2015	2016	2017	2018
mean	29,5	30,9	34,9	33,0	33,6	34,5	33,7	32,5
median	20,8	29,3	37,4	28,6	29,4	27,0	30,2	27,8
max	93,3	93,4	89,0	91,6	88,5	93,8	93,9	90,7
min	2,6	2,4	2,2	2,0	1,8	2,0	2,1	1,9

Source: Author's calculation

Fig. 2: Disclosure Index of Investment share in total assets over period 2011-2018

The average investment share in total assets measured by its mean (blue colour) is 29.5% in 2011 and it rises steadily up to 32.5% in 2018. If the median (red colour) is taken into account, we can see that it is below average. However, there was a clear increase in 2013.

The largest share of investments in total assets fluctuates around 90%, taking the lowest result in 2015 (88.5%), and the highest - in 2017 (93.9%). This result belongs to a company from the energy industry. This proves that the company is heavily invested and the business activity has been reduced to investment activity.

The lowest result can be recorded in a company from the raw materials industry (from 1.8% in 2015 to 2.6% in 2011). The analysis of the balance sheet and additional notes shows that due to the kind of business, the majority of assets are components of property, plant and equipment (fixed assets). We can also note that the number of companies whose investments accounted for more than half of their assets is growing over the period considered. This confirms the thesis about the significant role of investments in business operations of enterprises.

Socially Responsible Investments

The research problem boils down to examining the quality of information about SRI in reports prepared by companies.

This section analyzes the quality of SRI disclosures. The first step in the qualitative analysis of disclosures concerning socially responsible investments was to determine, which elements of the annual report will be assessed. Three important sources of information provided to stakeholders were selected:

- financial statement,
- letter to stakeholders,
- management commentary.

In the subsequent step, research questions were formulated:

1) is there information on **corporate social responsibility** in the reports?
2) is there information on **corporate governance** in the reports?
3) is there information on **sustainability** in the reports?
4) does the company inform about its **social responsibility activity**?
5) does the company avoid investing in **dirty businesses**[2]?
6) does the term "**socially responsible investment**" appear in the reports?
7) does the term "**ethical investments**" appear in the reports?
8) does the term "**impact investments**" appear in the reports?
9) does the term "**green/ecological investments**" appear in the reports?
10) is there information about **investments for environmental protection**?
11) was the information concerning **investments for the benefit of local community** included?
12) is there information about the expenditure incurred to **improve the working conditions of employees**?

The next step of research is content analysis of the reports of the surveyed companies. There is calculated an information quality index on socially responsible investments (further QI) for each year-firm observation. The disclosed information relating to research questions has been quantified using a binary system, where:

- 1 denoted affirmative answer to the question posed,
- 0 denoted negative reply, i.e. no information.

The binary system adopted for coding means that the maximum test result (QI) is 12 points. Depending on the number of points achieved, 5 categories of information quality index on socially responsible investments were determined:

- First Category (I) - 0 points denotes no information,
- Second Category (II) - a score of 1- 3 points denotes low quality of information,
- Third Category (III) - a score of 4 - 7 points means average quality of information,
- Fourth Category (IV) - with a score of 8- 10 points means good quality of information,
- Fifth Category (V) - with a score of 11 - 12 points denotes very good quality of information.

Table 3 presents the results of the content analysis of the reports of the surveyed companies relating to socially responsible investments during the examined period.

[2] Dirty business is investment in companies related to the arms, alcohol, tobacco industries, etc.

Tab. 3: The number of companies in each category of SRI disclosure quality

Category	Interpretation	2011	2012	2013	2014	2015	2016	2017	2018
I	No information	0	0	0	0	0	0	0	0
II	Poor information quality	1	0	0	0	0	0	0	0
III	Average quality of information	9	7	7	6	4	3	2	2
IV	Good quality of information	9	12	12	13	15	16	17	17
V	Very good information quality	0	0	0	0	0	0	0	0
	Total	**19**	**19**	**19**	**19**	**19**	**19**	**19**	**19**

Source: Author's own elaboration.

Analysis of the quality of disclosed information on socially responsible investments show that 17 of the surveyed companies (89.5%) disclosed in 2018 information of good quality, while 10.5% of the surveyed companies presented average quality. This is a clear improvement, when compared to 2011, when only 9 companies (47.4%) presented good quality of information, 47.4% average and 5.2% poor quality of information. During the examined period, none of the companies presented very good information quality. The category "No information" is also empty.

