Natural Disasters	Mean	Rank	Remark
Flood	3.71	2nd	Often
Earthquake	2.10	4th	Rarely
Landslides	2.70	3rd	Less often
Storm	4.78	1st	Very often
Tsunami	1.05	5th	Less likely

Table 8 shows the occurrence of major natural disasters in the UAE. The result shows that the most common major natural disaster that occurs in UAE is storm. The result shows that storm very often occur as indicated by mean value of 4.78. The second most common natural disaster that often occurs in UAE is flooding. This is indicated by mean value of 3.71 thereby ranking second among the major natural disasters in UAE. Landslides disasters occur less often in UAE as indicated by mean value of 2.7 and ranked third among the major natural disasters in UAE. Another natural disaster that rarely occurs in UAE is earthquake as indicated by mean value of 2.10 and ranked fourth among the five major natural disasters in UAE. Tsunami is less likely to occur in UAE as indicated by mean value of 1.05 and ranked the least of the natural disasters occurrence in the UAE. This may be because the earthquakes that normally trigger tsunamis rarely occur in the UAE.

Natural Disaster Management in UAE

As shown in the preceding section, there are natural disasters that occur in UAE which require comprehensive natural disaster management in order to eliminate or minimise their impact. These natural disasters management include space technology, tunnelling technology, Geographical Information Systems (GIS) and training which cumulatively impact disaster management. Result of the impacts of these interventions in tackling natural disasters in UAE is presented in the following subsections.

Space Technology

The use of space technology in disaster management in UAE is presented in table 9 below.

Table 9: Space Technology

	Mean
Space technology helps in capturing data of natural disaster	3.84
It provides opportunity to get more information about the occurrence of the disaster	3.74
It gives more accurate data than other technologies when it come from the space	3.85
Available space gadgets help in tackling disaster	3.76
It provides information of the big data about natural disaster	3.84
Space Technology (Aggregate)	**3.8073**

The use of space technology in natural disaster management in UAE is presented in table 9 above. The result shows that the respondents agree that space technology helps in capturing data of natural disaster; It provides opportunity to get more information about the occurrence of the disaster; It gives more accurate data than other technologies when it come from the space; Available space gadgets help in tackling disaster; and It provides information of the big data about natural disaster as indicated by mean values of 3.84, 3.74, 3.85, 3.76, and 3.84 respectively. Aggregately, space technology has high application in tackling natural disasters in UAE as indicated by 3.807 mean value response.

Tunnelling Technology

This section presents information on the use of tunnelling technology in addressing natural disaster in UAE as presented in table 10 below.

Table 10: Tunnelling Technology

	Mean
Tunnels help in tacking flood disaster	3.85
Tunnels provide routes for motorist to evade disaster	3.80
Available tunnels in UAE will help tremendously in disaster management	3.85
Tunnel management is paramount to disaster management	3.92
Tunnelling Technology (Aggregate)	**3.85**

Table 10 is used to show the influence of tunnelling technology in talking natural disaster in UAE. The result shows that respondents agree that tunnelling technology helps in natural disaster management in UAE. This is indicated by agreed response to Tunnels help in tacking flood disaster; Tunnels provide routes for motorist to evade disaster; Available tunnels in UAE will help tremendously in disaster management; and Tunnel management is paramount to disaster management as indicated by mean values of 3.85, 3.80, 3.85 and 3.92 respectively. Aggregately, tunnelling technology has high application in tackling natural disasters in UAE as indicated by 3.856 mean value response.

Geographic Information System (GIS)

This section presents the result of descriptive analysis conducted on the use of GIS as a means of disaster management in UAE. The result of this analysis is presented in table 11 below.

Table 11: Geographic Information System (GIS)

	Mean
Performing tasks efficiently for disaster management	3.55
Provide information about natural disaster	3.75

Overcoming obstacles when disaster strikes	3.76
Solving problems related to geographical disaster	3.86
GIS (Aggregate)	**3.73**

The use of Geographic Information System (GIS) in natural disaster management in UAE is presented in table 11 above. The result shows that the respondents agree that Geographic Information System (GIS) is used in performing tasks efficiently for disaster management; Provide information about natural disaster; Overcoming obstacles when disaster strikes; and Solving problems related to geographical disaster as indicated by mean values of 3.55, 3.75, 3.76, and 3.86 respectively. Aggregately, Geographic Information System (GIS) has high application in tackling natural disasters in UAE as indicated by 3.731 mean value response.

Disaster Management

This section provides information on overall disaster management in UAE through the use of space technology, tunnelling technology, Geographic Information System (GIS) and training. The result of the descriptive analysis is presented in table 12 below.

Table 12: Disaster Management

	Mean
Space technology help in disaster management	3.88
Tunnelling technology help in disaster management	3.75
GIS help in disaster management	3.88
Training help in disaster management	3.79
Disaster Management (Aggregate)	**3.82**

The operations staff of National Emergency Crisis and Disasters Management Authority (NCEMA) in UAE agreed that Space technology help in disaster management; Tunnelling technology help in disaster management; GIS help in disaster management; and also Training help in disaster management as indicated by mean values of 3.88, 3.75, 3.88, and 3.79. Aggregately, disaster management construct have a mean value of 3.824 indicating agreement with all the statements posed to the respondents. The result shows that GIS and Space Technology have the highest mean values indicating respondents' higher rating for them in tackling natural disasters in United Arab Emirates (UAE).

Conclusion

This research examined the Role of Geographic Information System (GIS), Tunnelling Technology and Space Technology in Natural Disaster Management in UAE. Managing environmental disaster requires the use of technology into how technology is used to minimize the casualties and loss incurred when disaster strikes. Thus, natural disaster management plays a very vital role in UAE as many disasters occurred which have a devastating effect on human life. Therefore, to achieved the research objective a quantitative methodology was employed in this research work and Statistical Package for Social Sciences (SPSS) was used as the tools for data analysis. Questionnaire was used as a means of data collection in this paper. The relevant data were collected from the National Emergency Crisis and Disasters Management Authority (NCEMA). The results show that Aggregately, disaster management construct have a mean value of 3.824 indicating agreement with all the statements posed to the respondents. The result shows that GIS and Space Technology have the highest mean values indicating respondents' higher rating for them in tackling natural disasters in United Arab Emirates (UAE).

The Impact of Internationalization on Commercial Firms' Liquidity

Joanna WYROBEK

Cracow University of Economics, Cracow, Poland
wyrobekj@uek.krakow.pl

Abstract

The paper shows that exporters often suffer from liquidity shortages and suggests that to promote exports, the governments should take steps to provide exporters access to additional operational financing and information, which would reduce exporting risks. The paper also shows that corporate liquidity is impacted by the unstable economic situation in the country and excessive public debt, which forces companies to create additional liquidity buffers. In particular, the paper analyses the relationship between the internationalization of a company and its liquidity (and all significant determinants of corporate liquidity). The hypotheses which are positively verified in this paper are that there exists a positive relationship between the fact of internationalization and a quick liquidity ratio (H0) and that there exists a linear relationship between the level of internationalization and a quick liquidity ratio (H1). The paper shows that for four analyzed countries (Bosnia and Herzegovina, Greece, France, and the United Kingdom) there existed a positive relationship between the fact of exporting and the level of liquidity and also that there existed a relationship between the share of export sales in total sales and the liquidity. In other words, the paper results show that the more exports a company has, the higher is the liquidity it maintains in its assets.

Keywords: Corporate Finance, Internationalization, Corporate Liquidity

Introduction

The internationalization of a company can be perceived as the process of increasing foreign sales and learning how to make these sales profitable. The theory of international trade offers many explanations for why international trade is beneficial for both; the exporters and importers, but in terms of a microeconomic approach it can be brought down to the simple fact that sooner or later the domestic market becomes saturated with the company's products and then to increase the market share the business has to go abroad. Entering foreign markets also provides other benefits: the company learns how to become more competitive (Neubelt 1990, p. 48), it learns how to operate in a different legal, economic and cultural environment; finally, it also learns how to benefit from the cultural diversity of its employees and clients. Exporting usually also makes the sales revenues more stable (Neubelt 1990, Bennet 2007) over time (through diversification), allows for better utilization of the company's resources (Bennett 1990) through the economies of scope, improves competitiveness (Neubelt 1990), improves the employees' morale (Janssen 1992) and generally, makes the company grow faster regarding sales and assets growth (Richardson, Rindal 1996). The paper concentrates on presumably one of the negative side-effects of exporting, which is the necessity to maintain higher liquidity to secure the company against increased operating risk and additional expenses. Higher liquidity demand in exporting is so significant and important that only the companies that are not liquidity constrained can begin exporting and later increase their foreign sales. Internationalization of companies that try exporting and are incapable of accessing additional funding (overcoming liquidity constraints) is often unsuccessful. The paper attempts to prove this theory. In particular, the research hypotheses of the paper are that exporters maintain higher liquidity measured with a quick ratio and that there is a linear dependency between the percentage of export sales and the quick ratio (all liquidity ratios are highly correlated, so we chose only one ratio which is considered the most fragile measure of static liquidity).

Literature Review

From the financial liquidity point of view, there seem to be many reasons why the exporting companies report a higher demand for liquidity. First of all, an entrance to a foreign market requires costly

preparation (there are different entrance modes, but generally, all require a part or all of the following costs): advertising, finding cooperatives, hiring local consultants and lawyers, checking the credibility of the clients, paying for market research, learning local law and customs (Bugamelli, Infante 2003), fulfilling all local requirements and obtain all necessary certificates and licenses, overcoming non-tariff barriers (Gamba and Triantis 2011). Evidence that this affects liquidity can be found in Manova (2008) or Wilkinson and Nguyen (2003).

Secondly, when the company enters the foreign market it has to make significant initial outlays (Świerżewski 2006) to adjust its production to international requirements, to increase its production to meet the demand, to make adjustments to conform to foreign expectations (usually export production has higher quality), hire people with experience with exporting and foreign negotiations, overcome many problems that arise when the first transaction is completed. Evidence that these problems increase liquidity requirements of exporting firms can be found in Aw, Chung, and Roberts (2000), Clerides, Lack and Tybout (1998), Bernard and Wagner (2001), or Mundakkad and Sasiharan (2016).

When the company already entered the market, it is often necessary to offer foreign customers attractive credit terms; it has to deal with international disputes with non-paying customers and delayed payments (usually under foreign jurisdiction). Discussion of how this affects exporters can be found in Gamba and Triantis (2012) or Kaczmarek (2001).

Fourthly, the exporter operates on a higher operating risk than non-exporters: deliveries may remain in a harbor longer than it was expected, there might be adverse movements in foreign exchange rates, there might be unexpected problems with complying to foreign legal requirements (for example, unexpected necessity to put stickers on products which provide necessary information about the product in a foreign language (Forlani 2010)) and many other types of risk (2001) (evidence of so-called liquidity buffers in exporting companies which secure the company against unexpected payments resulting from enumerated risk factors can be found in works of Almeida, Campbell, and Weisbach (2004), Han and Qiu (2007), Bolton, Chen and Wang (2011), Gamba and Triantis (2011)).

Finally, usually, only the companies in the best financial situation begin exporting (it is the so-called self-selection theory (Manole and Spatareanu, 2009, Rehman 2017)). Evidence can be found in Bellone et al., (2010), Bernard, Jensen, and Schott (2003), Clerides, Lach, and Tybout (1998), Delgado, Farinão and Ruano (2002), Eaton, Kortum, and Kramarz (2004) or Baldwin and Gu (2012).

Theoretically, increased demand for liquid resources can be satisfied with various financial services such: factoring, forfeiting, export insurance, letter of credit, IOUs, and various financial instruments, but the availability of these instruments for certain firms may be limited. A bank or financial institution to avoid financial losses check the financial situation of an exporter before they offer their services: they take into account the risk of the exporter's target country, the profitability of the exporter, the size of the exporting company and quality of its cash-flow statement, cyclicality of negative results, size of a company, availability of assets which may secure the transaction. The general rule is that the higher is the transaction or export risk, the smaller are the chances for the support from financial institutions (Sisson 1997, pp. 663-691). In other words, the more the exporter requires support, the lesser are the chances of receiving it, and as a result, they remain in the local, national market (Hoshi, Kashyap and Loveman 1992, Chaney 2016). Good export projects should always find providers of the capital, but low information efficiency of financial markets can cause that it will not happen (Shaver 2006, Muuls 2008, Faceuglia 2012, Bermann and Hericourt 2010, Manova 2006, Manole and Spartaneau 2009, Minetti and Zhu, 2011, Rajan and Zingales 1998). Empirical evidence of this phenomenon can be found in works by Manova (2008), Rajan and Zingales (1998), Manole and Spatareanu (2009), Minetti, and Zhu (2011), Rajan and Zingales (1998)).

Research Problem

The research problem analyzed in the paper is whether there exists a statistically significant dependency between the export sales and the financial liquidity of a company. The dependency may take two different forms. The first form is a statistically significant difference between the liquidity of exporters

and non-exporters, which may suggest that additional liquidity is necessary to enter the foreign markets and gather adequate knowledge about these new markets. The second form is the linear dependency between the level of internationalization (measured with the percentage of export sales in total sales) and the financial liquidity, which suggests a constant dependence between the scale of foreign operations, which increases operating risk and the necessary liquidity reserves of a firm. These observations led to the formulation of 2 research hypotheses. The H0 hypothesis states that there exists a positive and statistically significant relationship between the fact of being an exporter and a quick liquidity ratio. The H1 hypothesis states that there exists a linear and statistically significant relationship between the level of internationalization and a quick liquidity ratio (H1). We chose the quick ratio because it efficiently measures the financial liquidity of businesses.

Research Method

To verify the research hypotheses, we used data downloaded from the Amadeus database. Financial data had to include information about export sales, and this reduced the number of countries to Bosnia and Herzegovina, France, Greece, and the United Kingdom. We wanted to prove that exporting increases liquidity and that there exists a linear dependency between the liquidity and the percentage of export sales in total sales revenues. In the model, we included other liquidity determinants that were proven by other research, which included: debt ratios and assets growth ratios taken from the paper by Bruinshofd and Kool (2012). From the article by Lins, Servaes, and Tufano (2010), we chose: operating risk measures (standard deviation of cash-flows), profitability ratios, property type of a company (whether it is a private or state-owned). From Levine, Loayza, and Beck (1999), we took macroeconomic ratios: national debt ratios, the relation of private loans to GDP, GDP growth rate, and interest rate in the economy. From Kim, Mauer, and Sherman (1998), we took the standard deviation of operating cash flows divided by total assets, cash conversion cycle, the variance of the cash conversion cycle. From Opler et al. (1999), we took: the percentage growth of assets, operating and financial leverages, insolvency risk of a company. From Faulkender and Wang (2006), we chose: interest divided by debt. From Manova (2008), we took the Herfindahl index and multifactorial productivity calculated as described by Kukuła et al. (1996, p. 170).

The initial sample included 672 thousand companies, but due to the gaps in data, the useful sample which could be used in model estimation was much smaller: this is why for every model estimated, we provided the number of companies that were used for estimation. Table 1 shows the definitions of financial ratios, which we considered as potential determinants of the quick liquidity ratio.

Table 1: Potential determinants of a company's financial liquidity

symbol	formula	direction	group
liq	(current assets - inventories)/current liabilities	x	liquidity
eksport_operrevenue	export sales revenues/total sales revenues	+	export
exporter	variable exporter = 1 if a company's export sales >10% of total sales revenues	+	
size	natural logarithm of employment size	-	Size
operrevenue	logarithm from the operating revenue	-	
growth	operating cash flow/total assets	+	
dev_ebitda	the standard deviation of EBITDA / total assets	+	Uncertainty
fix_as_change	the annual growth rate of fixed assets	-	Investments
tempos	the annual growth rate of sales revenues	-	

symbol	formula	direction	group
difference_returns	EBITDA/ fixed assets - the risk-free rate of return	-	
cash_conv_cycle	collection period + stocks cycle - credit period	+	Transactional liquidity demand
credit_period	short-term liabilities * 360/sales	-	
collection_period	short-term receibables * 360 /sales	+	
stocks_cycle	inventories * 360/sales	+	
debt_as	debt/total assets	-	
dol	Annual % change of EBIT/annual % of sales	-	
dfl	Annual % change of EBT/annual % change of EBT	-	
int	Interest/debt	-	
de	debt/equity	-	
dtl	sales/net financial profit	-	
ebitda_s	EBITDA / total sales	+	
ebitda_is	(EBITDA - fixed assets increases) / sales revenues	+	
cf_s	average cash flows for 3 years/assets	+	
non_operating	(dividend+fixed assets change+loans/20 + interest) / net operating cash flows	+	
liab_st_lt	short-term liabilities/long-term liabilities	+	
EMScore	EMScore=6.56*working_capital/totassets+3.26*change_sharehfunds/totalassets+6.72*ebit/totalassets+1.05*sharehfunds/(totalassets-sharehfunds)+3.25	+	
Zscore	Zscore=0.717*(currassets-currliab)/totalassets+0.847*(sharehfunds[t]-sharehfunds[t-1])/totalassets+3.107*ebit/totalassets+0.42*sharehfunds/(totalassets-sharehfunds) + 0.998*sales/total assets	+	
CBBF	CBBF=-1.255*interest/EBITDA+2.003*sharehfunds/totalassets-0.824*(plbeforetax+depreciation)/totalassets+5.221*plbeforetax/operatingrevenue-0.689*creditperiod-1.164*((operatingrevenue[t]-employeescosts[t]-materialcosts[t])/(operatingrevenue[t-1]-employeescosts[t-1]-materialcosts[t-1])-1)+0.706*collectionperiod+1.408*(fixedassets[t]-fixedassets[t-1])/(operatingrevenue[t]-employeescostst[t]-materialcosts[t])-85.544	+	
Taffler	Taffler=0.53*p/l beforetax/currliab+0.13*currassets/(totalassets-sharehfunds)+0.18*currliab/totalassets+0.16*ebit/totalassets	+	
kredyty_pkb	private loans / gdp * 100	-	Macroeconomic
pubdebt_gdp	gross national debt / gdp	-	
countryprodsold	the growth rate of industrial production sold	+	
gdprealgrowthrate	GDP real growth rate	+	
int_rates	country risk-free rate	-	

symbol	formula	direction	group
corp	corp = 1 if fixed assets increased by more than 100% or current ratio grew by more than 100%	+	Corporate changes
rosf	net financial profit / core (share) capital	+	Profitability
roe	net pl (profit of loss) / equity	+	
ebit_operrevenue	ebit/operating revenue	+	
roce	(EBT+interest)/(equity+debt)	+	
prod_e	sales revenues / number of employees	x	Productivity
prod_a	sales revenues / fixed assets	x	
TFP	TFP=A(t)/A(t-1) where A(t) - empirical turnover/theoretical turnover estimated with a panel model based on Cobb-Douglas function	x	
private	0 if a company is privately owned, 1 if a company is state-owned	X	ownership
HHI	Herfindahl index – the share of sales in total industry sales	+	industry
industry	dummy variables to distinguish different industries	x	
year	from 2005 to 2015	x	time

The selection of the model and estimation method used to verify the relationship was based on the following observations:

- the exogenous variable strongly depends on its historical (delayed in time) values; undeniably the model must include the process of partial adjustment of the endogenous variable over time,
- it is possible that features of objects that remain unchanged in time, for instance: location (region) or demographics are correlated with explanatory variables, and they are going to be included in fixed effects,
- existing methods of building static models with fixed effects which correct for the correlation between the delayed dependent variable and the error expression have their estimators only asymptotically fulfilling desired properties (that is, when the number of observations in time goes to infinity),
- individual effects represent omitted variables, which means that it is very likely that these properties of objects (enterprises) are correlated with other exogenous variables (Judson and Owen, 1996),
- the selected sample of enterprises is difficult to be called representative – it consists of all available records in the Amadeus database for which information about the export share in total sales revenues was found (Judson and Owen, 1996),
- the expected relationship is linear,
- there may be some autocorrelation and heteroscedasticity inside objects, but not between them - idiosyncratic errors are not correlated between objects,
- the variables used in the model have been adjusted for stationarity - they were built to be stationary (their construction makes them stationary).

The choice of the Blundell-Bond model and not the Arellano-Bond model resulted from the following premises:

- the Blundell-Bond model better deals with the variables which are not perfectly stationary (Bond, 2002),
- Arellano-Bond estimators are not correct for strongly autocorrelated variables (Blundell and Bond 1998),
- better properties for a small sample,
- in the case of weak instrumental variables, the Arellano-Bond model even for large samples may lead to biased estimators (the so-called large finite sample bias), when the variables do not change strongly in time (delayed variables are weak instrumental variables for increments, especially when there are few observations).

It should be noted, however, that in certain conditions, the Blundell-Bond model produces biased estimators if there are significant differences in the variances of individual effects or when there are substantial differences in the idiosyncratic error and autocorrelation (Hayakawa 2005).

The model was estimated by adding successive variables according to their correlation with the explained variable. The explanatory variables were removed from the model if the correlation level between them was higher than 0.3 - that is why sometimes more than one econometric model was created. If the sign of the variable in the model was incompatible with the expected direction, it was also eliminated from the model.

It is also worth mentioning that the data was subjected to pre-selection, which consisted of removing the highest and the lowest percentage of observations for variables (more than 2 standard deviations from the mean) - the aim was to remove outliers that could strongly affect the model coefficients (for example, a receivable cycle of 30 000 days). Due to the number of variables used and the limited volume of this study, we did not provide detailed descriptive statistics for individual variables.

The method of two-stage estimation with resistant residues was used. Hence we did not run the Pearson test but only Arellano-Bond.

The overall form of the model was as it is shown in Equation 1:

$$LIQ_{\mathrm{it}} = \sum_{k=1}^{K} \gamma_i LIQ_{\mathrm{it-k}} + \beta^T \mathrm{x}_{\mathrm{it}} + \alpha_{\mathrm{i}} + \varepsilon_{\mathrm{it}}$$
(1)

where $x_{it}$are explanatory variables, α_{i} – group effects, $\varepsilon_{\mathrm{it}} \sim IID(0, \sigma_{\varepsilon}^2)$ – residual errors, i- object number, t – time, k – time-delays, LIQ – quick liquidity ratio, endogenous variable.

Among exogenous variables (which were discussed above), there was either the discrete variable that identified which company (object) was an exporter or the variable which represented the export sales share in total sales revenues. The purpose of the model was to identify the significant determinants of the quick liquidity ratio and to check whether the additional variable identifying exporters or the export share in total sales were statistically significant in such a model.

Results

The results of the model estimation for four countries are presented in Table 2 and Table 3. Table 2 shows parameters of the model in which we wanted to find the relationship between the quick liquidity ratio and the discrete variable which determines whether a company has more than 10% of its sales as export sales (variable exporter) (less than 10% of export sales could result from random, unplanned transactions with foreign companies operating in the domestic market).

As can be seen from Table 2, models do not use identical determinants, which can be explained with different internal systems and economies. However, the financial statements which we used were adapted to the global standard (by the administrators of the Amadeus database), which made them comparable between various countries. Another reason why models for different countries employ different variables is the estimation method. To estimate the models, we tested variables from different groups (names of the groups are presented in Table 1 in the last column) and only one variable from every group, with highest statistical significance, was employed in the model (to avoid collinearity, variables within groups were highly correlated with each other). We only kept variables from a given group in the model if they were statistically significant and added explanatory power to the model. This approach is similar to a forward selection technique only under the condition that from every group, one can take only one representative.

Estimated models confirm a statistically significant relationship between exports and liquidity, and a significant impact of such factors as: historical liquidity ratios of a given enterprise, bankruptcy risk

(measured with different bankruptcy prediction models), financial leverage of a company (relation between debt and assets), total factor productivity, the company's growth rate (measured with a change of fixed assets), corporate transformations (mergers and take-overs and other organizational changes), profitability and macroeconomic situation.

The results presented in Table 2, therefore, seem to confirm that exporters have liquidity ratios significantly higher than those of non-exporters, after removing the impact on the liquidity of bankruptcy risk and other variables used in the model estimation. Therefore, we found no evidence to reject the H0 hypothesis.

If one looks at the factors other than the fact of being an exporter, which turned out to be statistically significant in the model, the first significant group of variables were the bankruptcy prediction models scores (the idea came from Opler et al. (1999)). They turned out to be statistically significant (any of these models) only for two countries: France and the United Kingdom. In the case of Greece and Bosnia and Herzegovina, we did not manage to find an international bankruptcy prediction model, which would be statistically significant. This could be due to the economic crisis in Greece and the unstable economic situation (as in the emerging market) in Bosnia and Herzegovina.

The next statistically significant group was the indebtedness ratios. The most significant ratio for Bosnia and Herzegovina was debt divided by total assets; for France, it was the degree of financial leverage, for Greece and the U.K. the most significant variable was long term debt divided by total assets. Generally, we expected the dependency between indebtedness and liquidity to be statistically significant based on Bruinshofd and Kool (2012) and Opler et al. (1999). If one tries to understand why different ratios were the most significant determinants in analyzed countries then one of the possible explanations is that in the case of Bosnia and Herzegovina the interest rates were relatively high for both: long term and short term debt and this made the total value of debt (through interest payments) to impact the liquidity of companies. The significance of financial leverage in France could result from the impact of financial leverage on the financial risk of companies, which hold liquidity buffers to cope with the potential negative consequences of that risk. For the UK and Greece, the relevance of only long-term debt could result from its higher cost compared to short-term debt.

The third group significant to liquidity ratios was the total factor productivity (based on Manova (2008)), but it was statistically significant only for two countries: Bosnia and Herzegovina and France. The lack of significance of these ratios for Greece and the UK could be due to the limited number of methods that we used to estimate this factor. Another possible explanation for Greece could be a difficult situation of companies in the economic crisis. For the UK as the most developed country of the analyzed group, the reason could be that this sector is highly automatized, and this impacted the relationship between liquidity and productivity. Generally, the more productive is a company, the less liquid resources it should requite to maintain because it spends every dollar more effectively.

The fourth group of significant determinants was the growth rate of companies (based on Bruinshofd and Kool (2012)). The most significant variable from this group was the growth of fixed assets, which was significant for companies in France and the UK. The faster is the growth of a company, the more liquidity is needed to pay for increased operating costs. The growth rate was not significant for Bosnia and Herzegovina nor Greece, which could be explained with disturbances in their economies and unstable economic dependencies.

The fifth group which appeared as significant in the models were corporate restructurings (based on Bruinshofd and Kool (2012)). This factor was only significant for companies from Bosnia and Herzegovina. We believe that the lack of significance for other countries was due to the imperfect method of detecting such transactions (we estimated this variable indirectly through rapid changes of total assets or liquidity ratios).

The sixth group of significant determinants was profitability ratios (based on Lins, Servaes, and Tufano (2010)), but they were only significant for Bosnia and Herzegovina, and it was the operating

profitability which turned out to be important. We believe that this could be caused by profit smoothing and tax evasion of companies which disturbs the picture of their true profitability.

The final group of determinants was the macroeconomic variables (based on Levine, Loayza, and Beck (1999)), which were often uncorrelated with each other, which was the reason why there appeared more than one variable from this group. It was difficult, though, to divide them into two separate groups because they all belong to the same set of a general, macroeconomic character. For companies from Bosnia and Herzegovina, we found no statistical significance of macroeconomic variables – probably due to the emerging type of the market in this country. For companies in France, we found the significance of the annual growth of production sold in a country and sales, whereas for companies in Greece, it was a GDP growth rate. For companies in the UK, we found the significance of interest rates and national debt. Both the GDP growth and production sold growth measure the rate of national growth, which probably allows companies to make profits, which eventually are converted into cash and liquid resources. As for the UK, we believe that his highly developed economy with its large GDP has a low rate of growth (due to the amounts needed to significantly increase its GDP in percentage terms), but the interest rates play an essential role in the control of the economy including the companies sector. The national debt can limit governmental support for companies, which in turn must take more care of their liquidity. The last significant variable was time, which could be interpreted as a general improvement of cash after the subprime crisis.

Table 3 shows the results of the model estimation, where we wanted to prove the relationship between the quick liquidity ratio and export share in total sales. As can be seen in Table 3, the obtained results confirmed a relationship between the share of export in sales and the liquidity level of the business. The higher the share of exports in the company's turnover, the higher the level of liquidity ratio the entity maintained. Other factors that proved to be important included: bankruptcy risk (measured with various bankruptcy prediction models), level of debt, total factor productivity, growth rate (measured with a growth rate of fixed assets), corporate restructurings (mergers, take-overs, other organizational changes), profitability and macroeconomic situation in a country.

The results presented in Table 3 show that the impact of exports on liquidity ratios does not end when the business commences exporting - it is continued throughout foreign sales, which confirms the impact of not only the sunk export costs but also the operating costs described in this paper. Based on present evidence, we fail to reject the hypothesis H1.

Models presented in Table 3 show that except for Bosnia and Herzegovina, an important group of liquidity determinants was the level of bankruptcy risk measured with various bankruptcy prediction models. Due to a smaller research sample (our models only worked on the full panel, so depending on the variables selected for the model, we had a different size of a research sample), the models turned out to be significant also in Greece.
The relation of total debt to total assets was statistically significant for Bosnia and Herzegovina and the UK, and no indebtedness ratio was an important determinant of liquidity in France and Greece. This suggests that this dependency was not very strong for a sample of French companies (different selection of variables in the model made indebtedness insignificant for France for this model). As with the previous models, total factor productivity was a significant determinant of liquidity only in Bosnia and Herzegovina and France. The same situation takes place with assets growth ratios, which similarly to the previous models, were only significant in France and the UK.

Corporate restructurings were significant in Bosnia and Herzegovina and France, but as we said previously, this could be due to an imperfect way of detecting these activities.

The next significant determinant was profitability, but only in Bosnia and Herzegovina. As we explained earlier, this could be due to profit manipulation or conflicting relationships between liquidity and profitability. On the one hand, strong companies have high and profitability and liquidity, and weak units have both of these indicators low. On the other hand, increasing liquidity must negatively affect profitability and vice versa, because either cash is retained in the company or reinvested (which improves profitability).

The last important variables was the public debt, which in Greece and the UK seemed to make companies rely more on their resources than on any government support and time, which could be interpreted as the improvement of corporate liquidity after the global crisis.

Conclusions and Recommendations

As the model estimation results suggest, selling products abroad by a company requires a measurable financial effort from the company. Export sales force a company to perform adjustments to its production process, pay the entrance costs, deal with the higher level of risk, and continuously learn the foreign markets' business rules. Significantly higher liquidity ratios in exporting companies can have many explanations, but as we tried to prove in this paper, it cannot be brought down only to sunk costs and self-selection of exporting companies. Higher operating risk and costly learning process continue with the increased participation of foreign sales in total sales of a company. As a result, exporters require support from the government to be able to acquire additional liquidity from the market to be able to pay for additional expenses.

Estimated models showed certain differences between analyzed countries. The youngest and least stable economically country was Bosnia and Herzegovina, and in the case of this country, the liquidity of companies was negatively impacted by their overall debt, which included a short-term debt. In no other country, short-term debt was so much visible to affect their liquidity. This suggests an underdeveloped financial market and problems with obtaining financing. We also did not find any bankruptcy prediction model which would fit the model for Bosnia and Herzegovina – probably due to unstable and young economy. The same problem we observed with macroeconomic variables – no macroeconomic variable turned out to be significant on a company's level in Bosnia and Herzegovina.

As for Greece, one could see that the country is going through a difficult period, and the liquidity of most companies was low, independently of their needs. This is why we could not find the dependency between investments and liquidity – probably Greek companies in the analyzed period had minimal investments due to the troubles in the economy. Greek government-debt crisis made this country to receive bailout loans in 2010, 2012, 2015 from the International Monetary Fund, Eurogroup and the European Central Bank. This situation can explain why the GDP growth rate and public debt turned out to be significant determinants of Greek companies' liquidity - macroeconomic situation changes in this country had a direct impact on consumption and, consequently, on the situation of companies.

Models estimated for France show that it is a developed and predictable economy where the sector of companies has excellent access to financial markets and funding. A surprising discovery for French companies was a relatively weak dependency between indebtedness and liquidity, which can be either due to a large data sample used in the study or the fact that contrary to other countries, corporate debt increased significantly during the analyzed period. French companies have built significant cash reserves and taken on new debt, whereas, in other analyzed countries, companies lessened their debt burden after the global crisis. Corporate debt rose to almost 175% of the country's GDP, which means 40 percentage point growth.

Looking at the models estimated for companies in the United Kingdom, one can see the stability of their situation and dependency of corporate liquidity on public debt. The public debt in the UK was one of the highest in the European Union rose from 40% in 2006 to 80% in 2015. This can be explained with the economic costs of joining the European Union (the United Kingdom was a net payer to the EU budget) and budgetary deficits during the global crisis. At the same time, it seems that British companies created liquidity buffers, probably for investments in Europe.

Independently on the differences found between the countries, in this study we intended to show that seems to be a need for financial preparation when a company is planning to enter foreign markets regarding maintaining proper liquidity. Companies should be aware of the level of difficulties that may arise. The governments should support exporting companies regarding their operational financing needs due to the high risk of foreign sales. Transactions with international clients may turn to be very profitable, but there is a risk that losses from bad debts and lengthy legal disputes may equally well force the company to announce insolvency. There might be periods when exporting companies may dramatically require liquidity injections to make them continue their operations.

There are many possible forms of supporting liquidity constrained exporters. The government may subsidize the postal services to make the shipment process easy and cost less. Another possibility is bank guarantees, cheap insurance, specialized agencies which hire experienced in foreign trade practitioners, exchange of export experience between companies, and dependable intelligence about international customers and their reliability. Since, to some extent, the liquidity reserves are necessary to tackle additional risk, the government may provide access to all essential information about the countries, their politics, and clients to reduce this uncertainty. This study also shows that a critical form of support for companies that can be "given" by the governments is economic stability in a country, reasonable public debt, and predictability of the economic relations in a country in the future.
(It is worth mentioning here that the variables used in this study were tested for causality whether they affect the liquidity of the enterprise or the relationship has the opposite direction. It turned out that they affect the liquidity of enterprises.)

The issue which form of government support could potentially have the most significant positive impact on the liquidity constraints of exporters and how effective are methods currently used by governments is going to be the future work of the authors. We also intend in the future to learn more about what financial and non-financial measures should be taken by national governments in various countries to promote the exports and support exporters.

Removing Barriers for Successful Technology Transfer Offices through the Development of a Holistic Tool

Abstract

Successful technology transfer is often linked to the performance of technology transfer offices (TTOs) within universities and research institutions in general. Although a number of tools have been proposed to improve the performance of TTOs, scarce literature concentrates on an overall approach that takes into account the whole set of dimensions impacting on performance. Drawing from literature on strategy and business development of SMEs, we reviewed the extant contributions where such critical success factors have been identified and assumed TTOs could be considered as small firms struggling to become competitive. Based on evidence from literature, we eventually propose a holistic tool to measure and improve the performance of TTOs.

Keywords: technology transfer, capacity building, technology transfer offices

Introduction

Knowledge transfer, and its more commercially focused component technology transfer, have become integral to the strategy of public research organisations (PROs) over the last 30 years.

In the U.S., the Bayh-Doyle Act of 1980 enabled PROs and individual inventors to own intellectual property (IP) generated by the use of government funds, opening up the possibility of commercial exploitation. Later, in the UK, the Lambert Review (Lambert, 2003) highlighted the importance of university-industry collaborations and helped introduce the so-called 'Third Mission' to drive economic growth (Laredo, 2007). Third mission is an additional mission of universities, beyond teaching and research, that encompasses knowledge and technology transfer activities and it is generally concerned with turning research results into factors of economic growth (Zomer & Benneworth (2011).

Particularly in last decade, within the Horizon 2020 framework, the European Commission has worked hard to promote the Third Mission across Member States to foster economic growth highlighting the fundamental role of Technology Transfer offices in such processes. Indeed, the Innovation Union Commitment 21 stated that "mechanisms are needed to further strengthen knowledge transfer offices in public research organisations, in particular through transnational collaboration". In the same vein, the European Commission adopted a Recommendation on the management of intellectual property in knowledge transfer activities and a Code of Practice for universities and other public research organizations (COM (2008) 1329), that is currently under revision with the perspective of a second, and tighter, recommendation.

Despite these intentions, the performance of European PROs in Technology Transfer appears largely variable and irregular. For instance, across Europe, the 10% of PROs secure 80% of all licensing deals

and the top 2% of PROs across 6 countries capture 40% of licensing revenues (Piccaluga et al, 2011). Whilst all countries in Europe have a high degree of variability in Technology Transfer performance, the problem is particularly acute in Southern and Eastern Europe and it also influences in a negative way the ability of PROs based in those regions to attract funding for Technology Transfer (Darcy et al., 2009, Swamidass and Vulasa, 2009).

In response to these issues, the European Commission launched a capacity building initiative to transfer best practices from high performing PROs to those underperforming, especially in Southern and Eastern Europe. This programme, lately renamed PROGRESS-TT, was delivered by a consortium of Technology Transfer experts from across Europe in response to a call for the Capacity Building Technology Transfer action (H2020-CBTT-2014).

This study is rooted within the PROGRESS-TT programme. The overall aim of this study is to develop a set of Critical Success Factors for successful Technology Transfer activities within PROs. Such factors form the basis of a diagnostic tool able to help single TTOs and their PROs identifying areas where changes could be made to improve their performance.

Metrics and Key Performance Indicators for Technology Transfer

Current scholarly and managerial debates suggest that there are a number of barriers to successfully transferring best practice between PROs. In view of any capacity building initiative, a first step is to define metrics able to capture how well a PRO is performing at present, and why it is not performing better. To this regard, well-known technology transfer metrics such as number of spin outs, licensing revenue, and revenue from contract research can be used to define how well a PRO is performing. Relating these metrics to organisational characteristics like size and research intensity can be instrumental in defining how efficient PROs are being. Also benchmarking these metrics against other institutions provides a picture of relative performance. However, none of these indicators identifies why the organisation is performing at that level, nor which factors need to improve to increase performance. Therefore, scholars and practitioners are left with a still underdeveloped understanding of how a measure to build capacity in a PRO by means of transferring best practices from higher performing PROs, would actually affect their performance.

This paper proposes a way to identify a PRO's performance potential and the factors that influence it, so that a diagnosis can be performed to identify areas where changes could be made to improve performance, irrespective of the initial rating of a PRO, compared to others. Whilst extensive work has been carried out over the past 30 years to identify factors that influence Technology Transfer performance (Oliveira & Castro Teixira, 2010), there is no single model bringing all of these factors together in a truly holistic tool of performance measurement for TTOs. Although it can be difficult to single out all the influencing factors (at individual, organizational, and policy level) of Technology Transfer performance, aiming at an overarching approach can provide a useful tool for improvement (see also York and Ahn, 2012).

Consequently, we have combined University's technology transfer literature with insights coming from technology and innovation management, to identify potential diagnostic tools that may be able to provide a framework for PRO diagnostics and suggest Key Performance Factors (KPFs) relevant to Technology Transfer, as described below.

There are many similarities between the domains of Technology Transfer performance in PROs and commercial business growth, since many university Technology Transfer Offices (TTOs) operate as independent businesses and to some extent are very close to small and medium enterprises. Barriers to growth in private enterprise have been studied extensively and a number of diagnostic tools exist. This paper argues that they could be suitable for the needs of capacity building actions to improve TTO's performance.

One of the most comprehensive of such tools is CCODETM, originally developed by the UK company Pera Consulting. CCODETM is a simple but robust model of analysis that has been applied across

startups, fast-growing businesses, and the public sector to measure several features of growth (e.g., such as exports). CCODETM states that all organisations pass through a series of stages in their development. To move to the next stage, it is important to have five elements in place:

- Capability of the management to drive growth
- Capacity (staff, equipment, facilities, etc.) to deliver at the increased level of performance
- An Opportunity to exploit intellectual property and technology to generate the growth
- Desire to achieve this higher level of growth
- An Environment (political, physical, logistical, etc.) supportive of that growth

If any of these elements is missing, sustainable growth will not be possible (just like a cog missing in a machine). This means that business support is of little value if it only addresses one barrier to growth when multiple barriers exist. CCODETM is aimed at providing a holistic approach to elements that relate to performance.

Within these five elements, there are unique sets of factors depending on the application (e.g., measuring innovation and export implies looking at different factors). However, across all application areas, these five elements remain consistent. Table 1 reports the factors for business growth.

Table 1: business growth CCODE^{TM} model

- **Capability**
  - Systems
  - Skills
  - Strategy
  - Leadership
- **Capacity**
  - Staff
    - Delivery staff numbers
    - Marketing and Sales capacity
    - Staff Skills
  - Existing Facilities
  - Operational Processes
  - Finance
  - Partnerships
- **Opportunity**
  - New National Markets
  - New Overseas Markets
  - Innovative Offerings
  - Innovative Processes
- **Desire**
  - Personal Ambition
  - Understanding of Growth
  - Necessity for Growth
  - Risk and Reward
- **Environment**
  - Government support
  - Legislation
  - Competition
  - Access to services
  - Availability of finance
  - Availability of skills

- Customer base
- Networks
- Infrastructure

In this paper, we hypothesize that a modified version of this tool would be effective as the basis of a diagnostic tool for TTOs. However, we also recognize that some of the factors for Technology Transfer may be different from those for business growth. For example, the existence of powerful research institutions and research facilities (and, as a consequence, quality and quantity of intellectual property) for a successful practice is much greater in the case of Technology Transfer compared to conventional business.

Using the CCODETM approach, the goal of this research is to develop a set of Critical Success Factors for successful Technology Transfer activities within PROs, which may be used to form the basis of a diagnostic tool to identify barriers to success. To do so, we conducted a literature review to identify: (i) which parts of the existing business growth CCODETM have been shown to be Critical Success Factors within the Technology Transfer environment; (ii) Critical Success Factors for successful Technology Transfer that are not currently covered by CCODETM. (iii) aspects within CCODETM that have not been sufficiently explored in the Technology Transfer scholarly literature, but may still be Critical Success Factors for PROs.

As a result, the paper contributes to the current debate on TTOs performance by developing a version of CCODETM specific to Technology Transfer, which can in turn be used to develop diagnostic tools and other services to assist PROs in increasing their Technology Transfer performance.

Literature review on critical success factors and adaptations to CCODE™

To ascertain the relevance of CCODETM to technology transfer, it is necessary to cross reference each factor within the five CCODETM elements with the findings of previous research on the barriers/Critical Success Factors for successful Technology Transfer. This was achieved by reviewing a number of papers and reports from surveys specifically addressing the topic of technology transfer barriers. Wherever possible, papers providing evidence of performance impact have been favoured. Eventually, 33 papers and reports were selected.

It was found that Capability, Capacity and Environment factors are broadly comparable between business and Technology Transfer: all but three of the 18 sub-factors examined received at least one reference in the literature. It was decided that three references would be a minimum threshold for applicability, giving an initial set of 10 factors directly relevant to Technology Transfer. Of these, the most widely cited factors were the following.

Staff skills – almost half the papers examined made reference to staff skills as a critical factor. Some aspects are related to experience. The European Knowledge Transfer Report 2013, Final Report (European Commission, 2013) notes that half of all TTOs surveyed were started after 2000, meaning that there has been little time to build expertise. This is exacerbated in places like Turkey, where several new public and private universities were founded after 2006. The blend of skills as well as the level of experience is also important (Conti et al, 2007), but it appears PROs do not always possess or recruit the required expertise (Phan and Siegel, 2006).

Delivery Staff Numbers – seven papers considered this important. For instance, the Kienbaum survey in 2006 (cited in von Ledebur, 2008) found that TTOs with more than five employees were more successful than smaller offices. The Lambert Review (Lambert, 2003) also identified a minimum efficient size for TTOs. Also the 'Dream TTO' described in the 2009 expert group on knowledge transfer final report (European Commission, 2009) proposes a figure 21 staff for a PRO of 10,000 students.

Strategy – This aspect was cited by seven papers as well. The issue was significant within the European Knowledge Transfer Report (European Commission, 2013), which found that PROs that set up policies

on IP, licensing and start-ups were more successful. The report also noted that strategy development was a leading issue in all the stakeholder workshops. Graham (2013) comments the importance of an effective institutional strategy and Lockett and colleagues (2003) found that "results indicate that the more successful universities [at spinning out companies] have clearer strategies towards the spinning out of companies".

Identifying Critical Success Factors not currently found in CCODE™

The review revealed that some areas of the business growth CCODE™ did not translate well into the TTO environment. In particular, the areas related to Opportunity to transfer technology and Desire to engage in technology Transfer needed to be reconsidered to enable them to function effectively within the model. Importantly, it is important to remind that TTOs are not active on any product market, but on upstream markets, otherwise defined technology markets (Arora, Fosfuri and Gambardella, 2001), where fundamental inputs for production (not final goods or services) are exchanged.

Opportunity

Within the business growth CCODE™, opportunity is defined through two key factors: 1) new markets (often export related); 2) differentiated offerings (innovation).

This structure works very well for established industries, where there is a need to constantly find new revenue streams in the face of fierce competition. However, Technology Transfer is still (at least in Europe) a relatively immature industry, with the majority of TTOs not performing in a consistent way within existing markets and with core offerings (contract R&D, licensing and spin-outs) for many countries to be considered as significant areas of improvement.

Having said this, customers (on markets for technology) are still obviously a crucial element of TT success. However, the literature does not seem to indicate that the identification of new customers, especially related to export, is the significant issue. Rather, absorptive capacity of existing markets is a crucial factor. This refers to the ability of customers to integrate the intellectual property into their business and effectively exploit it. Cohen and Levinthal (1990) in particular identify the absorptive capacity of SMEs as being a limiting factor. The 2009 Expert Group on knowledge transfer final report (European Commission, 2009) recommends a policy focus on increasing industry's absorptive capacity. Part of this capacity issue relates to time and money, as identified by industrial respondents in Gilsing et al (2011).

A closely linked factor is that of the culture clash between academia and industry. This is cited extensively in the literature. For example Harman (2010), Siegel et al (2003) and Salter et al (2009), and recent studies, evidenced how the same clash happens not only in hard sciences, but also in executive education (Ungureanu and Bertolotti, 2016; 2018). A lack of understanding of each other's cultures, procedures, needs and aspirations leads to delays, lack of trust and ultimately failed interactions. The literature thus seems to indicate that interacting effectively with identified customers is a more significant barrier than identifying new markets.