Fig. 3 : SRI disclosure quality over period 2011-2018

During the whole period investigated (i.e. each year) 5 companies (26.3%) reached good quality of information about SRI. However, none of these companies used the term socially responsible investments. There are expressions “corporate social responsibility”, “corporate governance”, “sustainability”, “expenditure on environmental protection”, “projects for the local community”, “improvement of working conditions of employees”.

The lowest disclosure quality measured by QI is evidenced for the Polish companies in 2011. Figure 4 compares the structure of the quality category of disclosed SRI information at the beginning and end of the examined period. Only 9 companies presented good quality information about SRI in 2011, while there were 17 companies in 2018.

Fig. 4 : Comparison of QI in 2011 and 2018

Table 4 and Figure 5 present the disclosure quality and its evolution during the examined period.

Tab. 4: Descriptive statistics of QI over period 2011-2018

Statistical measures	2011	2012	2013	2014	2015	2016	2017	2018
mean	7.16	7.84	7.89	7.89	8.32	8.74	9.05	9.16
median	7	8	8	8	8	10	10	10
dominant	10	10	10	10	10	10	10	10

Source: Authors' calculation

The average value of QI measured by its mean (blue colour) is 7.16 in 2010 and it rises steadily up to 9.16 in 2018. The improvement can be identified approximately in the middle of the period investigated. If the median (red colour) is taken into account, it produces a comparable compliance level, however with more stable movements. The line reveals a tendency of "average firms" to disclose the required information persistently in the same format, i.e. to use the same template of the notes as in the previous year.

Fig. 5: Quality Index over period 2011-2018 (years' means, medians and dominants)

Among the surveyed companies, there were cases in which the value of the quality index for disclosed information on socially responsible investments:

- did not change during the examined period - in case of 7 companies,
- increased - in case of 11 companies.

In one company, the value of the index both increased and decreased during the period considered. The quality index has not decreased in any company.

The largest progress was noticed in case of the timber industry company, where the 2011 value of the quality index was 4, while in 2018 already 10. In addition, it should be noted that none of the surveyed companies received 0 points, which indicates that all companies disclose information on expenditure in areas such as: environment, society, ethics, employees. However, the level of detail provided information varies. The qualitative analysis of content of the reports of the surveyed companies allows us to conclude that information on socially responsible investments is presented in various forms and in different places and with different detail. This variety of presentations makes it difficult to compare the quality of information.

Conclusion

Investing as a process of engaging financial resources in order to obtain benefits, assuming that these benefits from the investment will be greater than the funds involved. The author understands investments as a current commitment of financial resources to acquire specific assets, both material and immaterial, thanks to which the investor expects to achieve benefits.

The results of the research prove that listed companies in Poland have a significant percentage of investments in their assets, and the results obtained from investing activities largely contribute to the financial success of the company. The average value of total investments is PLN 4.25 million in 2011 and it rises steadily up to PLN 5.65 million in 2018.

The average investment share in total assets is 29.5% in 2011 and it rises steadily up to 32.5% in 2018. The largest share of investments in total assets fluctuates around 90%, taking the lowest result in 2015 (88.5%), and the highest - in 2017 (93.9%). This result belongs to a company from the energy industry. This proves that the company is heavily invested and the business activity has been reduced to investment activity. On the other hand the lowest result can be recorded in a company from the raw materials industry (from 1.8% in 2015 to 2.6% in 2011). We can also note that the number of companies whose investments accounted for more than half of their assets is growing over the period considered. This confirms the thesis about the significant role of investments in business operations of enterprises.

Recently, we can observe an increase in financial investments in accordance with the concept of sustainable development. The investments that take into account both economic, social and environmental factors are referred to as socially responsible investments (SRI).

Literature review and the analysis of data contained in reports prepared by the European Sustainable Investment Forum (Eurosif) confirm the growing interest in the concept of socially responsible investing in Poland.

The results of the research prove that listed companies show information of good quality about SRI (89.5% in 2018). The rest of the sample (10.5% of the surveyed companies) presented average quality. We can notice a clear improvement because at the beginning of examined period only 9 companies (47.4%) presented good quality of information. During the examined period, none of the companies presented very good information quality. The category "No information" is also empty. The analysis over the period 2011-2018 shows that the disclosure quality is steadily increasing which corresponds with recent studies on the importance of the SRI.