This evidence allows us to propose two new categories within Opportunity:

1. Customer base – absorptive capacity
2. Relationships (networks and understanding)

Also the offering side (the flipside of the customer transaction) needs to be reconsidered radically. Within industry, customers tend to buy a product or service that is clearly defined, and repeatable. In the case of Technology Transfer, the offer is usually based on intellectual property, or services to develop intellectual property (something happening at the level of technology markets). As such, all offerings are unique, and hence always innovative. Thus, the question is not 'do you have innovative offerings?' but 'are you able to access sufficient commercially attractive IP?'

The literature reveals four key areas within intellectual property that define the likely success or failure of Technology Transfer activity. First is the quality of the intellectual property (although the definition of quality referred to intellectual property rights is still a hotly debated topic). The European Investment Bank, citing Chukumba and Jensen (2005), states that "Universities producing higher-quality research, as measured by the quality of their doctoral programmes, generate more licenses and higher licensing income." Kumar and Uruthirapathy (2007) and Martyniuk et al (2003) also reference the ability of a given technology to address significant market needs. It is interesting to note however that Lambert (2003), amongst others, identifies that universities often over-value their IP, creating a difficult negotiation platform.

Of course, whenever quality is discussed, quantity cannot be neglected. However, it is not the quantity of IP held by an institution at any point in time. IP is a time-limited resource, meaning that a better measure is an organisation's ability to produce IP and achieving critical mass that can attract potential "buyers" and reduce their transaction costs (knowledge generation capacity). Lambert (2003) identifies an R&D expenditure of £20m p.a. to achieve critical mass. This is supported by the Handbook of research on techno-entrepreneurship (2007), which cites studies by Vohora, Wright, and Lockett (2004) and Powers and McDougall (2005) showing that spin-off activities are closely correlated with R&D expenditure.

An institution may produce excellent IP in large quantities, but there is no opportunity unless it is knowledge that the market wishes to acquire. For example, over 90% of all licensing deals occur within biotechnology and ICT (European Commission, 2013). Therefore, a critical success factor is the market relevance of intellectual property.

Intellectual property is an intangible asset, often stored in the heads of individuals. As such, it is prone to leakage and loss. Research reveals that IP security is thus an important success factor - if it cannot be protected, it cannot be exploited (Arrow, 1962; Sherwood, 2002).

These findings enable us to create a further four factors within Opportunity to replace the innovation factors within the business CCODE™ model:

1. IP quality
2. knowledge generation capacity
3. IP market relevance
4. IP security

All six of these new factors were validated, by making sure that each of the new factors receives at least three references in the literature, justifying their inclusion within a Technology Transfer CCODE™.

Desire

Within the business growth CCODE™ model, desire to grow is focused very much on the individual business leader, or its immediate senior management team. In the case of the Technology Transfer environment, this equates to the senior management of the TTO. However, the success of a TTO does not rest solely in the hands of that management team. Two other stakeholders play a significant role in the success of the supply-side activities.

The first of these is the IP creator. IP creators must be motivated to see their creations commercialised, otherwise they can become significant barriers for the TTO, rather than critical factors of success.
Both the TTO and IP creators are ultimately controlled by the PRO's management. Unless the university or research centre sees Technology Transfer as a key success indicator, they will not be motivated to support Technology Transfer activities, affecting, in turn, the desire of IP creators and of TT management.

As such, it is possible to replace the four factors of desire for business managers with a single aggregated factor for each of the three critical stakeholders:

1. Top management desire
2. IP creator desire
3. TTO desire

As for the other factors, also these new ones were validated with at least three references in the literature, justifying their inclusion within a Technology Transfer CCODE™.

Other Factors

In addition to the elements within Opportunity and Desire discussed above, the literature revealed a number Critical Success Factors not covered by CCODE™.

1. **Tools and methodologies** – Standardised tools and methodologies support the TTO staff to deliver high quality and repeatable services to their PRO. Mike Wright (2014) highlighted many of the issues related to insufficient standard tools and processes. These included mismatched support models for spin-outs and insufficient attention to building management boards. Kumar and Uruthirapathy (2007) highlight the value of decision checklists and commercialisation assessments in increasing TTO efficiency. Electronic resources and analytics tools are also acquiring importance (Sullivan and Mayer, 2011). Tools and methodologies are sufficiently differentiated from processes to warrant inclusion as an additional factor, albeit with only two references in the literature. As efficiency and shared best practice are emerging requirements for TTOs, this factor is likely to become more important as time goes on.
2. **Political/societal Environment** – PROs do not exist in a vacuum, and their TTO performance is influenced by political and societal aspects of their environment, as well as by their frequent involvement in complex organizations, such as hybrid partnerships, wherein performance is also influenced by vicious circles of decision-making processes (e.g. Ungureanu et al. 2018; Ungureanu et al., 2019; Ungureanu et al., 2020). The ECON Centre for Economic Analysis (2000) highlights political factors such as "instability, interventions in domestic markets (e.g. subsidy distortions), corruption and lack of civil society"; and linked economic factors such as "inflation, poor macroeconomic conditions and disturbed and/or non-transparent markets". Graham (2013) highlights the influence that the local quality of life has on Technology Transfer performance, as customers are predominantly local, as are staff. Chapple et al (2005) also find connections between regional economic performance and Technology Transfer efficiency, although they do not prove causation, nor the extent to which environment influences Technology Transfer (as opposed to Technology Transfer influencing the environment). Although there are few references in the literature examined, the above discussion supports the inclusion of political and societal influences as an additional factor.
3. **Proximity to market** – Among others, Villani et al. (2017), Lambert (2003) and Friedman and Silberman (2003) indicate that the physical proximity between industry and PROs is related to Technology Transfer success. Cummings and Teng (2003) cite numerous studies supporting this assertion, although their own studies find no such correlation. Despite the fact that only few papers from the last decade examine this issue, the available research indicates that proximity does have an effect on Technology Transfer performance and this is seen as important enough to be included as an additional factor within Environment.

Identifying potential new Critical Success Factors using CCODE™

Within the initial literature search, three factors of the original CCODE model were identified as having no references within the technology transfer literature and two factors were identified with only one reference. These were, respectively: Environment (Competition), Environment (Access to services),

Environment (Availability of skills), Capacity (Existing Facilities) and Capability (Leadership of the TTO)

A further literature search on Scopus database was conducted focusing specifically on these factors, and the following information identified:

Competition

Competition is one of the most important elements of business success. Very few markets exist in which there is no competition for customers. It therefore seems logical that there must be competition between research institutions for customers for their intellectual property. Importantly, competition has to be interpreted differently when referred to technology markets and intellectual property transactions, since IP makes the protected resource somehow unique and, to some extent, protected by competition. None of the papers examined in the initial literature review cited competition as a factor in the success of TTOs. Within the further search, just one significant reference to competition between TTOs was identified. Rossi (2014: 23) notes that "universities in regions with greater GVA per capita are more likely to be inefficient" and hypothesises that "this may reflect the more intense competition between universities for knowledge transfer engagements such as research and consultancy contracts and CPDs, as universities tend to concentrate in historically more prosperous regions."

Due to the importance of competition in conventional business markets, the authors argue that further research into the effect of competition between TTOs is essential. This is especially important for growing economies, where the university base is expanding rapidly. In the case of businesses, understanding of competition leads to innovation to enable market differentiation; such understanding within the technology transfer landscape may thus also lead to innovation and advancement within the sector.

Access to services

Access to services refers to the provision of supporting services within the technology transfer environment. These may include patent agents, intellectual property offices, export agencies and other organisations devoted to supporting the commercialisation of IP (including business angels and other funding institutions, such a proof-of-concept funds; Munari and Toschi 2019). The authors were unable to find any direct evidence proving that access to services has a direct impact on Technology Transfer success. This may warrant further research, as access to such support services is important within industry, suggesting there may also be a relevance to Technology Transfer success, especially transnationally.

Availability of skills

The skills of TTO staff were identified as a critical factor in the original literature search, with almost half of the reviewed papers citing their importance. However, none of the papers went on to examine the barriers to the acquisition of these skills by the TTO. For example, within business, there is a strong link between the education system and industry requirements, and a lack of graduates within particular subject areas can severely affect the success of an industry sector. It can therefore be hypothesised that a similar issue could exist with Technology Transfer skills. However, the authors were not able to identify if the problem is a lack of suitably qualified individuals, a lack of desire of those individuals to work in TTOs, or poor hiring practices by the PROs. Anecdotal evidence suggests that a blend of factors is the likely cause of skills deficiencies. However, we were unable to find any research examining this in detail. The authors suggest further research into this issue is important to inform both institutional and national policy regarding Technology Transfer skills development.

Existing Facilities

Kumar and Uruthirapathy (2007) mention facilities as a critical success factor for technology transfer from government laboratories. However, it is not clear if they are referring to research facilities or to the facilities of the TTO. The former represents a factor in generating the quality and quantity of IP necessary, and is dealt with under 'Opportunity'. Here we will discuss about the second factor: TTO facilities. In reality, TTOs have very few facilities requirements, as the majority of activities rely on the skills of individuals. Often facilities are just composed by office space equipped with computers. Whilst the provision of these is obviously important, based on the literature review conducted so far it cannot be identified as a critical success factor, as even basic facilities are adequate to allow skilled TTO staff to undertake their roles. As such, the authors propose to remove facilities from the Technology Transfer CCODETM model.

Leadership (of the TTO)

Within business, the leadership skills of senior management are a vital part of business success. Many growth programmes, such as the UK's Business Growth Service, include dedicated leadership and management activities in recognition of this fact. However, within the initial literature review and the subsequent extended review, just Kumar and Uruthirapathy (2007) mention leadership as a critical success factor. As with competition, it would be surprising if the leadership abilities of TTO management did not have some bearing on Technology Transfer success for an institution. As such, the authors suggest further research is needed into this topic.

Towards a TT-specific CCODE™ model

This paper has examined the suitability of a business support model, CCODE™, as a model for the critical success factors for Technology Transfer from PROs. A literature review of Technology Transfer success factors and barriers has revealed a broad alignment of the model with the Technology Transfer landscape. However, some factors, especially those in Opportunity and Desire, have needed to be adapted to suit the particular nature of PROs, especially the multiple stakeholders within the PRO itself. The review also highlighted a number of potentially influencing factors that had not been explored in detail by the literature. Based on the above-mentioned work, we propose a new a Technology Transfer-specific version of CCODE™, as shown below (*new factors shown in italics*):

- **Capability**
  - Systems
  - Skills
  - Strategy
  - Leadership
- **Capacity**
  - Staff
    - Delivery staff numbers
    - Marketing and Sales capacity
    - Staff Skills
  - Operational Processes
  - Finance
  - Partnerships
  - *Tools and Methodologies*
- **Opportunity**
  - *Customer Base – Scale*
  - *Customer base – Absorptive Capacity*
  - *Relationships (networks and understanding)*
  - *IP Quality*

    - *Knowledge generation capacity*
    - *IP Security*
    - *IP Market Relevance*
- **Desire**
    - *PRO Management Desire*
    - *IP Creator Desire*
    - *TTO Desire*
- **Environment**
    - Government support
    - Legislation
    - Competition
    - Access to services
    - Availability of finance
    - Availability of skills
    - *Proximity to market*

Limitations and Future Research Directions

Whilst the business growth CCODE™ model provides an interesting and valuable perspective on Critical Success Factors, and the literature review covered extensive studies, there is still the possibility that some Critical Success Factors have been missed. However, this TT CCODE™ model provides a foundational tool that can be refined as further data and insights becomes available.

The inclusion of factors was based on the number of references in the papers and surveys that were reviewed. To further refine this model, a meta-analysis of quantitative studies would be desirable, in order to develop some form of ranking and weighting of the factors. Such development would depend on the availability of a high number of quantitative studies focused on the extent to which factors influence outcomes.

As shown above, there are four areas of the business growth CCODE™ that have not been examined in detail by Technology Transfer research and that provide suitable direction for further studies. These are:

1. Environment: Competition – the effect of competition between PROs on the success of Technology Transfer
2. Environment: Access to services – the extent to which the availability of support services, such as export agencies and patent offices, affects Technology Transfer performance
3. Environment: Availability of skills – the extent to which the skills needed for Technology Transfer are available within the labour market
4. Capability: Leadership (of the TTO) – the effect that the leadership skills of the TTO management have on Technology Transfer performance.

Investigation of these topics is an area of potential interest for management studies especially in relation to the availability of skills. Skills emerged as the most referenced factor in the success of Technology Transfer, so it is vital that the relationships between PROs, the labour market and education are fully investigated to ensure that the required skills are available.

Our research was conducted to provide a foundation for a diagnostic tool to be developed within the EU-funded PROGRESS-TT project. The next stage will be to identify the question sets necessary to profile a PRO against the TT CCODE™, as well as the relative weightings and thresholds to help identify areas requiring intervention. PROGRESS-TT and its legacy could be a platform to assess the validity of the TT CCODE™ and its associated diagnostic tools.

A Discussion on the Use of Review Aggregators as a Measure of Quality of Video Games

Maciej D. SOBOCINSKI

Czestochowa University of Technology, Czestochowa, Poland
maciej.sobocinski@wz.pcz.pl

Abstract

Assessing the quality of video games raises many difficulties, as there is no single, accepted framework for this task. This article discusses the use of a review aggregator, particularly Metacritic's "Metascore", as a tool for measuring the quality of video games, based on literature study, statistical analysis of existing data and example case studies. While numerous sources highlight the importance of the metric, there is only limited proof of its actual impact on the market, and there is some controversy around using it as a base of business decisions. The alternative User score shows moderate correlation (r=0.565) with the Metascore and its distribution is slightly closer to normal, as the "amateur" reviewers tend to use a wider part of the grading scale, however it is easy to manipulate in a number of ways.

Keywords: Video Games, Quality, Review Aggregators, Metacritic, Metascore

Introduction

There is a popular belief that "anyone can make video games", as their development does not consume any material resources and both hardware and software tools are common and affordable. That statement is only partially true. It is possible for anyone with enough self-determination to develop a game that works; to compete in a saturated market, however, modern video games are often expensive projects that require countless work hours to finish, with budgets surpassing $100 million (Hodges 2019). Such costly investments are tied to a high risk, therefore it would seem sensible to ensure the developed product will be of highest quality. The quality assessment of video games raises several problems.

The video game industry is considered a "creative industry" (Howkins 2001; United Nations 2004; BOP Consulting 2010), and as such, it generates income by creation and exploitation of intellectual property. Video games (as well as other software) once designed, are not subject to change during replication - unlike more tangible, physical goods. This makes the use of statistical quality control methods, including Shewart's control charts or Six Sigma debatable (Binder 1997; Raczynski and Curtis 2008). Other "classical" quality tools may also prove problematic. Ip and Jacobs (2006) tried to adapt a QFD (Quality Function Deployment) method for game development; they developed a list of 45 VOC (Voice of Customer) factors, determining the customers' quality expectations. Given the niche character of their focal game genre (rally racing games), that is an overwhelming number, while the level of detail of particular items constrains the transferability of the framework to other genres; the "benchmarking" nature of the method may also limit creativity and uniqueness of games in development. To illustrate the complexity of video game quality phenomenon from the user's perspective, a preliminary research was conducted on a small sample of students (n=53, of which only 42 admitted playing video games), who were asked to define the quality of video games and point out factors contributing to their quality (Sobocinski 2019). The simple survey resulted in 93 differently phrased factors (later reduced by the author to 41 by subjectively grouping the synonymous ones), while a bigger sample would most probably bring even more. The factors covered a wide array of characteristics, technical, functional, artistic, social, emotional, and even market-related elements. While most video games are subject to at least some degree of quality assurance

(QA), the process (as described by Ruuska 2015), consists mostly of functional, linguistic and platform compliance tests, but does not include the evaluation of creative elements of video games such as their story, art style or soundtrack. Similarly to other fields, where the concepts and models of service quality (see e.g. Parasuraman et al. 1985) are displaced by concept of "experience quality" (see Otto and Richie 1996), also in relation to video games there are several different specialized frameworks for the consumers' experience own-assessment through questionnaires. Ryan et al. (2006) provide Player Experience of Need Satisfaction (PENS), elaborated from self-determination theory (SDT). Poels et al. (2007) provided a through-out documentation of preparing their Game Experience Questionnaire. Nacke (2009) includes user experience analysis as a part of a broader model of game usability. The myriad of suggested factors affecting the quality of player experience motivate a need for an objective, third party assessment tool.

Video Game Reviews

A possible tool for assessing the quality of a video game may take the form of a review. Video game reviewers usually evaluate many different aspects of those products, basing their judgment on their vast experience with both similar and different types of games, previous entries in the series, market situation, socio-cultural context, and sometimes even in-depth technical knowledge (a breakdown of common review can be found in Zagal et al. 2009). Reviews were already discussed as a powerful marketing tool, both in case of "professional" reviews (Ribbens and Steegen 2012), as well as online consumer reviews (Fruth and Neacșu 2014). An experimental study (see Wilde 2010) ran by EEDAR shown a positive impact of reviews on game perception, likelihood of recommendation, and preference of receiving a copy of the game instead of $10 cash). The role of reviews on the design process was also discussed. Bond and Beale (2009) analyzed reviews to find key design factors determining if the game is "good" or "bad", similarly Swain (2008) discussed the choice of game features based on games with highest and lowest review scores aggregated by the Metacritic website (metacritic.com). Ribbens and Steegen (2012) postulated that review scores are correlated with game sales, both variables used in their research was mostly limited to the Flemish Region.

Reviews have their shortcomings, however. Ribbens and Steegen (2012) stressed the lack of professionalism among video game journalists, as they often vary in experience, base their judgment on varied criteria and use different jargon. The subjective, not standardized character of reviews can be problematic, as even researchers have different views on the topic of video game criticism. Bogost (2006) discussed if video games should be analyzed from a new, monothematic academic field (which he refers to as an "functionalist" approach), or through "comparative criticism", in relation to other forms of human production. Konzack (2002) suggests a framework for computer game criticism, building upon existing methods from other fields, but also considering the "uniqueness" of video games as a medium; the proposed method includes the analysis of 7 "layers" of video games, from the hardware and program code, through the functionality and gameplay, to the game's meaning, referentiality and socio-culture. The presented approach highlights the complexity of video games, however a complete analysis of a single game would require broad knowledge, including electronics, programming, culture and social sciences, as well as at least some experience with ludology and game design. The author himself, while providing an example analysis of Soul Calibur, admitted that he was not an electronics expert to say much about the hardware, and did not have access to the game's code (nor skills to understand it, if he had; p. 91-92). Despite acknowledging many layers of the game, the method did not provide much information regarding assessment of the audio-visual side, which is very often discussed by both consumers and professional reviewers.

The Power of Review Aggregators

A logical solution dealing with differences in the reviewers' subjective point of view, would require a way of gathering several individual opinions and developing a common agreement. Review aggregators seem to provide this solution. A review aggregator can be generally defined as a "platform that regroups opinions and makes them available, allowing both objective and subjective information on a product to be easily accessible to potential consumers" (Piolatto 2015, p. 2). There

are many "aggregator elements" in different websites, i.e. most e-shops and shopping platforms provide a possibility for customers to rate and/or review offered products; for several dedicated services that functionality is one of their biggest assets. Although concerning different media (video games, movies, TV shows, music), Metacritic (metacritic.com) is probably the most popular review aggregator website in the video games industry specifically. The service, launched in January 2001 (see *About Us*), gathers various professional reviews, transforms their scores to a single scale (0-100) and calculates a weighted average called the Metascore. Additionally, the service allows users to provide their own scores (scaled 0-10) with an optional review, and calculates an average User score (also 0-10, but with one decimal place).

Some academics rely on Metacritic in their studies, referring the source as "objective" (Koeffel et al. 2010), and an "indication of game quality" (Baldwin et al. 2013). There is also a strong belief that the Metascore has a significant effect on the market. According to different reports based by EEDAR (Electronic Entertainment Design and Research) data, there is some correlation between the average review scores and sales (North 2012), however it decreased overtime (Walker 2014). A study of 88 Xbox 360 and 80 PS3 titles from 2012 showed that review aggregators scores are weakly (c.a. 0.3) correlated with actual sales (see Khan 2020, and the provided dataset). A slightly larger sample of X360 and PS3 titles (196 total) but without time constraints (X360 was released in 2005, PS3 in the following year) returned a correlation of 0.55 (Greenwood-Ericksen et al. 2013). It is important to note, that the volume of sales used in most research is based on VGChartz (vgchartz.com); the website does not use actual sales numbers (which are, in fact, very rarely disclosed through official channels), but estimates based on reports from a sample of stores and statistical models (Walton 2007). On the other hand, study shows that in the case of the movie industry, basically none of the analyzed review aggregator scores - Rotten Tomatoes' (see Rotten Tomatoes) Tomatometer and Audience scores, IMDb (see IMDb) and Metacritic - showed any meaningful correlation with the box office revenue (Wolf 2016).

It seems that the Metascore can affect the market in other ways. Market analysts suggest it can influence the game publisher's share prices (Baker 2011). It can influence the seller's range of products, as Microsoft delisted from their digital shop those Xbox Live Arcade titles (limited in size, often independently published by small studios), which had a Metascore lower than 65 (Remo 2008). There are proofs of using Metascore as a part of hiring policy; one example showed a requirement of previous experience in developing a title with a Metascore of at least 85 (Greenwood-Ericksen et al. 2013). Drachen et al. (2011) also found a slight correlation between the Metascore and volume of piracy (number of BitTorrent peers) of a given game (r=0.29, although using log transformation).

Possible Drawbacks

One particular effect of the Metacritic in the video game industry causes some controversy: the practice of basing developer's remuneration on the Metascore. While the phenomenon is seemingly not recent (signs of it were highlighted in Totilo 2008), it brought much attention in 2012, after Chris Avellone (creative director of Obsidian Entertainment) shared that his studio did not get a bonus for developing *Fallout: New Vegas* from its publisher, Bethesda Softworks, since the contract required the game to achieve a Metascore of at least 85 (see e.g. Gilbert 2012, Orland 2012, Greenwood-Ericksen et al. 2013, Schreier 2013) Unofficial sources hint that said bonus was worth 1 million USD (Schreier 2013), and could be the reason for Obsidian's lay-offs and cancellation of future projects (Gilbert 2012).

One of the reasons for the controversy over this case is that in fact, said title missed the target score by only 1 point, scoring 84 for PC and Xbox 360, and slightly less (82) for the PlayStation 3 (PS3) shortly after release. Another dire fact is related to the history of the franchise. First two *Fallout* games were developed by Black Isle Studios, a subsidiary of Interplay; the studio was closed in 2004 and Interplay sold the *Fallout* IP rights to Bethesda Softworks. The latter developed the third installment, changing a lot of the game's basic concepts. Obsidian Entertainment was founded by former Black Isle Studios employees, who were responsible for the first two games, and as Bethesda

(busy with its own projects) issued them the development of *New Vegas*, they somewhat "reclaimed" the franchise (see *Obsidian Entertainment*), although only for a moment. Bethesda Softworks decided to develop future *Fallout* games on their own. To be clear, there are no reasons to suspect that this decision was based on *New Vegas*' Metascore, as there are no official sources that confirm it was. The next *Fallout* installment, however, did not gather much better Metascores, and another one (the online-only *Fallout 76*) collected very mixed reviews. User scores of both titles released after *New Vegas* show a significant drop (see Fig. 1), which raises concern over trusting the Metascore as a base for business decisions.

Fig. 1: Major installments in the Fallout series and their corresponding Metascores and User scores (multiplied by 10 for comparison; Source: own elaboration based on Metacritic.com, last accessed 04.24.2020)

The sole process of calculating Metascore is somewhat controversial (see Greenwood-Ericksen et al. 2013). Particular critics or publications use different scales (0-5, 0-10, four or five stars with possibilities of halves, A-F letter grades) which are converted to a 0-100 scale. Only a few of the conversion tables are illustrated (see *How We Create The Metascore Magic*). Later, the weight of particular reviews is based on the "credibility" of a given critic and publication source, as perceived by Metacritic staff; the weights are not publically disclosed. That motivates the question: is the more "liberal" User score a better indicator of the game's quality, both for academic analysis, and for business decision?

Metascore vs. User Score

The Metacritic's User score tends to gather a lot less attention than the Metascore. Still, there is some research analyzing the two metrics. Johnson and others' (2014) study showed both metrics do not seem to fully reflect the game consumers' experiences, as the group found little to no correlation between the Metascore and the factors of aforementioned GEQ questionnaire, and weak correlation with the factors of PENS questionnaire. In the second case, the correlations were even weaker and less significant for the Metacritic's User Score. Park and Byun (2016) compared the two variables, however their results are not fully consistent (the final sample size is not specified, other than being smaller than 2069). Santos et al. (2019) presented a through-out analysis of both "professional" (journalist) and "amateur" (user) reviews from Metacritic. The authors pointed out several important findings, including (among others): (i) differences in style of professional and amateur reviews (detached vs. emotional), (ii) more "extreme" (either low or high) ratings from amateurs, sometimes highlighting disagreement with professionals, (iii) "nostalgia" effect, as amateur reviews tend to become more positive over time since the game's release (iv) early reactions may predict the long-term game performance. Despite its complexity, the research focuses only on text reviews, and omits the user ratings that were not backed with explanation.

To fill that gap, it was decided to provide a statistical comparison of both scores. The data for analysis was taken from a publically available dataset provided by Andrea Cadeddu (2019) via Kaggle.com. The dataset includes (i.a.) Metascores and User scores from Metacritic.com for every game (and major add-ons) dated from 1995 to 2018, covered by the website, and gathered in November 2019. It's important to note, that while the website was established in 2001, some earlier titles were added to the catalogue "retroactively", but their number is limited. Every "port" of a single title (a release on a different "platform", or "game system") is counted as a separate release, since it has a separate page on Metacritic, with different scores. Not every title received enough professional reviews and/or user scores to calculate the overall score, in which cases Metacritic gives a "TBD" (to be disclosed) label instead of scores. Those cases were removed from the dataset for further analysis, to enable some simple statistical methods. The number of reviews (positive/neutral/negative) provided in the dataset for some reason proved incorrect through random checking, thus had to be omitted from analysis. Only one error in the dataset was found concerning the Metascore (one title had a numerical score listed instead of TBD on the actual site) and was removed, and no other errors were found throughout the analysis. After cleaning the data, the dataset consisted of n=17822 cases. The descriptive statistics of the focal variables are listed in Table 1.

Table 1: Descriptive statistics of analyzed dataset, n=17822 (Source: own elaboration based on dataset from Cadeddu 2019)

	Metascore	User score (x10)
Avg.	69,864	69,462
Mode	80	76
Min.	8	1
Max.	99	94
Range	91	93
Q_1	63	63
Mean	72	73
Q_3	79	79
SD	13,239	14,057
Var.	175,262	197,602
Skewness	-0,881	-1,240
Kurtosis	0,893	1,742

Fig. 2: Two-variable histogram representing the distribution of Metascores and User scores (multiplied by 10), n=17822; source: own elaboration based on Cadeddu (2019)

At first glance, both the Metascore and User score statistics seem similar, with near identical average, mean, lower and higher quartiles. The first hints of difference appear with skewness and kurtosis, representing non-normal distribution of both values (which is typical to review aggregators in the movie industry, as mentioned by Wolf 2016), with a bigger "peak" and left "tail" of User scores. The difference is clearer with a histogram of both variables, illustrated in Fig. 2. The Gaussian curve (black) of the User score distribution is slightly more flattened, which can possibly reflect users' tendency to give more polarized scores (either bad or good, with less middle grades), although

effectively, the average user scores end up using a wider scale than average of scores from professional reviews.

The calculation of the Pearson's correlation coefficient (Pearson's r) of the two variables returned the result of r=0.565. Not surprisingly, given the size of the sample, the result was significant (p<0,0001). While many academics would eagerly use such result as enough to confirm a hypothesis (as there is a significant correlation), the "strength" of this correlation in most works is considered "moderate" (see e.g. Taylor 1990). To better illustrate the differences between the Metascores and the User scores, a scatter graph was developed (see Fig. 3), with darker dots representing the more clustered areas (i.e. many games share the same combination of Metascore and user score).

Fig. 3: Scatter graph of video games' Metascores and corresponding User scores (n=17822); high density areas highlighted with darker colors (Source: own elaboration based on Cadeddu 2019)

To better understand the disagreements between the Metascores and User scores, a further analysis was conducted. The major differences between those variables were calculated as absolute values and color-filtered in an calculation sheet, to highlight the biggest gaps; then the professional and amateur reviews of a game with a considerably big gap were compared on the game's Metacritic page, with some additional study on the game background in the gaming news websites. Unfortunately, this approach had to be abandoned before all significant gaps were checked, due to time constraints, and poor outcome. In a great amount of cases, even though a title has a User score based on several numerical user ratings, it has very few – if any – "written" user reviews, and it was often impossible to determine the reason for the difference in scores. Often the written reviews contradicted the overall user score, as either the reviews were positive while the overall score was low, or the other way around. One obvious finding that emerges, is that users are way more likely to simply give a numerical rating, than to motivate their grade, and analysis of users quality perception should considerate both the overall numerical score as well as written reviews, as taking into account only one of them can give false overall impression. Most of other findings only confirm those of Santos et al. (2019). There is an evident polarity in the user scores, and a lot of users usually explain their

different grades by simply disagreeing with the Metascore (in the type of "This game is underestimated, it deserves a higher score - 10" or "A total disappointment, can't see why it has such high scores - 0"). Some gaps can be explained by a clearly visible "nostalgia" factor, especially with the titles released for the Sony Playstation 2 and Sega Dreamcast. "Trolling" seems to be one phenomenon that Santos' team had omitted. It can be observed as many games with the lowest Metascore values – that are often clearly badly designed, unoriginal and/or filled with technical "bugs" - have a surprisingly high user scores, and written user reviews often describe those titles as a "best game ever", most probably in a sarcastic manner. Another "new" finding is the effect of consumer boycotts on the user scores, called "review bombs" – organized actions of lowering the overall score by giving minimal ratings by numerous users.

One major "bomb" found concerned Electronic Arts' *Star Wars Battlefront II* (2017), with the Metascore ranging from 65 (PC) to 68 (PS4), but with a user score of 1.3-1.4 (on a 0-10 scale). The main reason for both the "bombing" and relatively low professional scores is the introduction of a "loot box" mechanic in a fully priced game, which sparked the record breaking Reddit thread (Leskin 2019), drop in EA share prices (Kain 2017) and new anti-gambling policies (Webb 2018). Although the microtransactions were halted at the games' release, and later reworked to only provide cosmetic changes instead of "paid" advantage, the Metacritic scores failed to rise to this day. Another example is *Company of Heroes 2*, which "bombing" has more historic and political foundations. The game's storyline focuses on WWII's Eastern Front, and shows the ruthlessness and brutality of war. It raises controversy, as it is believed to put the Soviet Army in a "bad light" (not to cite directly) by Metacritic users from Russia and other post-soviet regions, responsible for the "review bombing".

Recently, there are also examples of "positive" or "reverse review bombs". One instance is *Assassin's Creed: Unity*, which received rather mixed reviews from critics and users alike, due to numerous bugs upon the game's release in 2014. The game, featuring a realistic virtual recreation of Notre Dame, was offered for free after the real-world chapel's fire in 2019. This decision resulted in a significant positive shift in Steam user's review scores (Orland 2019). Another, yet different case concerns *AI: The Somnium Files*. Its "review bombing" changed the Metacritic's User score from 8.2 to 1.9 in a single day, forcing the game's developers to ask fans for high grades, to help rise the score. Shortly after, one individual claimed responsibility for the bombing, motivating this act as a proof of Metacritic's faulty User score system. In effect, Metacritic staff decided to delete the negative ratings, which in result raised the overall user score to 9.0 - 0.8 point higher than before the "bombing" (Denzer 2020).

It is also important to mention that not only the more or less organized crowd can influence the user score, but also companies, as there are proofs of "abusive" raising of the score by developers of a given game, without disclosing their affiliation (Greenwood-Ericksen et al. 2013). It is not confirmed, but not impossible, that at least some of the past "review bombs" were actually administered by a competitive company. That being said, the user score metric, while being more "liberal" or "democratic" (as anyone can post a rating, and the overall score does not use weighted average) is relatively easy to manipulate.

Summary

Among the review aggregators used for video games, Metacritic's Metascore, based on "professional" review scores from game journalists, seems to be the most popular. Although there are signs of its significant impact on design and business decisions, there are flaws both in the methodology of calculating the metric (e.g. different scales of source data, unknown weights for calculating the average), as well as the distribution of professional review scores (using only a limited part of the grading scale). The alternative User score metric, based on "unprofessional" scores, is only partially correlated with the Metascore (r=0.565), showing a lot of discrepancies between the "professional" and "amateur" quality perception. The user score, while more "liberal" and inclusive, also has its shortcomings; the users tend to give more polarized, emotional ratings, with small (if any) explanation, and the overall score is vulnerable to manipulation by organized actions ("review

bombs") or as a form of a joke ("trolling"). While both metrics have a potential as a marketing tool, caution should be advised when using them as metrics of video game quality, as well as a base for business decisions. A methodology for assessing the quality of video games has yet to be developed, which leaves a field for future research.

Abstract

This research aims to discover whether a traveler's level of life satisfaction could affect destination decision making. Additionally, the present study also wants to discover the effect of social media on the traveler's decision. This study involves two hundred tourists who participated in an online survey. Hypotheses testing has successfully revealed some findings. First, the level of life satisfaction is significantly creating brand consciousness, developing awareness of price over value, and adding confusion by over-choice. Second, the tourist's level of life satisfaction has no significant effect on high-quality consciousness and habitual orientation. Furthermore, the largest critical score was found between life satisfaction and brand consciousness. It indicates that visitors who were satisfied with their lives tend to choose well-known travel destinations.

Keywords: Life Satisfaction, Decision-Making Style, Tourism Destination

Introduction

Decision-making styles or ways of decision making in management have been studied for four decades (Cox & Rich, 1964; Kim, Ferrin, & Rao, 2008; Malhotra, 1982; Olshavsky & Granbois, 1979). The main focus in this field is carried out to understand deeply how the flow of a product purchase decision is made by individuals (Häubl & Trifts, 2000; Hoyer, 1984; Shiv & Fedorikhin, 1999). Further, studies on decision making elaborate about the antecedents and consequence models that significantly influence consumer decision making (Sirakaya & Woodside, 2005). The study from Tsiros and Mittal (2000) introduced a model of "regret" as a decision-making process. Furthermore, Han, Lerner, and Keltner (2007) also introduced "feelings" as an extension of the appraisal tendency framework (ATF) model. Consistent with these studies, some researchers have confirmed that studies on decision making will come on the strength or weakness of repurchase intention (Chalip, Green, & Hill, 2003; Kim, Ferrin, & Rao, 2008; Macdonald & Sharp, 2000). However, they don't focus on the style of selecting tourist sites.

One of the early contributions that received much attention was the findings of Sprotles and Kendall (1986) regarding the methodology of the analysis of decision-making styles. In the following decade, research on consumer-related decision making also developed in the tourism sector (Fakeye & Crompton, 1991; Smallman & Moore, 2010; Tsaur & Tzeng, 1996). The study of tourist decision making styles on tourist destination selection is complex. Correia and Crouch (2004) and de Freitas (2003) argue that the decision-making process for taking holidays is strongly influenced by natural environmental conditions such as the intensity of the sun, climate, and beach quality. In contrast, Alegre and Juaneda (2006) have elaborated on tourist's economic behavior related to the decision on the choice

of tourist sites. However, various studies above still have not found any formulation about the style of tourist decision.

Tourists themselves as a unit of analysis have also been reviewed by several researchers with a psychological approach (Decrop & Snelders, 2005; Dellaert, Ettema & Lindh, 1998). They found that psychological aspects such as "rational" and "hedonic" are closely related to the decision-making process in traveling to a location. Decision making related to tourist destinations was also analyzed from the perspective of cultural attractiveness (Correia, Kozak, & Ferradeira, 2011; Handaru, Nindito, Mukhtar & Mardiyati, 2019). Other studies also explained that decisions about the choice of the tourist sites are influenced by the quantity and quality of initial information search conducted by visitors (Dodd, 1998; Fodness & Murray, 1997, 1999). However, various studies also did not specifically discuss the decision-making styles that are associated with the background of life satisfaction of visitors.

Previous studies have been conducted to discover the concept of decision-making styles. Some antecedents and consequences of the decision-making styles have been examined with a quantitative and qualitative method to get a better result. However, there is a lack of discussion about decision-making styles relating to the role of life satisfaction of middle-income tourists. Contribution of middle-income tourists for local tourism is huge, but unfortunately, the correlation of their life satisfaction and how they choose a specific destination is rarely elaborated. Further study is important to get a deeper understanding of the decision-making style which influences by the conditions of tourist's life satisfaction. This goal is the main motivation for this research as well as to contribute to the field of strategic management and tourism management. To achieve this goal, this research is organized based on the following stages: first, mapping and literature review is conducted; second, the selection of quantitative methods to test causal effects between variables; and third, a discussion of the results of hypothesis testing. The research concludes with a discussion and in-depth interpretation of the results of the hypothesis test and explanation of conclusions as well as further research suggestions

Literature Review

Life Satisfaction and Its Effect on High-Quality Consciousness

Life satisfaction could be interpreted as the level of satisfaction on financial condition, career, or family welfare. Life satisfaction is one of the strong antecedents of high-quality consciousness related to holiday destination choice (Decrop & Snelders, 2005). The level of life satisfaction which is perceived by some people essentially be subjective, but still associated with the style of the consumer when deciding the purchase of products or services (Correia, 2002; Hsu Tsai & Wu, 2009). The level of life satisfaction that influences the style of decision-making to travel is reflected in many aspects. Generally, monetary satisfaction was derived from the monthly income. Consumers who have higher incomes tend to choose high-quality travel destinations. The high-quality destination normally is expensive, and it may only be afforded by those who have high monetary income. In this study, life satisfaction reflected by economic conditions, good career, and family welfare. Based on the explanation above, the first hypothesis is:

H1: Travelers who have high life satisfaction are preferred to choose a high-quality travel destination.

The Relationship between Life Satisfaction and Brand Consciousness

Visitors who understand the situation and conditions of a tourist location, usually have an established educational and occupational background (Jenkins, 1999; Milano, Baggio & Piattelli, 2011). People who are dissatisfied with their lives tend not to be interested in finding information related to travel packages. In other words, people who are satisfied with their lives will be more motivated to ensure the safety of the travel itinerary (Kassean & Gassita, 2013). Brand awareness is the level of tourist's knowledge about a specific tourism destination. Previously studies explained that the Brand Consciousness is obtained by searching for information through the Internet such as social media or website (Leung, Law, Van Hoof & Buhalis, 2013). The intensity to use online media and tourism

websites provides a strong awareness of a specific destination and its supporting infrastructure (Kruger & Saayman, 2010; Miguéns, Baggio & Costa, 2008). By accessing online media, tourists have the information to be used as the basis of decision-making. Based on the description above the second hypothesis could be stated as follow:

H2: Travelers who have high life satisfaction are preferred to choose famous travel destinations.

Life Satisfaction and Its Impact on Price and Value for Money

Consumers bought a tour package to get a memorable experience (Hays, Page & Buhalis, 2013). Hays et al. (2013) explained that the value of money is a very important proposition in tourism marketing. The value for money aspect is important because tourists are divided into several segments. For tourists who are sensitive to price, the cost of travel is vital for making a decision. Price sensitivity is a part of life satisfaction associated with status and economics. Other researchers also mentioned that value for money proposition is fundamental in destination decision making (Hudson & Thal, 2013). For that reason, the extent of life satisfaction can make visitors more sensitive to cost travel and tourism package because they want to make sure all things are hassle-free. Consequently,

H3: Travelers who have high life satisfaction are more selective related to value for money of particular destination

Life Satisfaction and Its Effect on Confusion by Over Choice

At the time when the extent of life satisfaction is high, the buying power of tourists toward a tourism package will be increasing. This condition widens the alternatives to holiday destinations. Unfortunately, this will also create confusion to choose the best holiday options. On the contrary, when life satisfaction is low (for instance caused by poor economic condition), "confusion by over choice" rarely occurs (Patterson, 2007; Petrick, Li & Park, 2007). Therefore, it can be concluded that confusion by over choice is often happening in visitors who have a high level of life satisfaction (Garg, 2015; Jenkins, 1999; Wong & Yeh, 2009). Based on the description above, the fourth hypothesis is:

H4: Travelers who have high life satisfaction are often confused to choose a specific holiday destination

Life Satisfaction as Antecedent of Habitual and Brand Loyal Orientation

Visitors who have accomplishments in terms of education, career, and finance tend to visit a high-quality tourist destination. (McKercher 2002: Nicoletta & Servidio, 2012). Visitors who have good educational background also tend to choose a secure and hassle-free destination. A set of pleasant memories fosters a tendency to revisit the same destination. Therefore, it can be concluded that visitors with a high level of life satisfaction will choose a high-quality destination and willing to revisit the location in the future (Hung and Petrick, 2012; Kassean & Gassita, 2013). For that reason, the fifth hypothesis is:

H5: Travelers who have high life satisfaction are often visited the same holiday destination

The relationship between all variables and hypotheses in this study arrange in figure 1.

Fig. 1: Conceptual Framework

Method

This study used structural equation model/SEM analysis to test all hypotheses. Covariance based SEM was applied and supported by two hundred online respondents. Some criteria were applied in the online survey process. First, respondents must have a social media account. Second, they must be active in social media for at least two years. The online survey instrument is adopted from Decrop and Snelders (2005), Tsiros and Mittal (2000), Alegre and Juaneda (2006), Correia, and Crouch (2004), also Nicoletta and Servidio (2012) with total 23 questions. Score 1 to 5 of the measurement scale has been used in the online survey. Options are ranging from 1 "not me at all" to 5 "so much like me". The level of life satisfaction measured by option 1 "very dissatisfied with my life" to 5 "very satisfied with my life right now" answer. Tourist destination to examined is Bali, which is very popular in global tourism and meets the requirement of holiday destination for middle-income tourists. The goodness of the research model was evaluated by some criteria which are included in the goodness of fit (GoF) model measurement (Hair, Black, Babin & Anderson 2014).

Results and Discussion

Sample Profile and Most Popular Social Networks

The online survey reveals some information. Participants are 135 males (67.5%) and 65 females (32.5%). There are 92 males (68.12%) who work in government institutions. The rest of the male participants are having a family business or work in a private company. The majority of female participants are working in various private companies (61.5%) and the rest of them are unemployed or being housewives. The extent of life satisfaction which reflects on the financial condition reveals some important facts. There are 172 participants (86%) who have a monthly income of more than 450 USD, which is relatively high for average workers in Indonesia. The intensity to use social media is also high.

All participants are having a personal social media account. Furthermore, there are 168 people (84%) who have more than one social media account. Additionally, there are 122 people (72.6%) who have more than two social media account. The most popular social network is shown below:

Fig .1: Social Networks User (Own Personal Account)

Goodness of Fit Result

The evaluation of the structural research model discovers a satisfying result as presented in table 1.

Table 1: P-Value of Default Model

Model	NPAR	CMIN	DF	P	CMIN/DF
Default model	31	72,158	60	,135	1,203
Saturated model	91	,000	0		
Independence model	13	358,590	78	,000	4,597

The score of the default model (p-value) is 0.135, indicating a good fitness level of the research model. Another evaluation of the goodness of fit (GoF) shows good consistency. In table 2, the GFI score is 0.949 and the AGFI score is 0.922, indicating the research model can represent the phenomenon. The parsimony test result is also satisfying. In table 3, the PNFI and PCFI scores are 0.614 and 0.736, indicating the research model is relatively simple yet effective.

Table 2: AGFI and GFI Weights Result

Model	RMR	GFI	AGFI	PGFI
Default model	,011	,949	,922	,625
Saturated model	,000	1,000		
Independence model	,039	,733	,688	,628

Table 3: Parsimony-Adjusted Measures

Model	PRATIO	PNFI	PCFI
Default model	,769	,614	,736
Saturated model	,000	,000	,000
Independence model	1,000	,000	,000

Several reflective indicators are removed because the loading score is low. Therefore, the final model has been modified according to the modification indices (MI) score. The final model of this research is in figure 2 below.

Figure 2: Final Model

Response from respondents in the online survey shows good consistency related to empirical fact. The result of life satisfaction level measurement is high, indicating our participants are mostly satisfied with their lives. Next, from the measurement of "perfectionist or high-quality consciousness style", the highest loading score occurs from the statement "I often go to a high-quality holiday destination". This indicates that people with a high level of life satisfaction are prone to choose a high-quality holiday destination. Rajesh (2013) argued that a high-quality holiday destination can provide pleasant attractions, comfortable accommodation, easy access, superb amenities, and activities. The level of life satisfaction is also creating "a holiday destination which often appears in social media is a good choice" opinion. This opinion is logical since our survey participants are highly active in social media. In terms of "price and value for money" style, most of the participants answered "I often visit cheaper holiday destinations". This finding shows that the extent of life satisfaction can make people more aware of benefits and cost calculations. Moreover, a high loading score also occurs in the statement "the more I search for information, the harder I choose a holiday destination". This result consistent with the prior issue that social media usage can bring much confusion to select a specific holiday destination.

Hypotheses Testing Result

Hypotheses testing has discovered some important findings as presented in table 4.