The conducted research broadens the cognitive achievements of current research on the scope of disclosures of socially responsible investments in companies reports. They also have practical significance for the companies themselves, as well as for users of reports, and especially investors.

Abstract

Managing environmental disaster requires the use of technology into how technology is used to minimize the casualties and loss incurred when disaster strikes. This research is on the Role of GIS, Tunnelling Technology and Space Technology in Natural Disaster Management in UAE. Natural Disaster management plays a very vital role in UAE as many disasters occurred which have a devastating effect on human life. Therefore, quantitative methodology was employed in this research work and SPSS was used as the tools for data analysis. Questionnaire was used as a means of data collection in this paper. The relevant data were collected from the National Emergency Crisis and Disasters Management Authority (NCEMA). The findings show that Aggregately, disaster management construct have a mean value of 3.824 indicating agreement with all the statements posed to the respondents. The result shows that GIS and Space Technology have the highest mean values indicating respondents' higher rating for them in tackling natural disasters in United Arab Emirates (UAE).

Keywords: Natural Disaster, Technology, Tunnel, GIS and Space Technology.

Introduction

Although the United Nations designated the 1990's as the International Decade for Natural Disaster Reduction (IDNDR), there was a global failure to reduce natural disaster impacts during that time. Eventually contributing to this trend are environmental degradation, rapid urbanization and social marginalization (Parsons et al., 2015), particularly in developing countries. The increasing number of disasters suggests that vulnerability to natural hazards is also rising and so equates to changing the geography of risk. By way of expansion, more people are living in low-lying coastal zones, seismically hazardous areas and concentrated urban environments (Dunaway et al., 2017). Vulnerable populations will be at increased risk, for example, as the geography and magnitude of hydrometeorological hazards that are historically associated with some of the greatest disasters change with global climate (Erdelj et al., 2017).

They are defining the geography of risk of major concern in general and in particular in developing countries, where disasters jeopardize important social development goals such as addressing poverty, ensuring adequate food, water, and sanitation, and protecting the environment, (Oloruntoba et al., 2018). Because natural disasters have the greatest overall impact in developing countries (Oloruntoba et al., 2018). Although natural disasters cannot entirely be prevented, disaster losses (including

human, environmental and infrastructure/personal property) can be minimized with effective disaster management process of mitigation, preparation, response and recovery (Haworth et al., 2015).

Simply put, natural disasters are unpredictable acts of nature, characterized by extremes in physical processes (Carley et al., 2016). Examples of natural hazards include earthquakes, tsunamis, hurricanes, typhoons, droughts, wildfires, tropical storms and floods. The fundamental determinants of natural hazards are location, timing, magnitude and frequency. Landslides, for example, have a local impact, whereas major floods can affect a large region. Earthquakes occur with little warning and last only a few seconds to minutes, while drought may build up over months over large regions and last even longer. Thus, a distinction can be made between 'rapid-onset' natural hazards such as floods and earthquakes, or slower 'creeping crises' hazards like drought or disease (Akgün et al., 2015). However, Coppock (1995) points out that those slowly developing hazards have more in common with natural resource management, at least from a mitigation perspective.

McEntire (2001) describes natural disasters as the disruptive and deadly and destructive outcome of triggering agents when they interact with and are exacerbated by, various forms of vulnerability. Simply put, when a hazard intersects the zone of human use there is the risk of disaster. The number of people affected by disasters resulting from natural hazard events of rapid onset is increasing (Erdelj et al., 2016). In particular, hydrometeorological related natural disasters (e.g., floods, landslides/avalanches, forest/ scrub fires, windstorms and waves/surges) have more than doubled since 1996 and caused over 90per cent of deaths from natural disasters during the 1990s.

However, the United Arab Emirates (UAE) and its archipelago that extends over the Arabian Gulf cover 83,600 sq km. The Emirati coastline extends for approximately 700km. The country shares land borders with Qatar to the west, Saudi Arabia to the south and west, and Oman to the east and south. Four-fifths of the UAEs land mass is desert. The littoral zone of the UAE is characterised by active coastal sabkhas, a phonetic translation of the Arabic word for a salt flat. In 1980 the total population was 1 million. It increased to 8.4 million, only 30 years later. By 2050 the UN expects this figure to reach 15.5 million. The overwhelming majority of the population lives in urban areas in coastal zones, which is also prone to several natural and manmade hazards.