Table 4: Regression Weights Result

			Estimate	S.E.	C.R.	P	Label
qual	<---	life	1,227	,733	1,675	,094	
brand	<---	life	4,413	1,929	2,287	,022	
price	<---	life	3,505	1,561	2,245	,025	
conf	<---	life	3,220	1,446	2,226	,026	
habit	<---	life	,172	,543	,317	,752	

			Estimate	S.E.	C.R.	P	Label
qc2	<---	qual	1,000				
qc3	<---	qual	1,017	,297	3,429	***	
bc3	<---	brand	1,000				
bc4	<---	brand	,938	,156	6,011	***	
pc1	<---	price	1,000				
pc2	<---	price	1,040	,221	4,710	***	
cc1	<---	conf	1,000				
cc2	<---	conf	1,126	,211	5,332	***	
bL2	<---	habit	5,849	17,780	,329	,742	
bL3	<---	habit	1,000				
LS3	<---	life	1,000				
LS1	<---	life	,475	,323	1,469	,142	
qc4	<---	qual	,493	,144	3,419	***	

First, the participant's level of life satisfaction does not automatically make them choose a high-quality destination (p=0.094). This opens a new discussion because Decrop and Snelders (2005), also Rajesh (2013) have a different argument. In this case, the survey participants are more likely to choose the "viral" holiday destination, as they get the information from social media. This information confirms the prior study of Leung et al. (2013), also Macdonald and Sharp (2000) who mentioned that social media provides many "viral" holiday destinations. Second, destination awareness correlates to the level of life satisfaction (p=0.022). This supported by a wide network of participants who actively socialize in various online media. Information regarding holiday destination now is very easy to access. Participant's level of education and health economics condition support this finding.

Third, the participant's level of life satisfaction can create a strong awareness of cost and benefits before they choose the best holiday destination (p=0.025). This finding is similar to some previous studies of Alegre and Juaneda (2006), also Correia and Crouch (2004). They mentioned the same information that the evaluation of cost and benefit is often found in a high education environment. Fourth, confusion to choose a specific holiday destination caused by a high level of education and good economics condition (p=0.026). Some scholars like Sharifpour, Walters, Ritchie, and Winter (2014) have explained the same fact. This finding also confirms Rewtrakunphaiboon and Oppewal (2003) also Milano et al. (2011) who claimed that education and economics open more opportunities and thus create much confusion. Fifth, destination loyalty does not correlate to the level of life satisfaction (p=0.752). Some participants are fond to try different holiday destinations. This evidence confronts Sönmez and Graefe (1998), Wong and Yeh (2009) also Poria, Butler, and Airey (2004). In this case, the age factor might be the reason why they choose to travel to various locations rather than to one location repeatedly.

Conclusion

This study aims to discover the impact of tourist's life satisfaction on their style in choosing vacation destinations. To achieve that, an online questionnaire has been distributed to 200 travelers who active in social media. Some findings show that the level of life satisfaction has a strong impact on the decision to choose a "viral" holiday destination. The level of life satisfaction makes travelers more aware of cost and benefit calculation. Confusion to choose specific holiday destinations also found amongst participants who have a high level of life satisfaction. The recommendation for further research is using cultural and religious aspects to determine destination decision-making process.

Acknowledgment

We would like to extend our gratitude and appreciation for Faculty of Economics Universitas Negeri Jakarta and Faculty of Economics Universitas Negeri Semarang for their significant support in this research.

Abstract

The new EU industrial policy is aimed at implementing key priorities: maintaining global competitiveness of European industry and equal playing conditions, both domestically and globally, ensuring Europe's climate neutrality by 2050 and shaping the digital future of Europe. These vectors define a comprehensive set of principles for state regulation of industry and the specifics of future actions in the field of common European industrial policy. This publication attempts to identify the key drivers of industrial development and industrial policy in Europe and to outline the transformation vectors of European industrial and economic development. Based on the analysis of official data and analytical reports, space-time and sectoral features of industrial production in EU countries are determined, factors that influence industrial development are identified, major trends in industrial development are considered, socio-economic effects of industrial policy for EU countries are identified.

Keywords: Industrial Policy, Public Administration, Economic And Regional Development, Production, European Union

Relevance of Research

In the European Union, attention to industrial policy is increasing. Increasing attention to industrial policy is driven mainly by economic trends. Developed industrialized countries are gradually losing their competitive position to developing countries that have substantially increased their industrial capacity in recent years, including through active industrial policies.

Despite the decline in the share of the European Union in world GDP at purchasing power parity over the past decade, its combined contribution to the global economy remains significant (according to the IMF, 15.8% in 2019). As of January 1, 2019, more than 513.5 million people lived in the EU. The EU is characterized by a significant difference in development levels between the two groups of states, which can be described as “EU-15” (“old” EU members with a higher level of development) and “EU-13" (13 states that entered into the union after 2004 of the year).

The dynamics of the EU-15 and EU-28 GDP are similar, since most of the gross output of the EU as a whole is the GDP of the fifteen “old” members of the union (almost 90%). After 2000, the growth rate of the EU-13 countries became higher than that of the "old" member countries of the association, which led to a convergence of the level of development of countries. According to IMF estimates, in 2016-2019, the growth rate of the gross output of the "new" members of the European Union averaged 3.9% annually, and the "old" – 1.9%. It is important to note that the high growth rates of the EU-13 countries were provided by a strong increase in domestic demand and consumption. During 2016-2018, the gross output of the EU increased on average by 2.3% annually. According to IMF estimates, in 2019, the growth rate of the EU economy fell to 1.5%. Such dynamics of gross output is due to the negative conjuncture of the world economy, a slowdown in world trade growth, tariff conflicts between individual countries and the uncertainty associated with geopolitical risks, in particular the UK's exit from the EU, and the implementation of the obligations of a trade deal between the United States and China.

Analysis of Previous Studies

Studies of particular aspects of industrial development and industrial policy in the European Union and in some of its countries are sufficiently thoroughly discussed in the scientific community. In the concept by Stiglitz (2016), industrial policy in the most general sense is a government policy aimed at changing the structure of the economy, increasing production potential and ensuring competitiveness in world markets. The transition from vertical to horizontal industrial policies with their distinguishing characteristics is shown in a study by Singh (2016).

The features of new industrial policy in EU countries at the sectoral and regional levels are explored in the work by Landesman (2015). Vectors of activation of industrial development and directions of an exit from economic crisis are investigated in works by Ambroziak (2017). Some issues of stimulating the innovative component of EU industrial development are presented by Pianta (2015).

Starikov (2017) examines the economic content of industrial policy and its structural elements, examines the tools and mechanisms for its implementation, explores the global experience of industrial policy formulation and implementation, and principles for evaluating its effectiveness.

A study of the impact of sectoral impact on industrial development of the EU-Ukraine Free Trade Agreement is reviewed by Bazhenova (2018). Tsyplitskaya and Yannenkova (2018) analyze the socio-economic, political and institutional prerequisites for shaping the European Union's industrial policy and the specific features of its implementation.

Dhéret and Morosi (2014) analyze the de-industrialization process that is currently taking place in Europe and the role that government plays in the evolution of European industrial policy.

The study by Alexa and Alam (2019) focuses on a review of the current status, as well as the implications and challenges of the Industry 4.0 concept among European industries, in the direction of innovative development and changes at all levels of business models and value chains of industrial products.

In the work of the authors Danilova, Pravdina, Dzenzeliuk and Kochegarova (2019) suggest the rationality of the existing structure of the regional economy and the actual development priorities of the industry based on the positioning of territories in coordinates "integral index of efficiency" – "integral index of localization" and identify outsider regions and leading regions, assess the impact of basic industry localization in the region on industry performance.

Purpose and tasks. This publication embodies an attempt to summarize industrial production trends and outline the existing mechanisms for state regulation of industrial policy in EU countries. To achieve this research goal, based on the analysis of official data and analytical reports, identify the sectoral and regional characteristics of industrial production in EU countries, determine the factors influencing industrial production, consider the main trends, determine the socio-economic consequences of modern industrial policy mechanisms for European countries, outline regulation of industrial production in EU countries.

Information base and research methods. Information base for the analysis of state regulation of industrial policy in EU countries is official data of the European Union, European Commission, World Economic Forum, World Trade Organization, European Central Bank, open Eurostat data, analytical reviews, reports and reports, scientific articles, sociological research data, specialized and socio-political press, the results of the authors' own research. The study used methods of analysis and synthesis (to identify the structural features of industrial production), systematization (to group industrial policy principles), comparative-time method (to identify the dynamics and trends of industrial production in EU countries), comparative-spatial method (to identify regional features of industrial production in EU countries), generalizations and others.

Outline of the material. In 2017-2018, the EU economy continued to grow, but in the second half of 2018, growth rates slowed down somewhat due to several factors, including increased trade tensions, global uncertainty, the UK's exit from the EU and so on. The EU's real GDP growth rate is expected to increase to 1.6% in 2020, up from 2.0% in 2018 and about 1.4% in 2019. In recent years, significant progress has been made towards reducing unemployment and poverty, correcting macroeconomic imbalances and improving the financial position of EU member states.

Figure 1 shows the dynamics of the cost of products sold in the EU-28 from 2008 to 2018. After the economic crisis in 2008, the cost of production in the EU fell sharply in 2009 with a sharp drop of 18%. However, between 2009 and 2011 there was a turn when the cost of products sold increased by 15% and remained stable over the next three years. The results of 2018 show the consolidation of production growth after a full recovery and exceeding the level of 2008. This upward trend in industrial production in the EU was continued in 2018 and was mainly related to the production of cars, trailers and semi-trailers, other transport equipment and machinery, as well as equipment.

Note: EU-28: Except Cyprus, Luxembourg, Malta
Analysis based on constant price ref. 2015

Fig. 1: Evolution of EU-28's value of sold industrial production, 2008 - 2018 (2015=100)
Source: Eurostat (online data code: DS-066341)

According to Eurostat, during 2016-2019, the growth rate of production of cars, trailers and other transport equipment maintained a high amplitude of fluctuations, reaching a maximum in April 2016, when the growth rate was 10.6% in annual terms. Since the second half of 2018, production of this category of goods has significantly decreased. In 2019, the negative dynamics continued: in April 2019, the decline rate reached its maximum over the four-year period (–8.2%) in annual terms, and at the end of December 2019, production decreased by 7.7% in annual terms. In the following countries, the decline in production of this category of goods was more than the indicator for the EU as a whole: Greece (-29.2%), Denmark (-20.3%), Germany (-13.5%), Hungary (-10.5%), Czech Republic (-10.4%) and France (-9.1%).

The share of external trade in EU goods and services relative to GDP was about 35% in 2018. The EU's share of total world trade in goods and services has fallen to 16.7% in 2017-2018 (a downward trend has been observed over the last two decades). At the same time, the EU remains an important trading partner for over 80 economies. Despite the fact that the volume of trade in goods with third countries continued to grow, in 2018 the external trade balance of the EU was negative, primarily due to the significant shortage of fuel and lubricants. The United States, China and Switzerland remained the main export destinations for EU goods.

Analyzing the cost of products sold in the EU-28 by individual EU member states in 2018 (fig 2), three quarters of the cost of products sold in the EU-28 (77%) was received by six EU member states. Germany recorded the highest cost of products sold, equivalent to almost 28% of the total EU-28, followed by Italy (16%), France (12%), the United Kingdom (9%), Spain (8%) and Poland (5 %). The remaining 22 EU member states contributed smaller shares (up to 3%).

Note: EU-28 except Cyprus, Luxembourg, Malta
Due to confidential reasons the EU-28 total is rounded and do not sum up the countries' total

Fig. 2: EU-28 value of sold industrial production, by country, 2018 (% of total value of sold production)
Source: Eurostat (online data code: DS-066341)

Industrial goods continued to dominate the EU's export structure (mainly transport equipment and chemicals), but their share gradually declined from 81.9% in 2016 to 80.4% in 2018.

Considering the production sectors in more detail, Slovakia stood out for the production of cars, trailers and semi-trailers, as well as other transport equipment, which accounted for 50% of the total cost of products sold in the country in 2018.

More than 42% of the value of products sold in Greece was derived from the production of food, beverages and tobacco. The Netherlands was close to this share with 33%, followed by Croatia, Spain, Bulgaria, Belgium and Lithuania with shares from 26% to 29%. In contrast, the Czech Republic and Slovakia are the least specialized countries in food production, with the lowest share in sales - 9% and 6%, respectively.

The share of production activities in the cost of products sold in the EU-28 in 2018 is shown in Fig 3. The cost of products sold in the EU-28 is concentrated in fourteen groups of activities; six of these groups account for nearly three quarters of the total for both accounting years. The sectors of food, beverage and tobacco production, the production of basic metals and finished metal products, and the production of automobiles and other transport equipment together accounted for 47% of the cost of products sold in 2018. Production activity in the EU-28 the cost of products sold remained stable from 2008 to 2018.

The production of pharmaceutical products and pharmaceuticals in 2018 increased by 49% compared to the cost of products sold in 2008, and, on the other hand, the production of computer, electronic and optical products decreased by 6%.

Fig. 3: Value of sold production by group of manufacturing activity, EU-28, 2018 (% share of total sold production)

Source: Eurostat (online data code: DS-066341)

Fig 4 shows the dynamics of the cost of products sold for the five largest manufacturing enterprises in the EU-28 for the period from 2008 to 2018. Between 2008 and 2018, the production of cars, trailers and semi-trailers was the most unstable. activity among the five leading manufacturing assets. From the point of view of the reported value of the products sold, this activity has increased the most compared to 2008 (from 31% or 180 billion euros). Food production increased in 2018 by 102 billion euros (16%) compared with 2008, while the largest growth was 110 billion euros in 2017.

Fig. 4: Evolution of the value of sold production for top 5 manufacturing activities, EU-28, 2008–2018 (2015=100)

Source: Eurostat (online data code: DS-066341)

Analyzing constant prices, in 2018 the production of machinery and equipment decreased by 1%, the production of chemicals and chemical products decreased by 2%, and the production of finished

metal products, except machinery and equipment, by 4% compared to 2008. Food production increased by 5%, and the production of cars, trailers and semi-trailers - by 21% over the same period.

The total value of the sold products produced by the production of cars, trailers and semi-trailers in 2018 amounted to 755 billion euros; this value is 14% of the total cost of products sold EU-28. In 2018, the cost of products sold for this manufacturing sector reached its peak, it grew by 31% compared to 2008 and by 7% compared to last year. In 2018, this amounted to approximately 467 billion euros, which is almost two-thirds of the cost of products sold, accounted for automobile production (61%). The production of other parts and accessories, bodies (bodies), electrical and electronic equipment for motor vehicles, trailers and semi-trailers accounted for the rest of the products sold in this type of activity, which is 39% (fig 5).

Note: EU-28: Except Cyprus, Luxembourg, Malta

Fig. 5: Sold production of motor vehicles, trailers and semi-trailers in EU-28, 2018 *Source:* Eurostat

The slowdown in economic growth in 2019 was not typical for all countries of the union. Acceleration of GDP growth was noted in Ireland, which showed the highest value among the countries of the European Union (+ 4.3%), Greece (+ 2.0%), as well as in most countries of the EU-13 group: for example, in Hungary (+4, 6%), Latvia (+ 2.8%), Lithuania (+ 3.4%) and Poland (+ 4.0%).

According to Eurostat, during 2016-2017, industrial production in the EU grew steadily: in 2016, the growth rate was 1.8%, in 2017 - 3.1%. Starting in 2018, the growth rate of industrial production began to slow down. In 2018, the value dropped to 1.2%, in 2019, industrial output decreased by 1.0%. In 2019, the largest contribution to the reduction in industrial production was made by such countries as Germany (-4.7%), Luxembourg (-3.0%), Romania (-3.2%), Portugal (-2.4%). However, a decrease in the growth rate of industrial production was not characteristic of all countries. For example, in Denmark this indicator increased by 2.7%, in Lithuania - by 3.5%, Hungary - by 5.4%, Poland - by 4.4% of Slovenia - by 3.0% (table 1).

Table 1: Dynamics of industrial production of the EU countries, 2016-2019

	Index 2015 = 100		Growth rate,%, to предыдущему году	
	2016	**2017**	**2018**	**2019**

Some experts consider current EU industrial policy to be similar to a mercantilist economic policy. Particularly doubtful is the possibility of involving private companies in a continuous continuous process of production and research. The European Commission expects that enterprises will be able

to "give their future in the hands of technological policy". The result of such an EU industrial policy may be the elimination of free competition between enterprises and the transformation of the European model of division of labor.

EU industrial policy today is based mainly on a horizontal approach, but industry support is also present. Sectoral assistance in the EU is strictly regulated as being detrimental to competition and subject to clear conditions and restrictions (fig. 6).

Fig 6. Current sectoral assistance in EU industrial policy
(summarized by the authors)

The application of an economic approach to EU industrial policy is necessary to ensure a level playing field for the entities of the common market. This means that state aid decision-making is based on economic analysis and a comparison of the positive effect of the aid with its negative effects on competition and trade (fig. 7).

Fig. 7: Principles of EU industrial policy
(summarized by the authors)

It should be noted that any state aid in the EU is interpreted as distorting market mechanisms and restricting competition. State aid which favors individual enterprises or goods and impairs trade between countries is incompatible with the common market.

The conditions and types of assistance that are eligible in the EU are clearly defined, including:

- aid for the development of regions where the standard of living is particularly low or where there is significant unemployment;
- assistance in the implementation of important projects of common European importance;
- assistance in the recovery of Member States in times of severe economic downturn;
- assistance for regional development and economic activities that will not have a negative impact on trade.

The need to identify priority areas for industrial policy and state aid (Fig. 8) is explained by the fact that public resources are limited and the lost benefits from the possible implementation of alternative options can be significant.

Fig. 8: European Commission's industrial policy priorities
(summarized by the authors)

The European Commission has unveiled in 2020 a new strategy to help European industry lead the dual transition to climate neutrality and digital leadership. The strategy is aimed at enhancing Europe's competitiveness and strategic autonomy during a period of shifting geopolitical plates and increasing global competition. By mid-2020, the European Commission will approve a «White Book» that will combat the devastating effect on the single market from foreign subsidies and determine the parameters of external participation in European public procurement programs. Work should be completed by establishing a legal instrument for foreign subsidies as early as 2021. At the same time, the EU will continue to support global rules on industrial subsidies within the WTO and the principle of reciprocity with third countries in public procurement policy.
To meet the objectives of the industrial strategy, a so-called EU Industrial Forum should be set up by September 2020, which will be a technology platform open to industry, including small and medium-sized enterprises and social partners.

Two more initiatives in the renewed industrial policy package will address the development strategies of small and medium-sized enterprises and the creation of favorable conditions for their activity in the internal and external markets of the European Union, as well as the prospects of developing a single EU market for the benefit of both producers and consumers.

Some countries, such as Germany, are negative about the EC's argument that the European Union must create absolute independence in the most important sectors of industry and shape Europe's self-sufficient economic system. It is considered impossible to have the know-how in all important sectors of the industry, to implement import restriction policies to reduce the competitive pressure of external competitors, while ensuring full openness in the domestic market. The results of the industrial economy and the new theory of international trade put at the heart of the question of the contradiction between industrial and competitive policies in the field of merger and acquisition control in the European Union. European business associations can also become part of industry strategies and programs and claim grants for productivity development.

Conclusions

The slowdown in the global economy can slow down the economic growth of the "new" members of the union, slowing down the convergence of economic development of the EU countries. This is confirmed by IMF estimates: according to the forecast, in 2020 the growth rate of the gross output of the EU-15 will increase to 1.5%, and the EU-13 will decrease to 3.2%. At the same time, the EU-28 GDP growth rate is expected to increase to 1.6%. However, in 2020, coronavirus (2019-nCoV), which affected all European countries, could become an additional uncertainty factor for the economy of the European Union.

In the European Union, there is a rigid system for monitoring and controlling the implementation of State aid programs to the industrial sector. The process of convergence of industrial policies can take a long time, because with the changing global markets, the transformation of the EU structure and the ever-increasing global challenges, conflicts of interest will arise between nations, regions and, especially in the future, between large industrial groups. This includes the fight for markets, which will stimulate industrial integration under the microeconomic scenario, but will hinder the convergence of industrial policies that is happening from above. In the next stages of the convergence of EU industrial policies, there will be a constant imbalance of interests between selfish industry groups, including non-European ones, and supranational institutions, seeking to minimize the effects of profit-oriented company policies. Industrial policy will be accompanied by a number of lobbying bills and increasing opposition from supranational authorities and business representatives.

The new approach to European industrial policy should include a number of measures to support all players in European industry, including large and small companies, innovative start-ups, research centers, service providers, suppliers and social partners. Specifically, it is an intellectual property action plan aimed at supporting technological sovereignty, promoting a level playing field globally, more effectively combating intellectual property theft and adapting the legal framework to green and digital transitions.

Another important area of industrial policy is to clarify the rules of competition both domestically and globally, including measures to prevent unfair competition. The EU's strategic autonomy should be aimed at reducing the dependence on critical raw materials, developing strategic digital infrastructure and relevant key technologies. Also, comprehensive measures should be envisaged for the modernization and decarbonisation of energy-intensive industries, support for sustainable and intellectual mobility, and energy efficiency.

Abstract

Organized data investigation has been a colossal achievement formerly, nevertheless, the examination of huge scope unstructured information as a troublesome zone. YOUTUBE has trillions of clients, and consistently these clients watch YOUTUBE for a countless number of hours and create trillions of views [1]. Another statistical figure indicates that consistently and over the entire world more than 1.2 million recordings on YOUTUBE are downloaded. Moreover, to study and comprehend the activity that happens on such a monstrous scope, a relative database is no more adequate; you need a circulated and equivalent system similar to HADOOP. The primary goal of this paper is to concentrate on how data is created on YOUTUBE and how it might be utilized by various companies to target more clients and improve their purchases. Our project utilizes the YOUTUBE data API. When the API key has been produced, python content will be employed to utilize this API to recover video information as indicated by the search standards. In this paper, we use SQL type inquiries which will be executed in HIVE to remove the critical output which can be used for the examination. Our objective via this research is to treat the key words in relation to intelligent transport, especially in some Moroccan cities.

Keywords: Youtube API, Big Data, Hadoop, intelligent transport, SQL

Introduction

Every day we generate more than 2.5 trillion bytes of data [2], this amount of data to give birth to a new concept called Big Data, this data is mainly generated in real time from social media websites which exponentially increases on a daily basis. Youtube is one of the most popular and attractive social media platforms in the world, it is a source that provides a huge amount of data via comments, the likes, the number of subscribers, etc.Analyzing these points is an interesting data source to gain insights into users to help businesses target and make informed decisions.Indeed, most companies launch their product on YouTube and anxiously await the opinions of their subscribers. Big production houses launch movie trailers and people give their first reactions and comments on the trailers. It also creates a buzz and excitement about the product. Therefore, the data points listed above become very critical for companies so that they can analyze and understand the feelings of customers about their products / services.

Hadoop is an open source software framework for storing data and launching applications on clusters of standard machines. Its various components are used by many companies for their Big Data projects. This solution offers massive storage space for all types of data, immense processing power and the possibility of taking on a virtually unlimited number of tasks. Based on Java, this framework is part of the Apache project, sponsored by Apache Software Fondation [3]. Hadoop consists of two main components [4]:

- **HDFS**(**Hadoop Distributed File System**): is the foundation of Hadoop since it is responsible for storage, whose management is made easier by the framework it integrates.
- **MapReduce**: HDFS efficiently stores large data, reads and writes it with robustness and speed. But he does nothing. MapReduce is a framework for writing applications processing large volumes of data and paralleling processing on HDFS.

This paper starts by presenting the Hadoop distributions in section 2. Section 3 describes the application model. After that, section 4 is added to illustrate and clarify the result and discussion of the current research study. Finally, a conclusion with future contribution is involved in section 5.

Hadoop distributions

While Hadoop offers the possibility of collecting data on HDFS (Hadoop Distributed File System), many applications available on the market (such as **MapReduce, Pig** and **Hive**) can be used to analyze the data. The following table (see table 1) presents the functionalities and the comparison of the main Hadoop Data Analysis technologies available on the market [5].

Table 1: Comparison between Pig, Hive and MapReduce

Featured	MapReduce	Pig	Hive
Language	Algorithm of Map and Reduce Fonctions (can be implemented in C, python, java)	PigLatin (scripting languge)	SQL like
Schemas /Types	No	Yes (implicit)	Yes (explicit)
Partitions	No	No	Yes
Server	No	No	Optional thrift
Lines of code	More lines of code	Fewer (Around 10 lines of PIG = 200 lines of Java)	Fewer than MapReduce and Pig due to SOL Like nature
Development Time	More development effort	Rapid development	Rapid development
Abstraction	Lower level of abstraction (Rigid Procedural Structure)	Higher level of abstraction (Scripts)	Higher level of abstraction (SQL like)
Joins	Hard to achieve join functionality	Joins can be easily written	Easy for joins
Structured vs Semi-Structured Vs Unstructured data	Can handle all these kind of data types	Works on all these kind of data types	Deal mostly with structured and semi-structured data
Complex business logic	More control for writing complex business logic	Less control for writing complex business logic	Less control for writing complex business logic
Performance	Fully tuned MapReduce program would be faster than Pig/Hive	Slower than fully tuned MapReduce program but faster than badly written MapReduce code	Slower than fully tuned MapReduce program but faster than bad written MapReduce code

For our study we chose to work with Hive, this choice is based on the following criteria:

- A familiar programming model for people who know SQL.
- Avoid difficult coding in MapReduce programming.
- Development time is fast.
- Less line of code due to SQL nature.
- Easy for joins.

On the market, there are a variety of solutions, each with its particularities; we can cite three distributors in the Hadoop ecosystem:

- **Cloudera**: it is the leader, which gives it legitimacy with a number of customers greater than that of its competitors. Having the creator of the Hadoop framework in these ranks is a great advantage [6].
- **MapR**: this distribution offers a solution a little distant from Apache Hadoop because it integrates its own vision of MapReduce and HDFS. She comes right after Cloudera [7].
- **Hortonworks**: this distribution is the only fully Hadoop platform. Its strategy is to base itself on stable versions of Hadoop rather than on the latest versions [8].

Cloudera distribution is the solution chosen for carrying out our tests, it has been used for several reasons. First of all the fact that Cloudera offers an open source version which uses the main components of Hadoop. Then, the distribution of Cloudera is the most mature on the market with already the fourth version named CDH5. But above all, the Cloudera distribution is the most used in business. Indeed, according to the white paper « *Where is the adoption of Big Data?* » Published by *Talend* in 2013, 12% of people replied that they considered for the future or were already using the Cloudera distribution compared to 4% for the distribution of MapR and 3% for the distribution of Hortonworks. The rest of the answers concerning other solutions [9]. Another reason to choose Cloudera is that it uses less memory space (4 GO). Cloudera exists in three versions: Free Edition, Standard and Enterprise, we decided to work with the Free Edition version.

Application Model

Figure 1 shows the general model of the application, we retrieved the YouTube data from the channels using the YouTube API. We then used Google Developers Console to generate a unique access key required to retrieve data from public YouTube channels. Once the API key is generated, a python script is designed to use the YouTube API to extract video information based on a search criteria. The output of the file generated from the script is then loaded into the HIVE database. Next, we execute queries on HIVE to extract meaningful output that can be used by management for analysis.

The study uses the YouTube Data API which allows applications/websites to integrate functions used by the YouTube application to extract and display information.The above data can be used in many ways. To retrieve information from YouTube using their data API, our app must be authenticated. Once the application is authorized, we can recover data that can be used to analyze and represent.

To communicate with the YouTube API, an application program interface key is required. Google Developer allows you to create a unique key to connect to YouTube [10].

Figure 1: model of the project

Result and Discussion

The script we used is developed in python, it is based on a set of libraries among others: **Pandas** which provides high performance data structures and data analysis tools, **unide code** which takes Unicode data and tries to represent it in ASCII characters, CSV for Reading and writing in files, **Argparse** module facilitates the writing of user-friendly command line interfaces, **Apiclient** to Easily access YouTube APIs from Python.

Subsequently the script obtains the user credentials from "Key" and uses the credentials to establish the connection to the service. Then, based on the search criteria list item. The following modules were used in a **youtube_search** function to retrieve video information:

- **Snippet**: the object contains basic details about the video, such as its title, description and category.
- **ContentDetails**: the subject matter contains information about the content of the video, including the duration of the video and an indication of whether subtitles are available for the video.
- **Localizations**: object contains translations of video metadata.
- **Statistics**: the object contains statistics on the video as an example: The number of times the video was viewed, the number of users who indicated that they liked the video or not.
- **Status**: The object contains information about the download, processing and privacy statuses of the video [11].

After generating the file, it was loaded into HDFS.

In the phase of loading and analyzing data on HIVE, we will present some requests for data processing (see figure 2), which we retrieve from the script and whose search criteria were "Animals" and we will interpret the result in the form of diagrams for a more simplified visualization.

Figure 2: DataSet retrieved via the application

- **Calculation of the ten best channels that have the most likes**

The output describes that for a specific video channel, how many likes we received. The results shows that the chain "***Spinnin records***" which has the most number of likes (see figure 3). And therefore, if a company concerned by the search criterion publishes its video on YouTube, it will be aware of the competing chains on the market, so that it will choose the procedure to follow to deal with it.

Figure 3: Bar chart

- **Calculate the five best categories of videos with maximum comments**

According to data collected in the dataset, the output results show « Entertainment » and «Comedy» are some of the largest categories (see figure 4). On the other hand, the number of comments generated was most marked for the videos marked under the category «Comedy». This result shows whether there is an interest affinity model for a certain category and for which category a meaningful discussion can be triggered. For example, if a business falls under the « Entertainment »section, it would be better to launch its new.

Nowadays, a field of research is the subject of particular attention: the analysis of feelings. In a very general way, it is about the process which makes it possible to determine the emotional tone which is hidden behind a series of words. This analysis is used to better understand the perception, opinions and emotions expressed in an online mention [12]. This type of analysis therefore opens the way to automatic surveys on the participative web and social networks as well as to buzz detection; the idea behind this is to take advantage of this area for the analysis of YouTube comments, after processing the data on Hive and after knowing the best videos in relation to the search criteria.

Figure 4: Pie chart

Conclusion

The task of Big Data analysis is not only important but also a necessity and a requirement. In fact, many rail transport organizations that have implemented Big Data achieve a significant competitive advantage over other organizations without Big Data efforts. The project aims to analyze the big data of the transport organizations in order to improve the satisfaction of these customers and offer better comfort service for travelers.YouTube data analytics project output shows key information that can be extrapolated to other use cases. One of the output results describes that for a specific video ID, how many likes were received. According to YouTube Analytics, the number of likes or thumbs up in a video has a direct impact on the ranking of the YouTube video [13]. So if a company of transport posts their video on YouTube, the number of YouTube likes you can determine whether the company or its competitors appear more prominently in YouTube search results. Indeed, Data has become in a very short time a new wealth coveted by all. Comments are one of these riches, this is why analyzing YouTube comments is an important research subject to exploit because it will provide a very useful data source for businesses in their advertising and decision-making.A possible extension of this research work could be the YouTube Comments Analysis, so that the company can target users directly. Using sentiment analysis, we can determine whether the general attitude of people is positive, negative or neutral towards a specific subject or video.Another possible extension is to improve the extraction script, in order to be able to lean the search on the comments. The script this time will extract all the comments related to the search criteria, subsequently analyze these comments, namely the positive ones and the negative ones, and directly target users who have a positive attitude towards the product. A point to add on Youtube and which will improve the analysis, is to add the emoticons in the button “I like” so that the feelings of the user will be better expressed, the thing which will filter the search well and will lead towards more precise results.

Santander Group and Its Environmental and Social Responsibility in the Banking Sector

Justyna ZABAWA

Wroclaw University of Economics and Business, Wroclaw
Poland, justyna.zabawa@ue.wroc.pl

Abstract

The paper concerns aspects of Corporate Social Responsibility (CSR) in the banking sector. The special attention was focused on Santander Group as a benchmark for financial institutions and its environmental and social responsibility. According to the financial statement, Santander is one the biggest financial institution in the Europe and in World as well. The bank is evaluated by different of ESG indexes: Dow Jones Sustainability Index (DJSI), Vigeo Eiris (DJSJ), FTSE4Good Index Series, Bank Ecologisation Index (BEI) and Respect Index (RI) as well. The paper consists of five parts: introduction, Santander Group on the international financial market, green and social orientation of Santander, Santander in evaluation of ESG indexes and analysts and conclusions. Research and publication have been financed by National Science Centre, Poland, project number 2016/23/D/HS4/02841, "Green banking versus economic efficiency of Polish banking sector in the context of implementation of the Directive UE 2014/95/UE".

Keywords: Bank, Environmental Responsibility, CSR, Sustainability, Santander Group

Introduction

The main aim of the paper is to present Santander Group as a benchmark in the aspect of environmental and social responsibility in banking sector. Santander is evaluated by the variety of indexes concerning ESG aspects. There were analyzed the ESG indexes in the world connected with the specific aspects of banking e.g. DJSJ, FTSE4Good Index Series, Bank Ecologisation Index (BEI) and Respect Index (RI). The indexes concern a range of dimensions: environment, social, human rights, management of human resources, relation with clients, suppliers and other partners. Special attention was focused on environmental and social responsibility in banks. Research described in the paper concerns project financed by National Science Centre, Poland, project number 2016/23/D/HS4/02841, "Green banking versus economic efficiency of Polish banking sector in the context of implementation of the Directive UE 2014/95/UE".

CSR entered the popular lexicon in the 1950's with R'Bowen's book: *Social Responsibilities of the Businessman*. Then, the concept was underlined in the 1960's, with R. Carson's critique of the chemical industry in *Silent Spring* (Visser, 2015). It supported to birth the environmental movement. It was one the reasons for the develop of environmental directions in banking sector.

The main mission of the green bank is to connect business and ecology for the benefit of costumers (Paluszak, Wiśniewska-Paluszak, 2016). The approach to green banking varies from bank to bank in different countries. The term green banking concerns banking practices that foster firstly environmentally responsible investments and as well environmental friendly internal processes in banks (Paluszak, Wiśniewska-Paluszak, 2016). Environmental responsibility can be defined as respect for natural resources at all three levels of the bank's activity (supporting activities, internal management and products addressing pro-environmental projects, these levels will be discussed in more detail later in this article) (Zabawa, Kozyra, 2020). Ecologization can mean a process consisting of taking action to protect natural resources, therefore it is a manifestation of the environmental responsibility of banks. Green and sustainable finance and corporate social responsibility have become central issues in

measuring organizations' success, competitive advantage and influence on the marketplace (Popescu, Popescu, 2019).
The structure of the paper is organized as follows. The paper consists of five parts: introduction, Santander Group on the international financial market, green and social orientation of Santander, Santander in evaluation of ESG indexes and analysis and the last part: conclusions.

Santander Group on the international financial markets

Santander Group is one of the biggest financial institution in the Europe and in World as well. At the end of December 2019, Santander was the second largest bank in the Eurozone by market capitalization and it was also the 25th biggest bank in the world among financial entities - EUR 61,986 million (Financial Report, Santander 2019). The number of shares amounted 16,618,114,582. The share's weighting amounted 7.1% in the DJ Stoxx Banks and 1.5% in the DJ Stoxx 50. In the domestic market, its weight in the Ibex 35 as at end-December amounted 12.5%. In 2019 a total of 19,334 million shares were traded for an effective value 77,789 million euro. It was the largest figure among the shares that comprise the EuroStoxx. Liquidity ratio in 2019 was at the level of 118%. Additionally, it is worthy to notice that the daily trading volume was 76 million shares with an effective value of 305 million euro. The selected items from the balance sheet and the profit and loss account are presented in the table 1 and in the table 2.

Table 1. Balance sheet (EUR million)

	Dec-2017	Change in % (y/y)	Dec-2018	Change in % (y/y)	Dec-2019
Total assets	1,444,305	1,04	1,459,271	4,35	1,522,695
Loans and advances to costumers	848,915	4,01	882,921	6,72	942,218

Source: based on: Financial Report, Santander, 2019 and own calculations

Gross loans and advances to customers in Santander went up to 942,218 million in December 2019, 7% growth year-on-year. The Group uses in 2019 gross loans and advances to customers excluding reverse repos for the purpose of analysing traditional commercial banking loans. Compared to December 2018, gross loans and advances to customers excluding reverse repos and the exchange rate impact increased by 4%, with the following trends in the regions (Financial Report, Santander, 2019):

- the growth in South America was at the level 9%, with Brazil and Chile growing 8% and Argentina 40%, the latter driven by peso balances and the impact of the currency's depreciation on dollar balances,
- in North America, the increase was by 10%, with the US up - 12%, with growth in SC USA and SBNA and Mexico 5%,

- in Europe, moderate growth for gross loans and advances to customers was 2%. Increases in Santander Consumer Finance (+7%), with all countries growing, Poland (+5%) and the UK (+4%), where the increase in mortgages and other retail loans was partially offset by lower exposure to commercial real estate. There were declines in Spain (-6%), due to lower wholesale balances and with institutions, and in Portugal.

Customer deposits went up to 824,365 million euro. It was 6% growth compared to December 2018. customer funds, excluding the exchange rate impact, increased at the level of 6%, as follows (Financial Report, Santander, 2019):

- customer funds rose in all countries except Mexico, which remained stable. Additionally, it is worthy to underline: Argentina (+24%), Brazil (+12%), Chile (+12%) and the US (+11%). There were more moderate increases in Portugal and Santander Consumer Finance (+8% each), Poland (+6%) and Spain (+3%),
- the strategy of the bank focused on increasing loyalty was reflected in demand deposits (+6%), which increased in all in regions except Mexico. Time deposits remained virtually unchanged overall. Mutual funds rose 15%, with increases in all core markets.

Medium-and long-term covered bonds placed in the market of 8,941 million euro and senior debt amounting to 20,057 million euro. This value includes the 1 billion euro green bond issued initiating the Bank's global sustainable debt issuance plan. Green bonds confirm environmental responsibility of the bank. In 2019, there were 19,191 million euro of securitisations placed in the market. Additionally, the contractual maturity of 1.2 billion euro of securitisations was extended, with the total amount EUR 20,391 million. In the period under the consideration, issuances to meet the TLAC (Total Loss-Absorbing Capacity) requirement amounted 3,850 million euro, in order to strengthen the Santander Group situation: senior non-preferred - 2,778 million euro, preferred - 1,072 million euro.

Green and Social Orientation of Santander

The bank got our start in Spain, but it has been serving customers in the Northeast since 2013[1]. Santander has got over 575 branches and more than 2,000 ATMs across the Northeast. For more than twenty years, the bank has worked with universities, research centers and colleges to empower STEM (Science, Technology, Engineering, Mathematics) students around the world. The bank has taken a lot of activates concerning Corporate Social Responsibility. People working there believe, that supporting higher education is the best way to contribute to the economic & social development of the communities they serve. They can have a positive impact on the communities where they work and live. They have given back to their communities every day through the financial education website and program, their charitable contributions program and by partnering with higher education institutions.

The Santander Bank, N.A. Charitable Contributions Program is an example of non-profit organization which the main aim was providing support to market area that focus on civic, community and public affairs, health and human services, education and other organizations. Santander Bank has developed an Inclusive Communities plan which sets a goal of 11 billion in loans, investments and charitable contributions during last five years. The plan outlines Santander's commitment to communities across its eight-state northeastern U.S. footprint for years: 2017 - 2021. During this time Santander will increase its Community Reinvestment Act activity by 50 percent and us well triple its investment in charitable grants and projects and triples its charitable giving, compared to 2012 to 2016[2].

Additionally, it is worthy to notice, that the bank has continued fostering financial inclusion and empowerment. Over the year, the bank financially supported more than 1,600,000 people by its microfinance programs and granted loans for 277 million euro. Santander has continued to invest in

the communities. It helped more than 1,200,000 people by community investment programs and supporting higher education with more than 66,000 scholarships granted and projects.
Santander is recognized as an environmentally responsible bank in Europe and as well in the World. It means that it is actively looking for ways to reduce its carbon emissions and use technology to benefit customers in the world. The bank is engaged on the high level in eco-management inside the company, it means: using paper, electricity, water, gas and others. Santander supports financing investments concerning environmental protections, especially projects connected with Renewable Energy Sources (RES). During last years, the Santander Group has taken many activities regarding sustainability and it has been active fighting climate change. The bank supported the customers in their transition towards a low carbon economy. Santander has mobilized 18 billion euro in green financing, and it issued the first green bond, 1 billion euro, under a global strategy of sustainable issuances for the coming years. The funds from this bond will be used to finance solar energy and wind power projects.

Santander joined the twenty fifth edition of the UN Climate Change Conference (COP25) in Madrid. Santander organized various events and activities aimed at enriching the debate and increasing environmental awareness, and participated in the Eje Castellana Verde agenda. During the Conference, the bank announced its commitment to being carbon neutral in 2020.

Previously in the year at the climate summit in New York, Banco Santander participated as one of the founding members of the Principles for Responsible Banking. It committed to strategically aligning its business to the UN's Sustainable Development Goals. Additionally, Santander joined the Group Commitment to Climate Action, along with 30 other banks. It is needed to underline the fact, that Santander is the first financial entity in Spain to obtain the Zero Waste certification from AENOR (The Spanish Association for Standardization and Certification)[3].

Santander in Evaluation of ESG Indexes and Analysis

Santander sustainability performances are periodically evaluated by many indexes and ESG analysis (Santander, Annual Report 2019). These evaluations and their results are used internally to measure its performance and identify improvement opportunities. In 2019 its results stand out in the Dow Jones Sustainability Index (DJSI), and us well Vigeo Eiris. The Dow Jones Sustainability Indices (DJSI) were launched in 1999[4]. DJSI are a group of indexes which evaluate the sustainability performance of companies trading publicly. They are operated under a strategic partnership between S&P Dow Jones Indices and RobecoSAM (Sustainable Asset Management) of the S&P Dow Jones Indices.

It needs to be highlighted that Santander was recognized as the most sustainable bank in the world by the Dow Jones Sustainability Index. This index is an international benchmark which assesses environmental, economic and social impact of over 175 banks globally. The bank achieved a total score of 86 points out of 100. In this way Santander achieved the maximum score in a number of areas, including: environmental reporting tax strategy, privacy protection, corporate citizenship and philanthropy, and us well financial inclusion. As a result, the bank has received the Gold Class distinction.

Vigeo Eiris included Santander's ESG rating profile in November 2019. The new ESG overall score achieved shows a notable improvement. It had moved from a position of 22nd in the banking sector in December 2016 to 5th in 2019. Vigeo Eiris noted upward trends in four areas of performance: Environment, Human Rights, Community Involvements, and us well Corporate Governance.

Additionally, Santander is included in the FTSE4Good Index Series. This bank is also evaluated by other ESG analysts such as Sustainalytics, ISS-ESG (Institutional Shareholder Services) and MSCI. ISS-ESG was founded in 1985 with the goal of promoting aims of sustainable growth and corporate governance. Its fundamental mission is as follows: "Empowering investors and companies to

effectively manage governance, environmental and social opportunities and risks to realize long-term value"[5]. The evaluations of Santander are presented in the table 3.

Table 3. Santander in the ESG evaluations[1]

Rating/Scoring	2018	Vs. last year	2019	Vs. Sector average
DJSJ	86	=	86	First position within the banking sector. Gold class
ISS-ESG	C	=	C	> (decile rank of 2 out of 280 companies in the industry)
MSCI	A		BBB	-
Vigeo Eiris	57	<	63	> (rank 5 of 31 companies in the sector)
Sustainalytics	30.8	<	32.7	> (52nd percentile in the industry group)

[1] latest ISS-ESG rating (on a scale of A+ to D-) available at January 2020, compared to December 2018. The ISS-ESG decile rank of 1 indicates the highest relative ESG performance, and 10 the lowest. Latest MSCI ESG rating available (on a scale of AAA to CCC) at June 2019, compared to October 2018. Latest Sustainalytics scores (on a scale of 0 to 100) available at December 2019, compared to November 2018. Since September 2018 Sustainalytics has applied a new methodology for its ratings, where the score indicates a company's exposure to and management of ESG risks. Latest Vigeo Eiris overall scoring (on a scale of 100 to 0) available at November 2019, compared to December 2018
Source: Santander, Annual Report 2019

In Poland, Santander operates as Santander Bank Polska SA (earlier: Bank Zachodni WBK SA). Based on researcher (Zabawa, Kozyra 2020), (Zabawa 2019) this bank was recognized as the most environmental oriented bank in Poland. Santander Bank Polska SA received the highest value of BEI index (Bank Ecologisation Index): 0.626. It was the first research concerning measurement of environmental responsibility in the whole banking sector in one country. The envoronemtal orientation of banks was analyzed in banks in three levels of criteria (Zabawa, Kozyra 2020), (Dziawgo 2010):

- Level I—Supporting activities,
- Level II—Internal management,
- Level III—Products addressing ecological risk and those designed to protect natural environment.

Santander Bank Polska SA has been included also in Respect Index (RI) (Zabawa, 2018). The Respect Index project (with the first edition in 2009) aims at identification of companies managed in a responsible and sustainable manner. Additionally, it puts strong emphasis on investment attractiveness of companies that are characterized by reporting quality, level of investor relations or information governance[6].

Conclusions

Currently, aspects concerning Corporate Social Responsibility play an important role in functioning of companies, as well including financial institutions. Most financial institutions, including banks, at least at the level of declarations, treat "being compliant" as part of their policy on corporate social responsibility (CSR) (Losiewicz-Dniestrzanska, Nosowski 2017). Modern banks are aware that this context of their activities is evaluated by many kinds of stakeholders: clients, suppliers, employees, communities and others. For that reason, helpful can be special indexes: Dow Jones Sustainability Index (DJSI), Vigeo Eiris, Bank Ecologisation Index (BEI), Respect Index (RI). It's turned out that

[5] More information: https://www.issgovernance.com (available on 14.04.2020).
[6] More information on: http://respectindex.pl/project_description (available on 14.04.2020).

some of financial institutions are on the top in the engagement of social and environmental responsibility. As an example, it can be pointed Santander Group. This financial institution, in all countries, is recognized as an environmental and social oriented bank. It is confirmed by ESG indexes.

Theories of Financial Innovation

Krzysztof Biernacki

Wroclaw University of Economics, ul. Komandorska 118/120, 53-345 Wrocław, Poland
krzysztof.biernacki@ue.wroc.pl

Abstract

Recent changes, especially caused by the COVID-19 pandemic, deeply affected financial markets all over the world. For years, the development of international financial markets has depended on the implemented financial innovations. Those innovations have created new financial instruments, minimized risk and supported liquidity. It can be assumed, that in the nearest future the fluctuations will require some new proposals, supporting the financial markets in staying in motion
The study presents theories of financial innovation along with a classification framework. In the article, the author hypothesized that many existing theories of creating financial innovations make it impossible to determine precisely which temporary factors can eventually become the cause of creating new innovations. However, alternative scenarios that do not assume innovations in the long run may provide constraints or even declines in financial markets - because they are well known at present.

Keywords: Financial Instruments, Theories of Innovation, Innovations

Introduction

In previous analysis and research works there are many factors that are presented as common catalyst to financial innovations. At least three are prominent: the worldwide trend toward deregulation of markets, high inflation in the United States in a few decades in last century and the progress in computer and telecommunication industry (Obay, 2000). Thus scientists begun to verify, what are the causes and processes of innovations. Finally the issue of innovation in the capital markets has been finally encapsulated in a number of scientific theories that seek to elucidate the circumstances of its origination.

Theories on Financial Innovation – Classification Framework

The lack of single theory implies that the issue of financial innovations is complex. The difficulties to determine that concept in a clear-cut way result also from the varied development of areas of the international capital market (e.g. the United States and Western Europe, see: Franzen, 1998). The so-far arisen notions may be grouped as follows: demand-oriented group, supply-oriented group, mixed (demand and supply-oriented) group, a group based on the capital market theory as well as institutional economy theory (Hastenpflug, 1991). The grouping criterion is hinged on the structure of elements that impact development of an innovation. Each of those theories attempts to find a specific condition that directly affects the development of a new financial instrument. Individual theories, along with their authors and recognition clues, are presented in Table 1.

Table 1: Theories on financial innovation.

Theory type	Representative	Conditions substantiating development of innovation
1. Demand-oriented	S. I. Greenbaum, C. F. Haywood	Income and substitution effects in capital market
2. Supply-oriented	W. L. Silber	Competitiveness
	E. J. Kane, W. L. Silber and M. Ben-Horim	Legal restrictions
	C. R. Dunham,	Interest rates and risk
3. Based on capital market theory	J. C. Van Horne	Increase in effectiveness and aiming at market completeness / cohesion
4. Based on institutional economy	G. Dufey, I.H. Giddy	Institution malfunctioning

Source: own study based on W. Hastenpflug, Das Securitizationsphänomen, Wiesbaden 1991, p. 45.

The demand and Supply Oriented Theory

In the demand-oriented theory, the income and substitution effects in the capital market are construed as a function that interconnects demand for financial instruments with growing income or movements in interest rates, taking account of the available (alternative) products (see: J. G. Gurley, E. S. Shaw, 1956). Advancing those hypotheses, S. I. Greenbaum and C. F. Haywood pointed to a significant correlation between an increasing value of assets subject to investment in the capital markets and costs of their diversification (S. I. Greenbaum, C. F. Haywood, 1971). In relation with the theory by H. M. Markowitz, where a greater portfolio diversification results in risk diminishing, the investors endeavour to generate the highest possible rate of return at the given risk level. At the same time, the costs related to the portfolio management, including portfolio diversification costs, originate. Those costs are on increase if the value of the portfolio is growing. According to the theory, the demand for a financial innovation arises when the costs of the portfolio management begin to exceed the gains on those assets. The disappearing benefits trigger a search for alternative solutions in the capital market in order to downsize those costs or increase the income. The latter element is manifested in the substitution effect that regards interest as remuneration for the use of the capital.

Every financial service may be perceived as an n-element vector, which may be described with the use of specified attributes such as time, risk, liquidity etc. Potentially, there exists an unlimited number of different combinations of those attributes, which translate into an unlimited number of financial services. Under this theory, an innovation shall be a product that combines those elements in an innovative way and develops an instrument unknown before. At the same time, it provides for a response to demand occurring on the part of the capital market participants.
Development of an innovation may be schematised in the following way:

Fig. 1: Conditions of innovation development according to the demand-oriented theory.
Source: own study based on S. I. Greenbaum, C. F. Haywood, Secular Change in the Financial Services Industry, Journal of Money, Credit, and Banking, Vol. 3, 1971, No. 2.

As opposed to the demand-oriented theory, supply-oriented concepts may be split into a few trends, each of which highlights a different aspect of an innovation development. A model by E. J. Kane, named also as *regulatory dialectic*, recognizes innovations as a reply to a legal regulation that limits the freedom of action. The theory is based on an assumption of cyclical changes and adjustment of two opposing trends: political interventionism in the economy, which is manifested in establishing legal regulations, and pursuance of business processes to evade those regulations. The struggle between those drives may be compared with an interaction of visible and invisible forces, where the first one is represented by the actual transactions in the market, and the second mirrors the introduced regulations (E. J. Kane, 1981). The temporarily reached equilibrium is thrown off balance due to an action of one of the parties and the whole process starts anew. Such a speculative presentation of the entire change process, to which the theory owes the name "dialectic", has been confirmed in the course of actual financial market operation. An example may include statutory restrictions, introduced as early as in the 30s of the last century in the United States, with respect to determination of the maximum interest rates for deposits. The growing inflation in 60s resulted in opening new possibilities of depositing, which enabled evasion of the then existing regulations (E. Glogowski, M. Münch, 1996). However, recent survey shows, that financial crisis may also be caused by implementing financial innovations (D. Awrey, 2013).

Sequential approach to the innovation process by E. J. Kane is based on a premise of *innovation and regulatory lags* that arise from the calculation of the costs of innovation. Introduction of a given regulation makes an innovation arise only if the probable profit from the innovation is greater than the cost of such an introduction. The lag may be a consequence of "accumulation" of factors, which will determine profitability of its introduction. If influence of the regulation is immaterial for the increase in the costs of the market operation, then an innovation does not arise immediately. It may originate in the future if the costs of its introduction become reduced. This may be affected with external changes such as the higher inflation rate in the already presented example of deposits, or technological changes. Then, while the profit remains constant, the costs of implementation may be downsized to such an extent that development of an innovation will turn profitable. If, however, a regulation impacts profitability of the market transaction in a vital way, it may encounter a relatively prompt response in

the form of a new financial service aimed at evasion of those unfavourable regulations. The same may be applied in the other way round, where the significance of the innovation is reviewed from the legislator's perspective. Figure 2 presents the innovation process described above.

Fig. 2: Development of innovation according to the regulatory dialectic theory by E. J. Kane.

In his theory, W. L. Silber deepens the understanding of the restrictions that trigger innovations. In addition to the legal regulations, as external factors, he also takes into account internal restrictions occurring in a given market (e.g. demand for given products), or the ones imposed by the entities themselves (e.g. mutual deposit securities). The source of an innovation development is sought in two aspects (W. L. Silber, 1975). The first one involves dropping profits from operations of financial institutions in given markets. As a consequence of external changes, such as decreasing demand for credit, banks are forced to introduce new products or search for new market segments at the expense of the developing security market that provides for immediate financing. The second one involves the costs related to the existing and implemented regulations. Those alterative costs derive from fulfilment of certain conditions, both external (legal regulations), and internal, which require additional expenditures to be incurred in order to track the changes, modifications and adjust accordingly. An innovation arises when the profit from given services is on decrease or the costs of operation under certain regulations are too extensive. The chart below schematises development of an innovation.

Fig. 3: Development of innovation according to the theory by W. L. Silber.

Source: study based on W. Hastenpflug, Das Securitizationsphänomen, Wiesbaden 1991, p. 63.

The last theory in the supply-based group belongs to of C. R. Dunham, who assumes that every financial intermediary operates within the frame determined by the correlation of risk and interest rates, in which they are compelled to offer their services all the time. This means assumption of both active as well as passive role towards the market in such a way so as to enable demand to balance in those areas. An innovation arises in a situation where the existing demand and supply structure is subject to transformation in the financial service market as a result of changes in the structure of risk and interest rates (C. R. Dunham, 1980). Factors of two kinds may trigger development of those changes. The first group involves transformations of the very structure of risk and interest rates. Co-existence of the capital markets and the commodity and service markets leads to establishing certain equilibrium in which demand for tangible investment financing equals the financial service supply. Changes on either part (e.g. increase in investment expenditures) strike the whole system off balance and a process of adjustment is set off. During such a period, financial entities strive to re-adjust to new market conditions, which may bring about development of an innovation. The second group of conditions involves diversity in risk approaching assumed by the participants in the transaction. Similarly to the previous case, the changes result in a need to adjust to new conditions and, therefore, bring about development of an innovation.

The theory may find it difficult to determine the factors that substantiate the changes within the operating structure of the market. It is hard to define them, and in particular the weight of their influence, in a clear-cut way.

Effectiveness of The Capital Market and Institutional Economy as A Reason for Creating Innovation

The theory by J. C. Van Horne is founded on two bases: reaching for operating effectiveness of capital markets and making them total, more complete (J. C. Van Horne, 1985). The notion of operating effectiveness assumes that the costs of capital flow between the entities should be as low as possible. An innovation provides, therefore, for reduction in paid commissions, interest etc., and enables more

efficient and immediate allocation of the existing funds. Totality does not imply here any struggle for total (weighty) market effectiveness in the meaning of asset valuation models (J. Czekaj, M. Woś, J. Żarnowski, 2001), but it rather involves the occurrence of such financial instruments as are in correspondence with that given point in time and that specific economic situation. It is, hence, possible to conclude a transaction with the use of securities or their combination, to provide for inclusion of any future event. An innovation is an instrument that is introduced to cover the existing gap, as there has been no possibility so far to conclude a transaction in view of a given period or with respect to a given event. An example of such an innovation may be creation of a product that will secure the transaction in the forex market for a period longer than it is possible with the existing instruments.

According to that theory, a financial innovation would not occur in a market of complete effectiveness, where all information was reflected in the price of the assets. As markets are not effective in the above sense, there are incentives that may trigger development of innovations. C. Van Horne listed variability of economic ratios (inflation, interest rate), impact of legal regulations as well as technical and social progress among such incentives.

Functioning of social structures defined as institutions substantiates development of an innovation, according to the theory by G. Dufey and I. H. Giddy. Within the frame of the institutional economy, in order to function properly the society requires to minimize the so-called transaction costs that constitute a material aspect of the agreements made (O. E. Williamson, 1998). If no relevant protection of competition and property rights (incl. intellectual property rights) exists, the incentives to trigger an innovation are on decrease (G. Dufey and I. H. Giddy, 1981). A paradox in this theory may be the fact that the actual capital market development since the 80s of the last century has denied the necessity to protect patents for the introduced innovations, and their imitations became the drivers of the global financial market development.

The authors of this theory split the financial innovations into two types. The first one is called *aggressive innovation*, which is a result of a search made by the companies that specialise in generation of products of this kind. Potential buyers will be more willing to acquire new instruments from known and reckoned companies, as that involves less risk. On the other hand, such solutions are more expensive than the imitations to come in the future, as their price includes an additional cost related to both research on the innovation as well as a possible risk to fall in disrepute in case a faulty solution is introduced. We may even speak about a peculiar monopoly on introducing innovations, which is hold by reckoned financial institutions. The second group comprises the so-called *defensive innovations* that address the changes in regulatory laws, or asset interest rates and risk. Notion of this kind refers explicitly to earlier theories by E. J. Kane and W. L. Silber (legal regulations) as well as by C. R. Dunham (interest rates and risk).

Summary

Considering the theories of innovation, presented above, it must be reiterated that financial innovations are unique solution, which must be analyzed in many dimensions. Literature abounds with macroeconomic perspective, which justify innovation process, where microeconomic base has been rather limited.

The theories presented in the article emphasize that innovations arise in those branches of the economy where no clear-cut rules of operation of public and private institutions exist. Parallelly, an essential reason for developing an innovation is an attempt to downsize the statutory costs of transaction, as attributed to assertion of the ownership title.

As a good example from recent reality, the COVID-19 crisis can be mentioned. This epidemic has been caused by supply shock as well on the commodity, as financial market. The oil derivatives market is a perfect example, with negative prices for the May-2020 contract. The W. L. Silber may be adopted to such changes. It refers closely to the influence of an external factor on the process of creating financial innovation. Thus in the future, changes in the financial markets shall be perceived in the light of this concept.

Developing A Multicriterial Framework for Selecting A Critical Infrastructure Protection Strategy Based on Financial Instruments

Radu BORES

Stefan cel Mare University, Suceava, Romania
radu.bores@gmail.com

Abstract

The purpose of this paper is to develop a decision-making framework intended to for selecting the optimal strategy for the protection of an infrastructure considered critical. As infrastructure management is a problem of complexity management, the preferred approach was employing a Multi-Criteria Decision Analysis, specifically the Analytic Hierarchy Process technique. Based on the main interactions and processes involved in infrastructure management, a set of 6 criteria was proposed to establish the decision space. A panel of 5 experts provided pairwise comparisons as inputs for the AHP application from which priorities and weighs were derived. To validate the framework, consistency tests were performed as well as a consensus indicator was calculated to determine whether mathematically consolidating the opinions is representative for the individual inputs. The results obtained provide sufficient confidence for validating the model as a trustworthy starting point in a decision process.

Keywords: AHP, Critical Infrastructure Protection, Strategic Decision-Making, Governance Tools

Introduction

The advent of innovative financial technologies such as distributed ledgers, blockchain platforms and smart contracts, as well as efficiency improvements in financial markets facilitate new approaches for building strategies for protecting critical infrastructures. Beyond currency and payment solutions, some of the newer technologies specifically address interactions between citizens, corporations and the public sector within the arising concept of a smart city, as the Internet-of-Things changes the way data is exchanged and stakeholders are connected. While the promise of increased energy efficiency, improved flow of traffic, better decision-making processes and other infrastructure optimizations is appealing from a practical point of view, more scientific research is needed to accurately asses actual use cases. The technologies themselves are in the early stages of development, with various technical and economic challenges affecting their adoption. Studies that investigate core infrastructures such as voting mechanisms (Karlof, Sastru and Wagner 2005; McCorry, Shahandashti and Hao, 2017) and smart city energy applications (Swapna 2011; Mahmood, Chaudhry, Naqvi, Kumari, Li and Sangaiah 2018; Castellanos, Coll-Mayor and Notholt 2017l; Leonhard 2016; Zhang, Pota, Chu and Gadh 2018; Pieroni, Scarpato, Di Nuzio, Fallucchi and Raso 2018) show potential for more efficient processes facilitated by cryptographic instruments, but not without potential weaknesses and new challenges. Additionally, smart contract platforms and blockchain technologies with capabilities for applications in infrastructure projects are facing intense competition, both from within the blockchain ecosystem and from other substitutable conventional solutions. Given the limited availability of developers and experts in these new fields of technology as well as the slow rate of innovation propagation within public institutions, even the more advanced projects are in their infancy. With ample evidence of technological advantages provided by the new generation of instruments based on distributed ledgers, more research is required to properly facilitate a transition to real use cases.

Before considering the technical factors of such endeavors, the problem of choice arises as selecting the optimal instruments and subsequent strategy is not straight forward. As the fundamental problem is one of complexity management, the deciding factor, be it government or a business organization, requires a multicriterial framework to analyze and organize the decision process. The purpose of this

paper is to develop such a framework in aid of decision makers seeking to identify a suitable protection strategy for their specific infrastructure application. The chosen Multi-Criteria Decision Analysis (MCDA) method is the Analytic Hierarchy Process (AHP), proposed by Thomas L. Saaty (1980, 2012) and perfected over time through business and academic use. This is a reliable technique for accurately determining the weighs of decision criteria.

The main purpose of the envisioned framework is to formulate a set of criteria that comprises the essence of critical infrastructure interactions pertaining to a protection strategy, and determine the priority and relative importance of each with regard to potential solutions. To achieve this task, we have enrolled 5 experts to express their opinion on the presented criteria, from which we derived a consolidate result that will constitute the foundation for the decision framework. To validate the result, we verified that both the individual resulting decision matrixes and the consolidated one are consistent. Additionally, we studied whether the consolidation data is representative for the individual expert opinions by calculating a consensus indicator. Without a sufficiently high consensus indicator, more research would be needed for finding a valid decision framework. The obtained results provide sufficient confidence for validating the model as a trustworthy starting point in a decision process. Expectations based on the criteria formulation before conducting the AHP analysis included bias towards specific areas of interest deriving from the background of individual experts, as well as a more even distribution of preference. However, the results showed little evidence of bias in the experts' judgements and a clearer than expected clustering of preferences. Regarding the final weights of the criteria, the relative low importance of the cyber security aspect is surprising considering the nature of the instruments and the background of experts. A reasonable explanation would be that as these technologies mature, then security becomes an intrinsic feature, resulting in less strain on the decision process.

Formulating the criteria in a MCDA is an important undertaking, but thankfully extensive classification of critical infrastructures provides enough detail to anticipate the decision space and it allows us to bypass the decision-making paradox. Choosing the most reliable method of making a decision is, in itself, a decision-making problem for which we don't have an a priori answer (Triantaphyllou and Mann, 1989). Velasquez and Hester (2013) provide an extensive review of the most used MCDA methodologies, underlining advantages and disadvantages as reflected by literature and various use cases. Based on their conclusion, as well as other studies (Triantaphyllou and Mann, 1989; De Felice, Petrillo, 2010), we have established that AHP is a reliable and appropriate solution for this particular use case, as it has been used in problems regarding system performance improvement strategies, resource management, business strategies, government policy planning including in the infrastructure sector. It has advantages regarding scalability, flexibility, low input data intensity as well as adaptability to various decision-making scenarios. Disadvantages of this method regarding ranking reversal due to changes in criteria or strong inter-dependencies between them can be mitigated through separate independent analysis and are not a critical factor in determining the validity of the final model.

The essence of any AHP analysis is structuring the decision problem as a hierarchy with a top-down unidirectional relationship between the levels. An advantage is the ability to concurrently include varied criteria, both qualitative and quantitative, in a homogenous analysis system. Also, the origin of this method is the general theory of measurement allowing for concurrent deductive and inductive judgements without using syllogisms (Saaty and Vargas, 2012). The diagram presented below showcases the architecture of an AHP hierarchy, with the top layer – the decision objective being parent to the middle layer – the criteria, each of which is connected to the alternatives.

Source: Adaptation from Thomas L. Saaty and Luis G. Vargas, 2012, pg. 3

Figure 1: A three-layer AHP hierarchy

This format of expressing the decision problem allows a better overview of the complexities and interactions within the decision space and offers more information regarding the order of magnitude between various elements that are compared in pairs. To achieve efficiency in the decision-making process, the criteria should balance sufficient detail of the underlying problem with sensitivity to changes in the environment or in system elements.

Methodology

From a methodological stand point, the first stage of the paper was defining the hierarchy. The decision objective is the selection of a strategy for critical infrastructure protection, in essence, a form of dealing with complexity. The criteria are derived from the main characteristics of the underling infrastructure systems and define the decision space. The criteria and their importance are presented separately in the third part of this paper, but are the main components of the numeric application and determined the format of the questionnaire sent to the experts. The third layer of the hierarchy is left open ended.

The second stage was expert selection and organizing individual sessions to obtain the pairwise comparisons. To this effect, a custom electronic questionnaire was designed and shared, together with a document explaining the criteria and evaluation procedure. The participant selection process was centered on maximizing the relevance of the final results by providing an extensive perspective through diversification of backgrounds and expertise, as well as mitigating potential biases that arise from the experience and education of each expert. Considering the contents of the questionnaire, the expert elicitation process is a simplified version of the technique proposed by Ayyub M. Bial (2001). Among the 5 main types of experts classified by Ayyub: proponents, evaluators, resource experts, observers and peer reviewers, our participants are evaluators, as they asses the credibility of presented comparison hypothesis, offer input based on experience and education and establish qualitative relationships among the concepts that comprise de object of analysis. Each expert input has the same weight in the final result. While the experts requested to remain anonymous in this study, their expertise and background is presented below.

Table 1: Individual background profiles of study participants

Expert	Background
Expert 1	Sector of origin: ITC Position: Senior programmer Expertise: Various software applications, automation, hardware programming Blockchain experience: Yes, personal investments
Expert 2	Sector of origin: ITC Position: CEO of a company with over 200 employees

	Expertise: High complexity hardware and software projects, including applications for critical infrastructure Blockchain experience: No
Expert 3	Sector of origin: Academic, Government Position: Former high-ranking government official, currently university teacher Expertise: Risk management, Security research, Communication, Foreign Affairs Blockchain experience: Limited
Expert 4	Sector of origin: Academic, Scientific Research, Engineering Position: Associate Professor at various American and European Universities, member of research organizations Expertise: Infrastructure systems modelling, risk analysis, emerging technologies, critical infrastructures Blockchain experience: Yes, through research
Expert 5	Sector of origin: Military, Government Position: High ranking official in office, secretary of state level, Former expert in various EU institutions, former adviser in the Romanian Ministry of Defense Expertise: International relations research, public administration policies, political sciences, Strategic consultancy Blockchain experience: Undisclosed

The pairwise comparisons were conducted using the Saaty value scale, described below. Judgements on the Saaty scale are characterized by reciprocity. If activity a compared to b has a value from 1 to 9, then the inverse statement is a reasonable assumption. This is expressed by constructing a decision matrix A = (a_{ij}), where a_{ij} signifies the dominance of criterion i over criterion j, the reverse being respected through a_{ij}= 1/ a_{ji}.

Table 2: The fundamental Saaty value scale

Intensity of importance	**Definition**	**Explanation**
1	Equal importance	Two activities contribute equally to the objective
2 **3**	Weak Moderate importance	Experience and judgment slightly favor one activity over another
4 **5**	Moderate plus Strong importance	Experience and judgment strongly favor one activity over another
6 **7**	Strong plus Very strong or demonstrated importance	An activity is favored very strongly over another; its dominance demonstrated in practice
8 **9**	Very, very strong Extreme importance	The evidence favoring one activity over another is of the highest possible order of affirmation

Source: Adapted from Thomas L. Saaty, Luis G. Vargas, Models, Methods, Concepts & Applications of the Analytic Hierarchy Process, pg. 6

The third stage of consisted in doing the numerical analysis with a specialized application for AHP in order to derive the priorities and weighs for each criterion. We used an implementation proposed by Klaus D. Goepel (2013) that allows consolidating sufficient inputs and provides transparent calculations for verification. Identifying the weight of a criterion is a problem of linear transformation, more precisely solving the eigenvalue problem for a matrix of ratio comparisons. The solution arises from the assumption that priorities with respect to each criterion are known, so that the initial comparison values can be recovered by deriving the vector of priorities. An easy approximation is obtained through the normalization of the geometric means of the rows (Row Geometric Means Method, or RGMM). A more accurate solution is obtained by using an algorithm for raising the matrix to a sufficiently large power to determine the eigenvector (EVM method). The AHP implementation

proposed by Goepel uses the power iteration algorithm to solve the eigenvalue problem (Larson, 2013). Additionally, see Andrilli & Hecker (2016). We use both approaches to aid consistency calculations.

To determine the consistency of the data, that is the transitive property of judgements, the largest principal eigenvalue of the matrix, λ_{max}, must be calculated. The closer the value is to the number of criteria, the less overall deviation for the judgments. For numerically determining the consistency across all judgments an index can be defined using the following relation:

$$C.I. = \frac{\lambda_{max} - n}{n - 1}$$

Saaty furthers this with the Consistency Ratio (C.R.) obtained by comparing the index with an average consistency index derived from a sample of randomly generated reciprocal matrixes using the Saaty scale. In our particular case, the Random Index used as comparison is valued at 1,25, corresponding to matrix of rank 6. The application we employ uses a formula for C.R. perfected by Alonson / Lamata (2006):

$$C.R = \frac{\lambda_{max} - n}{2.7699n - 4.3513 - n}$$

For additional consistency validation, the Geometric Consistency Index (G.C.I.) is calculated (Williams and Crawford, 1985; Aguaron and Moreno-Jimenez; 2003), but by estimating the vector through RGMM. This does not detect individual errors, but offers an additional heuristic indicator to test whether the comparison matrixes are acceptable or not. The formula following formula is used:

$$ICG = \frac{2\sum_{i<j} \ln a_{ij} - ln\, {}^{p_i}/_{p_j}}{(n-1)(n-2)}$$

Saaty suggest a threshold value for CR of 0.1, however other implementations have determined that this value is unrealistic, especially for applications with more than 5 criteria. To this effect, we have used 0.15 as a value of testing the consistency with the CR. CGI is a direct analogue to the consistency ratio, Aguaron and Moreno-Jimenez (2003) suggest an estimate maximum value of 0,555 for a matrix with more than 4 criteria to pass the consistency test.

Apart from these two main consistency descriptors, we also analyze the overall dissonance of the matrix. The dissonance indicator ψ (Psi) reflects ordinal inconsistencies in the comparisons, and its calculation is done following the methodology propose by Sajid Siraj (2011), with the following set of relations:

The function is defined: $step(x) = \begin{cases} 1, if\ x > 0 \\ 0, if\ x \leq 0 \end{cases}$

The following matrix is compiled $\psi_{ij} = \frac{1}{n-2}\sum_k step(-\log(a_{ij})\log(a_{ik}a_{kj}) > 1$

Overall dissonance is determined by the following relation.

$$\Psi = \frac{2}{n(n-1)}\sum_{i=1}^{n-1}\sum_{j=i+1}^{n}\psi_{ij}$$

All 5 individual matrixes have been verified for consistency with both methods, while dissonance was interpreted in conjecture with the variation of the priorities. As the objective of the paper is unaffected by the need for absolute ordinal consistency, no particular thresholds have been appointed.

The final stage of the methodology consisted in determining whether the obtained consolidated priorities and weights are representative for the opinions of the experts. One of the main uses of AHP applications, as an objective mathematical method, is for informed group decisions. That all opinions are incorporated in the result does not guarantee acceptance by the participants. To validate the decision-making framework, a consensus indicator must be determined to increase the likelihood that opinions are accurately reflected in the final decision model. The approach is a departure from the classic dispersion analysis proposed by Saaty and Vargas, with a framework proposed by Lou Jost (2006) inspired by biological diversity. The assessment is made through a diversity index determined as a measure of homogeneity of priorities appointed to each criterion. The concept of diversity can be partitioned into two distinct components determined as Shannon entropy, (1949): specifically, alpha,

the average entropy for all individual participants of the group and beta, as the difference between aggregated group priorities entropy and alpha entropy. A small variation of the distribution of priorities between the experts will relay a high consensus indicator.

The criteria and their importance

A defining step for any AHP analysis is criteria formulation, as they define the decision space and influence the final decision. An effective tool for the decision maker offers the possibility to understand the problem, the purpose of the decision and to correctly evaluate the alternatives. For a proper comparison and ranking, it is necessary that the wording of the criteria covers how the decision will impact the stakeholders and all implementation interactions. A correct assessment involves a wide range of interactions, processes and implications, which determines the need to include both tangible, measurable and intangible criteria. The main factors considered for establishing the criteria in this study are the development, operation and maintenance of infrastructure, under the following premises:

a. The criteria are not expressed in absolute terms (admitted / rejected). The format allows comparisons between various decision-making options.

b. The criteria must correspond to specific objectives subordinated to the general decision objective.

c. The decisional problem implies the formation of some correlations between the analyzed alternatives and the formulated criteria. In our situation, the relationships are formed according to a "top-down" process, i.e. from criteria to alternatives, so that the decision-making apparatus has the possibility to identify the relevant alternatives.

d. The criteria and the resulting hierarchy must be sufficiently extensive to include all major issues that may affect the implementation of the solution, from the decision-maker's perspective, and detailed enough to allow for timely changes.

e. Further examination on costs, patrimonial impact and the resource management dynamics is required as a secondary problem for each choice.

f. It is reasonable to assume that successful implementation of the final decision is contingent on the competence of the involved parties.

Considering the above premises, the following criteria have been considered in the configuration of the AHP application:

1. Financial aspects of the project

The comparative evaluation of the solutions and strategies from this perspective will determine whether the projects are financeable and sustainable after the implementation duration. For a comprehensive analysis, the following information can be considered: initial set-up costs, operating and maintenance, budget availability, revenue generation, net present value, if the operation of the underlying infrastructure is supported from a public budget or is financially autonomous.

Evaluation involves drafting and implementation of a methodology by which a suite of indicators can be consolidated in a general index or score allowing for pairwise comparisons of alternatives.

2. The human component

This criterion is related to the availability of adequate personnel with relevant technical and managerial competence. It also considers the organizational or expertise gap between the current state and the ideal one. The following issues are relevant:

- The need for substantial changes in the infrastructure management structure from the perspective of stake holders;
- The complexity of the necessary organization hierarchy;
- The need for programmers able to write code, to translate functionalities and policies into computer programs or smart contracts, with the ability to identify computer risks and potential consequences;
- The need (or absence thereof) for an active network management structure.

3. Public appeal and utility

This refers to specifications of the final solution that determine general public opinion in regards to actual usage. Among the evaluated aspects we mention the following:

- transparency - network transactions and stored information are traceable and independently auditable;
- anonymity and management of personal data;
- whether it has the effect of streamlining the use of public resources, simplifying administration or increasing accountability in the public sector;
- If it allows the optimization of the use of resources in the private sector (at personal level, at the level of a household or in a business);

4. Operational opportunity

This criterion refers to how the system is used after implementation. The degree and intensity of use of a system can be adversely affected by multiple factors, ranging from errors in tracing the fundamental architecture to mistakes in the implementation of the system itself. The evaluation will take into account:

- The risk that the established system will register low usage;
- The speed of transactions and the performance dependence on the underlying infrastructure usage level;
- The level of automation and autonomous execution and consensus conditions;
- System scalability and technological constraints;
- The existence of direct and predictable transaction costs;
- The risk of indirect transaction costs, including scalability issues;
- Overall system reliability
- How uncertainty factors can be identified; The ambiguity component includes both non-cognitive sources (statistical uncertainty, limited information, excessive simplification of working hypotheses) and cognitive sources (definition of working parameters in an infrastructure or protection system, qualitative aspects, human factors, etc.)

5. The consequence of failure

This criterion is concerned with assessing how the protection mechanism may deviate from the initial objectives. In particular, the focus is on adverse effects on the supporting infrastructure in the event of protection failure. These may include costs of deviating from the proposed objectives. Also, the integration of the strategy with the contemporary legal system implies the analysis of the legal implications in situations of failure through aspects such as:

- Whether or not there is a risk of ambiguity in the legal interpretation of the effects of a transaction;
- The extent to which the terms and conditions of use, as well as the general intentions of the strategy, are translated into code to avoid misinterpretation and the possibility of resolving a legal dispute.

6. Cyber security and resilience

This assessment will be done both in terms of risk and intrinsic characteristics of the used tools. At least the following aspects can be considered:

- the decentralized nature of transactions, the transfer and storage of information, the immutable nature of the distributed database;
- reversibility of transactions - whether or not it is possible and under what conditions;
- In the case of computer programs or smart contracts, problems related to the transposition in the code of the desired functionalities, respectively vulnerabilities regarding the manipulation and malicious execution of the code;
- The level of complexity of the contract and the existence of appropriate complexity management tools.
- The sensitivity of the system to the operating capacity of the IT infrastructure of the infrastructure manager / operator;
- Vulnerability and resilience to various types of cyber-attacks;

- The general level of maturity of the technology involved;

The Analytic Hierarchy Process Analysis

The inputs were used to construct decision matrixes, and priorities were computed for each expert with both methods, Row Geometric Mean Method and Eigen Vector Method via power iterations. Initial values for priorities p_i have been obtained by normalizing the geometric means of r_i values of n rank matrix A=a_{ij}, with the formula: $r_i = (\prod_{i=1}^{n} a_{ij})^{1/n}$

The *exp* function was used with the following relation (the value of *e* raised to the power of a number): $r_i = \exp[\frac{1}{n}\sum_{j=1}^{n} \ln(a_{ij})]$. Normalization was done using $p_i = {r_i}/{\sum_{i=1}^{n} r_i}$. Normalized values are error adjusted with the formulas proposed by Tomashevskii (2004):

$$w_{adjusted} = w_i * \cosh\left(\sqrt{\frac{1}{n-1}\sum_{k=1}^{n} ln^2\left(a_{ik}\frac{w_k}{w_i}\right)}\right)$$

Power iterations method was used to determine the eigen value considered for the final results.

Before consolidating the individual matrixes and computing the final weights of the criteria, each expert input was tested for consistency. Additionally, absolute errors were determined for each individual priority, so not to overlap with the error range. In the case of priorities determine via EVM, the following calculation was used to determine errors:

$$\Delta w_i = \sqrt{\frac{1}{n-1}\sum_{k=1}^{n}\left(\frac{n}{\lambda_{max}} a_{ik}w_k - w_i\right)^2}\ , \qquad where\ i = 1, \dots, n$$

To pass the error check test, the absolute error should be lower than the percentile value of the criteria weigh. Additionally, the mean relative error across all criteria was determined using $\boldsymbol{MRE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(\frac{\Delta w_i}{w_i}\right)^2}$.

This average is used to assess the overall error range for the matrix, although there is no particular threshold that needs to be met. Tables 3 to 7 synthetize the comparison matrixes for the five participants to the study, along with the primary consistency indicators. Supporting calculations are included in Annex 1.

Table 3: Decision matrix synthesis for Expert 1

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*	*RGMM*
1 - Fin	1	5	4	1	6	5	35.4%	19.0%	34.9%
2 - Hum	1/5	1	1/5	1/3	3	2	8.0%	4.1%	8.0%
3 - Util	1/4	5	1	1/3	5	7	20.1%	11.0%	20.6%
4 - Oport	1	3	3	1	3	4	26.8%	14.7%	26.5%
5 - Fail	1/6	1/3	1/5	1/3	1	3	5.8%	3.0%	5.9%
6 – SCyb	1/5	1/2	1/7	1/4	1/3	1	4.0%	1.8%	4.0%
	λmax=6,706	C.R.=11,3%	GCI=0,41	Ψ = 11,7%	MRE 52,1%				

For expert 1, a clustering phenomenon can be observed, with over 82,3% of the decision being attributed to 3 of the criteria. Feedback from this participant also mentioned the possibility that

preference for the criterion regarding consequence of failure to change depending on the specificity of the underlying infrastructure. The assumption made to provide this consideration was that for a particular infrastructure, failure mechanics are similar regardless of chosen strategy, hence a lower overall preference.

Table 4: Decision matrix synthesis for Expert 2

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*	*RGMM*
1 - Fin	1	1	1/2	1/2	1/3	1/3	10.0%	10.9%	8.9%
2 - Hum	1	1	3	3	4	4	35.9%	20.2%	38.8%
3 - Util	2	1/3	1	1	1/2	1/2	10.3%	3.8%	9.7%
4 - Oport	2	1/3	1	1	1/2	1/2	10.3%	3.8%	9.7%
5 - Fail	3	1/4	2	2	1	1	16.8%	6.1%	16.5%
6 – SCyb	3	1/4	2	2	1	1	16.8%	6.1%	16.5%
	λmax=6,749	C.R.=12%		GCI=0,42		Ψ = 20%		MRE 58,4%	

Expert 2 provided with results that are visibly less convergent with those of the other participants, making a clear hierarchy more difficult. Having the highest number of employees under direct supervision can be a reasonable explanation for the bias towards Human component. Additionally, there is an anomaly regarding criteria 1 with a high absolute error, but because preference distribution is relatively homogenous for all criteria apart from C2, and because the matrix passes the consistency test, it is not enough to warrant a re-examination of the pairwise comparisons.

Table 5: Decision matrix synthesis for Expert 3

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*	*RGMM*
1 - Fin	1	3	4	2	2	3	30.3%	3.4%	30.1%
2 - Hum	1/3	1	3	1	1/4	1/3	10.8%	7.4%	11.3%
3 - Util	1/4	1/3	1	1/3	1/3	2	8.2%	6.5%	8.0%
4 - Oport	1/2	1	3	1	2	3	20.8%	9.1%	20.9%
5 - Fail	1/2	4	3	1/2	1	1	17.9%	10.6%	17.5%
6 – SCyb	1/3	3	1/2	1/3	1	1	12.1%	8.9%	12.2%
	λmax=6,902	C.R.=14,4%		GCI=0,51		Ψ = 20%		MRE 60,3%	

The third participant to the study generated a clear hierarchy of preferences, despite coming closer to the consistency thresholds. Additional feedback included the recommendation for further steps to develop instruments for numerically quantifying infrastructure failure and associated risk.

The comparison matrix for the fourth expert relays a clear preference toward the financial criterion, and is the only one that includes judgements higher than 6. One of the arguments provided in the session pertains to past experiences with infrastructure projects adversely affected by sub-par financial performance. Additional feedback is given regarding extending the decision model with a separate methodology for this criterion, achievable by introducing a distinct layer in the decision hierarchy. Considering that for 4 of the 5 participants C1 was ranked highest is a strong incentive to pursue this line of research, achievable by enrolling a separate panel of financial experts and developing a performance index.

Table 6: Decision matrix synthesis for Expert 4

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*	*RGMM*
1 - Fin	1	5	4	5	8	7	47.3%	31.9%	46.7%
2 - Hum	1/5	1	4	5	5	6	24.7%	14.5%	25.3%
3 - Util	1/4	1/4	1	1/2	4	3	8.9%	4.4%	8.8%
4 - Oport	1/5	1/5	2	1	4	5	11.4%	4.7%	11.6%
5 - Fail	1/8	1/5	1/4	1/4	1	4	4.8%	3.0%	4.7%
6 – SCyb	1/7	1/6	1/3	1/5	1/4	1	3.0%	1.7%	3.0%
	λmax=6,817	C.R.=13%		GCI=0,46		Ψ = 10%		MRE 56,8%	

The fifth session resulted in consistent matrix data as well as feedback regarding formulation of the criteria, specifically the need to further detail potential impact in organization architecture, especially in government. Also, as a complementary tool to the AHP analysis, the expert suggested a study regarding uncertainty, how it can be better understood and how strategies can cope with it by design.

Table 7: Decision matrix synthesis for Expert 5

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*	*RGMM*
1 - Fin	1	5	3	1	5	6	34.4%	16.0%	35.0%
2 - Hum	1/5	1	4	1/6	1/2	1/3	6.8%	4.5%	6.6%
3 - Util	1/3	1/4	1	1/5	1/3	1/4	4.5%	3.1%	4.6%
4 - Oport	1	6	5	1	5	3	32.2%	11.5%	31.9%
5 - Fail	1/5	2	3	1/5	1	3	12.1%	7.6%	11.8%
6 – SCyb	1/6	3	4	1/3	1/3	1	10.1%	5.7%	10.1%
	λmax=6,835	C.R.=13,3%		GCI=0,47		Ψ = 20%		MRE 57,5%	

With all 5 matrixes passing the consistency tests, the data can be consolidated in a single decision matrix called C=c_{ij}. Consolidation is achieved by determining the weighted geometric mean of the values in the individual matrixes with the following formula:

$$c_{ij} = \exp \frac{\sum_{k=1}^{n} w_k \ln a_{ij(k)}}{\sum_{k=1}^{n} w_k)}$$

Consolidating the data leads to a clear distribution of preferences with lower absolute errors than found in the input data. Additionally, consistency indicators are improved significantly, apart from dissonance that remained unchanged. Mathematically, the consistency checks indicate that the pairwise comparisons were correctly done and transitivity of judgments is maintained across the matrix. This, however, is not sufficient to determine that the final results are acceptable as a decision-making framework.

Table 8: Consolidated decision matrix

Crit	*1 - Fin*	*2 - Hum*	*3 - Util*	*4 - Oport*	*5 - Fail*	*6 – SCyb*	*EVM*	*Absolute Errors*
1 - Fin	1.00	3.27	2.49	1.38	2.76	2.91	31.9%	9.3%
2 - Hum	0.31	1.00	1.96	0.96	1.50	1.40	15.7%	4.4%
3 - Util	0.40	0.51	1.00	0.41	1.02	1.39	10.4%	1.9%
4 - Oport	0.72	1.04	2.46	1.00	2.27	2.46	21.8%	3.5%
5 - Fail	0.36	0.67	0.98	0.44	1.00	2.05	11.6%	2.9%
6 – SCyb	0.34	0.72	0.72	0.41	0.49	1.00	8.6%	2.1%
	λmax=6,141	C.R.=2,3%		GCI=0,08		Ψ = 15%		MRE 23,8%

To assess the representative quality of these values, a consensus indicator must be calculated in order to measure statistical deviation of the mean compared to individual opinions. The software documentation establishes indicative thresholds for interpretation, <50% very low consensus, 50-65% low consensus, 65-75% moderate consensus, 75-85% - high consensus, and very high for over 85%. To characterize diversity, the diversity index S, based on alpha and beta Shannon entropy is calculated:

$$S = \left[M - \exp(H_{\alpha min}) \ / \ \exp\left(H_{\gamma max}\right)\right] / \left[1 - \exp(H_{\alpha min}) \ / \ \exp\left(H_{\gamma max}\right)\right]$$

Where $M = 1 \,/\, \exp\left(H_{\beta}\right)$ și $H_{\alpha\beta\gamma}$ is Shanon α, β, γ entropy of the priorities of all K participants, respectively:

Shannon alfa entropy: $H_{\alpha} = \frac{1}{K}\sum_{j=1}^{k}\sum_{i=1}^{N} -p_{ij} ln\, p_{ij}$

Shannon gamma entropy: $H_{\gamma} = \sum_{j=1}^{k} -(\frac{1}{n}\sum_{i=1}^{n} p_{ij}) ln\, (\frac{1}{n}\sum_{i=1}^{n} p_{ij})$

Shannon beta entropy: $H_{\beta} = H_{\gamma} - H_{\alpha}$

$H_{\alpha min}$ is determined via adjusting the values by the c_{max} scores according to the scale used: $H_{\alpha min} = -\frac{c_{max}}{N+c_{max}-1} \ln\left(\frac{c_{max}}{N+c_{max}-1}\right) - (N-1)\frac{1}{N+c_{max}-1} \ln\left(\frac{1}{N+c_{max}-1}\right)$

$$H_{\gamma max} = \ln(n)$$

To improve reliability of the study, two sets of data have been processed, in order to test the impact of the priorities of expert 2, whose opinion was further apart. After the calculations. the following values were obtained:

- 72.4 % consensus level for AHP 5 data;
- 83.5% consensus level for AHP 4 data.

Despite a somewhat drop of the consensus indicator on inclusion of all 5 experts, there is no rank reversal and priorities remain unchanged across the decision matrix. The graph below shows in bar form the weigh variation for each criterion. Solid bars reflect a drop in overall weigh, while empty bars an increase in weight. Vertical bars show min-max variations across all input data.

Figure 2: Weigh variation across the AHP analysis

Considering these results, one can deem with sufficient confidence that the final weight and priorities is representative of expert opinions and allow for a validation of the decision-making framework.

Conclusions

The availability of technology and innovative instruments with applications in critical infrastructure protection does not alleviate the initial decision problem. Considering the multitude of underlying infrastructure interactions and complexity of the systems, a multi-criteria decision-making approach can provide more insight selecting a better strategy. Using the Analytic Hierarchy Process method, a framework can be developed to aid decision makers in this respect.

For this study, a panel of 5 independent experts has been assembled to provided inputs for an AHP application. The selection of the experts was done to provide a wide expertise coverage as well as to mitigate potential biases. The six criteria have been phrased to best define the decision space and to allow pairwise comparisons of strategy candidates. Their importance is reflected in trying to convey a large spectrum of interactions, processes and implications in the underlying infrastructures, including both measurable and unmeasurable aspects.

The decision-making framework consisted in expressing the relative importance of the asserted criteria. The weight and priority of each was determined through pairwise comparisons, and tested for consistency. The final stage was determining whether the final result is indicative of individual opinions, and the consensus indicator suggests that the constructed decision model is sufficiently accurate to be used in a real-world decision-making scenario. Using such a tool could improve the probability of a decision maker to identify the optimal choice regarding a strategy design to increase de protection and resiliency of an infrastructure.

Table 9: Synthesis of AHP results

NR.	CRITERION	NOTATION	WEIGHT	RANK	EXPERT RANKS				
1.	Financial aspects of the project	1 – Fin	31.9%	1	1	6	1	1	1
2.	The Human component	2 – Hum	15.7%	3	4	1	5	2	5
3.	Public appeal and utility	3 – Util	10.4%	5	3	4	6	4	6
4.	Operational opportunity	4 – Oport	21.8%	2	2	4	2	3	2
5.	Consequence of failure	5 – Fail	11.6%	4	5	2	3	5	3
6.	Cyber security and resilience	6 – SCyb	8.6%	6	6	2	4	6	4

From a scientifical point of view, this study provides a tool for inferring the most important determinants in the success of an infrastructure protection solution. Additionally, it has practical and research implications, both for decision makers that seek a framework for developing complex strategies and for developers that seek to create and perfect instruments capable of meet high standards of real-world applications. By using an established multi-criteria decision analysis technique, the collected data was used to construct a decision framework suitable from an infrastructure complexity management stand point.

The results of the study provide a sufficiently clear ranking between criteria, with favorable consistency tests results as well as adequate representation power for individual judgements. The financial aspects of the underlying infrastructure strategy are clearly of the highest importance in any decisional selection process. The relative importance of cyber security and resilience was significantly lower than initially expected, indicating perhaps that such projects are feasible only in the context of robust informational infrastructure with instruments that have intrinsic security characteristics. Hence, there is lower operational burden in the project implementation, given pre-existing cyber security features. Another relevant finding is a degree of dependence between the human component and the financial aspects, with the final weight of latter including aspects that are specific to human resource problem. Thus, we can safely assume that the human component is of critical importance to the final result, but part of the problem is financial in nature.

This study also opened up addition research opportunities that could refine the framework and provide further insight into the subject matter. The most obvious is obtaining additional validation concerning the detail and coverage of the criteria. Also, applying real-world scenarios can provide the opportunity to conduct a sensitivity analysis. Finally expanding the decision hierarchy with a sub-level dedicated to the financial criterion, which is, incidentally, the one with the highest priority.

Abstract

The depopulation, corroborated with population ageing has made the Romanian rural areas vulnerable both from economic and social point of view. This vulnerability is acutely manifested within the agricultural sector due to shortage of personnel, limited financial resources and the effects of climate changes being more and more present. A possible solution for the revival of the rural area is represented by the establishment of agricultural cooperatives with the role of protecting and developing the production and the agro-food chain. Romania is at the beginning of a new road in the development of cooperation between farmers. Due to the increase in the acknowledgement degree of European and global cooperatives, many initiatives for the creation of new cooperatives have been performed in the last years. In this context it is important to understand the activity of modern agricultural cooperatives, the factors influencing it and their impact on agro-food producers, in order to identify and promote adequate policies ad legislative measures which would lead to a sustainable development of the rural area.