The UAE is prone to various natural hazards, including those atmospheric, geological and anthropogenic in origin. There are also meteorological and tectonic hazards to consider. As development continues in the nation, the country and its people become even more vulnerable to the effects of those hazards (Al Ghasyah et al. 2010). As one might expect, rainfall is few and far between.

Increasing frequency and intensity of disasters have resulted in severe disruptions to communities and built environment facilities around the world. There is an evident increase in human and property losses from disaster events over the past few decades. In the period between 2000-2011, 2.7 billion people have been affected by disasters, 1.1 million of which were fatalities and the financial cost of disaster impact was estimated at $1.3 trillion (Wex et al., 2014). Evidence suggests that disaster risks are rising at a rate faster than affected communities can build resilience (Al Khaili and Pathirage, 2014). Fast-growing cities and urban areas of the world increase disaster vulnerability due to economic growth and fast population expansion. Cities, where more than 50% of the global population resides and where much of the economic assets can be found (Haworth et al., 2015), are very much the epicentre for destruction and loss brought about by natural and man-made disasters. Therefore, this research paper intends to identify the most devastating disasters that frequently occurred in UAE.

Methodology

The study employed a quantitative approach to achieve the research objective. The use of quantitative methods provides a concrete manifestation of the findings in an actual setting. In the same light, the use of this type of research allows the researcher to measure the parameters held in the objective of this research paper (Lewis, 2015). Using survey research strategy and a convenience sampling

technique, a total of 400 questionnaires were distributed to the target respondents which were employees of the National Emergency Crisis and Disasters Management Authority (NCEMA). A total of 329 questionnaires were used for the analysis. The sample size was calculated to guarantee a sufficient number of respondents. Thus, the following formula was used to estimate the population sample size (The Survey System, 2007):

$$(n) = \frac{t^2 * p * (1-p)}{m^2}$$

where:

n = Required sample size (minimum size)
t = Confidence level at 95% (standard value of 1.96)
p = Estimated fractional population
m = Margin of error at 5% (standard value of 0.05)

The number of respondents was calculated based on the collected data from the 329 respondents. Similarly, the questionnaire constituted of two sections A and B. Section A sought information about the respondents' socio-demographic data while section B contained questions with respect to the research constructs (Natural Disasters in UAE). The question format in the section B was designed in a Likert-scale format in a scale of 1 to 5. The data analysis was conducted using SPSS software.

Analysis and Result

The result of the analysis conducted on the collected data is presented in this section. The analysis is conducted in accordance with the research aim and objectives. The major aim of the research is to identify the major natural disasters occurred in the UAE. In order to achieve the stated research objective, several analyses were conducted. Prior to the main analysis, the data was coded, screened and cleaned by assessing outliers, normality, multicollinearity, and reliability. The research used descriptive analysis to achieve objective. The analyses were conducted with the aid of Statistical Package for Social Sciences (SPSS) software. The following subsections provide detailed information on the various analyses conducted and the results obtained. Before the analysis, the questionnaire administration outcome is first presented.

Questionnaire Administration

This research utilised survey research design using questionnaire as a means of data collection. As stated in in the methodology, the study adopts a sample size of 350 respondents. However, to ensure adequate response, 400 questionnaires were distributed to the operations staff of National Emergency Crisis and Disasters Management Authority (NCEMA) in UAE. The detail of the questionnaire administration is presented in table 1 below.

Table 1: Questionnaire administration

Questionnaires	Frequency	Percentage
Distributed	400	100%
Returned	366	91.5%
Responded	350	87.5%
Useable/Valid	329	82.2%

The result of questionnaire distribution is presented in table 1 above. The result shows that 400 questionnaires representing 100 percent were distributed out of which 366 representing 91.5 percent were retrieved with 350 representing 87.5 were fully responded to. After data cleaning and screening

for outlier, normality and collinearity, 329 responses were considered useable and valid for subsequent data analysis.

Data Cleaning and Management

The nature of survey data is such that it does not always absolutely meet the requirement of most multivariate analyses. Accordingly, the data after it's collected and coded into software, need to be screened and cleaned prior to detailed analysis. This is in accordance with the recommendation of Pallant (2011) that prior any significant analysis of data, it is of significant importance to screen and clean the data set so as to avoid errors that could distort the quality of the analysis which could jeopardise the result. The most common threats to data quality are the missing values, wrong posting, outliers, non-normal data, and multicollinearity. After, data cleaning, the instrument's reliability using internal consistency is established. These data cleaning and management procedures are discussed in the following subsections.