Keywords: Agriculture, Cooperatives, Romania

Introduction

The rural area has become more and more depopulated and aged demographically in the last years, which has systematically compromised the development tendencies (Lutz et al., 2008). The impact of these factors are intensely manifested in the economic, social and political system, being necessary a series of significant measures (Kholer et al., 2017; Șerban, 2012).

In the context of ensuring better living conditions, the international bodies have established a series of objectives named Sustainable Development Goals (SDGs) with direct impact on the reduction of poverty, starvation and inadequate exploitation of resources at global level (Townsend et al.,2018).

Food and Agriculture Organization (FAO) considers the sustainability of agriculture and food chain as one of the most important paths for the revival of the rural areas (FAO, 2018). For the

development of a sustainable agriculture, the role of cooperatives is essential (Aref, 2011; Stanciu et al, 2018).

At the same time, Wanyama (2014) highlights the importance of cooperatives in the process of reaching SDGs objectives, as they have been already activating in all sustainable development areas, as we have presented in Figure no. 1.

Supporting the association of farmers in order to consolidate the agro-food sector has represented a measure highly debated in Romania in the last years (Wolz et al, 2019).

Figure 1: Structure of the Food Supply Chain

Source: Chicago Council on Global Affairs

As can be seen in Figure 1, cooperatives are tools with which to better negotiate transaction prices. But their role is not limited to this, as they have major implications for the other components of the food chain.

The cooperation idea appeared in the second half of the 19th century in Romania, based on "apportionment of property and emancipation of peasantry" (Petrescu, 2013).

Although the cooperatives have made their mark since 1889 as founding member of the International Cooperative Alliance and have had a beneficial effect on the economic evolution of agriculture, they have reached the limit of the evolutional potential before the 1989 Revolution without having too many things in common with the Western cooperation principles (Cruceru, 2010; Petrescu, 2013).

After 1989, the agricultural production cooperatives had directly or indirectly self-bankrupt (by lack of usage and maintenance), destroying the local or regional investments, including those from agricultural infrastructure (cereal silos, irrigation systems etc.) (Schmitt, 1993; Florea et al, 2018).

One of the fundamental deficiencies of Romanian agriculture and of cooperatives was the inexistence of an adequate strategic program for the management and development of economy in general and especially for agriculture (Aceleanu et al., 2015; Schmitt, 1993; Lapusanu, 2010).

The export of raw materials and import of value added products after 1989 have contributed to the impoverishment of the rural areas and to decreasing the desire to activate in agricultural sector (Wolz et al, 2019). As no stable association alternative and no series of well defined principles had existed for almost 15 years, up to the implementation of the Cooperation Law in 2004, no significant progresses within Romanian agriculture have been registered (Lapusanu, 2010).

The main objective of the present study is to identify the steps taken, the appropriate measures and recommendations in order to improve the business of agricultural cooperatives and successful entrepreneurial development in associative forms.

The sustainable development of the Romanian rural area is closely related to the efficiency of the activity of agricultural cooperatives and agricultural companies in Romania. It is therefore necessary to establish a strategy to guarantee the socio-economic environment and long term viability of rural areas.

Methodology

The researches for the performance of the present article are based on fundamental and applicative aspects, starting from the specialty literature identified with the help of international databases: Scopus, Science Direct, Google Academic, ResearchGate.

The research was performed using key words such as: poverty, depopulation, agricultural cooperatives, Romania, social development, association and food chain.

After the description of the phenomenon, the following step was data collection from the websites of the Ministry of Agriculture and Rural Development (MARD), Ministry of Public Finance (MPF), National Trade Register Office (NTRO), the National Institute of Statistics (NIS) and Eurostat.

The legislative framework regulating the activity of agricultural cooperatives and the modifications performed in order to increase the agricultural cooperative's activities has been consulted.

Background Information and Data

Otiman (2012) ascribes the economic and social problems manifested at Romanian agricultural level and rural area on the expense of the agricultural company's structure. Accordingly, it is considered necessary the alienation from the concept of subsistence agriculture and rethinking the agricultural policy in order to some avoid undesired effects (Ciutacu et al., 2015).

The Romanian farmer faces also a series of difficulties in the trading of the production, the farm gate price being much smaller than the sales price to the final consumer. In other words, the added value does not return to the farmer. This assertion is supported by Eurostat reports (2019) according to which the evolution of the agricultural income is much smaller as compared to that of other sectors of the economy (Figure no. 2).

Figure 2: Evolution of agricultural income as compared to other economic sectors from Romania

Source: Eurostat

According to figure no. 2 we observe that the incomes realized in the agricultural sector in the period 2017-2018 remain constant compared to the evolution manifested within the other sectors.

The development of some short food chains can significantly contribute to increasing the value added in agriculture (Stanciu, 2015).

At the same time, the negative effects of the climate changes with direct impact on the productivity level of the agricultural sector bring into discussion the necessity of efficient management of agricultural lands. (Prăvălie et. al, 2020)

Romania faces phenomena like intensification and extension of drought and desertification due to natural and artificial causes (no irrigation). (Mateoc-Sîrb et. al, 2014).

In these conditions, MARD supports the association as a modality to protect small and medium farmers against the generated risks, as well as a method of social and economic development (MARD, 2015).

A series of authors consider the agricultural cooperatives as an instrument conferring the farmers the power to face the market challenges (Hendrikse and Bijman, 2002; Bijman et. al., 2012).

The agricultural cooperatives in Romania have been staggered throughout history, due to the implications of agricultural production cooperatives for people during communism, but also after 1989, due to the lack of legislation that should stimulate their development, without having any benefit against any type of private legal person (Lapusanu, 2010).

The bases of Romanian agricultural cooperatives were laid in 2004, through Law no. 566/2004 (Wolz et al, 2019). The law stipulates a series of benefits that have been effectively applied starting with 2019.
According to the data published on the website of the National Trade Register Office (NTRO), the period 2018-2019 represents a re-launch of agricultural cooperatives in Romania, as we presented in Figure no.3.

Figure 3: The number of established agricultural cooperatives per regions, according to NUTS II classification

Source: NTRO

There is an evolution in the sense of increasing the number of agricultural cooperatives, especially in South-West Oltenia where in 2018, 83 such entities were established.

Another major problem faced by agricultural cooperatives in 2018 was the accounting misunderstanding of the taxation of cooperatives. According to the provisions of Government Emergency Ordinance no. 79/2017, agricultural cooperatives with a turnover of up to one million Euros should have been taxed only on the profit made by the cooperative and not on the value of the income that was previously taxed.

The harmonization of the differences between the Tax Code, Law 566/2004 and the other legislative aspects has been carried out starting with 2017. By the beginning of 2019, the understanding of the way of taxing cooperatives as well as the granting of fiscal facilities was achieved.

The promotion of cooperatives by professional organizations and authorities, as well as the introduction of selection criteria that favor cooperatives when accessing European non-reimbursable funds, has led to the development of associative forms. At the same time a number of national

projects, such as Agricoop have had a positive influence in increasing the number of agricultural cooperatives. The program for consultancy services for agricultural producers proposed to establish and develop associative forms in the agricultural sector, with the ultimate goal of establishing 350 cooperatives (Agricoop, 2019).

Results and Discussions

Although the bases have been laid for the adhesion of agricultural producers to an agricultural cooperative in order to ensure the profitability of an agricultural exploitation no matter its dimension, there are still necessary some measures and time in order to create the space for the development of the modern cooperation system from Romania.

The Law no. 21 of 13th January 2019 has brought a series of improvements in the commercial activity of agricultural cooperatives which stimulates the association based on correct, transparent, stimulating principles, the efficiency of the cooperation activities and their trade in order to add value to the primary products of the members and supplies finished food products which will be sold directly to the consumer by cooperatives or by retailers.

Conceptually speaking, the Romanian cooperatives are still at the beginning of their operation, even though we compare them with the European ones which have been operating with the same principles for decades. In Romania, in the last 14 years, everything has started from scratch, being made small steps, but the cooperatives must be rebuild based on solid principles, granting special attention both to reconstruction and to recruitment of some capable persons and of course, staff. Law 566/2004 represents the initial moment from which the process of reconsolidation of agricultural cooperatives in Romania began. The first step is now made by encouraging the establishment of cooperatives as many as possible, which would lead to a period of rationalization, merger between them and the unavoidable extinction of those not operating due to various reasons. According to the legislation and the measures taken, this period of development and consolidation of the cooperative sector can be a reasonable one of up to 5 years or it can be extended.

Progresses had been registered in 2018 to this sense and the measures, sub-measures, projects and programs must be followed up in order to stimulate the association in efficient and correct agricultural cooperatives, which:

- Contribute to the optimization of the predominant production costs of the small and medium-sized farmers;
- Increase the accommodation degree of agricultural product offer in what concerns the quantity, quality and assortment at consumer's request;
- Lead to performance of joint investments which add value to the primary production, balancing the income from the food chain by generating economic value added for their members and more so, with a relevant economic activity, they resist on the market and develop;
- Distribute correctly the results of the cooperative according to the economic activity of each member;
- Approach the market volatility risks as compared to the individual sales activities of each producer;
- Contribute to the re-launching and socio-economic stabilization of rural areas by encouraging the development of agrarian structures integrated in the market flows and efficient from economic point of view;
- Offer services and information specialized to their members, which would be too expensive individually;

From legislation point of view, more conditions, criteria, measures of orientation and control have to be introduced in order to guide the cooperatives to the balance element, to ensure the patrimony of the cooperatives and the introduction of pecuniary measures for those which do not comply with the agriculture law.

Both the leaders of the agricultural cooperatives / branches / professional organizations and the State's institutions, by their representatives, should encourage and promote steady and transparent agricultural cooperatives with economic and social results, with history and which distribute equally the cooperative result according to the economic activity of each member.

The agricultural producers must understand that the national and EU legislation in agriculture area is in continuous change and it is essential to report certain irregularities they might face with, to join the cooperatives, industrial unions, specific professional organizations, to be involved actively in order to be able to cope with the competition, to ensure profit and have a social-economic impact on the sustainable development of the rural area.

Increasing the number of agricultural cooperatives is a good thing if efforts are made to make them work and develop according to the principles of cooperatives. It is also important to note how many of these cooperatives generate profit. Figure no. 4 presented the percentage distribution per year of agricultural cooperatives that recorded profit, loss or no activity.

Figure 4: The structure of cooperatives according to the financial results in the period 2015-2018

Source: Issued by the author, based on NTRO and MPF data

There is a decreasing trend of cooperatives without activity from 21.37% in 2015 to 19.42% in 2018. There is also a percentage increase in 2018 of cooperatives that registered profit compared to 2016 and 2017. The analysis showed that 51% of the cooperatives that registered a profit were established in the period 2016-2018.

Functionality is another issue as can be seen from the analysis on the data published on MPF website on the status of agricultural cooperatives at the end of 2018, corroborated with the information supplied by NTRO and presented in Figure no. 5.

Within the figure no. 5 were represented only those cooperatives that reported / submitted the financial statements in 2018. Reporting them to the total number of cooperatives, it is observed that only 47.88% of them submitted the financial statements to the Financial Administration.

Functional cooperatives are those having a turnover higher than 250 de euro, out of which the contribution of members is excluded. The pseudo-cooperatives are defined by Gertler (2011) as those entities being characterized by a minimum involvement of the members and with reduced socio-economic impact on the rural community.

Figure 5: Status of agricultural cooperative according to the financial statements of 2018
Source: Issued by the author, based on NTRO and MPF data

If we extend the analysis in Figure 5 and set a threshold of complex functionality represented by cooperatives that have a turnover of more than 25,000 euros, we will see that only 9.2% of the 654 cooperatives that submitted financial statements meet this criterion.

This threshold was estimated on the basis of the areas exploited and the average number of members corroborated with the obligation to market 50% of the production.

Conclusions

One of the factors of the certain progress in the sustainable development of agriculture and rural area is the construction and development of efficient and correct agricultural cooperatives, actors absolutely essential in the creation of predictable and everlasting value-added chains in the Romanian agriculture.

In the cooperative sector in Romania there is an evolution of the number of newly established agricultural cooperatives. But we consider that for their consolidation and operation at optimal parameters it is necessary an average period of 2-3 years from the establishment.

Fiscal facilities, financing programs and the adaptation of the legislative framework are the dynamic factors that encourage farmers to form cooperatives.

At the same time, a declining share of agricultural cooperatives between 5 and 10 years old has been observed. This is due to the difficulties in maintaining the homogeneity of the group and is a major problem in the development of cooperatives because these long-standing cooperatives should be the beneficiaries of large-scale projects starting from the experience they are supposed to have gained.

A good direction for the development of agricultural cooperatives in Romania is represented, in the opinion of the authors, by encouraging the establishment of agricultural cooperatives and supporting the functional ones. At the same time, special attention must be paid to non-functioning agricultural cooperatives, by making a selection of those that can be recovered and those that are not set up in accordance with the principles of cooperation.

Abstract

Rationale of the research was the observation on the dynamics of knowledge generated on Industry 4.0. Analysis of the number of scientific papers on the subject proved that it is exponentially growing. The research question that emerged after that analysis was: Is the knowledge generated by academics used to support companies willing to benefit from Industry 4.0 solution? The question was roughly answered after analysis of reports on Industry 4.0 implementation barriers. Lack of knowledge was recognized there as one of the main reasons for delaying decisions on implementation of Industry 4.0 tools and methods. That inspired authors to developing model of knowledge gap filling. Hence, the ambition of the paper is developing the model of knowledge gap filling. The methodology implemented encompasses causal diagrams and system dynamics.

Keywords*:* Industry 4.0, Knowledge Transfer, Causal Loops, System Dynamics

Introduction

Industry 4.0 is the topic interesting from both, academic and business perspective. Researchers model and analyse solutions that are then implemented by companies. The result expected are increased knowledge resources and improved competitive advantage.

Rationale of the research was the observation on the dynamics of knowledge generated on Industry 4.0. Analysis of the number of scientific papers on the subject proved that it is exponentially growing. The research question that emerged after that analysis was: Is the knowledge generated by academics used to support companies willing to benefit from Industry 4.0 solution?

The question was roughly answered after analysis of reports on Industry 4.0 implementation barriers. Lack of knowledge was recognized there as one of the main reasons for delaying decisions on implementation of Industry 4.0 tools and methods.

That inspired authors to developing model of knowledge gap filling. Hence, the ambition of the paper is developing the model of knowledge gap filling. The methodology implemented encompasses causal diagrams and system dynamics.

The paper is structured as follows: First section briefly introduces the dynamics of knowledge on Industry 4.0 generation and outlines barriers to Industry 4.0 implementation. The second presents knowledge dissemination models. The third section presents model of knowledge gap filling from qualitative perspective. The fourth gives quantitative model of the phenomena. The last section summarizes the paper, concludes the research and introduces further research opportunities. Authors expect to identify the manageable variables that can improve efficiency of knowledge gap filling process to formulate recommendations for academia on knowledge dissemination and for companies on cooperation with academia to not only to acquire knowledge but also to inspire and support research in their efforts of new knowledge generation.

Industry 4.0 Knowledge Development Dynamics

Industry 4.0 concept was designed to stimulate German industry and economy and soon it became universally, globally recognized approach discussed and implemented worldwide. Over the last nine (the concept was introduced in 2011) Industry 4.0 was defined from many perspectives and with various precision. Selected examples of the definitions are presented in the Table 1.

Table 1: Definitions of Industry 4.0 concept

Source/author	Definition
High-Tech Strategy 2020 plan	A paradigm shift from centralized to decentralized smart manufacturing and production. Smart production becomes the norm in a world where intelligent ICT-based machines, systems and networks are capable of independently exchanging and responding to information to manage industrial production processes.”
McKinsey and Company	The next phase in the digitization of the manufacturing sector, driven by four disruptions: the astonishing rise in data volumes, computational power and connectivity, especially new low-power wide-area networks; the emergence of analytics and business-intelligence capabilities; new forms of human-machine interaction such as touch interfaces and augmented-reality systems; and improvements in transferring digital instructions to the physical world, such as advanced robotics and 3-D printing
Industrie 4.0 Platform	The intelligent networking of machines and processes for industry with the help of information and communication technology
The Industrial Internet Consortium	The integration of complex physical machinery and devices with networked sensors and software, used to predict, control and plan for better business and societal outcomes
Boston Consulting Group (BCG)	A new digital industrial technology that is powered by nine foundational technology advances: big data and analytics, simulation, autonomous robots, horizontal and vertical system integration, the industrial internet of things, cybersecurity, the cloud, additive manufacturing, augmented reality
A. Merkel, OECD Conference (2014)	The comprehensive transformation of the whole sphere of industrial production through the merging of digital technology and the internet with conventional industry. In short, everything in and around a manufacturing operation (suppliers, the plant, distributors, even the product itself) is digitally connected, providing a highly integrated value chain
M. Brettel, N. Friederichsen. M. Keller, M. Rosenberg (2014)	A digitalization of product and processes through increased intelligence. It focuses on the establishment of intelligent products and production processes

R. Schmidt, M. Möhring, R. Härting, C. Reichstein, P. Neumaier, J. Jozinović (2015)	The embedding of smart products into digital and physical processes"
C. Toro, I. Barandiaran, J. Posada (2015)	An integration of complex machinery and devices, with sensor and software networks, used to predict, control and improve plan business and results in society
M. Hermann, T. Pentek, B. Otto (2016)	A holistic system of information technologies, people, machines and tools where CPS monitor physical processes, create a virtual copy of the physical world and make decentralized decisions
A. Sanders, Ch. Elangeswaran, J. Wulfsberg (2016)	An industrial revolution applying the principles of cyber-physical systems (CPS), Internet and future-oriented technologies and smart systems with enhanced human-machine interaction paradigms
J. Qin, Y. Liu, R. Grosvenor (2016)	A concept of manufacturing which consist of exchanged information and controlled machines and production units acting autonomously and intelligently in interoperable
R.Y. Zhong, X. Xu, E. Klotz, S.T. Newman (2017)	A holistic system combines embedded production system technologies with intelligent production processes to pave the way for a new technological age that will fundamentally transform industry value chains, production value chains, and business models
C. Santos, A. Mehrsai, A.C. Barros, M. Araújo, E. Ares (2017)	A comprehensive concept as well as a new trend in manufacturing (and relevant sectors) based on the integration of a set of technologies that enable ecosystems of intelligent, autonomous as well as decentralized factories and integrated product-services
A. Wortmann, B. Combemale, O.A. Barais (2017)	A vision of manufacturing in which smart, interconnected production systems optimize the complete value-added chain to reduce cost and time-to-market. It is the smart factory of the future, whose successful deployment requires solving challenges from many domain
J. Lu (2017)	An integrated, adapted, optimized, service-oriented and interoperable manufacturing process which is correlate with algorithms, big data, and high technologies

Source: Janik, A., Ryszko, A. (2018). Mapping the field of Industry 4.0 based on bibliometric analysis. Conference: 32nd International Business Information Management Association Conference (IBIMA) – Vision 2020: Sustainable Economic Development and Application of Innovation Management from Regional Expansion to Global Growth, At Seville, Spain

The definitions focus on digitization, intelligence and optimization, stressing various methods and tools to achieve these goals. With the development of technology, new solutions are considered, contributing to knowledge on Industry 4.0 development. The Industry 4.0 knowledge development dynamics as interesting phenomena, which was analysed with two parameters. Authors assume that there are two parameters that should be considered, namely the number of publications per year, and the number of citations. The first parameter was to show the size of the knowledge, while the second its impact on academic society.

Since the term "Industry 4.0" originated in 2011 from a German government project in the high-tech strategy, and it was first publicly introduced in the same year at the Hannover Fair scientific publications from 2011–2020 were searched with the term "Industry 4.0" in their title, abstract or keywords. The initial search for the defined basic concept of "Industry 4.0" included 4988 references in Web of Science Core Collection (Figure 1).

Figure 1 : Number of publications on Industry 4.0 topic (title, abstract, keywords: WoS core collection, March 2020)

The number of publications on Industry 4.0 is growing. The dynamics of the growth is presented in the Table 2. It displays the number of papers published and indexed each year, starting from 2011, and the increase in number of publications compared to the previous year and their share in the total number of publications so far.

The growth of the number of publications was the most dynamic in 2013-1016 period, after 2016 slight decrease in the growth rate is observable.

Table 2 : Dynamics of growth of publications on Industry 4.0 number over years (WoS core collection, March 2020)

Year:	Number of publications/years	Increase rate per year [%]	Share in total number of publications [%]
2011	0	-	0
2012	1	-	0
2013	12	1200	0
2014	35	292	1
2015	140	400	3
2016	429	306	9
2017	938	219	19
2018	1418	151	28
2019	1716	121	34
2020	299	17	6
Total:	4988	-	100

The publications are shared and the knowledge is disseminated which is proven by the citation count analysis, presented in the Table 3. The knowledge on Industry 4.0 spreads among academics, thanks to which it can be developed, improved and recognized by numerous environments, disciplines and industries.

Table 3 : Citation count for Industry 4.0 (WoS core collection, March 2020)

Results found	4988
Sum of the Times Cited	22054
Average Citations per Item	4,42
h-index	59

The average citations number per item is 4,42, which means that the publication spread in the academic world and contribute to generating new knowledge. The most often cited publication was referred to 528 times. The dynamics of growth of the number of citations (presented in the Figure 2) supports the thesis on growing interest in Industry 4.0 issues and proves the dissemination of knowledge between academics. The dynamics of growth is close to exponential, resulting in exponential growth of knowledge on Industry 4.0, its assumptions, methods and applications.

Figure 2: Number of citation of Industry 4.0 (WoS core collection, March 2020)

The knowledge is generated by academics at the high rate, which is the consequence of their scientific curiosity but also of the demand for knowledge that comes from industry willing to improve its performance with latest solutions. Nevertheless, the research show that Industry 4.0 solutions are not commonly implemented. The set of barriers for Industry 4.0 implementations is recognized and commonly accepted but the importance of the barriers differ on account of the country and region as it is economically driven. The list of the barriers is presented in the table (Table 4); the set presented encompasses the barriers to innovation implementation (general approach) and to Industry 4.0 implementation specifically. Authors believe that merging the sets is justified as solutions within Industry 4.0 are of a different character. Nevertheless, they are innovative in terms of both technology and organization.

Table 4: Barriers to Industry 4.0 implementation recognized by literature

CATEGORY	BARRIER	REFERENCE examples
Economic/financial	Lack of monetary resources	Kelley (2009),
	High investments required	Martinez and Briz (2000) and Frenkel (2003)

Source: own work based on Orzes G., Poklemba R., Towner W.T. (2020) Implementing Industry 4.0 in SMEs: A Focus Group Study on Organizational Requirements. In: Matt D., Modrák V., Zsifkovits H. (eds) Industry 4.0 for SMEs. Palgrave Macmillan, Cham

The categories identified in the table refer to resources: financial, human and technical, and to the culture and implementation process. The strength of the impact of the barriers is, as mentioned individual, based on situation in both micro-perspective (of a single company) and macro-perspective (of the economy in the region or country). The analysis of the barriers presented inspired authors to the

research on knowledge and competencies gap. Having noticed the dynamic increase in knowledge on Industry 4.0 represented by growing number of research and publications on the subject and identifying lack of competencies and knowledge as one of the barriers to Industry 4.0 implementation authors came with following research questions:

1. What is the mechanism of knowledge on Industry 4.0 dissemination and absorption?
2. What are the causes of the perceived knowledge gap?
3. How can the knowledge gap identified be minimized?

To answer the questions authors decided to implement causal diagrams for qualitative, descriptive model of knowledge dissemination and absorption development, and mathematical modelling and simulation for defining recommendation concerning knowledge gap minimization. The results of the research conducted are discussed in the subsequent sections of the paper.

Knowledge Dissemination – Theoretical Background

Much of the literature on economic growth in the last couple of decades has focused on the role of knowledge creation and diffusion. The theory of "endogenous growth" (see for example Romer, 1986 and 1990, and Lucas, 1988) is based on the idea of knowledge spillovers emanating from R&D.

Literature related with knowledge management covers among others such topics as knowledge transfer, knowledge acquisition, knowledge dissemination, knowledge sharing, knowledge technologies.

Evolutionary theory provides an appropriate analytical framework for better understanding of the processes of knowledge creation and dissemination. (See e. g. Metcalfe 1994, 1995; Cantner and Pyka, 2001; Smits et al., 2010) The main components of the necessary theoretical framework are incorporated in the theory of innovation systems (Carlsson & Stankiewicz, 1991).

Knowledge is the main transaction unit flowing through the structures of innovation networks. The knowledge-based view of the firm (Nonaka, 1991; Penrose, 1959) discusses that accessing external knowledge is required to improve the efficiency of innovations. Empirical studies suggest that the participation of organizations in innovation networks will not only speed the innovation process, but also bring them closer to obtaining new knowledge (Borgatti et al., 2013; Sternberg, 2000). Tacit and explicit knowledge represents the basic unit of transaction in innovation networks. Hence, the structure and dynamics of the network depend in great extent on the knowledge brought from each actor to the network and the representativeness of that knowledge to achieve innovation. The motivations of organizations to participate in collaborative innovation actions are related to the acquisition, assimilation and transformation of knowledge to accelerate innovation or to gain better competencies to improve their internal innovation process. (Batz A. et al, 2018)

Knowledge development refers to the accumulation of new knowledge for innovation, adaptation and achievement objectives of the organization. The organization accumulates knowledge from outside by renting (hiring a consultant and using his expertise for acquiring new acquaintance) or by buying (purchasing a society for the knowledge it holds) or from inside, through the dissemination of it from a particular source component and the development of existing sources.(Costache A. et al, 2017)
Whereas diffusion is the natural spread of ideas, dissemination is the conscious effort to spread new knowledge, policies, and practices to target audiences or the public at large. Despite numerous reviews and guidelines, a gap still exists in how knowledge is implemented and utilized (Green L.W. et al, 2014).

Dissemination is best described as the delivering and receiving of a message, the engagement of an individual in a process, or the transfer of a process or product. It is also helpful to think about dissemination in three broadly different ways, viz., dissemination for awareness, for understanding, and for action. Indeed, effective dissemination of a knowledge product will most likely require that it satisfy all three in turn: utilization is the goal (Ordoñez M. and Serrat O., 2009).

The sources of knowledge and the vehicles of dissemination of knowledge differ among high-tech clusters. Universities are anchors in the early phase of discovery-driven innovation. New knowledge creation tends to take place in large firms rather than universities. These firms tend to be connected to other large firms (suppliers of sub-systems and components), often via international networks through which knowledge is both created and shared via market-mediated processes. The role of universities is to supply skilled labor (Carlsson B., 2012).

Recently, scholars pay much attention on building knowledge dissemination model to investigate knowledge dissemination. Knowledge dissemination is a complex process that organizational global knowledge behavior is formed by the local knowledge interaction among individuals (Meng X.F. et al, 2004)

A wide range of approaches to knowledge dissemination is available. It is important that organisations choose an approach that is appropriate for the knowledge being disseminated and for the organisation's structure, culture and business goals (Kingston J., 2012).

Knowledge dissemination is crucial for progress in a discipline. It allows ideas, perspectives, and findings to collide—often spawning new advances that would not otherwise exist. It also allows ideas, perspectives, and findings to coalesce—as part of the fulfilling discipline's mission of making sense out of phenomena of interest. Researchers perceive Universities as one of the fundamental actors to guarantee the dissemination of knowledge and the development of competences related to the Industry 4.0 (Rios et all., 2017, Hadaś et al., 2020)

We can found numerous models, techniques describing how knowledge can spread and be disseminated. A number of qualitative and quantitative models have been developed to describe various aspects of knowledge dissemination in knowledge-based organizations, with or without intervention (see for instance, Kelliher et al. (2010), Chen et al. (2014), Su et al. (2018), Li et al. (2017), and Liu et al. (2017)).

Jiafu et al (Jiafu et al, 2018) developed an improved CA (cellular automation) model with heterogeneity to study the process and rule of knowledge dissemination in knowledge-based organizations. Their work investigated the process and mechanism of knowledge dissemination from the perspective of micro knowledge exchange among individuals, which can help decision-makers to forecast and monitor the trend of knowledge dissemination.

The European Institute of Innovation and Technology (EIT) will require effective structures for disseminating knowledge throughout the knowledge triangle of higher education, research and innovation. Knowledge dissemination schemes will need to be tailored to each context of application and to each class of intended recipients.

Entering the automatized era the dispersion of knowledge will increase and also an intensification of price competition has to be expected (Wilson and Doz, 2011). Thus, concepts like agile innovation or agile innovation process are emerging to respond to these new challenges (Similä et al., 2008; Wilson and Doz, 2011).

Model Assumptions

To answer the question on mechanism of knowledge on Industry 4.0 dissemination and absorption authors decided to develop the model based on causal diagram structure.

The first step of model development process was identification of the variables in the system and the relations between them. The objects and variables considered, together with brief description of their behaviour is presented in the Table 5

Table 5: Variables of direct knowledge gap filling model and their description

Variable	CHARACTERISTICS	TASKS of OBJECTS
Knowledge and competencies of companies	The scope of knowledge and competencies referred to covers Industry 4.0 issues, the **companies** considered are industrial companies, implementing innovation, striving to increase their competitiveness, adjusting to market requirements	Searching for innovation, implementing innovations, developing solutions (innovations)
Knowledge of academia	The scope of knowledge and competencies referred to covers Industry 4.0 issues, the **academia** is represented by Universities (Higher Education Institutions) and research centres generating knowledge	Conducting research on advanced solutions, innovation causes and barriers, developing innovations, innovation implementation methodology

The table focuses on the variables that when confronted represent the knowledge gap: the difference between knowledge available (represented by academia) and the knowledge acquired (represented by companies) is the gap. If companies were equipped with the knowledge available, lack of competencies would not be the barrier to Industry 4.0 solutions implementation. To minimize the gap, academia needs to disseminate knowledge and companies need to absorb it, so the process of knowledge transfer is required. The process of knowledge transfer requires defining some relations between objects. The relations identified are based on cooperation between academia and companies that takes form support provided by academia to companies when developing innovations with scientific expertise. There are programs (by local authorities, governments, UE etc.) financing such, cooperation and it can also take the form of joint industrial projects founded by companies themselves.

The dynamics of the relationship between the variables presented prompted the authors to present a model illustrating the knowledge transfer in the form of a cause-and-effect diagram. Visualizing relationships and, to some extent, their dynamics makes it easier to interpret the current situation and the consequences of changes in the system. Cause-effect diagrams consist of nodes representing variables and connections representing connections and relationships (Sterman J. D. 2000). Associations can be identified as unidirectional, which means that the observed changes have the same direction (S: same direction), or omnidirectional, which means that the observed changes have different directions (O: opposite direction). Because the observed changes are cyclical, the cause-and-effect diagram takes the form of a loop. Loops, in turn, can be reinforcing (R: reinforcing) or balancing (B: balancing), their orientation results from the feedback mechanism on which the relationship is based (Lopez-Caamal et al 2014). Unidirectional changes are a consequence of positive feedback between variables. In this arrangement, small changes are amplified by interrelated system components. Omnidirectional changes in balancing systems are a consequence of negative feedback between variables. Consequently, changes in one element of the system are balanced by changes in the opposite direction in the element associated with it. Using the above, embedded in the theory of systems, the author's approach illustrated the relationships between variables: level of knowledge represented by academia and level of knowledge represented by companies using a dynamic model in the form of a cause-and-effect loop (Fig. 3)

The lack of knowledge on Industry 4.0 perceived by companies as the barrier for Industry4.0 solutions implementation is being eliminated by cooperation with academia. The knowledge gap is filled in directly as presented in the figure 3.

Fig. 3: Direct knowledge gap filling, own source

The direct knowledge gap filling is driven by requirements of companies needing knowledge and innovation. It includes industrial projects and expertise provided by universities and its nature is determined by clear and comprehensive identification of needs. In this case, companies willing to implement or develop innovative solutions cooperate with academia on market basis, feeding it with data necessary to develop a solution. Product of such cooperation is customized to specific needs and requirements of companies. If the gap between expectations and products is recognized, it is immediately filled in. Knowledge flow is initiated by specified need; hence, it is pulled from both academia and industry. The relations presented are limited in time by project duration and the level of knowledge required is determined by project scope. The model presented refers to one aspect of relations between academia and industry – based on joint cooperation on developing and implementing innovative projects (Industry 4.0 scope).

Nevertheless, the relations between academia and industry can take other forms as well. One of them is via the students and alumni, equipped with knowledge by universities and employed by industry. Such relation is indirect. Consequently, more variables and objects need to be considered. Their presentation is included in the table 6

Table 6: Variables of indirect knowledge gap filling model and their description

Variable	CHARACTERISTICS	TASKS of OBJECTS
Knowledge and competencies of companies	The scope of knowledge and competencies referred to covers Industry 4.0 issues, the **companies** considered are industrial companies, implementing innovation, striving to increase their competitiveness, adjusting to market requirements	Searching for employees equipped with knowledge
Knowledge of academia	The scope of knowledge and competencies referred to covers Industry 4.0 issues, the **academia** is represented by Universities (Higher Education Institutions)	Providing educational offer for students, teaching
Knowledge of students/alumni	The scope of knowledge and competencies referred to covers Industry 4.0 issues	Acquiring knowledge from **academia** and using it in **companies**

The alumni are the intermediary with accumulated knowledge they were provided with and they are supposed to use in their work. The nature of the phenomena is more complex. Students during their courses are taught and trained, knowledge flow is pushed by academia. The expectations of industry and tasks to be performed are communicated to alumni/employees and this is the moment when the gap is recognized. According to research by Polish Ministry of Entrepreneurship and Siemens (Smart Industry, 2019) over 50% of engineers, working in industry think that educational offer is not well

adjusted to requirements of innovative industry (see Fig. 4.). They lack knowledge and understand that the knowledge they need was not provided to them during educational processes.

Fig. 4 : Managers' perception of adjustment of educational offer to requirements of innovative industry, Smart Industry Report, 2019

The indirect knowledge gap filling is through the University alumni, equipped with knowledge and working for industry. The indirect knowledge dissemination and absorption mechanism is presented in Figure 5. The model is based on the assumption that academia and other knowledge providers equip student with knowledge over the entire education process. Students absorb knowledge, and after their education process is finished, as alumni they start work. They are employed by companies, as they need human resources equipped with knowledge. Hence, through the alumni knowledge content provided by academia is confronted with task and expectations of industry, as presented in Figure 5.

Fig. 6: Indirect knowledge gap filling, own source

Size of the gap perceived by/within alumni is determined by the following factors: the range of courses offered by Higher Education Institutions and quality of teaching process (characteristics of academia), commitment (characteristics of students) and innovativeness of processes (characteristics of companies). The relations presented is long-term, as educational process takes time and over time is adjusted to available knowledge in the field and to the recognized requirements of industry.

The models developed show two mechanisms of knowledge on Industry 4.0 dissemination and absorption. The first is based on direct relations between academia and industry and knowledge flow focused on fulfilling predefined demand communicated by industry. The second is based on indirect relations and knowledge transfer through the alumni, who absorb knowledge from HEIs and disseminate in their work environment. The dynamics of knowledge gap filling is discussed in the next section.

Dynamics of Knowledge Gap Filling – Models and Simulation

The models presented in the previous section were based on the observed phenomena of knowledge gap perceived by industry (see Figure 4.0). The knowledge gap existence was proved by literature analysis (see Table 4). The research problems defined by authors are:

1. Identification of the causes of the knowledge gaps observed,
2. Identification of knowledge gap filling mechanism

The authors decomposed research problems basing on the following scenarios:

1. Knowledge gap filling is direct process, knowledge flows directly from academia to industry
2. Knowledge gap filling is indirect process, knowledge flows indirectly from academia to industry.

Considering the first scenario:

Knowledge is transferred from academia to industry to fill in the knowledge gap that arises from the need to develop or implement innovative solutions. The need to implement selected solutions within Industry 4.0 scope differs on account of a market, industry, company size. Authors identified the need based on research on polish companies (Siemens 2019). According to research results over 11% of SMEs plans to implement Industry 4.0 within the next three years (4,3% of micro companies, 10,0% of small and 16,0% of medium companies examined). The percentage of large companies considering Industry 4.0 implementation is close to 20,0%. The SMEs willing to implement Industry 4.0 more often operate in light industry (14,1% compared to 8,7% in heavy industry). These companies represent the need for knowledge on Industry 4.0. The process of knowledge gap filling is based on goal-seeking dynamics. The goal is predetermined knowledge level. It is based on comparison between knowledge required (academia's knowledge) and knowledge available (company's knowledge). The gap recognized is filled in by knowledge transfer during: customized trainings, consulting, industrial projects (corrective actions). The concept is presented in figure 7.

Fig. 7: Dynamics of gap filling: goal-seeking dynamic, own source

The loop dynamics shows that when considering the expectations and taking corrective actions, the knowledge gap can be easily filled in a given time period. The period differs because of corrective actions taken (training duration, consulting period or industrial project time range). The dynamics of the system is described by time-dependent Academia's (HEI: Higher Education Institution's) knowledge flow equation:

$$HEIs(t) = HEIs(0) - c_A \int_0^t (HEIs(t) - InExp)\, dt \qquad (1)$$

where:

$HEIs(t)$- *HEIs active offer* at the time (t),
$InExp$- *industry expectations,* expressing the knowledge gap bottom level,
c_A- *corrective actions*, determining the speed of knowledge transfer (here equal 1).

Equation (1) can be solved as a continuous time differential problem using numerical approximation procedures.

The resulting knowledge level in the enterprise is described with the following evolution formula:

$$K_n(t) = K_n(0) + c_A \int_0^t (HEIs(t) - InExp)\, dt \qquad (2)$$

The dynamics of the system is determined by corrective actions taken. The intensity of cooperation between Academia and Industry, disregarding the form could affect the time of knowldge gap filling. Hence, the recommendation to initiate joint projects and stimulate cooperation between the stakeholders.

The basic diagram of the simulation is presented in figure 9. It shows dynamics of gap-filling, increase of the knowledge $K_n(t) - K_n(0)$, over 120 months in case of continuous exchange of knowledge between enterprises, assuming that the initial knowledge of the company is about 10% of *HEIs* offer. Serie 1 describes a reference transfer with parameter$c_A = 1$.

As cooperation may take different form and be realized with various intensity, the coefficient of cooperation was introduced, to reflect the innovativeness of company, and consequently its need for expertise, the level of innovation coefficient was introduced. Considering flexibility of Academia emerging from knowledge it has and is able to generate, adjusting offer coefficient was introduced. The coefficients bring the model closer to actual causal relations within the system, as presented in Formula 3:

$$HEIs(t) = HEIs(0) - c_A \int_0^t c_C\, (HEIs(t) - l_I/a_L\, InExp)dt \qquad (3)$$

where:

c_C- *coefficient of cooperation*, expressing intensification of cooperation relative to the reference level,
l_I- *level of innovation*, estimates by fractional factor (≤1),
a_L- *adjusting offer,* estimates by fractional factor (≤1).

Level of innovation and *adjusting offer* ratio express mutual readiness to absorb knowledge provided (reference level of both coefficients is 1).

Figure 9 serie 2 represents the results for parameters $c_C = 2$and $l_I = 0.5$, which corresponds to the situation with intensified cooperation, while the lack of full conditions for absorbing innovation (lower level of adaptation). The transfer of knowledge is faster but it cannot be fully implemented.

Nevertheless, taking into account the operation mode of education system the process of knowledge gap closing or minimizing is disturbed by delays: in identification of divergences, as they are recognized after the students graduate, hence the feedback opportunities are limited. Moreover, there are some delays connected with designing and then implementing corrective actions. Thus, the Fig. 8 more likely reflects the gap filling dynamics.

Fig. 8: Dynamics of gap filling: oscillatory dynamics, own source

The delays make the knowledge gap filling more difficult, and time- and cost-consuming. To deal with them, identification of knowledge needs and corrective actions design and implementation need to be the processes carried on not only regular bases but also concurrent to providing education

$$t_K(t)HEIs(t) = HEIs(0) - c_A \int_0^t c_C\,(t_K(t)HEIs(t) - l_I/a_L\,InExp)dt \quad (4)$$

where the oscillation term $t_K(t)$with a period of 12 months was added.

Exp. (4) represents an extended form of the system's dynamics equation (1). The number of model parameters is significant and allows to model much more complex situations.

In the case of alumni activity a periodic factor overlaps with the basic knowledge absorption stream. On Fig. ZZZ serie 3 and 4 we observe fluctuation of gap-filling. It is connected with periodicity of the flow of alumni to industry, which however does not translate into well-established and absorbed knowledge transfer. The difference between series 3 and 4 results from the assumed smaller intensivity of HEIs-Industry cooperation $c_c$from 1 to 0.3

Fig. 9: Simulation of the knowledge gap filling, own source

The next step to consider in the model presented, is the relative importance of university-industry direct cooperation and through university graduates, which can express the size of the company and radiness to practic there by new graduates. An important necessary factor in subsequent research is also time delay in implementing innovations since the adoption of the concept of action, and in finding employment by alumni.

Conclusions

Contemporary economy generates numerous challenges for companies. Customers' requirements are changing immanently and these changes on one-hand follow technological changes, on the other induce them. The range and scope of changes in technology and management results in developing many methods and tools of different character but grouped under a flag of Industry 4.0. To implemented these innovative solutions companies seek for support. The most important aspects of the support respond to the need for financial resources and knowledge. Financial support can be obtained thanks to government programmes or EU projects and programmes and is not the subject of the paper. Knowledge support is provided by Academia and two models of knowledge gap filling were introduced in the paper. The first one assumes direct cooperation between academia and industry while the second is based on indirect relation via the alumni, equipped with knowledge by academia and using it in their work environment.

The models developed were presented from qualitative (descriptive) and quantitative perspective. The models are based on system behaviour archetypes recognized in the literature of the subject. Nevertheless, before they are used for further research, they will be validated by experts panel to identify potential deviations for archetypic behaviour. The expected outcomes from further research are practical, as authors strive for developing recommendations for companies and academia on forms and scope for cooperation, believing it could result in synergistic effect and make Industry 4.0 the solution vigorously spreading among companies.

Abstract

The purpose of the article is to identify and summarize the strategic factors of artificial intelligence having a particular impact on the development of the Polish banking sector. The SWOT analysis preceded by the conversations in panel discussions with specialists in the banking sector and study of fundamental static phenomena was used as the research method. The results of the conducted research indicate that institutions in the banking sector using AI tools represent an aggressive strategy. These institutions are development-oriented. 2020 brings a new conversational banking trend based on artificial intelligence. The publication is also enriched with an illustrated division of the possibilities of using AI in the Polish banking sector.

Keywords: Artificial Intelligence, Robotics, Financial Intermediation

Introduction

In the current era of robotization, artificial intelligence plays a significant role. Nowadays, this technology supports Polish economic activity and significantly affects the functioning of the entire society. Artificial Intelligence algorithms have improved many Polish industries, including a vital finance sector. The banking sector fully utilizes the potential of AI in its operations. Today's banks in Poland are not the same institutions as a decade ago. Today's banking customers are called mobile clients. According to data collected by PRNews.pl (2020) „in Poland at the end of 2019, the bank already served 13.9 million customers using smartphones. Such a large group of mobile banking users are people who operate the bank using applications, lite services and RWD (Responsive Web Design). The vast majority, because nearly 11 million use mobile apps."

The purpose of the article is to identify and summarize the strategic factors of artificial intelligence having a particular impact on the development of the banking sector. The secondary goal is to present a case study of artificial intelligence in the Polish banking sector. The implementation of the goals formulated requires verification of the following hypothesis:

• The most considerable changes taking place in the Polish banking sector in 2020 can be observed thanks to AI-based implementations.

The hypothesis formulated in this way was verified utilizing the SWOT matrix analysis comparing the most important factors affecting the current form of technology in the Polish banking sector. The review was preceded by the conversations in panel discussions with specialists in the banking sector and analysis of static vital phenomena. The article also includes a case study of artificial intelligence in Polish banking, which allows analyzing and evaluating the development of the current state of the discussed technology.

Artificial Intelligence in the light of theoretical considerations

According to the European Commission (2019) "Artificial intelligence refers to systems that display intelligent behaviour by analysing their environment and taking actions – with some degree of autonomy – to achieve specific goals. AI-based systems can be purely software-based, acting in the virtual world (e.g. voice assistants, image analysis software, search engines, speech and face recognition systems) or AI can be embedded in hardware devices (e.g. advanced robots, autonomous cars, drones or Internet of Things applications)."

In the report of the Polish Ministry of Digitization (2018) regarding the assumptions about the AI strategy in Poland, one can read that artificial intelligence is not a trend. Already 50 years ago, the first idea of its use emerged, but it was not until the 1990s that its first practical applications appeared, also in Poland. Initially, this did not translate into an economic breakthrough because then there was not enough data and computing power.

AI is understood as Artificial Intelligence interpreted in general perception by the Dictionary Cambridge as an IT department that focuses on creating developed machines/computers capable of performing activities intended for the human mind, and more specifically human intelligence, i.e. the ability to reason language or solve learning problems (2020). It is the definition introduced by McCarthy in 1956, who accurately described it as "the science and engineering of creating intelligent machines, especially intelligent computer programs" (2007). Since then, many new definitions of artificial intelligence have emerged. Nowadays, the division of artificial intelligence can be seen as narrow/weak and general/strong. In the article by Forbes the first one is to use AI for simple tasks or to solve simple types of problems. It is most often used in the form of voice assistants (e.g. Alex Amazon, Siri, Apple, Google Assistant or Microsoft Cortana). Thanks to that help, its users can manage their calendar, buy tickets or book various attractions. However, the general concept of AI is systems that can think independently, quickly and efficiently perform tasks on the same level as a human would do. General intelligence is characterized by generalized human cognitive skills that surpass people in almost any cognitive task (2019).

Depending on the participation of the human element in the AI paradigm, artificial intelligence may be interpreted differently. In the report by PwC (2017) by analyzing the term through the prism of specific systems, taking into account the human being, AI can be defined as Assisted Intelligence, namely a system that helps people in making decisions or their actions. In other words, they are wired systems that do not learn from their interactions. When the human factor is omitted, AI becomes the 2 basic version of Automation, i.e. automation that includes the elimination of manual and cognitive tasks that are routine for humans. However, when looking at artificial intelligence from the perspective of adaptive systems, the term AI becomes of Augmented Intelligence, i.e. systems that support human decisions by continually learning based on their interaction with humans and the environment. In the report of European Commission many (2019) AI applications, especially in the Polish financial sector, are Augmented Intelligence solutions, focusing on a limited number of intelligent tasks performed to support people in the decision-making process. In a research study by Pwc (2017) "if the human factor is subtracted in this case, AI will be called Autonomous Intelligence, meaning systems that can adapt to different situations and operate autonomously without human participation".

When mentioning AI concerning the banking sector, four basic areas of Artificial Intelligence implementation in a financial institution cannot be omitted: data management, technological infrastructure, organization and management, and analytical methodology.

The four areas mentioned are related to each other to form a coherent whole. In the publication by the European Commission (2019) the data management area allows the financial institution to control data used for the enterprise's purposes. To manage data efficiently, you should have information about where the data is located, where it comes from, and who has access to it. The area of technological infrastructure according to the American National Institute of Standards and Technology (2018) is divided into three components: infrastructure - responsible for network resources, data platform -

responsible for data management, processing - responsible for data processing according to their volume. Another important area is organization and management, whose task is to establish management procedures and measures and to develop skills and knowledge. The last area is the analytical methodology, developed to the implementation and adopt the process of building advanced analytical solutions.

AI analysis by the SWOT matrix method

SWOT Matrix Methodology

SWOT analysis is currently one of the most popular methods of strategic management. Its origins date back to the 1950s, and its procedure and scheme derive from a somewhat more complicated tool, which is K. Lewin's field strength analysis, which assumes that every behaviour is a resultant of two types of forces: driving and braking. In the research study by Nowicki (2015) rightly states that "SWOT analysis, being a simplified tool, retains, however, extremely high practical utility, being a 3 solid, flexible and relatively easy to use strategic analysis tool". In a book by Gornaczewski and Puciato (2010) this analysis can be used to create a development strategy (the so-called overall strategy) and a functional strategy (the so-called fractional strategy), which relates to a specific function to be performed by the state, local government units or an enterprise. Opposite to the generally accepted theory, Gierszewska and Romanowska (2002) argue that SWOT analysis is not a strategic analysis method, but is „a unique algorithm of the strategic analysis process, a system proposal and a broad assessment of external and internal factors that determine the current state of the enterprise and its development potential.”

Korczak (2010) emphasizes in his publication that "the SWOT technique is very widely used, especially in the initial stages of strategic planning". Determining the strengths and weaknesses of the methods of examining the role of Artificial Intelligence in the banking sector is a diagnostic part of the analysis, while determining potential opportunities and threats is its prognostic part.

Analysis of financial institutions in the banking sector using AI technology

The source of data used was information obtained from conversations during discussion panels as the conference between the meeting leaders and experts in the area of new technology in the financial sector. The data comes from presentations prepared directly by the advisers of Polish financial institutions and many reports, both Polish and English, thanks to which the internationalist overtones of the conducted research are given. This article carried out a SWOT matrix study to identify and summarize the strategic factors of artificial intelligence, having a particular impact on the development of the Polish banking sector. An internal analysis was carried out, detailing the strengths and weaknesses of Artificial Intelligence, and an internal analysis that allowed to determine the opportunities and threats arising from the role of AI in the Polish banking sector. The assessment of individual factors was divided into stages. Initially, all the strengths and weaknesses of banking sector institutions that use AI as well as opportunities and threats appearing in its environment are listed. Then, each group of factors was assigned weights, which after summary gave 1. Weights were given depending on the impact on the entire economy. Then, factors were assessed using a 9-point scale depending on their impact on the banking sector under study. The products of weights and scores for individual factors and weighted averages for individual groups were calculated (Kadłubek and Ingaldi, 2016).

Table 1: SWOT analysis of financial institutions in the banking sector using AI technology

STRENGTHS	WEAKNESSES
1. Saving bank labour costs 2. The institution's strong position in the financial market 3. High efficiency of the financial institution's operations 4. Elimination of bank employees' mistakes 5. High employee satisfaction 6. Fast and secure integration with other operating systems 7. Redirecting employees' processing capacity for more important tasks	1. Constant updating of processes to obtain the highest efficiency 2. Constant supervision of safety standards 3. Implementing new people in projects 4. Constant supervision over the process of impressing AI 5. Loss of important employees 6. Insufficient return on investment 7. The requirement of professional AI implementation due to her first contact with the client
OPPORTUNITIES	**THREATS**
1. Possibilities for further cost reduction 2. Reaching customer segments previously unavailable to the bank 3. Acquiring new valuable employees in line with the bank's business profile 4. Reducing the scale of fraud in the banking sector 5. Maximizing the security of banking customers by implementing the latest biometrics tools 6. Quick detection of so-called "Bad customers" 7. Bank fraud prevention	1. The emergence of more advanced technology 2. Privatization of new technology (AI) 3. Possible resistance from recipients in the implementation of new technologies (public reluctance) 4. The reality is faster than the law - the legislation is not keeping pace with the introduced changes 5. Misunderstanding by external recipients 6. Competitors can easily duplicate the AI model 7. New cyberattacks in the banking sector

Source: own processing

Tables 2-5 present a summary of individual groups of factors that affect the strategic position of the banking sector under study using AI technology.

Table 2: Classification of strengths of the surveyed banking sector institutions using AI technology

Lp	Element	Weight	Rating	Product
S1	Saving labour costs of the financial institution	0,15	6	0,9
S2	The institution's strong position in the financial market	0,2	9	1,8
S3	High efficiency of the financial institution's operations	0,2	8	1,6

S4	Elimination of employee errors	0,1	8	0,8
S5	High employee satisfaction	0,1	5	0,5
S6	Fast and secure integration with other operating systems	0,15	6	0,9
S7	Redirecting employees' processing capacity for more important tasks	0,1	5	0,5
		weighted average		**7**

Source: own processing

Table 3: Classification of weaknesses of the surveyed banking sector institutions using AI technology

Lp	Element	Weight	Rating	Product
W1	Constant updating of processes to obtain the highest efficiency	0,1	5	0,5
W2	Constant supervision of safety standards	0,25	8	2
W3	Implementing new people in projects	0,05	5	0,25
W4	Constant supervision over the process of impressing AI	0,1	5	0,5
W5	Loss of important employees	0,2	7	1,4
W6	Insufficient return on investment	0,15	6	0,9
W7	The requirement of professional AI implementation due to her first contact with the client	0,15	7	1,05
		weighted average		**6,6**

Source: own processing

Table 4: Classification of opportunities of the surveyed banking sector institutions using AI technology

Lp	Element	Weight	Rating	Product
O1	Possibilities for further cost reduction	0,05	6	0,3
O2	Reaching customer segments previously unavailable to the bank	0,2	8	1,6
O3	Acquiring new valuable employees in line with the bank's business profile	0,1	7	0,7
O4	Reducing the scale of fraud in the banking sector	0,15	9	1,35
O5	Maximizing the security of banking customers by implementing the latest biometrics tools	0,2	9	1,8
O6	Quick detection of so-called "Bad customers"	0,15	8	1,2
O7	Bank fraud prevention	0,15	9	1,35

			weighted average	**8,3**

Source: own processing

Table 5: Classification of threats of the surveyed banking sector institutions using AI technology

Lp	Element	Weight	Rating	Product
T1	The emergence of more advanced technology	0,1	7	0,7
T2	Privatization of new technology (AI)	0,1	4	0,4
T3	Possible resistance from recipients in the implementation of new technologies (public reluctance)	0,1	7	0,7
T4	The reality is faster than the law - the legislation is not keeping pace with the introduced changes	0,15	8	1,2
T5	Misunderstanding by external recipients	0,15	6	0,9
T6	Competitors can easily duplicate the AI model	0,15	8	1,2
T7	New cyberattacks in the banking sector	0,25	9	2,25
			weighted average	**7,35**

Source: own processing

Based on tables 2-5, a point has been determined that refers to the strategic position of the Polish banking sector, which will indicate the directions of its future strategic plans (Fig. 2). This point was determined according to the formulas as follows:

Y = | strengths | - | weaknesses | = 7.00 - 6.60 = 0.40

X = | opportunities | - | threats | = 8.30 - 7.35 = 0.95

Fig. 2: The strategic position of the surveyed banking sector institutions using AI technology

Source: own processing

Based on the analysis carried out, it appears that institutions in the banking sector using AI technology are in the most favourable position. Opportunities prevail, and their strengths prevail within them. Aggressive strategy (maxi-maxi) is based on the maximum use of opportunities and strengths to develop dynamically. For the examined institutions, the solution to success is diversified development.

Analyzing individual areas can be seen that the area of opportunities at the disposal of the surveyed institutions had an extraordinary impact on the results obtained. In particular, the highest ratio is assigned to areas related to the security of both customers and bank security, namely: maximizing the security of banking customers by implementing the latest biometrics tools (9), minimizing the scale of fraud in the banking sector (9) and preventing bank fraud (9).

It should also be noted that the aggressive strategy received is not placed very high. This is due to equally strong positions in the areas of weaknesses and threats, namely the possibility of new cyberattacks in the banking sector (9), situations in which legislation cannot keep up with the changes introduced by AI in the banking sector (8), and the ease of duplication AI tools by competitors (8) and constant supervision over maintaining security standards in a given institution (8).

Case study AI in the Polish Banking Sector

The banking sector is one of the more active sectors in the Polish economy using AI in its operations, although, according to experts from Bluemedia (2020): „the real change that will soon take place in Polish banking is still waiting around the corner. The implementation of the PSD2 directive will accelerate this process." Artificial intelligence ranging from detecting credit fraud, increased risk to customer experience allows you to increase the efficiency and precision of human effort making the bank more profitable.

In the research study by SAS (2020) AI in Polish banking is implemented primarily to combat fraud and financial crime, credit and regulatory risk management, improve customer service quality and generate sufficient capital. Institutions using AI tools quickly identify fraudulent transactions in real-time, protect revenues and reduce bank costs, detect good and bad clients in real-time by providing information about changes and inconsistencies in their clients' behaviour patterns.

Figure 3 illustrates the possibilities of artificial intelligence divided into three principal categories, namely: the criterion of security, consulting and communication.

Fig. 3: Case study AI divided into categories

Source: own processing

The first of these is responsible for both customer and bank security. Anti-money laundering is a great solution - AI can monitor transactions related to money laundering and terrorist financing. Elimination of fraud by detecting and preventing fraud in real-time is another critical area. Risk management is one of the bank's primary tasks while using AI it becomes more effective through proactive management using a comprehensive risk management environment.

Another criterion applies to both investment, credit and insurance consulting by offering support to advisers using specialized computer programs based on machine learning

The last area is communication, which is mostly focused on first contact with the bank's client. Nowadays, many banking institutions offer widely used bots, among others to recruit, modern VR (Virtual Reality) leaflets are created, and useful landing pages are created.

Conclusion

Changes taking place in the banking sector in 2020 can be seen thanks to AI-based implementations. A thorough SWOT analysis was carried out, which made it possible to identify and summarize the strategic factors of artificial intelligence, having a particular impact on the development of the Polish banking sector. This analysis indicated that banking institutions in Poland using AI tools in their activities adopt an aggressive strategy. The chances of artificial intelligence tools have surpassed other areas in the Cartesian system. It is worth paying attention to the most important possibilities of using AI tools, which are mentioned by world experts, above all, the security of banking customers through the implementation of the latest biometrics tools. It should not be forgotten that AI in Poland is just gathering momentum. A new trend that is developing in banking this year is the automation of customer service and the so-called conversational banking, which uses bots presented in Fig. 3.

The presented proposal is a narrow area of research carried out by the author. It should be added that the analysis and illustrated areas of using AI tools by the bank are valuable information, but they do not fully cover the issues raised. The research methods used are characterized by high subjectivity, but they can be a starting point for further strategic analyzes.

Development of Smart Contracts in The Process of Automation of Blockchain Projects

Agnieszka K. WASIK

University of Szczecin, Doctoral School,
Mickiewicza 16, 70-383, Szczecin, Poland,
Institute of Economics and Finance,
e-mail: agnieszka.wasik@phd.usz.edu.pl
ORCID: 0000-0002-3347-0936

Abstract

In the last few years there has been a dynamic development of smart contracts and the process of project automation based on blockchain technology. The purpose of the article is to present the global market for smart contracts and blockchain technology from 2016 to 2025 and the role of smart contracts in the process of automation of blockchain projects. The analysis was based on a report published by Market Research Future (2020) and Global Market Insights (2017) as well as the study of English-language article items. The article presents the benefits of using smart contracts and blockchain technology. These include increased customer satisfaction, increase in overall level of security, reduction of internal costs of the company, as well as increased awareness of end-users using automation processes of their services.

Keywords: Smart Contract, Blockchain Technology, Blockchain Project

Introduction

According to many opinions and interviews of financial industry experts, smart contracts show large potential, especially in emerging financial markets. A smart contract is a software used to carry out transactions in a given blockchain. In the article by Blockchain, smart contracts, and DAO (2016) transactions are carried out by a distributed network node, which greatly facilitates its use, by eliminating a third party, such as an intermediary or a court. Smart contracts play a significant role in the process of automation of blockchain projects. The creators of blockchain projects encounter obstacles in obtaining funds for their development in the environment, taking into account future potential recipients. Financing is often carried out using "ICO", which is the release of a specific crypto token on a public blockchain and its sale to anyone interested. The process of automating the blockchain project brings measurable benefits due to the use of the consensus phenomenon. This mechanism commits transactions and adds new blocks to the chain that are executed by blockchain network node software. Traditional solutions do not provide such a spectacular solution, because a third party is necessary. The article Blockchain - technological aspects and examples of applications (2020) states that the combination of these mechanisms is an agreed, automatic consensus of network nodes.

The concept of Blockchain Technology

Website - Business Insider (2020) informs that "blockchain technology is used to store and send information about transactions concluded on the internet. These transactions are arranged in consecutive data blocks. Each block contains information about a specific number of transactions. After filling it with transaction information, another data block is created, followed by the next and next block. This creates a kind of chain (hence the name: blockchain is a block chain). A new block appears on average every 10 minutes. It may contain information about various transactions, e.g. commercial transactions, ownership status, shares, shares, electricity generation, and the purchase or sale of

currencies, including cryptocurrencies, i.e. electronic currencies. The essence of blockchain is to maintain a joint and collective accounting ledger of transactions, in digital form, scattered throughout the network in the same copies. Blockchain is a collection of all transactions carried out at the moment in the blockchain. This technology is based on peer-to-peer networks without central computers, transaction management, and verification systems. Any computer on the network can participate in transaction transmission and authentication. In the case of blockchain, these will be blocks within the transaction book. The book is open to everyone, but fully secured by complicated cryptographic tools against unauthorized access. Thanks to this entry, transactions are public, available to everyone, but visible only as part of access rights for a given user. Their entire history, from the beginning of blockchain existence to today, can be reviewed and verified. Currently, blockchain can be used to handle various transactions, but work is underway to use the blockchain as an accounting book in banking, a document authentication system, a digital signature in state administration, and a notary record. All these transactions can take place outside the system that has been functioning for centuries - without the participation of public trust institutions, directly between the parties to the transaction. You can store any type of transaction in data blocks in the blockchain network. One of the applications are the cryptocurrencies mentioned (e.g. bitcoin - BTC)".

The concept of smart contracts and possible forms of application

Smart contracts are computer protocols that check and enforce contract performance. Contracts are usually created by programmers, using special programming tools and languages: Solidity, C ++, Python, or Java. They are converted into computer code. This code defines the conditions, obligations of the parties as well as the effects and penalties that bind both parties to the transaction. This information can be found in the article - Smart contracts for the uninitiated (2019). The main purpose of smart contracts is to meet common contractual conditions, i.e. payment, confidentiality, pledge and enforcement obligations. These protocols, after cryptocurrencies, are the most common use of blockchain technology, which is called the distributed database. The use of smart contracts in combination with blockchain technology will, therefore, result in many advantages and disadvantages arising from the properties of both modern solutions.

Szpringer (2019) mentioned that the most important advantages include, above all, autonomy and no need to trust the parties to the contract. This is due to certain operating conditions, namely - automatic programming of previous functions without the participation of third parties. Data and assets are sent automatically or retained altogether. Then, stability and security are exchanged. The code that has been developed will work as long as the blockchain running on it. Blockchain technology achieves a high level of security through cryptography. One of the cryptographic functions is responsible for this - the hashing function. It creates the hash value based on the user input. In the article – What makes a blockchain Secure? (2020) - the benefits mentioned are listed. The advantages also include the speed and efficiency of transactions and the elimination of intermediaries, which reduces the costs of both obligated parties. Smart contracts are also characterized by precision and transparency - they have detailed programming parameters. Using smart contracts allows verify and control the correctness of transaction.

On the other hand, smart contracts are characterized by immutability, which may indicate the weakness of this protocol in the event of potential errors in the code. A smart contract once launched in the blockchain is difficult to change - one mistake can cost even millions of dollars. The legal issue also raises a lot of controversy. Smart contracts are a relatively new technology, that's why there are no precedents regarding the legal treatment options. Disadvantages include the lack of proper control, which is a liquid issue in traditional systems. For example, one of the parties to the transaction decides to delay the transaction due to improper performance of the obligations of the other party. This is only possible in the traditional form. Costs are also contentious, which on the one hand, are significantly reduced by the liquidation of a third party, but storing data in a blockchain still causes high costs - this is due to complicated calculations performed by network nodes. Transactions based on a smart contract require, above all, possession of a cryptocurrency. It allows the user to conclude a contract and then send it to the blockchain. It will be automatically confirmed by the contractor concerned.

In the article - Blockchain - technological aspects and examples of applications (2020) – is written that smart contracts can have many practical applications - from the most prosaic - to applications with a global reach. The simplest example is the process of buying an apartment. Traditional purchase still requires the involvement of several third parties - especially intermediaries: agents, banks, notaries, lawyers. The prospect of using smart contracts when buying real estate, compared to the current system, looks very favorable for those interested in their apartment. It is projected, that in the future, real estate will be saved on a blockchain along with an electronic title. That title will indicate any real estate charges. The interested person after paying the advance will have an insight into the entire history of the selected property. An analogous use of smart contracts will be for mortgage or car loans. The processing of applications will be improved, and hence the user will be able to receive funds for the intended purpose faster. Smart contracts will also be used as a digital ID. Personal data will be saved on the blockchain and the data owner will be able to decide to what extent to share it. Besides, smart contracts can be used in all kinds of elections - they could minimize counterfeiting and the process of voting and counting votes. Currently, this process is used by Estonia and West Virginia. What's more, the management area can make great use of smart contracts in the context of obtaining approvals, signatures, elimination of contradictions, or simply in a better workflow. The insurance area (automatic settlement of damages, payment of claims, calculation of premiums, reporting events), health care (secure data transmission, prescription management, test results, order fulfillment), or logistics, where tracking product rights, can also be used favorably. The location and fulfillment of contractors' obligations will be significantly improved.

Case study of Selected International Companies

There are currently 884 development companies around the world that offer the implementation of blockchain smart contracts into users internal systems. Smart contract programming allows companies to easily trade cash, real estate, shares or anything of significant value while away from the broker administration. The blockchain of smart contracts can oppose rules and penalties, just like a regular contract.

In the article - Top Smart Contract Development Companies (2020) - the register of companies actively using blockchain smart contracts and offering technological services to their users has been published on the website goodfirms.co. Companies with branches based in Poland have been analyzed. There are currently twenty-four such enterprises in Poland. These include Eleks, Softengi, Espeo Software, Ulam Labs, Nopio, Try Codnet, Software Brothers, Profile Software, 10Clouds, Codahead, Concise Software, Itransition, Vazco, Anchor Blockchain Consulting, KLGSolutions, Look4App, Idego Group, 180 Creative, Crodu, Sparkbit, Rumble Fish Development, Codete GmbH, Pragmatic Coders, CreateIT.

As a reference point, according to article - Top 50 Blockchain App Development Companies (2020) - among the above-mentioned enterprises, the three most important enterprises that are pioneers of technological services in blockchain smart contracts were assessed.

The first enterprise was "Eleks", which facilitates the digital transformation of enterprises, providing specialized engineering and consulting services. More than 1,400 enterprise specialists are located in Supply Centers throughout Eastern Europe and sales offices in Europe, the United States and Japan. The company provides its users with a full range of programming services. These include dedicated teams, product development, research and development, and technology consulting. Finance and auditing companies are offered:

- the most advanced distributed accounting technology that eliminates the need to hire expensive lawyers, brokers, bankers and the others,
- reducing accounting costs, while ensuring the security of financial transactions, because third party intervention is kept to a minimum,
- optimization, efficiency and acceleration of growth,
- topping up financial operations, eliminating downtime and the long hours often encountered in cash transactions.

In the article - Blockchain's Smart Contracts for Business: Ready or Not? (2020) there is also an information about implementation of blockchain. Transactions take place within a few minutes - around the clock. "Eleks" optimizes data security, regardless of the environment in which smart contracts operate.

The next analyzed enterprise was "Softengi". The article - Car Fines Distributed Database Based on the Blockchain Technologies (2020) informs that this company develops software. It is recognized as one of the 100 best global IT outsourcing service providers. The company offers a service in which all parties can access smart contracts through a decentralized system. Any attempt to amend the contract may be rejected and all stakeholders will be automatically notified of such an attempt. The network connects the company with its users in a common system, which allows users to speed up transfer processes, increase transaction accuracy and offer the most competitive prices for its services. The advantage of using blockchain technology is also distributed data storage and an authentic reading of information. In practice, this service works as follows. Initially, in the first stage, the database is filled with basic information based on existing registers. It is also very important to create authorization rules for employees of regulatory institutions at the beginning. This is the stage of entering the primary data. Then enter into the system is recomended. The company ensures a high level of security at this stage. The user can use various methods of user authentication: password, face recognition, etc. To identify the user's access rights, a verification mechanism based on blockchain technology is used. In this way, violations and unauthorized access to the system are prevented. The next stage is the stage of data recording. All information entered by the user is automatically saved in the system using blockchain technology. Data regarding the new license number, car number change, new fine imposed, or fine paid will be securely stored in the system. Then the information is filtered. By using different filters, the user can filter records and receive specific information he needs. The last stage is information editing. The user can easily read, edit, or delete any information. At the same time, all data entered into the system is securely stored in the archive, and all changes are recorded.

The third company under analysis was "Espeo Software". On the official website of this company there is an article - Blockchain innovations (2020). According to this, the company is a consulting company with a team of engaged consultants and blockchain programmers with a strong international position. Using blockchain smart contracts they provide the following benefits: greater data transparency, increased security, reduced costs, increased performance, better traceability. Besides, comprehensive services are offered to any enterprise interested in using smart blockchain contracts in their internal systems. Such services include blockchain consulting for entrepreneurs, which will enable them to build an optimal business plan in a larger blockchain ecosystem. The company also offers a technical feasibility study. The "Espeo Software" team will analyze each enterprise and its functional and non-functional requirements. Then follows mapping to the appropriate framework and diagrams, by mapping the Tokenomics model. This is planning all mechanisms and projects so that the token ecosystem works perfectly in the cryptographic economy. What's more, the recipient can benefit from smart contract development, because blockchain development is the most important basic skill. The company will carry out the development of blockchain in the context of smart contract security by adapting the technology individually to the recipient. The user can also buy the landing page design - efficient and attractive design "UI/UX design" and full development of the project landing pages and code review. Testers analyze the existing smart contract code and related components and will prepare a full report on security vulnerabilities and problems.

In a Guide to Smart Contracts and Their Implementation (2020) the possibilities of using smart contracts in combination with blockchain technology are very diverse. Much depends on the resources and skills of the company that will provide services to the user and on the individual needs of the consumer. Examples of smart contract blockchain projects are e.g. in the health industry "Dentacoin", especially in article - Blockchain solution for the global dental industry (2020). Dentacoin aims to bring patients and dentists together in communities to improve dental care and make it available worldwide. Another example is presented in article - Implementation of smart contract technology on the peer-to-peer market (2020). The aim is the use of supply chains in the logistics industry. "Name Bazaar" implements smart contract technology on the peer-to-peer market, where users can exchange cryptographic resources for blockchain in the form of domain.

The global market for smart contracts and blockchain technology in 2016-2025

There are a number of scientific predictions about the future and evolution of smart contracts around the world. However, when analyzing the chart of smart contracts market in 2016-2023, it can be seen a steady increase in this trend from 2016 to 2020 with a forecast of further growth until 2023. Figure 1 shows the evolution of smart contracts.

Fig.1: Global market for smart contracts in millions of USD in 2016-2023

Source: Own processing based on an online report: https://www.marketresearchfuture.com, as of 27.03.2020

According to a report published by Market Research Future (MRFR) „…the global smart contracts market should reach a valuation of USD 300 million by 2023. The market is forecast to reach 32% CAGR in 2017-2023. The factor that maintains the growth of the smart contract is its tendency to define the rules and provisions of the contract, but also to automatically enforce any of the obligations. The development of smart contracts is expected to grow steadily over the anticipated period, while serving end-users such as banking, government, insurance, real estate, and the supply chain. In the case of government smart contracts, these contracts may prove to be the next advanced step towards improving the voting procedure and other legal formalities and tenders organized by the government. They may include any contract concluded between a government and private or public enterprises…".

Based on the report - smart contracts market 2019-2023: emerging technologies, business trends, size, share, global segments and profit growth in the industry (2020), the smart contract market is segmented by the available tools: blockchain platform, available technology, end-users, and regions. The blockchain platform includes: Bitcoin, Sidechains, NXT and Ethereum. The most advanced tool for coding and processing smart contracts is Ethereum, followed by Bitcoin and NXT. Using available technology, segmentation is based, among others: on Ethereum, Rootstock (RSK), Namecoin, Ripple. The market, which has many end-users, is divided into: banking, government administration, management board, supply chain, automotive market, real estate, insurance, and healthcare. In contrast, the regions covered by the above report are Asia-Pacific, Europe, North America, and the rest of the world. Of these regions, the European smart contract market is recognized as a leader. North America is on the second place. This is mainly due to the rapid digitization of European and American industries. Many European entrepreneurs integrate digital solutions to increase their competitiveness. Market players in many regions are actively focusing on product innovations and implementing strategies that allow them to strengthen their market position. Many companies also invest in mergers and

acquisitions. The number of partnerships and cooperation on the European smart contract market has also increased.

Another essential report - Market Research Reports (2020) is presented Blockchain Technology Market size by providers - Infrastructure Provider, Application Provider, Operators, Application - Smart Contract, Payment & Wallet, Digital Identity, Exchange, Compliance & Risk Management, End-user - BFSI, Government, Healthcare, IT Service, Media & Entertainment, Transportation & Logistics. It is an industry analysis report, regional outlook, growth potential, competitive market share & forecast for the years 2019 – 2025. According to the report - Global Market Insights (2017) „…Blockchain Technology Market size surpassed USD 488 million in 2018 and is predicted to grow at more than 69% CAGR between 2019 and 2025. The digital identity application is estimated to grow at 78% CAGR over the forecast timeline. Blockchain-based identity platforms have various applications in unregulated countries or countries with weak identification systems. Various governments have implemented blockchain technology-based identification platforms at the national level to facilitate secure & transparent transactions across private & public sectors. For instance, in June 2018, Estonia used a blockchain at the national level with its e-citizenship program. The country created its identity system, ID-Kaarts to reduce bureaucracy and digitalize all public transactions through secure digital identities...". Figure 2 shows europe blockchain market size by providers.

Fig. 2: Europe blockchain market size by providers in millions of USD in 2016-2025

Source: Own processing based on an online report: https://www.gminsights.com/industry-analysis/blockchain-technology-market, as of 27.04.2020

When analyzing the Blockchain market report Global Market Insights (2017) „…The infrastructure provider market in Europe had a dominant share in 2018 and is expected to maintain its position until 2025, as organizations develop their private blockchain networks. Major infrastructure providers develop the basic software components that are necessary for network deployment. They can be further segmented based on protocol companies and network companies. The main goal of the companies involved in the development of protocols is to develop a basic protocol layer on which distributed ledger networks can be built. Network development companies build custom distributed book networks for clients…".

Conclusions

Over the next few years, the development of smart contracts and blockchain technology will certainly grow in the aspect of the process of automating blockchain projects. The perspective of the global trend of smart contracts, especially over the next three years, looks very positive. This aspect is confirmed above all by the analyzed Market Research Future and Global Market Insights reports. In this study, the global smart contract market was analyzed in 2016-2023. There is a growing trend that will reach a valuation of USD 300 million by 2023. Just like the smart contract market, the blockchain technology market will grow over the next five years and is predicted to grow at more than 69% CAGR between 2019 and 2025. Therefore, both presented markets will face large-scale growth and development in the future. The factor that will maintain the growth of the smart contract is its tendency to define contract rules and regulations, but also to automatically enforce obligations. Service providers will be a factor that will continue to increase Blockchain technology. What's more, the global smart contract market offers many positive applications resulting from the simultaneous use of smart contracts and blockchain technology. The examples of enterprises presented in this article, which offer consultancy in the implementation of smart contracts, offer their users the following benefits: increased level of customer satisfaction, increase in overall level of security, reduction of internal costs of the enterprise, as well as greater awareness of users using automation processes of blockchain projects. However, the most important factor that will determine the general level of user satisfaction with the use of smart contracts will remain the fact of eliminating the third party of contract. Thanks to which transactions will be marked by a significant increase in confidentiality and a high level of their security. Although the development of smart contracts and blockchain technology around the world is extremely dynamic. In Poland it is still at the initial stage of evolution. However, according to the article - Europe can become a leader in the field of crypto assets. What should she do not to miss this opportunity? (2019), this does not exclude the opportunity to become a leader in the development of innovation in this area in the future.

The Fields of Supervisory Boards Activities in Different Kinds of Subsidiaries: The Case of Polish Business Groups

Krzysztof ĆWIK

Wroclaw University of Economics & Business, Wroclaw, Poland
krzysztof.cwik@ue.wroc.pl

Abstract

The business group is a specific type of an economic entity, because subsidiaries must achieve goals, which are a consequence of their role in the group and their supervisory board (board of directors), in addition to obligations under the law, may engage to the management of subsidiary in many different ways. There are three generic types of subsidiaries: operational, cooperative and conglomerate. The results of the research conducted by the author show that depending on the type of the subsidiary, the supervisory board differently affects the management process in the subsidiary. In the case of operational subsidiary in the largest number of cases the supervisory board was identified as an industry-oriented type, in the case of cooperative type it was the active board type and in the case of the conglomerate type – finance-oriented type.

Keywords: business group, board of directors, supervisory board, subsidiary

Introduction

Proper supervision over enterprises, where ownership and management are separated, is an issue considered on many levels for years (see e.g. Jensen & Meckling, 1976; Claessens *et. al.*, 2000; Young *et al.*, 2008; Heyden *et. al.*, 2014). The question of effectiveness of such supervision is usually raised after reports about the bankruptcy of another corporation, as a result of which the owners had to accept loss of the capital invested. Thus, despite broad literature on conducting effective ownership supervision, there is still a need for theoretical and empirical analysis of this phenomenon. Despite relatively good knowledge of this subject, an efficient theoretical model of ownership supervision has not been developed yet (Starbuck, 2014; Paine & Srinivasan, 2019). Simultaneously, modern economy demonstrates a desire to "consolidate" organizations and combine them into broader economic organisms. As a result of merger and acquisition processes, entities operating in corporate group structures replace entities which are independent in terms of organisation and making decisions. And conversely – large companies "fall apart", e.g. by means of asset outsourcing a single organization is replaced by a number of legally independent entities connected by "capital ties". Supervision over such an entity is likely to be different from the supervision over an independent company. This is primarily due to the fact that the purpose of a subsidiary's operation is often directly dependent on the role it has been assigned by the parent entity. It may be implementation of a "part" of the parent entity's or the whole group's goal. Thus, supervision over performance of a subsidiary is crucial in the context of effective functioning of the whole business group (Khanna & Rivkin, 2001; Colli & Caplan, 2016; Aluchna, 2017; Sakawa & Watanabel, 2018). A supervisory board is the main tool for the exercise of supervision, but also for affecting its current activities (Przybyłowski *et. al.*, 2011). The aim of this paper is to analyse theoretical aspects of the supervisory board operation in a subsidiary, as well as to present the results of research on the role and activities of a supervisory board in various types of subsidiaries.

The structure of the paper is as follows. The first part discusses the nature and perception of a business group as a research object. The second part discusses the concepts of supervisory board functioning models. The third part presents a subsidiary typology, proposed by the author, research hypothesis and the results of empirical research. The study was conducted with the use of a questionnaire on a sample of 107 subsidiaries. The data was being collected in two periods of time: from 2014 till 2015 and from 2016 till 2019. The respondents were members of supervisory boards of these entities. The sample size does not allow for drawing conclusions with the use of descriptive

statistics tools. These results, however, may be a basis for discussion, a contribution to further research as well as may let us formulate practical recommendations for actions of a supervisory board in subsidiaries of a business group.

Theoretical Background

Business group as an object of study

A business group is an unusual object in the management science. Legally speaking, such an organization consists of a number of separate companies, but in economic terms it is acknowledged an economic "unity". Therefore, on the one hand it is a multi-entity enterprise, as it consists of business units of different legal and economic status, on the other hand, these units form a single economic entity, common objectives and principles of operation of which are imposed and enforced by a "managing medium" (Allan, 1978, Granovetter 1995, Khanna & Yafeh, 2007).

A business group can therefore be perceived in two ways. It can be treated as a single economic entity but one can also recognize performance of its parts. In theoretical terms, the group consists of two types of entities: the parent company and its subsidiaries. The parent company is a "commander" of the group. Through appropriate coordination of various elements it seeks to achieve its objectives. Subsidiaries are obliged, by various types of relations, to carry out the tasks arising from these objectives. Obviously, research on business groups has been carried out, but usually its proposals concern functioning of the group as a whole from various perspectives including management, business history, sociology, role in the modern economy (Khanna & Palepu, 2000; Colpan *et. al.*, 2010; Iacobucci & Rosa, 2010). Research on business groups considers governance to be a relevant topic, and a greater part of management research emphasizes an instrumental perspective of business groups rather than an operational one (Colli & Colpan, 2016; Lin *et. al.*, 2019).

Nevertheless, a methodological question arises: can management science treat a subsidiary of a business group equally to a financially independent company? If not then, should business groups be analysed only as a whole or can one study its subsidiaries as separate entities, which in many ways differ from independent companies? The latter seems to be a more appropriate option. A subsidiary's incomplete autonomy in decision making the necessity to adapt its strategy to the group's objectives, restricted or completely "closed" path to external market, an imposed role in the value creation chain, limited technological and product-market innovation, these are just some aspects of strategic and operational management, which seem to differentiate subsidiaries from independent companies.

According to the data of the Central Statistical Office of Poland (GUS), entities which belong to a particular business group employ over 50% of all employed in enterprises, and their total revenues are twice as big as total revenues of financially independent businesses (GUS, 2018). Simultaneously over 80% of entities which belong to business groups are "single-storey" subsidiaries i.e. companies which simultaneously are not dominant towards any other entity of the group (GUS, 2018). These statistics show that subsidiaries of business groups should be "under constant observation" of researchers, especially that in some developed economies, their number begins to outweigh independent enterprises (excluding self-employment) (Heugens & Zyglidopoulos, 2008).

The issue of business group subsidiaries operation has not been particularly explored in management science, nevertheless this topic has been covered, but mostly by perception of subsidiaries through the prism of analysis of companies created and managed by foreign business groups. This field of research is quite common and resulted in a number of publications. Moreover, this matter, though not new (White & Poynter, 1984; Putti & Chong, 1985; Birkinshaw & Hood, 1998; Legewie, 2002; Harzing & Noorderhaven, 2006), seems to be gaining in importance in the face of ever increasing globalization of the world economy and far-reaching internationalization of business organizations (Doherty & Teague, 2011; Lin *et al.*, 2013; Pisoni *et. al.*, 2013; Schleimer & Pedersen, 2014; Miao *et. al.*, 2016; Belenzon *et. al.*, 2019). However, it is unjustified to limit the study on performance of subsidiaries only to such companies whose parent entity is based in another country. Given the

prevalence of this type of organizations and their role in modern economy one should gradually fill this gap, both conceptually and empirically.

The role of supervisory boards

Business group subsidiaries can be an object of research conducted from several different perspectives, for instance, economic efficiency, organizational culture, strategic management, people management, etc. It seems, however, that one of the first positions "on the list" should be held by the analysis of business groups from the perspective of ownership supervision held over subsidiaries, as in spite of extensive literature in this area, there still is a need for theoretical and empirical analysis of this phenomenon. An economic operator in turbulent environment demonstrates the need for an effectively functioning system of supervision. Supervisory boards (often also called board of directors) are an essential element of such a system in the modern enterprise. The interest they raise is steadily growing. At the same time there is a relatively strong conviction about the need for fundamental changes in their functioning. Issue of understanding the role of a supervisory board in the process of enterprise management is gaining in importance. It should be noted that it does not seem sufficient for the board to perform only functions resulting from generally applicable legislation. A supervisory board should also operate in areas that do not fall within its "legal" duties. For instance, many strategic management specialists and researchers for years share the concept that board members should work closely with managers at the strategic decision-making process (e.g. Forbes & Milliken, 1999). They usually have broad experience and an ability to assess a situation correctly which increases the effectiveness of the control functions performed by the boards agrees with the view that the sphere of strategic management should be a special area of a supervisory board's interest (Haynes & Hillman, 2010; Tuggle *et al.*, 2010).

Understanding of the role of the supervisory board as a solely "supervisory" and controlling body refers to the agency theory, in which the board cares primarily about the implementation of the owners' interests (Bathala & Rao, 1995; Hendry, 2005). Its main task is then to monitor implementation of ownership objectives by those who manage the company. The so-called steward theory represents a completely different point of view, the keynote of which is not only to control the activities of managers but mainly to support them with knowledge and experience. The board by fulfilling their obligations in terms of initiating, approving and controlling the activities of management, should focus on the aspects of long-term survival and development of the company (Huse & Rindova, 2001). Also, management practices seem to head in the direction of increasing the supervisory board's role in the management process (Shen, 2003; Boyd *et. al.*, 2011).

The typology of supervisory boards

One of supervisory board typologies is based on the criterion of activities undertaken by them. According to this theory, supervisory board members communicate with each other, as well as with the management, shareholders and business partners at the process of preparation, decision-making and control. Orientation adopted by the board in this process is crucial. This orientation can be of two types. Where the priority is the board's position in the capital market and/or financial results, we can talk about the **financial orientation** of the board. An **industry-oriented** board focuses primarily on technological innovation, research and development, product quality improvement, market opportunities or forecasts of the development of industries in which the company operates as well as the company's manner of operation in the market. The second criterion of distinguishing supervisory board types, according to this concept, is the degree of their involvement in activities specific to one and the other orientation. A low level of involvement indicates that functions of the board are limited, basically only to approving decisions of managers and *ex-post* control of their effects. A high degree of involvement demonstrates not only control but also initiation of certain actions. The board is actively involved in preparing decisions and the control process is based on the *ex ante* control of plans and *ex post* control of results. A combination of these two criteria allows to distinguish four types of supervisory boards (Działo, 2001; Jonnergård *et. al.*, 2004; Jonnergård & Kärreman, 2004), as shown in Figure 1.

Fig. 1: Types of supervisory boards distinguished by the type of orientation and the degree of involvement

Source: (Działo, 2001)

An active board is focused on both financial and industrial areas of the enterprise and while making decisions it takes the consequences of both these aspects into account. **An industry-oriented board** is mainly focused on industrial aspects of the company and thus on the situation on market for products and services. It pays less attention to financial issues. Similarly, a **finance-oriented board** focuses its attention on the issue of the company's (joint stock company's) position in the capital market. **A passive board** leaves active involvement almost exclusively in the hands of management. These two concepts form the basis for formulation of hypotheses concerning the types of operation of the supervisory boards of subsidiaries.

The typology of subsidiaries

Subsidiaries of a business group do not form a homogeneous group. Their most characteristic feature as economic entities is obviously being a part of a business group. However, there are many criteria that can be used to differentiate these entities. Some of these differentiate a whole class of companies. Such criteria may include for instance company size, geographical area of operation or industry. There is also, however, a number of criteria which differentiate subsidiaries within a business group. These criteria include: a level of location in the group's structure, the objective of functioning within the group, the method of "incorporation" of the entity into the group and the time of existence in the group, ownership structure of the company, "distribution" of decision-making powers in the supervisory bodies, the method of exercising supervisory functions by authorized bodies, etc. Therefore, various combinations arise, which increase the number of all possible types of subsidiaries to the extent that it seems impossible to carry out research, especially of a quantitative nature, which could cover all possible types thereof. Another issue is the (questionable) point of distinguishing research object classes based on so many criteria as well as the fact that due to the research focus, not all criteria seem to be relevant. Therefore, the author decided to focus on one differentiation criterion, namely on the subsidiary's "purpose of existence".

A typology of business groups according to this criterion was formed by Trocki (2004). It has been based on a modified classic typology of forms of economic interdependence by Thompson (1967). According to this concept, we can differentiate between the following types of business groups (Trocki, 2004):

1) operational – subsidiaries conduct activities supporting the primary operations of the parent company, which runs key business operations,

2) management – subsidiaries conduct operations focused on maximizing the synergistic effect between them, through functioning as successive stages of the value chain or assist each other in carrying out separate operations,
3) financial – subsidiaries conduct diversified operations, whereas the parent company focuses solely on managing its interests/shares.

On the basis of this typology the author divided subsidiaries into:

1) operating entities – activities focused almost exclusively on supporting the activities of the parent company,
2) cooperative entities – activities focused on collaboration with other entities within the group to maximize the synergistic effect, occurring in a particular subgroup,
3) conglomerate entities – the value for the group's operations is contributed in the form of a suitable financial result generated by them,
4) Hybrid entities – engaged in an activity that meets the demands of two or three different types.

The measure, which was adopted for the purpose of identification of a type of subsidiary is a subjective measure of involvement in activity which meets the demands of a given type. An objective measure could be for example the amount of revenue derived from activities of a particular type, however, first of all, the turnover size does not always reflect the company's level of commitment. Secondly, in the case of a capital group these values may not correspond to the actual involvement due to the application of transfer pricing for intra-group transactions (Amershi & Cheng, 1990; Pffeifer & Wagner, 2006).

Research questions and hypothesis

The objects of study were subsidiaries with a "single storey" structure, in which the subsidiary simultaneously was not a parent company to any other entity of the group. The second criterion for qualifying a subsidiary to the research group was that the parent company owned at least 95% of the shares of the subsidiary. This condition was aimed at exclusion of forcing upon the subsidiary "tunnelling-like" activities (Baek *et. al.*, 2006; Siegel & Choudhury, 2012), namely conscious acts to the detriment of the members or minority shareholders. At the same time, subsidiaries had already been operating for at least six years and, at the time of the study, were not designed to disintegrate (sale or liquidation). The study sample included only such subsidiaries whose nature, according to the purpose of functioning in the group, was unequivocal – operational, conglomerate and financial entities. The research hypothesis was not verified for hybrid entities. The number of possible "combinations" and thus the number of units that would have to be examined is so large that attempts to collect a minimally representative sample proved impossible.

The results of a survey conducted by the author were to answer, among others, the following question: is there a correlation between the subsidiary type and the role and type of actions undertaken by the supervisory board? The research aimed to provide information about what type of boards (active, finance-oriented, industry oriented, passive) are present in subsidiaries. The main goal was to find a relationship between a subsidiary type and the type of supervisory board, on the basis of the criterion of its actions, as well as to try to answer the question of why such a model prevails in subsidiaries of a given type.

On the basis of the analysis of literature and the author's research according to the case study methodology, a hypothesis has been formulated. It consisted of three parts verification of which was to answer the question posed.

Hypothesis 1a: The dominant (the largest number of cases) mode of action of a supervisory board in operational subsidiaries is based on the industry-oriented supervisory board type.

An operational subsidiary is designed to support the activity of the parent entity, thus the main interest of the supervisory board should lie in the matters of technological innovation, research and development, product quality improvement, forecasts for the development of industries in which the entity operates, and the like. The monitoring function performed by the board of such an orientation

can be performed by tracking changes concerning for example the quality of the subsidiary's products or changes in the technological process.

Hypothesis 1b: The dominant mode of action of a supervisory board in cooperative subsidiaries is based on the active board type.

The purpose of a cooperative subsidiary operation is to maximize the synergistic effect in the subgroup, thus the board needs to focus on both financial and industrial aspects of the company's operations, it must also demonstrate a high degree of involvement in the implementation of its functions. The synergistic effect is dependent on the harmonious cooperation of all stakeholders, which is possible with strict control of the subsidiary operation.

Hypothesis 1c: The dominant mode of action of a supervisory board in conglomerated subsidiaries is based on the finance-oriented supervisory board type.

Conglomerate subsidiaries operate "independently" of other entities in the group, thus the dominant model of functioning of the supervisory board in these entities should be finance-oriented, implementing the control function by monitoring the position of the company and tracking financial indicators, e.g. indicators of profitability or liquidity. Operational issues in such companies remain at the discretion of the board.

Research Methodology and Results

A questionnaire was the research tool of the study, whereas chairpersons of supervisory boards in subsidiaries were its respondents. Each of the possible board focus models (industry and finance) were assigned six areas in which a supervisory board may demonstrate commitment by counselling or initiating decisions.

In the case of an industry-oriented board the issues covered production and service efficiency, product quality improvement, organizational and personal potential, technological innovations, technical and production potential, as well as anticipated technical changes in the industry. In the case of a finance-oriented board the assigned areas included the subsidiary's value, financial results and profitability, financial situation, debt levels, market position and anticipated changes in the market.