Missing Values and Wrong Postings

Perfection is not an attribute of survey research design, as such, it's almost impossible to have a perfectly responded data. Issues of missing or non-response are mostly bound to occur such that some questions are left unanswered by the respondents in the questionnaire resulting into missing values during analysis of the data. This could have adverse effect on the result of data analysis. Accordingly, due diligence is required to identify the missing entries and treat them accordingly (Pallant, 2011). The major point of concern is how to minimize occurrence of missing entries in the first instance. This is normally achieved at the initial stage of questionnaire preparation to ensure that the questions are understandable, simple and unambiguous. To achieve this, the drafted questionnaires were moderated by expert and reviewed to ensure understanding by the respondents. Similarly, the missing data were checked at the point of collection and immediately returned to the respondents by the research assistants to fill them. By so doing, the missing data were greatly minimized. Those missing data that appear after the initial processes were made; the cases with severe occurrences were removed from further analysis. In this case, 16 cases were found to contain substantial missing values and were therefore removed from the data set leaving 350 fully responded questionnaires. A critical issue was whether the samples available will remain sufficient for subsequent analysis. With total 350 samples achieved after omitting the severe cases missing values, it is considered sufficient for multivariate analysis (Hair Jr et al., 2016).

Wrong postings, on the other hand, have severe effect on research result. It either inflates the result or deflates it with serious consequences on the normality of the data. Before the detail analysis of the data, wrong postings were checked by means of frequency distribution table. The wrong postings were all treated by referring to the original filled questionnaires and corrected accordingly.

Outliers

Outliers are serious issues in multivariate data analysis. Outlier is like an outcast, an observation with extreme value on one variable or a combination of extreme values on two or more variables that adversely affect statistical analysis (Tabachnick & Fidell, 2007). The major aim of outlier evaluation is to identify the cases with extremely high or low value from the rest of the data and treat them by deleting the extreme cases so as to improve the quality of the data for subsequent statistical analysis.

There are two forms of outliers the univariate and the multivariate outliers. The univariate outliers are outliers on individual variables which this research assessed by means of 'explore' option in SPSS. The outliers were identified by means of Q-Q plot, histogram and detrended Q-Q plot. The multivariate outliers on the other hand were were assessed based on the recommendation of Tabachnick and Fidell (2007) that Mahalanobis value is compared with the Chi-square table such that any Mahalanobis distance value above the computed value is considered as multivariate outlier. Accordingly, a Mahalanobis distance was save from regression equation with all the research constructs as the independent variables and compared by the tabulated Chi-square. Mahalanobis

distance at 0.01 significance level were considered extreme multivariate outliers and were subsequently deleted from the data set for subsequent analysis. Accordingly, 21 cases were extremely affected by both univariate and multivariate outliers and were deselected for further statistical analysis. Subsequently, 329 usable cases that are not affected by extreme outliers and missing data were retain for further analysis. The summary regressions table containing Mahalanobis Distance information is presented in table 2 below.

Table 2: Residuals Statistics including Mahalanobis Distance

	Minimum	Maximum	Mean	Std. Deviation	N
Predicted Value	141.6626	222.9533	175.500	11.47151	350
Std. Predicted Value	-2.950	4.137	.000	1.000	350
Standard Error of Predicted Value	5.587	30.784	12.238	5.106	350
Adjusted Predicted Value	145.5145	232.3196	175.451	11.79464	350
Residual	-185.3074	176.47865	.00000	100.52813	350
Std. Residual	-1.830	1.743	.000	.993	350
Stud. Residual	-1.850	1.783	.000	1.001	350
Deleted Residual	-189.3513	184.64038	.04878	102.22965	350
Stud. Deleted Residual	-1.857	1.788	.000	1.002	350
Mahal. Distance	**.065**	**31.261**	**4.986**	**5.399**	**350**
Cook's Distance	.000	.037	.003	.005	350
Centered Leverage Value	.000	.090	.014	.015	350

As presented in table 2, The Mahalanobis distance for the 350 cases has a minimum value of 0.065 and a maximum value of 31.261 with mean value of 4.986 and standard deviation of 5.399. However these values cannot show the significance of the distance. Accordingly, the value is compared with chi-square tabulated value as presented in figure 1 below.