The degree of activity of a supervisory board was assessed on the basis of frequency of involvement against a five-degree scale ranging from 0 points (very low involvement) to 4 points (very high involvement) in every of six assigned areas. Therefore, the total score ranges from 0 to 24 points. Depending on the number of points, assignment of the studied board to one of the four types followed. The assignment method has been demonstrated in Figure 2.

Fig. 2: The method of assigning supervisory boards to particular types
Source: author's own.

Assumptions about verification of the research hypothesis, especially the "point boundaries" between individual types, are subjective and may give rise to doubts. The collected research sample, however, did not allow for a more detailed breakdown of the typology of Jonnergård, Kärreman and Svensson (2004) to, for example, a strongly industry-oriented board or to some hybrid orientation boards. In the study participated respondents from 30 operational subsidiaries, 39 from cooperative subsidiaries and 38 from conglomerate subsidiaries. Every subsidiary of the sample represents a different business group. The study was based only on interviews with use of a questionnaire. Because of the requirement of confidentiality, there can be only shown the structure of the industry of these subsidiaries (see table 1.). There was not significant correlation between the type of industry and the type of the board.

Table 1: The structure of the sample

operational subsidiaries (n=30)			
services	trade	standard production	high-tech production
11	7	8	4
cooperative subsidiaries (n=39)			
services	trade	standard production	high-tech production
12	7	13	7
conglomerate subsidiaries (n=38)			
services	trade	standard production	high-tech production
14	10	8	6

Source: author's own.

Having made the above assumptions about the study result assessment, the following results were obtained:

1) In the case of operational subsidiaries, in 18 cases (60.0%) the supervisory board was identified as an industry-oriented type, in 3 cases (10.0%) as an active board, in 5 cases (16.7%) as a

finance-oriented type and in 4 cases (13.3%) as a passive board. It can therefore be concluded that these results support the hypothesis 1a.

2) In the case of cooperative subsidiaries, in 11 cases (28,2%) the supervisory board was identified as industry oriented, in 17 cases (43.6%) as an active board, in 5 cases (12.8%) as a finance-oriented type and in 6 cases (15.4%) as a passive board. It can therefore be concluded that these results support the hypothesis 1b, although the results are not as clear as in the case of the hypothesis 1a.
3) In the case of conglomerate subsidiaries, in 5 cases (13.2%) the supervisory board was identified as industry oriented, in 13 cases (34.2%) as an active board, in 16 cases (42.1%) as a finance-oriented type and in 4 cases (10.5%) as a passive board. It can therefore be concluded that these results support the hypothesis 1c.

The results above demonstrate that the subsidiary type appears to have a large impact on the model of cooperation with the management adopted by the supervisory board. If these results were confirmed on a larger sample, one could on such basis formulate certain recommendations for the boards of parent companies and members of the supervisory boards of subsidiaries. Assuming of course, that the choice of the board's model of action is in most cases based on reasonable grounds, stemming for instance from knowledge and experience as well as that the model is a result of evolution of the board performance leading to the best, optimal model.

Final Conclusions

Business group functioning has still not been thoroughly identified, which in the context of their high economic importance, poses significant challenges. The subject of business group efficient management, despite the long-lasting discussion, is still very important and valid. The issue of ownership supervision over subsidiary operation, signalled on theoretical grounds may indicate possible directions for further empirical research. The presented results of the empirical research can be a contribution to further considerations of "tools" for influencing a subsidiary's behaviour by the parent company. Further research could try to answer the question to what extent the orientation of activities adopted by the supervisory board is effective in a given subsidiary. Another issue may be the question of the operation of supervisory boards in subsidiaries whose activities are a "mix" of different types. Such studies may provide answers to fundamental questions concerning management of these specific business objects which may contribute to the comprehension of various aspects of business group functioning and provide a basis for creation of effective tools for managing their components.

Abstract

The purpose of this paper is to provide the growing range of literature review and offers a comprehensive review for new researchers with a specific focus on the relationship between knowledge management and succession planning at a higher education institutions.This study will get a better idea of how higher education institutions deal with the danger of face the risk of knowledge loss due to long absence at workplace. Most of the literature on succession planning was focused on healthcare and limited literature for the education sector.The study has categorized the literature representing knowledge management introduction, challenges facing by higher education for knowledge retaining, succession management and linking relationship of knowledge management and succession planning. Today, higher education institutes are playing a big role to create university leaders.The changing role of the higher education system is all part of the globalization process. This study sets the global context which can help for new leadership processes in the higher education system. There are some challenges faced by knowledge management in terms of retaining leadership within the organization, which includes culture, knowledge retaining, technology and directive leadership. The relationship between knowledge management and succession planning can improve the decision making capabilities of academic leaders.

Keywords*:* Higher Education, Knowledge Management, Succession Management

Introduction

Higher education institutions are responsible to prepare and retain employees within their institutionswhen leaders are expected to retire. The biggest mistake of organizations is replacing staff not retaining them.The specific problem is the lack of effective succession planning practices that support the transfer of technical older employees to younger experts before they leave the institution. Zain et al., (2010) mentioned organizational knowledge as information that is relevant, actionable, and based on experience, context, interpretation, and reflection in the organization. Besides, transferring specific knowledge, skills, and culture from retiring organizational leaders to successors is one of the more challenging tasks of leadership (Joshi et al., 2010).

It has been observed that most of the public organizations only focus on the efforts of succession planning for senior management positions. Most of the cases organizations neglect the middle management and even do not have staff available will take over to the top posts. Therefore, more organizations are at risk. Although in some cases, it is not feasible to plan succession for every unexpected event, it is important to have a roadmap to prepare future leaders when a key position is vacant. Succession planning is difficult in some situations when the lower management staff departs

from an organization because it could lead to a lack of awareness of expertise required for specific positions.

Literature Review

The literature review is classified into two main intentions. The first intention is to explore the relevant literature review on the importance of knowledge management and succession management in association with higher education. The second intention is to identify the theoretical and practical connection between knowledge management and succession management. The field of Knowledge management has certainly advanced and developed in significant new ways in recent decades. This study takes existing research on knowledge management and succession planning succession which is currently limited to abstract concepts and models for deeper understanding in academic world.

Knowledge Management Introduction

The existence of knowledge is not new. However, Knowledge management has been highlighted around fifteen years ago. Knowledge management has gained popularity in both the business and education sectors (Wiig, 1993; Bhatt, 2001; Metaxiotis et al., 2002,2005). Higher education institutes play also a major economic role in the business and education sectors. The highest mandate for higher education is to prepare a workforce to enter learning situations of all types of organizations.

Universities prepare graduates to enter learning culture of institutions. Brewer & Brewer (2010) stated that "Preparing students to succeed in a knowledge-based economy requires an integrated educational environment that encourages creativity and a commitment to lifelong learning. Educational institutions are challenged to prepare students to compete in a knowledge society made more complicated by globalization" (p.6)

There are two main approaches to knowledge management. One is human or people approach, and another approach is information technology. The study of (Chong, 2005) is a key driver to knowledge management. The human or people approach is crucial to any organization for the Knowledge management process. It is the truth that the knowledge management process cannot be successful without people. The information technology approach plays an important role in filtering knowledge. without information technology and computer, knowledge cannot be stored (kotoroy & hsu,2001; Abs).

In sum, the human approach is more common since knowledge existed long ago before information technology. Besides, information technology is only a human creation that can act as a catalyst to speed up the activities of knowledge management processes (Chong, 2006a).

Generations of Knowledge Management

Several authors has focused to the improvements of the knowledgege management genrations. Historically ,it can be divided into main three categories by the study of Metaxiotis et al(2005).The First generation of knowledge management was from 1990 to 1995. During this period several initiatives were taken for the identification of knowledge management which includes determine the potential benefits of knowledge management for businesses, designing projects for specific knowledge management projects (Senge, 1990; Nonaka, 1994, Quinn, 1992; Wiig, 1993). Some other authors including study of Ignizio(1991) has taken initiative to work on artificial intelligence influenced research on knowledge management, mainly in the direction of knowledge representation and storing.

The second generation of Knowlegde management was started in 1996 with creation of coorporate jobs with specific skills and knowlegde officers . During this period knowledge management research focused on Knowledge definitional issues business philosophies, system framework, operations and practices. The second genertion of knowledgege management was more focused on advance technologies which includes systematic organization change (practices, system, tools). This generation has also emphasized on emerging with new solutions and outcomes.

The third generation of knowledge management is from 1997 to 2000. The study of Paraponaris(2003)mentioned that during this period knowledge management emerged from an individual knowledge focus in the 1970s and 1980s to a group knowledge focus in the 1990s and 2000s. The third generation was more focused on relationship between knowledge and action.

Challenges Faced by Higher Education System for Knowledge Management

Higher education institutes all over the world are facing some challenges but this study will determine some of the crucial challenges facing by higher education institutes such as Culture, organization knowledge retention, technology, and directive leadership.

Culture: The first challenge is the adaption of changing knowledge at higher education institutions is organizational culture, hiring practices and employees' work habits. The study of Tseng & Fan (2011) culture consists of common beliefs, ideas, basic values, mutual norms, and practices. Most of the time knowledge is stored in individuals or organizations. The implementation of a succession planning process in higher education institutions is exceedingly difficult due to cultural shift and recruitment practices (Kelly,2011, Grossman,2014).

Organizational culture has been identified as a fundamental determinant of the success or failure of Knowledge management, and extensive research has been conducted to identify cultures that promote knowledge sharing (Al-Adaileh and Al-Atawi, 2011). The study of Ragab and Arisha (2013) stated that "organizational structure has also been studied as being as important as a culture with Success" (p.8)

Organization knowledge retention: The best way to retain knowledge at higher education learning institutions is the review of knowledge regularly. It is suggested that all knowledge documents must be updated during the validity period. Higher education institutes are facing internal knowledge loss due to departs or retiring (Rajasegaran et.al, 2005; Wiig, 1997). The study of Busine & watt (2005) mentioned about organizational knowledge that "the functions, processes, systems, products, services, or technologies of an organization and industry that a leader must understand; knowledge 'holes' need to be identified and filled"(p.7).

Knowledge retention was defined by Martins & Meyer ,2012), as "maintaining, not losing, the knowledge that exists in the minds of people (tacit, not easily documented) and knowing (experiential action manifesting in behavior) that is vital to the organization´s overall functioning" (p. 80).

Directive Leadership: The higher education institutes are playing an important role to cultivate talents, develop new technologies and enrich human knowledge. To fulfill these needs, the leaders in higher education institutes are expected to be directive and participative. According to McCauley et al(1998) leadership development is stated as expanding the collective capacity of organizational members to engage effectively in leadership roles and processes.

Leadership roles come with or without authority whereas in the leadership process group pf people work together. All organizations including higher education institutes are facing challenges in leadership development. The study of (Rothwell,2002) mentioned some leadership difficulties such as shortage of resources for employee's development, a rapidly aging workforce which causes a shortage of experienced talent for top positions. Another study relevant to this article by Kilian et al (2005) mentioned some more challenges including lack of a mentor, stereotyping, career advancement, that women and people of color often face in the corporate world.

Technology: In today's dynamic world, technology is an increasingly important factor for a successful business to provide accurate information. The top management of higher education institutes needs to use the latest technology, not only the ability to use technology but with an orientation that creates new technologies**.** The invention of technology between 1700 AD and 1881 was called applied knowledge (Allee,1997). The study of Hsu (2001) focused that without information technology, knowledge cannot be stored, filtered and process.

The technology facility can help to narrow the gap between knowledge management processes and knowledge management performance outcomes in the higher education sector. Information technology advancement has been recognized to esteem the search for suitable information to solve our daily and academic problems, but are limited by ability in critical information technology policies, infrastructures, usage, personnel, deficit in funding and basic information technology services (Ifinedo & Ololube, 2007).

Succession Management

In today's highly competitive global business environment, succession planning is considered a powerful tool to retain leadership within an organization. Succession planning requires more than just a plan. Some institutions prepare a succession plan for a loss or a change of employment for an unexpected event. For example, the military has some sort of succession plan for leaders who can take over quickly during unexpected events. The study of (Grossman,2014) mentioned that previous studies have done to evaluate the lack of succession planning in higher education institutes (William & Mackey,2008; Richards& Neefe,2009; luna,2010; Green,2011).

Some successful institutions are recognizing the importance of succession planning and they are willing to devote their time and resources to retain the best talent and prepare leaders by providing pieces of training. On the other hand, some organizations such as universities, public agencies, and nonprofit organizations face financial issues to retain their best talent within. For example, hiring of a vice chancellor for university or hiring a CEO for a big company requires a lot of time and considerable budget. Ultimately, these organizations prefer to hire an external consultant or outsourcing provider. There is a little discussion for academic leaders for succession planning as compared to the health sector which is more focusing on the importance of mentoring sessions (Phillips,2019).

Succession Planning definitions

Some authors mentioned succession planning as a systematic activity to help top management to identify, select from the pool of candidates. On other hand, succession planning is referred to as a strategic activity to ensure the vacant positions without any favoritisms. Several authors have studied about succession planning and defined as under.

According to Rothwell(2010), the definition of succession planning is "a deliberate and systematic effort by an organization to ensure leadership continuity in key positions, retain and develop intellectual and knowledge capital for the future, and encourage individual advancement"(p. 28).

The study of (Mackey,2008) has given succession planning as a tool to assist with professional development on the individual employee and promoted cross-trained employees from within the organization.

Sambrook (2005) stated that "succession planning is an attempt to plan for the right number and quality of managers and key skilled employees to cover promotions, retirements, deaths, serious illness and any new position which may be created in the future organization plans"(p.580). This definition provides an example that succession planning is a long-term approach.

The relevant study of Getza & Peterson (2005) also defined succession is encouraged to internal successors involve themselves within. succession planning is viewed as an important way to address retirement and its consequences (McQuade et al., 2007).

Best time to prepare succession planning

The rule of thumb for starting to prepare for the next successor is no less than five years. Some organizations realize the importance of succession planning too late. The ideal time to start succession planning is when the business is starting to take off. According to (Butler et al.,2002) "Succession

planning is a complex task that requires constant attention and ongoing resources. Successful organizations devote considerable time and resources to mapping out skills and competencies so that they can hire and train appropriately and achieve a distinct competitive edge" (pg.202).

Succession planning process

Typically, succession planning involves in major four steps from design to implementation phase.

Figure 2.2.3 Succession Planning Process

The first step is to identify the existing competencies related to both leader's needs and organization needs. The second process evaluates or assesses the current employees to determine their matching skills and expertise with the organization. The third process involves many factors such as mentoring, coaching, training and hiring approaches (internal or external) according to organizational needs. The last process involves developing the actual plan. Some organizations such as small institutions only focus on succession plan charts, but big organizations focus on applications such as human resources management systems.

Create a successor Profile

Creating a successor profile is very important when organizations start thinking to identify successors and create critical positions. This process includes having the right people and financial structure, documenting their experience, skills, behavior and technical knowledge which can be needed to be successful in a specific role. More than anything else, succession planning requires the full structure of the organization from top to bottom. The key role of successor in higher education institutes has been accepted for many decades. Less experienced candidates may be unappealing for the executive post. succession planning model which always focuses on developing a within candidate competency skill profile.

The selection criteria to find out the selected successor is to keep the track record of leaders with their relevant job experience, their professional skills, leadership style, and new leadership competencies. As a result, competency profiles can be determined for the selected successor. Succession planning identifies talented successors as potential leaders and granting them systematic leadership development programs (Broome, 2013, Wilkes et al., 2015, Philllips,2019)

The Aging leaders at higher education institutes workforce

Most of higher education institutes are facing the aging workforce within the organization. This institutional loss is long term skilled and experienced employees. Higher education institutions are beginning to realize the high impact of retiring workforce which can decrease workforce size withing the organization. These workers include the mature workforce those who are reaching their minimum retirement age and who are retiring from all levels. In this case, the role of senior management is highly important to identify the managerial functions on each level. The study of (Robbins et al, 2003) identified the main functions of senior leaders as planning, organization, directing and controlling. These managerial functions are the social and technical skills of a successful manager.

The study of (Jacob,2016) in Malaysia found that the number of old age has been increased from 7% to 15% within 28 years. It is expected that by 2030 the number of aging populations will be double. The first things come in everyone's mind about the aging stereotype. The older employees are discriminated in many terms such as employment promotions and their skill recognition. The study by Posthuma, Wagstaff, and Campion (2012) defined age stereotype as judgments about an individual employee based on their age rather than on their actual knowledge, skills or abilities.

Internal Vs External Practices and Preference

Internal recruitment might be beneficial to educational institutions as in some cases internal candidates are very loyal to the institution with clear organizational goals and familiar with the current leadership. However, some institutes are not in favor of hiring an internal candidate due to budget constraints. The external preferences require identifying qualified candidates with technical skills and experience for top leadership positions.

External Vs internal leadership hiring in higher education is always highly debated. The study of(Grossman,2014,p.44) stated that "various higher education institutions do not grasp the business model for promoting strong internal candidates as hiring data suggested that there is a distinct preference for external candidates (collins,2009)".

Moreover, the study of Barden (2008) also identified difficulty in an internal successor in the academic sector. Succession planning is a purposed and efficient action developed by academic institutions to recognize cultivate and assess internal employees to prepare internal employees for critical leadership positions (Rothwell, 2010a).

The Link Between Knowledge Management and Succession Planning

This study exhibits the close connection between succession planning and knowledge management. Both topics are linked to playing an important role in having adequate actions in place to handle the challenge for long term absentees of employees. The study of Lahaie (2005) estimated that 42% of organizational knowledge exists exclusively with employees, which has serious implications for institutions of higher learning.

There is an urgent need for a study on succession planning and knowledge management strategies for higher education institutes. The study of (Grossman,2014) mentioned that "as expected, shortages of academic leadership have received increased attention, limited literature is available to address the importance of succession planning and its relationship to the organizational knowledge-based theory"(p.30)
The succession planning process is considered a high-level plan for knowledge management. Transferring organizational knowledge from leadership to successors is a challenging task during the leadership change. Organizational knowledge transfer studies make clear the potential loss of information when knowledge transfer is not planned at an organization, providing validation to the value of leadership succession planning (Grossman,2014).

The study of Sambrook (2005) has suggested the three types of knowledge requires for successors. The first type of knowledge is K1 which requires Technical Knowledge and a threshold competence. This knowledge can be passed on and learned. The second Knowledge is K2 which is about a firm or an organization and how it works. This knowledge can be relatively easily made explicit and transferred to a potential successor. The last type of knowledge is K3 which covers specific tacit knowledge that relates to decision making and risk-taking. This is more difficult to make explicit and the transfer of it. This depends on the leader's willingness and capacity to share this knowledge as a successor.

The study of Grossmna (2014) mentioned that previous studies have done to evaluate the lack of succession planning in higher education institutes (William & Mackey, 2008; Richards& Neefe,2009; luna,2010; Green,2011). Successful Organizational sustainability is depending or knowledge transfer. Because when an experienced workforce departs from the organization, it is a potential loss of institutional knowledge (Rothwell,2011). Organizational knowledge has been learned from experience with work and people. (Rothwell,2011).

The study of Grossman (2014,p.18) mentioned that "the lack of effective succession planning for higher education institutions may limit organizational knowledge transfer as well as organizational effectiveness at a time of projected leadership shortages (Jacobson, 2010; Peters, 2011; Taylor & Machado, 2008)". In addition to this succession planning is the best technique for knowledge management withing organizations to protect institutional knowledge for organizational effectiveness (Cabrera-Suarez,2005).

The sharing of knowledge at the workplace is the only method of organization collaborations and employees can pass the acquired knowledge. Although knowledge is known as an influential factor in the succession process. The study of Durst et, al (2015) mentioned that "Loss of knowledge may represent the most critical aspect related to succession planning (p.8). In addition to this study "lost knowledge means the decreased capacity for effective action or decision making in a specific organizational context" (DELONG, 2004, p. 21). The study of Tonet & Paz (2006) mentioned that the loss of knowledge causes knowledge sharing.

According to Durst et, al (2015, p.8) the study of Sambrook (2005) mentions" different types of knowledge that need to be considered from a successor's point of view. These are the technical knowledge (easily codified); knowledge about the firm (made explicit relatively easily), and the specific tacit knowledge related to leadership, decision-making and risk-taking (most difficult to make explicit)".

In conclusion, this study reviewed the situation of limited literature review about knowledge management and succession planning in public learning institutions. In addition, this study clearly exhibits the close relationships between knowledge management and succession planning. Furthermore, limited academic research can integrate knowledge at risk.

Methodology

This paper is based on extensive traditional literature review search of published articles that primarily address the concept of knowledge management, succession management and the importance of the link between knowledge management and succession management. The criteria for inclusion are peer-reviewed journals from the world scientific Scopus, science direct and emerald insight published from the last decade to present. The exclusion criteria are non-academic researchers and other languages. Three main key words knowledge management and succession management and higher education were used in the database for search. This study has reviewed more than 70 references, of which 26 are cited in this study. Most of the articles were published in the highest-ranked journals in the relevant field. The results of the literature review indicate that higher education institutes are aware of the importance of knowledge management, succession management. Although, few studies exist, and it gives strong evidence in the education sector.

Discussion

The concept of knowledge management is complex. Public higher institutes have significant opportunities to apply knowledge management to achieve organizational goals. Using knowledge management techniques at higher education institutes is fundamental as in the business sector. lack of knowledge management and succession planning at higher learning institutions along with the aging workforce is a problem. Succession planning is not vital in higher education if knowledge transfer strategies are in place. (Grossman,2014).

In today's global business environment, there is a need for Succession planning due to retired workforce and a lack of interest in younger employees. The study of (Dezure et al., 2014; Mintz-Binder, 2013; Vogelsang,2014) mentioned that organizations facing the problem of lack of interest by the younger generation for the leadership positions. Susanne& Stefan(2012) emphasized that " universities and other educational institutions the findings reveal that there is a need to stronger incorporate the handling of knowledge loss into their curriculum, to help future managers and business owners to better tackle this issue in an increasing knowledge has driven business environment respectively in firms with an aging workforce"(p.9). Higher education institutions always expect adaptable knowledge employees who can lead and produce new knowledge.

Top management in higher education cannot be ignored the practice of succession planning. The study of Phillips (2019) has focused that "Succession planning is a systematic approach to ensuring leadership continuity within an organization by encouraging individual employee growth and development, through purposeful identification, development, and mentoring of future leaders. The benefits of succession planning include job satisfaction, leadership stability, retention, and ensuring inherent knowledge of the organization is not lost" (P.8).

The brief review clearly explains the close relationship between knowledge management and succession planning which can tackle the threat of long-term absence of employees from the institution.

Conclusion

This study concludes that Succession planning should not be limited to focus on employee's identification and selection of successors, but also focus on the transfer of technical and critical knowledge within the higher education institutes. The departs of technical knowledge can be resulted in financial and non-financial losses. Therefore, Higher education institutions must focus on developing a knowledge workforce that can be excel in a today's challenging environment. This study finds that higher education institutes are familiar with the crisis of knowledge attrition. However, some factors such as culture, advanced technology, lack of directive leadership influence the implementation of knowledge management. The results of this article are expected to serve as a reference guide for higher education institutions involved in knowledge management projects. In addition ,a strong connection between knowledge management and succession planning was another finding of this study.

The Size of The Organization as A Moderator of Relation Between Organization's Resilience and Organizational Performance

Anna ZABŁOCKA-KLUCZKA

Wroclaw University of Science and Technology, Faculty of Computer Science and Management, Wyb. Wyspianskiego 27, 50-370 Wrocław, Poland, anna.zablocka-kluczka@pwr.edu.pl

Abstract

The paper is devoted to the analysis of the potential influence of organization's resilience on organizational performance. In particular the analysis concentrates on organization's resilience. It is assumed that organization's resilience is one of factors potentially influencing organizational performance, and that relation is influenced by the size of the organization. It must be stressed that, although the size of the organization is measured here directly, it is treated as a proxy (a category followed by a set of specific, organizational characteristics). Empirical research was conducted to verify formulated hypotheses based on results obtained from 268 organizations from Poland.

Keywords: organization's size, organization's resilience, organizational performance, management

Introduction

Organizations every day face internal and external factors that can induce crisis. Some of them successfully deal with those events and prosper even better than before, benefiting from the opportunities that arise that way, while others suffer severe damages or even bankrupt. Understanding how and why organizations avoid or survive crises and outline the drivers of crisis avoidance, handling and recovery has been for long a subject of interest of researchers and practicioners (companys' owners, executives, managers). To explain it the concept of organizational resilience emerged, incorporating insights from crisis management and contingency theories, natural accidents theory (NAT) or high reliability organizations (HRO) concept (Perrow 1984; Pearson & Mitroff, 1993; Pearson & Clair 1998; Sutcliffe 2011; Vogus et al. 2014). There is no a widely accepted definition of organization's resilience, however most of researchers agree that it refes to the organizaton's ability to function despite the presence of challenging, unfavourable conditions or ability to recover from untoward events (Sutcliffe & Vogus, 2003; Manyena 2006; Vogus & Sutcliffe, 2008; Lengnick-Hall et al. 2011; Lee et al. 2013; Zabłocka-Kluczka 2014; Linnenluecke 2017). In literature there is also a lot of different research streams regarding organization's resilience. They focus on the ways how resilience arise, drivers of resilience and their implications for organisations' functioning. Due to the fact, that "many factors influence organizational resilience simultaneously, and in different and often competing ways" (Andersson et al. 2019, p. 36), that concept is still characterized by the lack of clarity. Moreover, it is often underline that organizational resilience is contextual – it is atrributed to a number of organizational (often latent) characteristics that "can be activated, combined and recombined in new situations as challenges arise" (Koronis & Ponis 2018, p. 34). All them contribute to organizational resilience, but often none of them is sufficient on its own to explain it (Andersson et al. 2019). In scientific research that confusing complexity is often reduced by focusing on selected factors contributing to resilience. At the beginning of XXI century the accent in research was shifted from the activities and actions purposefully undertaken in the hope of ensuring resilience (e.g. business continuity management) to the attributes (features) of the organization as a resilience drivers (i.e. leadership, strategic or cultural factors, or organizational structures). However, among the latter group there are still relatively few works devoted to the size of the organization as a resilience driver. Hence, from the research gap indicated above is arising the need to verify if the size of the organization can indeed be treated as a "protective umbrella" and to deepen the knowledge on mechanisms shaping organization's resilience in order to contribute for both theory and practice. In that context the main aim of the paper is to verify if the size of the organization influences organization's resilience, and

going further, if it is a moderator of the relation between organization's resilience and organizational performance.

Literature Review and hypotheses Development

Organization's resilience and the problems with measuring it

As it was already pointed, neither it is easy to define the concept of organization's resilience, nor to measure it. A widely accepted definitions, as well as widely adopted instrument to measure organization's resilience has not yet emerged.

Organization's resilience can be understood as a *capacity* (for successful adaptation or positive functioning despite unfavourable conditions (Hamel & Välikangas (2002)) or a *property* of the organization (that enables its survival and sustainable development (Zabłocka-Kluczka 2014)), an *outcome* (positive end, "positive state that every organizations aim to achieve" (Kantur & Iseri-Say, 2015), a state of organization "conditioned by entirety of management processes designed to restore the integrity of the internal environment" (Zabłocka-Kluczka 2014, p. 319) or as an *process* ("linking a set of adaptive capacities to a positive trajectory of functioning and adaptation after a disturbance" (Norris et al., 2008), or "the maintenance of positive adjustment under challenging circumstances such that the organization emerges from those conditions strengthened and more resourceful" (Vogus & Sutcliffe, 2007, p. 3418)).

Moreover, organization's resilience can be understood both as the organization's ability to absorb or cope with disturbance or other challenging event (capacity to preserve position), but also as the developed capacity to recognize and adapt to unexpected changes (Sutcliffe & Vogus, 2003; Manyena 2006; Vogus & Sutcliffe, 2008; Lengnick-Hall et al. 2011; Lee et al. 2013; Linnenluecke 2017; Koronis & Ponis 2018). In that context two forms of understanding of organizational resilience have been distinguished: *reactive (passive)* resilience (being a form of absorptive capacity that refers to survival in the face of threat) and *active* resilience, that refers to the ability to transform the organization in response to environmental shifts or even to grow with challenge (Giezen et al. 2015; Sawalha 2015). According to it organization's resilience can be "static, when founded on preparedness and preventive measures to minimize threats probability and to reduce any impact that may occur, and dynamic, when founded on the ability of managing disruptions and unexpected events to shorten unfavourable aftermaths and maximize the organization's speed of recovery to the original or to a new more desirable state" (Annarelli & Nonino 2016).

From this combined approaches different drivers of organizational resilience are derived. They vary widely across studies, however most of researchers agree that to the most important one belong: situation awareness, preparedness, responsiveness, resourcefulness, redundancy, robustness, rapidity, adaptability, agility, integrity, learning processes or organizational culture (Norris et al., 2008; Scholl & Patin, 2012; Bruneau et al. 2003; Wicker et al. 2013; Kantur & Iseri-Say, 2015; Koronis & Ponis, 2018). They are also often the basis for building organization's resilience assessment tools. This variety of possibilities points the difficulties that scholars have experienced trying to measure, evaluate and compare organizational resilience. In practice it is difficult to meet research conducted according to the same scheme and with use of the same research instrument. And although the 4R model (referring to resourcefulness, redundancy, robustness, rapidity) repeats most often (Bruneau et al. 2003; Wicker et al. 2013), items and measuring scales are usually constructed by researchers individually.

Organization's Resilience, Size of The Organization and Organizational Performance – Hypotheses Development

It is obvious that the size of the organization cannot be neither main nor the only factor determining organizational resilience (as organizations' should be resilient regardless of its size), however it can influence resilience alongside other organizational characteristics. The size of organization could be treated as a proxy – a category followed by a set of specific, organizational characteristics.

"Empirical studies have documented a systematic connection between organizational size and age" (Larsen & Lomi 2002, p. 281), as well as other organizational characteristics. According to size usually grows routinization, formalization, and institutionalization. As the organization becomes larger (grows older and gains experience), the initial variability in production activities, quality and administrative behaviour decreases due to routinization and learning (Larsen & Lomi 2002, p. 279). Grows also structural inertia (defined by (Larsen & Lomi 2002) as the tendency of organizations to resist change), which higher level slows downs the creation of new capabilities. According to size grows also inherent complexity of organization which inhibits processing and hinder the transfer of information.

Structural characteristics are not the only features that distinguish small and large organizations. Small companies have their own specifics. These are usually organizations with a homogeneous, non-diversified profile, operating in market niches that are not profitable or not capacious enough for large companies. They have limited access to the capital market, which also means limited financing investment options. Due to the lack of capital links, on the one way their decisions' freedom is higher, however range of cooperation possibilities – lower. Smaller organizations usually have not broad access to network of industry connections. Lower size of organization is also usually positive correlated with lower market share and negative connotations attached to risk-taking which in turn discourage innovation. Small and large firms possess fundamentally different resources and capabilities. Small organizations have limited resources in the form of time, money and human capital (Van Gils 2005), however "small businesses possess certain resources that allow them to overcome some barriers which create greater difficulties for their larger counterparts, as well as allow small businesses to exploit certain industry opportunities more readily than larger ones" (Dean et al. 1998). Also the way they run the business, the way they are organized and managed, and the markets they serve are significantly different than in case of large enterprises. With the help of all these qualitative criteria, it is difficult to distinguish between small and medium-sized enterprises. They are most often presented together as one category (SME) and characterized in opposition to large enterprises. In general, it is widely recognized that are substantial differences of SMEs in comparison to large organizations.

According to Ates and Bitici (2011) SMEs are characterized by a number of patterns of behaviours which may hinder their ability to become more resilient. They tend to think and plan in the short term, focus on day-to-day problems, apply rather firefighting management style than strategic management, "accept their environment as given and install the mechanisms to react to its forces rather than leveraging internal capabilities for proactive change, which is an essential driver for resilience" Ates and Bitici (2011, p. 5602). It seems also that due to restricted resources (personal or financial) smaller organization are in disadvantage to implement an organizational resilience management systems or business continuity management solutions, because planning and preparing for crisis is potentially costly. However, there are also suggestions that lower organization's size does not necessarily go hand in hand with lower organizational resilience. Leflar & Siegel (2013) notice that lower complexity of small organization eliminates organizational silos, promotes faster decision making and greater flexibility and adaptability. SMEs are generally good at taking decisions quickly, especially in the face of challenges, and that speed in action can be regarded as an important resilience driver of SMEs. However, from four categories of capabilities that an organization's requires for resilience (resourcefulness, redundancy, robustness, rapidity), "SMEs fall short in all but rapidity" (Wishart 2018, p. 15). Considering all the above, the following research hypothesis can be formulated:

H1: There is a positive relation between Size of the organization and the Organization's Resilience.

Organizational performance is a key factor enabling the survival and achievement of success in the modern business and in that context it is a category desired by both large and small organizations. Although it is probably one of the most common construct (and output factor) used in research in the management field, it is surprisingly rarely precisely defined. According to Richard et al. (2009), organizational performance can be defined broadly or very narrow, as a part of wider and more general one - organizational effectiveness. In the narrow sense it is equated with financial performance (by usage of such measures like profitability, sales growths or stock returns), in the broader one – related to strategic and operational performance (and measured by using such measures like productivity, market share, product quality, innovativeness, competitiveness etc.) (Judge 1994). According to that

first category, taking into account only absolute measures, supremacy of larger organizations seem indisputable. This thesis has been confirmed among others by Judge (1994), who proved that larger organizations have an inherent financial advantage over smaller organizations. This positive effect of size on organizational effectiveness results from economies of scale (Amah et al. 2013). Also according to such performance measures like market share, productivity or innovativeness (conditioned by access to resources) dependence between organizational size and organizational performance seem to be similar, which means that size can be treated as an organizational performance driver. Although there are also measures that seem to be independent from organization's size (like product quality) and despite the fact that the Judge's (1994) research showed that the organization's size is negative related with social performance, considering all the above dependencies and accepting the predominant management outlook based on the belief that the size of a firm affects corporate efficiency, the following research hypothesis was formulated:

H2: There is a positive relation between Size of the company and the Organizational Performance.

It is often underlined that resilience is the capacity to rebound from adversity strengthened and more resourceful (Sutcliffe and Vogus 2003). To be resilient thus means to emerge stronger from the adversity the organization's was caught in and to achieve positive potential outcomes (like increased competitiveness or innovativeness, more adjusted internal processes or higher profitability). Moreover, as the drivers of organization's resilience are in many cases the same as those that are needed to gain a competitive advantage (Mitroff et al. 1989), one can suppose links between organization's resilience and business as usual profitability. Links between organisational resilience and profitability suggest i.e. Sundström and Hollnagel (2006). According to them "to be resilient, an organisation must be able to deal with unexpected and disruptive events as well as to understand the longer term impact of such events. (…) this translates into the ability to identify and successfully manage risk at all levels in the organization while sustaining a profitable business" Sundström and Hollnagel (2006, p. 1). The relationship between organizational resilience and organizational performance in the financial aspect had been proven by Carden et al. (2018). This relation can be also double-sided. Not only organizational resilience can influence organizational performance (i.e. profitability), also higher profitability can strengthen organization's ability to prepare and respond effectively to emerging threats. That observation seems to be valid also in relation to other categories taken into account when measuring organizational performance. Therefore, following hypothesis may be formulated:

H3: There is a positive relation between the Organization's Resilience and the Organizational Performance.

And finally, based on the arguments presented above, it may be stated that the size of the organization has the potential to moderate the influence of organization's resilience on organizational performance. That is mainly because of the differences between small and big organizations arising from organizational characteristics and practices of management. Bigger organizations enjoy the scales effect and the effects of networking, establish an unique, complex and supportive external relationship, engage more strongly in innovation processes and respond in more systemic way to crises and change in general. The effects of these practices affect both organizational resilience and performance. It can be thus assumed that in a larger organizations even a small increase in the level of organizational resilience can result in a greater increase in organizational performance than in the case of small organizations. So it can be another benefit of economies of scale. Considering all the above, in the context of planned research scheme, the following research hypothesis was formulated:

H2M: In bigger organizations, the influence of the Organization's Resilience on the Organizational Performance is stronger than in smaller organizations. Size of the company thus is a moderator for the relation between the Organization's Resilience and the Organizational Performance.

All developed hypotheses, showing the relation between Size of the organization, Organization's resilience and Organizational performance, are presented on Fig. 1.

Fig. 1: Size of the organization as a moderator of the relation between Organization's resilience and Organizational performance. Source: own research.

Research Methodology Description

Data Gathering Process and Characteristics of The Research Sample

The survey was conducted in order to verify the proposed hypotheses and identify the relations between organization's resilience and organizational performance. The research was conducted in December 2019 using online survey service: SurveyMonkey among organizations located in Poland, which was the only condition limiting the sample (organizations were surveyed regardless of size, industry or type of business etc.). Only one survey was carried out anonymously in one organization, and it was completed by employees who have a broad view of the entire organization. 268 valid responses were collected. According to the size of population of organizations operating in Poland the sample cannot be considered as representative, however, it is sufficiently diversified to be a basis for overall conclusions concerning the given topic. Characteristics presented in Table 1 clearly show that the sample is covering organizations of all sizes and all types. The sample is dominated by typically manufacturing organizations (approx. 49%), approx. 27% of the surveyed organizations conduct service activities, the remaining 24% - are trade organizations. Approx. 60% of respondents are local enterprises, the remaining 40% are economically independent organizations that are part of large international corporations and holdings, or cooperate with them and operate internationally.

Table 1: Research sample characteristics

Size of the organization	Manufacturing organizations	Trade organizations	Service organizations	Total
Micro (below 10 employees)	12	11	9	32
Small (10-49 employees)	37	15	11	63
Medium (50-249 employees)	42	26	24	92
Large (above 249 employees)	37	11	28	76
Total	128	63	72	263

Variables Measurement

In order to examine the proposed hypotheses, key variables were defined: *Organization's size*, *Organization's resilience* and *Organizational performance*.

Organization's size was measured by number of employees and operationalized as a four-group categorical variable with micro (employing less than 10 people), small (employing from 1 to 49 people), medium (employing from 50 to 249 people) and large (employing over 249 people) organizations in particular groups. This distinction was adopted after the EU recommendation (2003/361/EC, Official Journal EU L 124 from May 25th, 2003).

Variable *Organization's resilience* was build basing on four properties assigned to system's resilience: robustness, redundancy, resourcefulness and rapidity (Bruneau et al. 2003; Wicker et al. 2013). Within this four properties 4 measures (respectively one item according to one property) of the organization's resilience were indicated. They were rated on the 5-points' Likert scale (from strongly disagree to strongly agree, with middle point I do not have an opinion).

Organizational performance was measured based on Balances Scorecard concept (Kaplan & Norton, 1996). That framework allows to draw together multiple measures aimed at financial performance, internal business processes, customer perspectives, and innovation and learning. Within these 4 perspectives, 10 measures of the organizational performance were indicated. They were rated on the 5-points' Likert scale (from well below expectations to well above expectations with the middle point: as expected).

The Research Results Description

Descriptive statistics and reliability analysis of scales

As a first step in a research process, the reliability of scales of each variable was verified. The results of the analysis of the reliability of the measurement scales are presented in tab. 2. It is worth underlining that Cronbach's α was high for every variable, which indicates a high internal reliability of the scales and measurements.

Table 2: Defined variables along with the results of the reliability analysis of scales

No.	Variable	No. of scales	Alfa-Cronbach
1	Organization's resilience	4	0.809
2	Organizational performance	10	0.873

Source: own work.

Relations between Organization's size, Organization's resilience and Organizational performance

As the next step of the research, before verifying the main research hypotheses, it was investigated whether there were any statistically significant differences in the assessment of organizational performance and organization's resilience between organizations of various size. Table 3 presents the means assessments in groups of organizations of different size and they seem to be different, what could be a basis for the statement that in bigger organizations, organizational performance and organization's resilience was evaluated higher than in smaller organization, however it was important to check, if this differences are statistically significant.

Table 3: Differences in the assessment of organizational performance and organization's resilience between organizations of various size – means in groups

	Organizational performance			**Organization's resilience**		
Size of the organization	N	mean in group	standard deviation	N	mean in group	standard deviation
micro	30	3.02	0.786	30	2.89	0.955
small	62	3.26	0.716	62	3.00	0.871
medium	90	3.39	0.523	89	3.28	0.729
large	72	3.73	0.706	76	3.70	0.822
	254	3.41	0.695	257	3.29	0.869

Source: own work.

In order to check it ANOVA analysis was conducted preceded by verification of assumptions regarding statistical data characteristics. Results of variance homogeneity test for means in both cases confirmed

that the differences between the variances in the compared groups were not statistically significant, so it can be assumed that the variances are equal or at least similar to each other (F-Levene'a (3,250) = 2,41; p=0,068 for organizational performance and F-Levene'a (3,250) = 0,71; p=0,547 for organization's resilience). It allowed to carry out the ANOVA analysis, which results showed that there were statistically significant differences between the means in the compared groups of organizations of various sizes, both in case of evaluation of the organizational performance (F(3,250)=10,065; p<0,001) and organization's resilience (F(3,250)=11,399; p<0,001) as well. Due to the fact that the test results do not precisely indicate which of the compared medium groups differ from each other, *post-hoc* analysis was performed. Scheffe test showed that in both cases there was a statistically significant difference in means for organizations of different size only between SMEs and large organizations (see Table 4), which is in line in the overall thesis that there are substantial differences of SMEs in comparison to large organizations.

Table 4: Test Scheffe for difference of means of analyzed variables

Scheffe Test		**Organizational performance**			**Organization's resilience**		
Size of the organization	Size of the organization	difference in means	standard error	level of significance	difference in means	standard error	level of significance
micro	small	-0.23968	0.14683	0.448	-0.10833	0.18243	0.950
	medium	-0.36556	0.13918	0.078	-0.38642	0.17317	0.176
	large	-0.70500*	0.14346	0.000	-0.81228*	0.17687	0.000
small	micro	0.23968	0.14683	0.448	0.10833	0.18243	0.950
	medium	-0.12588	0.10896	0.721	-0.27809	0.13569	0.243
	large	-0.46532*	0.11438	0.001	-0.70395*	0.14038	0.000
medium	micro	0.36556	0.13918	0.078	0.38642	0.17317	0.176
	small	0.12588	0.10896	0.721	0.27809	0.13569	0.243
	large	-0.33944*	0.10439	0.016	-0.42586*	0.12811	0.013
large	micro	0.70500*	0.14346	0.000	0.81228*	0.17687	0.000
	small	0.46532*	0.11438	0.001	0.70395*	0.14038	0.000
	medium	0.33944*	0.10439	0.016	0.42586*	0.12811	0.013
**. the difference of means is significant at the level of 0.05*							

Source: own work.

The next step of the analysis was the correlation analysis between *Organization's size*, *Organization's resilience* and *Organizational performance* in order to verify hypotheses H1, H2 and H3 (see Table 5). The results showed that the size of organization is statistically significantly correlated with:

- *Organization's resilience* (r(257)=0,334**, p<0,001), which is the basis for positive verification of the hypothesis H1, and
- *Organizational performance* (r(254)=0,320**, p<0,001), which is the basis for positive verification of the hypothesis H2.

In both cases correlation is positive, although moderate. The obtained results showed also that there is positive, strong and statistically significant correlation between *Organization's resilience* and *Organizational performance*. It allows for the acceptance of H3 hypothesis.

Table 5: Correlation analysis between analyzed variables

		Organization's resilience	**Organizational Performance**
Size of the organization	r	0.334**	0.320**
	Sig.	<0.001	<0.001
	N	257	254
Organization's resilience	r	1	0.541**
	Sig.		<0.001
	N	259	247
***. Correlation is significant at a level of 0.01 (two-sided)*			

Source: own work.

Summarizing, the obtained results clearly show that there is a statistically significant and positive correlation between all analyzed variables, however definitely the highest in case of the relation between organization's resilience and organizational performance.

Organization's size as a moderator for the relations between Organization's resilience and Organizational performance

The relation between organization's resilience and organizational performance was analyzed in the context of the size of the organization to verify whether this variable is a statistically significant moderator of the relation, which existence is verified above. Regression analysis with moderator was used to determine that, using the pattern proposed by Tworek & Zabłocka-Kluczka (2018). According to that, as a first step, new variable – moderator – was introduced. The moderator variable was built as a product of two standardized independent variables (*Size of the organization* and *Organization's resilience* as a second independent variable). As a second step, 3 regression models were built (the analysis was performed using Process macro for IBM SPSS Statistics):

- first model was built as a base model for comparison and only independent variables (*Size of the organization* as a second independent variable) were added as predictors,
- second model was built to verify whether the moderating influence is occurring in sample, using independent variables (*Size of the organization* still as a second independent variable) together with the moderator as predictors
- to confirm that, the third regression model was built (using only one independent variable (without *Size of the organization* as a second independent variable) and the moderator as predictors).

The results of the analysis are presented in Table 6.

Table 6: Regression models' statistics

Model description	R^2	*Delta* R^2	*Moderator coeff.*	*Standard error*	*t Stat*	*P Value*
The size of the organization, Organization's resilience, Moderator *dependent v.:* Organizational performance	0.330	0.015	0.098	0.042	2.314	0.022

Source: own work.

The obtained model clearly shows that the size of the organization is a moderator of analyzed relations. The delta R2 and obtained model are statistically significant ($F (1, 243) = 5,356$, $p < 0,05$). Therefore, obtained results are the basis for positive verification of hypotheses H3M confirming that *Size of the company is a moderator for the relation between the Organization's Resilience and the Organizational Performance.*

Discussion

Although, according to Mitroff et al. (1989) insights, the size of organization will not protect it from hitting and the effects of the crisis, conducted research showed that in the context of organization's resilience, the size can matter. Larger organizations achieve higher resilience scores and moreover, it appears that the size of organization strengthens the relation between organization's resilience and organizational performance. However, it must be underline that this difference in resilience level is not so much because of the size of the organization itself, but because of the proxy effect it creates (that results from the internal inertia, possessed resources, management practices, network of relations or the support instruments that follow the size).