	OganisationalPerformance	MAH_1	P_MahH
1	3	48.55477	.0000005
2	3	46.55624	.0000011
3	2	46.06388	.0000014
4	3	44.34075	.0000029
5	3	44.04924	.0000032
6	3	40.37903	.0000145
7	3	40.40349	.0000144
8	1	40.06928	.0000165
9	3	40.09900	.0000163
10	3	39.70226	.0000191
11	5	39.06152	.0000248
12	2	38.87705	.0000267
13	1	37.84866	.0000403
14	1	37.72802	.0000423
15	4	37.78252	.0000414
16	5	37.14867	.0000533
17	3	36.17975	.0000784
18	3	36.02644	.0000833
19	4	35.88399	.0000881
20	2	34.80667	.0001347
21	2	34.52856	.0001502
22	3	33.23275	.0002489
23	3	33.14077	.0002579

Figure 1: Saved Mahalanobis Distance Variable

The saved Mahalanobis distance variable and its corresponding tabulated Chi-square p-values are presented in Figure 1 above.

Data Normality

Most multivariate analyses require data to be normally distributed. The term normality is derived from the concept of normal distribution that describes the shape of population as being in that of a bell curve, a shape like symmetrical mountain. A data that does not comply with such a distribution makes statistical distribution analysis much more difficult (Hair *et al*., 2016). Data normality is checked using statistical or graphical techniques. These involve normality probability plots (Normal Q-Q plot), histogram and skewness and kurtosis. While skewness shows the symmetries of the data distribution, kurtosis revealed the peakedness of a variable's distribution as either too peaked (with short, thick tails) or too flat (with long, thin tails).

This research checked the normality of the data distribution using skewness and kurtosis. Based on the recommendation of George & Mallery (2010), skewness and kurtosis values of -2 to +2 are considered a symmetry distribution which are suitable for parametric tests and presume a normal distribution. In this regard, the values of skewness and kurtosis for the entire constructs in this research were presented in table 3 below.

Table 3: Data Normality

	Skewness		**Kurtosis**	
	Statistic	**Std. Error**	**Statistic**	**Std. Error**
ST	-1.043	.130	.516	.260
TT	-.774	.130	-.322	.260
GIS	-.683	.130	-.692	.260
TR	-.765	.130	-.478	.260
DM	-.681	.130	-.568	.260

The result of mormality test of the constructs used in multivariate analysis using skewness and kurtosis is presented in table 3 above. The result shows that all the variables are within the recommended range of -2 and +2.

Collinearity Test

In multivariate analysis, independent variables are required to be distinct and measure different concept from what other variables are measuring in order to have accurate and robus result (Hair et al., 2016). When this assumption is violated, multicollinearity problem distorts the result. Multicollinearity happens when independent variables are highly correlated such that one variable is predicting the same thing as the other. Correlation value is considered very high when the value is above 0.9. Hair *et al*. (2016) suggest that when an exogenous variable can be explained perfectly by other exogenous variables in a regression model then multicollinearity problem is inherent among the variables.

Multicollinearity in independent variables is determined by assessing the tolerance level and Variance Inflation Factor (Hair et al., 2016). Hair et al. (2016) recommended a rule of thumb for assessing collinearity issues. Multicollinearity exist when the tolerance level is less than 0.1 or when the VIF is greater than 10. Hence, a tolerance level above 0.1 and VIF of less than 10 signify absence of multicollinearity. This criterion is used to assess the collinearity of the research constructs as presented in table 4 below.

Table 4: Collinearity Diagnostics

Model		Collinearity Statistics	
		Tolerance	VIF
	ST	.417	2.401
	TT	.325	3.079
	GIS	.293	3.410
	TR	.297	3.362

Table 4 above shows the tolerance level and VIF of the research constructs. The tolerance levels range from 0.297 to 0.417 all above the recommended 0.1 minimum. Similarly, the VIFs range from 2.401 to 3.410 all below the recommended minimun of 10. Therefore, the research constructs are all within the recommended thresholds and therefore they pass the collinearity test requirement and are suitable for multivariate analysis.

Reliability Test

Constructs that have multiple items are required to be internally consistent to have reliability. This implies that the items under the construct should be highly related. Reliability is the degree to which research measurement are free from random error and the extent to which a scale used produces consistent results if repeated measurements were made on the variable concern (Pallant, 2011). The most common measure of reliability is the Cronbach's alpha. Cronbach's alpha measures the reliability of the measurement scale. For internal consistency to be achieved, Cronbach's alpha is required to be above 0.7 (Pallant, 2011).

Accordingly, the reliability of the research constructs was evaluated using Cronbach's alpha as presented in table 5 below.

Table 5: Reliability test

	Reliability	
	Items	Cronbach's α
ST	5	.923
TT	4	.927
GIS	4	.951
TR	5	.950
DM	4	.941

The internal consistency of the research constructs' items measured using Cronbach's alpha is presented in table 5 above. The result indicated that all the constructs have cronbach's alpha value above the recommended 0.7 minimum. The construct with the least Cronbach's alpha is Space Technology (ST) construct which has an alpha value of 0.923 far above 0.7. GIS construct on the other hand has the highest Cronbach's alpha with a value of 0.951. The Tunelling Technology (TT), Training (TR), and Disaster Management (DM) have Cronbach's alpha values of 0.927, 0.950, and 0.941 respectively. Hence all the research constructs are internally consistent and reliable.

Respondents' Demographics

The profile of the respondents is presented in table 6 below. It contains information on the gender of the respondents, their age, marital status, and the highest educational qualification attained by the respondents.

Table 6: Respondents' Profile

S/N	Respondents' Details	Response	Frequency	Percent
1	Gender	Male	274	83.3
		Female	55	16.7
		18-29 years old	48	14.6
		30-39 years old	140	42.6
2	Age	40-49 years old	103	31.3
		50 years old and above	38	11.6
		Single	73	22.2
3	Marital Status	Married	244	74.2
		Divorced	12	3.6
		Secondary Certificate	10	3.0
4	Educational Level	Diploma	36	10.9
		Degree	231	70.2
		Masters	35	10.6
		PH.D	17	5.2

Table 6 is used to present the respondents' information regarding their gender, age, marital status and educational level they attained. The result shows that the respondents are predominantly male as indicated by 83.3 percent response while felames account for the remaining 16.7 percent response. Similarly, Majority of the respondents are within the age bracket of 30-39 years as indicated by 42.6 percent response followed by those within the age bracket of 40-49 years as indicated by 31.3 percent response rate. The younger respondents of between 18 and 29 years account for 14.6 percent while the elderly above 50 years account for the remaining 11.6 percent. Majority of the respondents have degree qualification as indicated by 70.2 percent followed by those with Diploma and Masters as indicated by 10.9 percent and 10.6 percent response respectively. 5.2 percent of the respondents have PhD qualification and the remaining 3 percent of the respondents have secondary school certificate.

Response Evaluation Criteria

The first research question and objective of this research are descriptive and therefore required descriptive analyses to determine the level. As such, an evaluation criterion is adapted from other studies in order to evaluate the various constructs of the research. A 5-point likert scale was used throughout the research with different constructs having similar or different scale descriptors. However the difference in descriptors, the construct have uniform mean ranking scale. Accordingly, the ranks were numbered between level one (1) which was lowest level to level five (5), which was highest level. This research adapted the mean score decision interval based on the works of Kasim *et al.* (2013), from which the following interval decisions were deduced. This is shown in table 7 below.

Table 7: Response evaluation criteria

S			Mean Interval
1	Less Likely	Strongly Disagree	1.00-1.80
2	Rarely	Disagree	1.81-2.60
3	Less often	Neutral	2.61-3.40

4	Often	Agree	3.41-4.20
5	Very often	Strongly Agree	4.21-5.00

Table 7 contains the evaluation criteria used to evaluate the responses to the questionnaire questions. The first research objective seeks to identify the major natural disasters that occurred in the UAE. Thus, a response of less likely, rarely, less often, often and very often shows the level or frequency at which natural disasters occur in UAE. Accordingly, the research constructs are evaluated descriptively using tables and mean ranking as presented in subsections below.

Natural Disasters that Occur in the UAE

This section presents the level at which natural disasters occur in the UAE; it shows the frequency or level at which the following natural disasters - flood, earthquake, landslides, storm, and tsunami happen at UAE. The result of the analysis is presented in table 8 below.

Table 8: Major Natural Disasters in UAE