Unlike SMEs, large organizations have a much larger network of connections, often international and definitely greater access to external resources (capital, politicians or contractors). Also, by design, a

larger organization has a larger amount of internal resources that, if needed, can be allocated to other areas of its operations, which can paradoxically can provide more organizational flexibility. In smaller organizations the possibility of such substitution is usually limited by access to resources (often there is nothing they can allocate). Moreover, other instruments of external support available to small and large enterprises, result from the importance of organizations of various sizes for the economy. While the collapse of a micro or small enterprise can be treated in the context of a natural economic system regulator (capital is transformed and transferred to those who can use it better), the collapse of a large organization is usually associated with serious consequences for the economy of the region or even the country. Weighing tax revenues that can be lost, as well as the extent of social problems that can be caused by the failure of a large organization (e.g. unemployment, and following it decline in the purchasing power of citizens, recession in the region or poverty), it is often in the interest of the state to support big companies in trouble. All this makes it easier for larger organizations to remain resilient, to function despite the presence of challenging, unfavourable conditions or to recover from untoward events.

The research whose results are presented in this paper, were conducted before the COVID-19 pandemic, that hit the world at the beginning of 2020 and drastically changed the way and the context of all around the world organizations' functioning. In that specific situation organizations were suddenly facing the unprecedented challenge of surviving in a situation of almost complete market paralysis, disruption of global supply chains, interruptions to production, unavailability of physical and human resources. And although the problems they face were common for organization of various size (lack of earning opportunities, change in market structure, new demand trends), the vulnerability to the caused that way crisis seems specific not only to industry, but also to size. Due to their lower availability of resources (e.g. limited cash reserves or number of employees)), SMEs seem to be more vulnerable thus less resilient. The dramatically changing number of SME bankruptcies in March and April 2020, actually in all countries where the pandemic has developed, despite the scope of support given to SMEs by governments of various countries, seems to confirm this thesis. That case clearly shows that size can be indeed treated as "an protective umbrella".

Conclusions

The ability of organization to continue to operate despite the impact of adverse factors determines its survival and future performance. Practitioners and researchers have long been looking for factors building and strengthening organization's resilience, however a widely accepted organization's resilience theory still does not exist. This paper is not in main stream of research, as it neither explores the new way of understanding and defining the essence of organization's resilience, nor develops an universal tool that can be used to measure resilience, however it explains how and why the size of organization influences the organization's resilience and strengthens the relation between organization's resilience and organizational performance, and in that way also contributes to that theory.

Performed empirical study is burdened with certain limitations. The obtained sample of 263 organizations is by far not a representative sample and verified only in one business context, so in future it is worth to consider the verification of formulated hypotheses in organizations operating in other countries. Moreover, only one factor influencing organization's resilience is taking into consideration. However, although the obtained results seem to be a solid first step in the analysis of the role of organizational attributes (features) arising from the size of the organization in shaping the organization's resilience, they clearly need further research and in-depth analysis. It is also worth to explore simultaneously more than only one organizational factor influencing resilience. That would allow to assess the strength of influence and significance of each of them, providing the same interesting hints for organizational resilience management.

Abstract

The rise of digital start-up companies plays a vital role in various industries and affect the economy globally. Most of these companies initiate their businesses out of intriguing ideas and necessitate a business incubator to foster and nurture the initial ideas' development. The role of business incubators in developing digital start-ups becomes essential as well as the proses of executing this role. This study endeavors to elaborate on the role of business incubators in developing digital start-up companies using a systematic literature review and expands the understanding using the case of Indonesia. To have better information and enrich the literature review, we utilize in-depth interviews with three business incubators and four digital start-up companies. Business incubators have a significant role in the development of digital start-up companies through daily operations as a business mentor as well as ecosystem development.

Keywords: Business Incubator, Digital Startup, Roles, Literature Review, Qualitative Methods

Introduction

The emergence of new digital start-up companies become more important to some countries since they are very innovative, creative, and provide new opportunities to help push the economy forward. By the year 2014, many governments give easiness to create a company to start a small business; such as the United States in just six days, Saudi Arabia five days, Singapore three days, and even New Zealand in only one day ("10 Fun and Surprising Small Business Facts,"). Moreover, the United States Census Bureau reported that the start-up companies created over 2 million jobs in 2015 in the United States (Bureau, 2017). Indonesia has also adapted to this change; it took forty-seven days previously to only ten days with the 12th economic stimulus policy package starting in the second quarter of 2016 (Post, 2016).

Nevertheless, besides the economy, digital start-up companies have breached many things by changing the map of competition in various industries; for instance, Facebook, Uber, WhatsApp, Twitter, with novel ideas creating users feel more comfortable in their life. In Indonesia, we are also observing almost the same phenomenon; there are Gojek, Traveloka, Tokopedia, Bukalapak, and OVO, which have become Unicorn digital start-up companies, i.e., start-up companies with a valuation of more than $ 1 Billion (Post, 2019). That achievement was obtained in a relatively short time, under ten years since the establishment of these companies. In terms of impact, with many users, each of these start-ups "disrupts" conventional businesses. A similar question is remains; how Gojek disturbs the transportation business, how Tokopedia and Bukalapak disturb the conventional market and mall businesses, how Traveloka disturbs the travel business, and how Ovo disturbs wallet and payment mechanism. These so-called revolutions have become pro and contra for many parties, ranging from businesspeople, users, to regulators.

Furthermore, there is an interesting issue that can be explored, when these digital start-up companies start ideas and seek for potential users, they are faced with the choice to develop their company self-taught or learning from a business incubator. By learning from the business incubator, of course, it is expected to increase their knowledge until the digital start-up companies are finally ready to plunge into their operating industries. From the business incubator side, are they ready to provide the right experience or guiding program for the digital start-up business makers? It might be that the guiding program has played an essential role in developing the digital start-up company's plans to develop ideas and continuous improvements to "hit" other industries.

Based on the described phenomenon, how is the relationship between business incubators and digital start-up companies may promote beneficial conditions? In other words, what are the roles of business incubators? This study identifies the roles of business incubators in fostering digital start-ups. We argue that the roles have a significant impact on the start-ups so that they can take advantage of the guidance program provided by the business incubators. We explore previous studies using a systematic literature review (SLR) to provide an analytical overview of the current knowledge and examine the research theme under study (de Araújo, Alencar, & de Miranda Mota, 2017). Based on the SLR, we further qualitatively elaborate on the findings using Indonesian cases.

Literature Review

With the start of the era of the digital start-up company that disrupts everything, the existence of business incubators cannot be underestimated. The business incubators facilitate the initial phase of the development of digital start-up companies, with various services they can provide to the digital start-up companies that they fostered. According to Alon and Godinho (2016), business incubators are institutions whose design is to help new firms, which are regularly small and creative, to build their opportunity of endurance and their future development. This definition also means business incubators are a shared office that seeks to provide firms with a strategic, value-adding intervention system of monitoring and business assistance.

In different journal articles, there is a kind of expectations on the positive effects of business incubators on start-up growth, some of these positive effects include: to initiate and boost innovation in a region and accelerate the development and growth of innovative firms through the provision of high value-added services; provides innovative start-ups with a sheltered environment; provides access to financial resources and entrepreneurial start-up support in the form of training, coaching, or mentoring, as well as access to internal and external networks. Nevertheless, in the prior study, convincing evidence was not found that would justify the spending of public money on business incubator support in the short run, despite some indication that incubated innovative start-ups may experience faster revenue growth during their third or fourth year. Moreover, incubators often try to "pick winners" and provide them with a sheltered environment (Lukeš, Longo, & Zouhar, 2019).

Business Incubators Roles

The role of business incubators in facilitating innovation in general, and social innovation in particular, has been highlighted via a focus on open collaboration, network formation, learning and knowledge transfer, entrepreneurship, and leadership in ways that are context-dependent in terms of their capacity to create impact. Several of the businesses that have grown subsequently address in much more explicit manner agendas of sustainable development and priorities that could well locate them within the scope of the 'quintuple helix' model (Nicolopoulou, Karatas¸-Özkan, vas, & Nouman, 2015). Cultural and creative work appears to be particularly susceptible to precarious conditions, which have given rise to various responses from the antiprecarity movement. Since the business incubators become the third place, they help freelance designers become more embedded in business networks (in terms of collaborations or customers), both local and foreign, compared with working in isolation, as lone eagles. The third-place appears to counterbalance the pervasive im-materialization of labor successfully. This phenomenon is also reflected in the relatively higher level of job satisfaction reported by those working in third places (Avdikos & Kalogeresis, 2017). The incubator sponsors play a role in the choice of the incubation model. Different types of sponsors, due to differences in their missions and resources, systematically opt for different models, resulting in sponsorship specialization (Mrkajic, 2017). Business incubator as an experience accelerator, the incubator houses a wide range of firms under one roof, turns the business incubator into an area that integrates and accelerates relations between businesses (Redondo-Carretero & Camarero-Izquierdo, 2017).

Business Incubators Impact

Business incubators have both internal and external impacts. The internal impact is felt directly by the start-up fostered by the business incubator, as described above. In contrast, the external impact is the influence given by the business incubator for the surrounding environment, starting from a particular area to increase the economy of a country. For instance, emerging-market countries may benefit from business incubators to encourage the entry and growth of multiple forms of business actors. They tend to operate in parallel rather than in sequence in different stages of development. However, there is some tendency toward government sponsors in lower market development stages and private sponsors in higher market development stages (Dutt et al., 2016). The efficiency of business incubators may be enhanced by understanding the sustainable ecosystem concept and the relevance of the three dimensions of social capital theory (relational, cognitive, structural), which may enhance the development and

implementation of the strategy of business incubators (Theodoraki, Messeghem, & Rice, 2017). As an organization, the business incubators mechanism's governance needs to be explored for the relationships between management, client firms, and other key stakeholders.

In summary, business incubators are successful as a policy for economic and technological growth (Mian, Lamine, & Fayolle, 2016). The role of the business incubators is unexpectedly active in fostering entrepreneurship in a full process scale specified in the idea of an "entrepreneurial university." Such intermediaries act as a facilitator (and a very official broker) between local government, professional associations, university, and industry–which they found to be highly relevant as an enabler for university-industry collaborations (Brem & Radziwon, 2017). The role of the business incubator can also be seen from the valuation of start-up valuations, where incubation efforts and personnel may siphon limited resources away from exploitative programs, the presence of an incubation capability does not seem to be reflected directly in firm market valuation. Instead, the value of incubation investments appears to be leveraged through exploratory discovery investments. In other words, it appears that to translate exploratory, advanced research into profitable products and associated market valuation, firms need an incubation capability (Markovitch, O'Connor, & Harper, 2017).

From information based on the prior research, the existence of a business incubator can be seen from its effectiveness in influencing various parties, both internal and external, on a small scale in the surrounding environment to a large scale in a particular country. The results of previous studies indicate the potential of business incubators in developing a digital start-up company. Through the guidance program from the business incubators, as well as services as the third place for start-ups beside home and work-place, business incubators offer an accessibility/ networking to related parties such as sponsors, business partners, access to customers, suppliers. All these reasons make business incubators as one of the channels that quite powerful to support the business of a new firm to expand ideas and solutions to their users.

The primary characteristics a business incubator must have is to help start-ups generate ideas, do incubation, and make scaling of the business. Having new ideas that do not meet the market test, having market-tested ideas that cannot be scaled, or scaling ideas that are not market validated are all recipes for failure. Success needs all three. The fundamental proposition is that for new ideas to become a new business, they require leaders to master all three disciplines. Each of the three stages—ideate, incubate, and scale—is distinct and necessary, but only when all three are in place is it likely that new ideas will result in new businesses that enable incumbents to lead disruptive innovation in their markets (O'Reilly & Binns, 2019). It is necessary to deepen the guidance program by the expectations of digital start-up companies to provide support for these results. Whether what has been done by business incubators is right to help digital start-up companies to create an integrated ecosystem to provide a positive impact on improving the economy. Therefore, we attempt to elaborate on this matter and find the answer to the following question: What are the roles of a business incubator to digital start-ups?

Research Method

We utilize a two-stage research design. First, we employ a systematic literature review (SLR) to elicit current information related to the roles of the business incubator; second, we conduct in-depth interviews to expand and strengthen upon the understanding obtained from the SLR (Venkatesh, Brown, & Bala, 2013).

Systematic Literature Review Process

The systematic literature review is conducted via three academic databases, namely EBSCOHost, Science Direct, and SCOPUS using the keywords: "business incubators" AND "(start-up or start-up or start up or start-ups or start-ups),". The search is limited to academic articles (journals and conference proceedings) published since 2016. Articles from journals are limited to Q1, Q2, and Q3 classification based on Scientific Journal Ranking (SJR). The pooled articles are reviewed, first, by title and abstracts; second, by skimming the content and evaluating the relevance (the influence of business incubator to digital start-ups). The initial pool is 160 papers; the final pool after the filtering process is 21 articles.

In-depth Interviews

In-depth interviews are further utilized to expand and strengthen the result of the literature review. The interviews conducted to business incubators and their fostered digital start-up companies. They already finished the incubation program and should have a better understanding of the program as well as implement it in the real business world.

Topics related to the interviews are significant roles from SLR results. In total, there are three business incubators and four digital start-up companies. We analyze the interviews using qualitative data analysis by phase filters and create specific codes to groups, and organize the data needed. These codes are generated using the ATLAS.ti 8 application, by two phases: first, organization and preparation for analysis, and second, coding and analysis (Bandara, Furtmueller, Miskon, Gorbacheva, & Beekhuyzen, 2015).

We interviewed managers from three different business incubators because they run the incubator daily operation and directly communicate and collaborate with the digital start-up. From the digital start-up company side, we interviewed founder or co-founder, because they are the one who follows the entire incubation process starting from idea creation until entering the market. For each interview, we took 75 minutes discussion on average and focus on the roles of the business incubator as the business mentor and ecosystem development based on the prior findings.

Result and Discussion

From the resulted articles by systematic literature review, we noticed that not all these articles indeed inform about the influence of the business incubators on the digital start-up company. Twenty-one articles fit with the research objectives. In the following section, we identified the most significant roles of the business incubator from the selected publications:

- Business incubator as a business mentor.
  For digital start-ups companies, the role of a business mentor to help them grow, learning the business, and following step by step to increase performance and deal with the business itself. Process structure: Define as part of the start-up development process, whether it is strategic, administrative, and human capital, which is structured. Moreover, the structure is carried out by the business incubator to run the incubation process for its fostered start-ups. Related information for business incubator as a business mentor in-process structure was stated in 12 articles (Bezerra, Borges, & Andreassi, 2017; Bocken, Boons, & Baldassarre, 2019; Cohen, Fehder, Hochberg, & Murray, 2019; Fukugawa, 2017, 2018; Markovitch et al., 2017; Messeghem, Bakkali, Sammut, & Swalhi, 2018; O'Reilly & Binns, 2019; Patthirasinsiri & Wiboonrat, 2017; Sousa, Carmo, Gonçalves, Cruz, & Martins, 2019; Tripathi, Oivo, Liukkunen, & Markkula, 2019; Vanderstraeten, van Witteloostuijn, Matthyssens, & Andreassi, 2016).
- Ecosystem development
  The critical element of the start-up ecosystem requires businesspeople, technology, market, finance, human capital, supporting factors, education, and demography (Tripathi et al., 2019). Sustainability: Define as the scheme to provide sustainability on business incubator influence for the digital ecosystem. Related information for ecosystem development in sustainability was stated in 4 articles (Baglieri, Baldi, & Tucci, 2018; Fan, Urs, & Hamlin, 2019; Theodoraki et al., 2017; Zhou, Wang, Lan, & Yang, 2017).
  Support system: Define as a system established by the business incubator to support ecosystem development. Related information for ecosystem development in support system was stated in 4 articles (Brem & Radziwon, 2017; Dalmarco, Hulsink, & Blois, 2018; Parasol, 2018; Tripathi et al., 2019).

There are two articles which were pulled out since it was not strongly related to the process structure, sustainability, and support system.

The interview results are used to deepen the business incubator is best practice in Indonesia to make a better understanding of their role to develop digital start-up companies. The results are:

a. Business incubator as a business mentor-process structure

Table 1: Business Mentor-Process Structure Interview Results

Literature Review	Interview Results
Strategic Development	
• Ideas development thru interaction with local partners. • Incubation capability within a firm: the presence of incubation • Gaining understanding through start-up development stage: formation, validation, growth.	• Mentor, whether global or resident, play a significant role in validating ideas. • Requirement on three persons based on character: Hustler, Hacker, Hipster. • Coordination inner and outer the business incubator's incubatee could happen. • Learning on customer validation, product validation, business model validation, market validation. • Mentors play a role in guiding, not giving a solution.

Literature Review	Interview Results
• Start-ups stages are business plan, structuring idea, prototyping, analysis on market and product, evaluation.	• The start-ups should be full time to allocate their resources, especially the founder and co-founder of the incubation program. Focus on doing business instead of learning how to do business. • Adaptive to the situation, the possibility of changing curriculum when needed. • There is no standard curriculum among business incubators. It depends on their plan and area of fostering the digital start-up companies. • The business incubator's primary goal is to make the fostered digital start-ups known their business and how to run it well. Any other issues such as legal issues on how to register a company or how to make partnerships are bonuses to the digital start-ups to get information from the business incubators or their partners.
<u>Administration Development</u>	
• Experience of the founder affect their minimum viable product (MVP) development • Adapting from Balanced Scorecard to identify KPI of the business incubator: Local Development Performance, Incubatee Satisfaction, Incubation Process, and Learning.	• Product development based on customer focus, periodically test the product to fulfill customer's needs • A daily progress report is a must • Determine Key Performance Indicator (KPI) with minimum requirement and achievable. • The way to make KPI is based on the plan on doing something and target to be achieved at a particular time. This result means each start-ups have a different KPI. • Recording system developed by each start-ups, it is applied to make compliance management and learning the journey of making the progress
<u>Human Capital Development</u>	
• Founders should be aware of such tradeoffs and align their goals and objective with those of the accelerator. • The role of experienced and inexperienced founder and team members to the	• Business incubators give way to start-up to meet their network; it depends on the start-up whether they want to use or not. • Develop the product & learning the business model will generate the capability of human capital.

Literature Review	Interview Results
minimum viable product affection.	• Challenge for the start-ups team member, collaborating with other start-ups, and with the incubatee alumni. • There is no specific agenda to develop human capital, but it merges with business events such as seminars, workshops, or talks.

Ecosystem development-sustainability

Table 2. Ecosystem Development-Sustainability Interview Results.

Literature Review	Interview Results
Value Chain	
• The framework of innovation incubation value chain, divided into upstream resources investment, research and development midstream, and economics transformation downstream. • Evaluating innovation incubation ability, not only at the scope of incubators but also widen its understanding to regional incubating carriers.	• The investor is before and after the incubation process. Early investors to support business incubators to give grants to the digital start-ups company, while the latest investor will become the shareholder of the start-ups. • Each business incubator has its scenario to bring the fostered digital start-ups develop into a good company, using their resources in partnership. • Business incubators make partnerships to make way for their fostered digital start-ups to meet their market. • Business incubators also try to involve the government to help them give way to their fostered digital start-ups companies.
Ecosystem Concept	
• The development of a digital ecosystem is by following the rules: coordination and collaboration, increase climate trust, social capital, and interaction to increase performance & sustainability	• Business incubators use collaboration with ABCGM (academic, business, community, government, and media) to build the digital ecosystem for start-ups. • Business incubators make events such as seminar, workshop, training, talks, or specific event (demo day and/or business matching opportunities) • Business incubators build environment to synergize among fostered digital start-ups to back-up each other's business. • Start-ups are willing to give their share to business incubators to have some percentage if they get the benefit of it.

Literature Review	Interview Results
	• In the latest situation, the ecosystem is not created entirely. There is room to develop the ecosystem.
Technology Transfer	
• Technology transfer to spread innovation, giving access to the market, and orchestrating the SME.	• Business incubators act as the co-innovation and co-creation of digital start-ups companies. • There is some learning to digital start-ups companies to upgrade their skill, get from the business incubator. Mostly is about how to use the technology that suits their business plan. • Business incubators use their network to help them give transfer of technology to the digital start-ups companies.

b. Ecosystem development-support system

Table 3. Ecosystem Development-Support System Interview Results.

Literature Review	Interview Results
Digital Innovation Network	
• Bridging companies closer to the university, fostering technology transfer, entrepreneurship, academic research. • The creation of high-tech start-ups upgrading the industrial sector • Key element of start-ups ecosystem: entrepreneurs, technology, market, supporting factors, finance, human capital, education, demography.	• The strong point is that resources from each member of the ecosystem were linked. • Business incubators make events to link the digital start-ups companies to the investors. • Channeling which provided by business incubators are extensive, not to mention government, market, investor, prospecting distribution channel, et cetera. • Business incubators define a schedule to evaluate the effectiveness of a business incubator program to match the start-ups needs.
Intermediaries	
• Such intermediaries act as a facilitator (and a very official broker) between local government, professional associations, university, and industry–which they found to be highly relevant as an enabler for university-industry collaborations.	• One of business incubator declares their reason to exist is as the intermediator between digital start-ups companies to the market, investor, and other networks. • Digital start-ups company felt their business incubator is very helpful when they want to enter the market.

Literature Review	Interview Results
	• Digital start-ups company realizes that the most important is how they use the networking channel from a business incubator.
Tools & Equipment Provider	
• Human capital and supporting factors play a role by providing required business and technical skills to the process, and this is evident in the difference between experienced and novice team members in start-ups.	• The standard tools & equipment provided by the business incubator to help digital start-ups companies are co-working space. • Sometimes business incubators also provide technology-based equipment, such as connection to a server. • In advanced situations, business incubators have also made business catalog from their fostered digital start-ups companies. • The co-working space is useful for the newly established start-ups.

Business incubators run with collaborating, create a digital ecosystem, and use it for many purposes. The start-ups companies themselves know this condition, and they use it very well. The one who not understand the ecosystem established will not get the opportunity to grow and make differences.

Conclusion

We employ a systematic literature review followed by expanding and strengthening the understanding with in-depth interviews with related respondents from three business incubators and four digital start-up companies. The results show that business incubators have significant roles in developing digital start-up companies by being the business mentor and ecosystem development. From the business mentor, the business incubator's process structure was helping the digital start-up company reach its plan. No standard curriculum provides by the business incubators, but it much related to the typical stages of developing digital start-up companies; they are formation, validation, and growth. These typical stages bring opportunity to a digital start-up company to be developed with their needs.

From the ecosystem development, the business incubator's roles in making the ecosystem sustain and their support system are also shown by the result of interviews. Business incubators foster digital start-up companies and collaborate with ABCGM (academic, business, community, government, and media). For now, the role of a business incubator is significant since they provide the ecosystem by themselves, forming for their purposes. This result also is the reason that their program in the typical stages is suitable for the digital start-up company plan. Otherwise, the digital start-up company will leave the business incubator, finding another way to make them successful.

Due to the limitation of this research, therefore, the next study should consider other resources views (e.g., associations, industries, and government) to be unit analysis. With much information gathered, it will strengthen and widen the output of research. Finally, we hope that this research could provide more structured insights and knowledge about the roles of business incubators to the digital start-up companies, or even to economic growth and the creation of digital ecosystems.

Valuation of Cryptocurrencies in Selected EU Countries

Jana VODÁKOVÁ and Jiří FOLTÝN

Masaryk University, Faculty of Economics and Administration, Brno, Czech Republic,
Jana.Vodakova@mail.muni.cz, Jiri.Foltyn@mail.muni.cz

Abstract

The main aim of this paper is to analyse and compare valuation bases used for cryptocurrencies pricing in three selected European countries, i.e. the Czech Republic, the Slovak Republic, and the Federal Republic of Germany. Among others, fair and true disclosure of cryptocurrencies in financial statements, is influenced by valuation techniques used. That is why our paper analyses and compares attitudes to this problem within examined sample of selected European countries. This paper loosely follows our previous paper dedicated to disclosure of cryptocurrencies in financial statements as interpretation and disclosure of cryptocurrencies influence naturally valuation bases used for accounting measurement. We take into consideration also IAS/IFRS view in outline. Firstly, interpretation of cryptocurrencies in selected countries is discussed briefly. Further, valuation bases and basic valuation rules used for cryptocurrencies pricing are analysed and compared.
Obtained findings suggest that equally as a view on cryptocurrency interpretation and disclosure in financial statements differs among traced EU countries, also valuation bases used for cryptocurrencies measurement differ. The Czech Republic that treats cryptocurrency as inventory uses cost of acquisition for its initial evaluation in accounting. Cost of acquisition encompass also related expenses such as exchange fees. Similar attitude holds the Federal Republic of Germany that interprets cryptocurrency as either the long-term intangible asset or other receivables. It evaluates cryptocurrencies by cost of acquisition defined similarly as in the Czech Republic. Different stand takes the Slovak Republic that integrates cryptocurrencies into the short-term financial assets and evaluates them by fair value. This stand differs also from interpretation of IAS/IFRS that include cryptocurrencies either in inventories or in the long-term intangible assets and recommend to evaluate them initially by cost of acquisition.

Keywords: Cryptocurrency, Bitcoin, Valuation, Valuation Basis of Cryptocurrencies, IAS/IFRS

Introduction

Cryptocurrencies that belong to a broader category of cryptoassets still represent a relatively new phenomenon and so their accounting treatment differs not only among EU countries. Bitcoin, probably the first cryptocurrency, was firstly used approx. in 2008 in order to accelerate peer-to-peer transactions worldwide with utilization of blockchain technology. From accounting point of view, some countries recognize cryptocurrencies as cash or financial assets, some integrate them into the long-term intangible assets or the current assets. Evidently, financial reporting of cryptocurrencies is not unanimous and so their reporting in financial statements may signify relatively important differences among countries and used regulations.

Also understanding of a cryptocurrency may differ in literature. For example, it may be defined as means of exchange, similar as US dollar, but digital and using cryptographic tools to control production of currency units and to confirm transfers of money (PricewaterhouseCoopers, 2017). Martinák (2015, p. 47) states that digital currencies are a new kind of currency, electronically created and deposited which also represents their main specific in comparison with classic national or international money that naturally exist in a form of cash. Also Lánský (2018, s. 1) for example considers cryptocurrency as a type of digital currencies that use cryptographic means to confirm transactions. Martinák (2015, s. 55) summarizes characteristics of cryptocurrencies as follows: full decentralization of currency, an absence of agent, worldwide territory, low transaction fees, and anonymity. Cryptocurrencies are regulated by no central authority, transactions take place directly without any agent across the whole world and anonymously. Moreover, virtual transactions are subject to low transaction fees in

comparison with classic economic transactions. Lánský (2018, s. 19) supplements characteristics of cryptocurrencies as follows: specific production of new cryptocurrency units, provability of ownership, elimination of duplicity, no possibility of changes. Production of new units is regulated only by system, ownerships can be proved only cryptographically, duplicate transactions are excluded and once realized transaction cannot be changed or cancelled.

At present, more than 2 000 types of cryptocurrencies operate on market. The most important cryptocurrency as for market capitalization is Bitcoin (about 65 % of the total market capitalization at present). The second and the third position occupy probably Ethereum (about 8 %) and Ripple (about 4 %) while the total market capitalization according to CoinMarketCap (2019) represents approx. 180 billion US dollars at present. The total market capitalization values show significant fluctuation when the highest vales fluctuated about 830 billion US dollar at the turn of 2017 and 2018. Among biggest cryptocurrency exchanges can be put Bitstamp, Binance, Bitfinex or Coinbase currently. There must exist sufficient offer and demand on a cryptocurrency exchange to realize a transaction. It means a substantial difference in comparison with a common exchange office that holds the post of seller or buyer. The less active and smaller cryptocurrency exchange, the less liquid; which is also one of disadvantages of cryptocurrencies that can be characterized by lower liquidity generally. Further drawback represents a question of safety. Cryptocurrency exchange crashes are not extraordinary events and verifying client's identity happens by personal data provided.

Financial reporting and valuation of cryptocurrencies differ depending on particular jurisdictions. It usually comes from interpretation of cryptocurrency established by local financial or other central authority and from characteristics of cryptocurrency. As it was indicated above, presenting of cryptocurrencies in financial statements and their evaluation vary significantly among countries and these differences may be material depending on a ratio of cryptocurrencies on the total assets. That is way we decided to analyse and compare attitudes to disclosure and valuation of cryptocurrencies in selected EU countries.

Methodology and Data

This paper deals with cryptocurrencies from accounting point of view. Its main aim is to analyse valuation techniques used for cryptocurrencies measurement in the Czech Republic and to compare them with techniques used in the Slovak Republic and the Federal Republic of Germany. Comparison will be briefly discussed also with respect to IAS/IFRS interpretation. As valuation techniques we understand valuation bases used for cryptocurrencies initial recognition in financial statements, methods used for valuation at removal of cryptocurrency, their conversion, and rules for revaluation. At this paper we loosely follow our previous paper dedicated to comparison of cryptocurrency interpretation in above introduced countries as the interpretation and disclosure of cryptocurrency influence also valuation techniques used.

As a research sample we used three neighbouring EU countries, i.e. the Czech Republic, the Slovak Republic and the Federal Republic of Germany because they arise from similar accounting traditions, especially the Czech Republic and the Slovak Republic. In future we would like to enlarge our research sample by others, mainly European countries. It would be also desirable to enlarge a scale of compared elements.

For purposes of the paper we used literary search, description of cryptocurrency and review of its development as basic scientific methods. Further we used analysis of the basic valuation techniques in the Czech Republic, the Slovak Republic and the Federal Republic of Germany, and comparison of jurisdictional attitudes with IAS/IFRS. In the last part of the paper we used synthesis of main findings and discussion.

As main data sources we used monographies, scientific papers, expert comments, and accounting regulations issued by the Czech, Slovak, and German authorities.

Main findings and Discussion

Valuation of cryptocurrencies proceeds from their interpretation and recognition in financial statements which was described in our former paper dedicated to financial reporting of cryptocurrencies. For purposes of this paper we come from its main findings.

Though in the Czech accounting regulations cryptocurrency is not explicitly defined at present, it is possible to utilize communication of the Ministry of Finance of the Czech Republic (2018) that interprets virtual currency as an intangible asset and recommends to report it as a "supply of its kind". This treatment of course influences valuation of cryptocurrencies for accounting purposes that should apply the same rules as for inventories measurement.

According to the Czech procedures, virtual currency should be measured at costs of acquiring, i.e. either cost of purchase or cost of production if it was acquired by mining. (Ministry of Finance, 2018). The Ministry of Finance of the Czech Republic refers to relating paragraph 25 of the Czech Act on Accounting (1991). In practice it means that costs on initial recognition of cryptocurrency should encompass besides the initial price also related costs (closely see table 1). If a cryptocurrency was acquired by mining it should be measured either by real cost, or by cost coming from production calculation. So cost of production will encompass energies or expenses relating to hardware used for mining.

If cryptocurrencies are treated as inventories than in the case of their removal from assets (within exchange or sale) FIFO method or weighted average method can be used for evaluation of their decrease, which is also recommended by the Ministry of Finance of the Czech Republic (2018). Within one analytical inventory account however utilization of the only one cost method is allowed. Weighted average must be recalculated once in month at minimum.

Tab. 1: Cryptocurrencies recognition and valuation – international comparison

Recognition and valuation of cryptocurrencies		**The Czech Republic**	**The Slovak Republic**	**The Federal Republic of Germany**
Recognition of cryptocurrency	Trade and exchange activity	Inventories – goods	Short-term financial assets	Long-term intangible assets or Current assets – other receivables (possession no longer than one year)
	Cryptocurrency mining	Inventories – own products, work in process	Sub-ledger accounts until exchange or sale	
Valuation base	Cryptocurrency acquired by purchase	Cost of purchase (related expenses as exchange fees included)	Fair value (applied as market value achieved on public market)	Cost of purchase (related expenses as exchange fees included)
	Cryptocurrency acquired by mining	Cost of production: real or calculated (related expenses as energies included)	Fair value from the moment of utilization (exchange or sale)	Cost of production (related expenses as energies or hardware acquisition)
Valuation method at removal		FIFO or weighted average (recalculated monthly)	FIFO or weighted average	-
Conversion method		Average of exchange rates from several	Aggregation of exchange rates	Time value of delivered goods or

	bigger stock exchanges		services must not exceed time value of received bitcoins
Exchange differences	Debatable, probably do not comply with legal regulations	Disclosed as financial expense or revenue	-
Revaluation of cryptocurrencies	When closing the books cryptocurrency provisions recommended	Revaluation of cryptocurrency when closing the books not required	Lower of cost or market value (bitcoin in long-term assets) Lower of exchange or market price (bitcoin in currents assets)

Source: author's own processing based on jurisdictional regulations

A problem may occur in the case of cryptocurrency exchange to the Czech currency. Act on Accounting in § 4 demands to keep the books in the Czech currency so assets and liabilities recorded in foreign currency should be exchanged on the Czech Crowns (CZK) using exchange rates announced by the Czech National Bank on regular basis (§ 24 Act on Accounting). However, no exchange rates are announced for cryptocurrencies at present. In that case some authors (Kocourková Trnková, 2017) or Jelínek (2018) suggest to calculate exchange rates average of a cryptocurrency to foreign currency followed by the Czech National Bank (for example US dollar or EUR). Average of exchange rates should come from two or three bigger stock exchanges and consequently it should be recalculated to the Czech currency according to exchange rate of the Czech National Bank. Kocourková Trnková (2017) in this context recommends to specify a way of cryptocurrency conversion to CZK in internal regulations. Transparency of cryptocurrencies evidence would be strengthened by their monitoring on sub-ledger accounts.

Further question that is solved in the context of cryptocurrencies conversion is an existence of exchange differences. Some authors think that exchange differences should not be recognized because cryptocurrency does not comply with provision of § 4 Act on Accounting that regulates this area. As for stocktaking of cryptocurrencies, the Ministry of Finance of the Czech Republic (2018) prescribes the same duties as in the case of other assets and liabilities. Stocktaking must be carried out once a year at minimum at the date of financial statements preparation. Value of cryptocurrencies must be proved by relating documentation, for example by a virtual wallet statement. The same source (2018) recommends entering of cryptocurrency provisions with respect to prudence concept if needed. Taking account of cryptocurrencies rate volatility and temporary character of fluctuation, provisions can play significant role in fair and true valuation a presentation.

The Slovak accounting regulations (Amendment to the Act on Accounting and its implementing regulations) regard cryptocurrencies as short-term financial assets. For purposes of valuation and disclosure it is necessary to distinguish whether cryptocurrency was acquired against payment (for fiat currency or other virtual currency) or it was acquired by mining (Bagiová, 2018, s. 6). If cryptocurrency is acquired by mining it is initially registered on a sub-ledger account till the moment of its utilization (exchange, sale). Than it is measured at fair value in EUR. In other cases, (purchase, exchange) virtual currency is considered as short-term financial asset immediately at the moment of the acquisition (credit to virtual wallet for example). Also in this situation according to § 25 Act on Accounting cryptocurrency is measured at fair value.

Outflow of cryptocurrencies (for example because of their sale) can be measured by FIFO or weighted average method, similarly as in the Czech Republic. When closing the books, it is not required to revaluate cryptocurrencies held by fair value, resp. market value (§ 27 Act on Accounting). Exchange differences incurred when converting virtual currency to EUR are recognized as either financial expense or financial revenue. Fair value of virtual currency is defined in § 27 Act on Accounting as

market value achieved on public market at the day of transaction realization in a way selected by unit for given kind of cryptocurrency. Trávnik (2018) recommends to create internal directives and specify a way of fair value determination. The author (2018) finds aggregation of exchange rates as the most secure way of fair value determination. In fact, this is a similar method as that used in the Czech Republic in the case of revaluation.

In Germany cryptocurrencies are disclosed either as the long-term intangible assets or other receivables (when they are held till one year) and evaluated at their costs (Mazars, 2019). It is in accordance with HGB (§ 255). Valuation at acquisition cost is used when cryptocurrency is obtained as payment means when selling goods or rendering services, exchanging virtual currency to fiat currency, and converting one cryptocurrency to other. Cost of acquisition in German procedures is defined similarly as in the Czech ones. It consists of purchase price and relating expenses consumed in relation to acquisition, for example cryptocurrency exchange fees.

Mazars (2019) underline that payments in virtual currency for sale of goods or services should be treated as barter trade – delivery of asset (cryptocurrency) for a certain counter-value which is in accordance with the view of BAFIN (2013). The acquisition cost of bitcoin obtained by means of exchange, measured according to time value of delivered goods or services, must not exceed time value of bitcoin received.

In the case of mining a new unit of cryptocurrency should be measured in cost of production (§ 255 HGB). Generally, to the cost of production consumption of material and services used to produce, enlarge, or significantly improve assets should be encompassed. To cryptocurrency mining expanses mainly consumption of energies or expenses connected with hardware utilization could be covered (Kirchbaum, 2017).

To compare stands of three selected EU countries with approach of IAS/IFRS we can utilize an agenda decision concerning holdings of cryptocurrencies published at meeting of Interpretation Committee in June 2019 (IFRS, 2019). As for nature of a cryptocurrency, the Committee stated holding of cryptocurrency meets the definition of intangible asset according to IAS 38. The Committee further remarks when cryptocurrency is held for sale in the ordinary course of business IAS 2 Inventories should be applied to them. If IAS 2 is not applicable an entity should apply IAS 38 Intangible Assets to holding cryptocurrencies. It follows that used valuation base depends on cryptocurrency disclosure. If it is treated as inventory, the initial disclosure should be measured at cost of acquisition or net realisable value (with the exception of brokers). If cryptocurrency is regarded as intangible asset, it should be measured initially at cost of acquisition and consequently revaluated by selected valuation model.

As our analysis suggests The Czech and the German attitude to cryptocurrencies evaluation is similar and partly also closer to IAS/IFRS interpretation. Though cryptocurrencies are disclosed in different items of financial statements (inventories, long-term intangible assets or even receivables), they are initially disclosed at cost of acquisition. The Slovak procedures comes from disclosure of cryptocurrencies as the short-term financial assets and so require to evaluate cryptocurrency at fair value.

Conclusion

This paper is focused on comparison of valuation techniques used for cryptocurrencies disclosure in financial statements. As a research sample the Czech Republic, the Slovak Republic and the Federal Republic of Germany were chosen.

Our analysis suggests that disclosure of cryptocurrencies in financial statements differs among the research sample countries. Therefore, also used valuation bases differ. The Czech Republic and the Germany evaluate cryptocurrency initially at cost of acquisition while the Slovak Republic uses fair value. The Czech and the German access seem also closer to IAS/IFRS interpretation. On the other

hand, it seems, the Slovak attitude reflects real characteristics and functioning of cryptocurrency in practice.

Abstract

The authors tackle a problem of the experience marketing applied in wine business models successfully. From the theoretical point of view, it has been used the meaning field concepted as the original authors' view toward satisfactory experience at a winery. Because due to the experience marketing we should consider a wine business model as organizational capability ready to resolve emerging customer related issues in a friendly, creative and humanistic way. The shadow customer perspective was applied as a leading method of detection of tangible (infrastructure) and intangible (relationship and atmosphere) elements of wine tourism service experienced in three analyzed wineries from the Slovakian Tokaj region. Particular attention was put upon: professional and friendly wine visits, wine tours, wine tasting; qualified wine education and conversations; family-style and boutique hospitality, service flexibility in resolving emerging customer related issues.

Keywords: Wine Business Models, Experience Marketing, Wine Tourism Experience, Tokaj Region

Introduction

The main aspect of identifying a business models is to get a picture of consumer perception over company products, services and organizational process. This perceivable interaction between consumer and company is known as a consumer experience (Gentile, Spiller & Noci, 2007). For the sector of wine services delivering an authentic wine experience is one of the main winery's business characteristics since its success depends not only on wine production prosperity but also on wine tourism services (Hołodnik, 2017), e.g. wine visits, wine tasting, vineyard tour, wine education etc. Thanks to the latter a wine experience has become an interesting object of the experience marketing. According to this approach, each consumer experience is a composition of short-live, unrepetitive and ephemeral impressions, emotions and sensory feelings imbued in a moment of being in an interaction (Holbrook, 2006). So, a co-creation of consumer field of experiences in the wine service delivery was named by the authors a meaning field. Therefore, the main focus of this paper is to present the differences between meaning fields of the winery business models identified in the Tokay Region (on the Slovakian side).

Wine Business Models – Theoretical Background and Problem Formulation

Classically, consumer experience is a predominant unit of value creation process (Homburg, Jozić & Kuehnl, 2017). Its main managerial function is to link the tangible with intangible elements of consumer perception, which in wine tourism are expressed by wine production and wine tourism respectively (Figure 1).

Fig. 1: Orientations of the wine business models

Source: authors' own elaboration

The model from the left side of the Figure 1 says that the relationship of wine tourism and wine industry is predominated by the latter. The business model ontology is constructed on the demand principle based on wine profiling that targets the most profitable wine drinkers' markets (Becker 2013). This ontology favors wine sale & export rather than delivering a wine experience in-home. Wine drinkers' expectations and requests are more significant than wine tourists, thus, the central interest of a winery is to develop value creation process related with wine production, and in the same time, having reduced interest in improving wine tourism facilities and services, which then play a supporting role of wine promotion.

On the contrary, there are wineries, for which wine tourism is a supreme aspect of business architecture (Hall, Sharples, Cambourne & Macionis, 2002). This position in the wine business model (Fig 1 – the right side) means that wine service design dominates over wine production in a consumer's experience perception (Stickdorn, & Zehrer, 2009).

Nevertheless, a decisive element to indicate which logic is applied to the wine business model is a consumer experience process (service or product delivery). This is because while having been immersed in a winery experience field the emerging interactions with its staff and environment can be crystalized (Figure 2).

Fig. 2: Winery business models reflected in a concrete consumer's eye view

Legend:
WBM_{1-n} – winery business model
CE_{1-n} – consumer experiences at a winery
F_{1-n} – flows (of interactions with a winery's staff and environment)

Source: authors' own elaboration

In practice, especially in the field of impression marketing (referred as the experience or engagement marketing in the literature), consumers perceive through ideas, imaginations, expectations, feelings and projections of future or past experiences. But these, mostly psychological artifacts (impressions), have a very floating nature (appearing as inimitable, unrepeatable and changeable values), and flow as long as a consumer experience lasts.

For that reasons the following conclusion can be drawn out: the business model is an abstractive creation of intermediate and/or direct value flows between a winery and a consumer. Because the consumer imaginations as well as product and service delivery experiences are the drivers of value creation process (Figure 2).

To sum up, catching a dynamic picture of the business model is about finding and diagnosing its floating reflections in the consumer's perception through the content-based products and services experiencing. So, the key premise of this research is to depict a consumer's perception of the wineries' business models in Tokaj located on the Slovakian side of the region. In other words, the aim is to draw a comparison between the company's delivery of the product or service and the consumer's perceptions of offered experience.

Slovakian Tokaj Region – Research Aims and Method

As has been established above, business models can be constructed from the consumer's point of view and determined by specific parameters and characteristics that were crucial to the consumer's impression making process and value system. The authors propose to define and will further on call this process 'meaning field'. It is the main unity oriented toward analyzing the capabilities of the Slovakian Tokaj business model as an authentic terroir product (Spielmann & Charters, 2013) applied in the local wineries' identity. Therefore, the research was conducted by the mysterious-expert tourists that stayed for several days (around a week) in the region in order to eliminate the short-term perspective and limited knowledge of overnight stayers or one-time tasters.

It should be mentioned, however, that ordinary customers may not keep a wine business model in mind when engaging in their consumer experiences (Santos, Fernandez, M. C. & Fernandez, A.G., 2006). It would be unreliable to rely on such a consumer's individual impressions. Therefore, a professional researcher should be involved to conduct analysis of the cognitive aspects of the consumer's perception within the scope of the product or service experience.

So, each tourist's winery interaction in Tokaj that possesses some value, either positive or negatively, affecting the expected experience is included to the meaning field. That is quite a complex approach, because regards wine tourism management generally (Getz, 2000), as well as a particular aspect of wine experience co-creation (Ben-Nun & Cohen, 2008), e.g. wine attractions, wine festivals, wine testing, wine and gastronomy, tourist motivations, wine production etc. In this research, we propose to look upon wine business in a wider sense, so in a context of the whole tourist experience field (thus called the meaning field), so that the remarkable tourist experiences become fundamental for the construction of the business models of wineries. Therefore, a set of different experiences gained from each visit at Tokaj's wine producers, have created specific meaning fields.

But before presentation of the meaning fields of business models of research wineries, firstly it is worthy mentioning about Tokaj and its wine profile in general, which is shared across all wineries in the region (common meaning field).

The first research aim was to identify the Tokaj's common meaning field that refers to the macro scale of its recognition as a wine region. For foreign tourists, who are unfamiliar with the European wine map, it is difficult to conceive Tokaj as two-portioned regions between Slovakia and Hungary, rather they might think of it as the entirely Hungarian. And from this historical perspective they are right in doing so, because throughout most of European history, Tokaj belonged to the Hungary and subsequently to the Austro-Hungarian Empire. But after First World War it was shared by two countries Czechoslovakia and Hungary (today over 6.000 ha of vineyards belong to Hungary in comparison to only 900 ha on the Slovakian side). So, the worldwide fame of Tokaj has been gained by the Hungarian Tokaj. Therefore, it is very difficult for Slovakian wine producers to create their own identity of the business models based on the "Slovak Tokaj" image. This is why their business models had to be re-created by wine producer through recalling the local history, it's values, symbols, and traditions, which all together might reconstruct a different identity than Hungarian side does.

The Slovak Tokaj wine region is identified by a range of very unique features:

- possibility to grow grapes for naturally sweet wine,
- grapes are left on the bushes to become overripe and in favorable years become also *cibébs* (grapes covered with the specific mold called *Botrytis cinerea*, which give Tokaj wines their inimitable taste and aroma),
- specific climate for growing *cibébs* (mist in the morning and sun within day),
- at least two year ageing in the famous tuff cellars (where the specific mold easily spread around, covering walls, bottles, holy figures etc., tuff cellars are considered to have the best conditions for wine keeping: all year long stable temperature, old wines laid in quiet and locked quarters let them mature in peace).

From a wine tourism point of view worthy of note are the following attractions[1]:

- historic tuff cellars: dated from around XIII centuries (offered mostly in Velká Tŕňa and Malá Tŕňa),
- variety of -the- picturesque bike routes: called *cyklotourism* or *cyklotrasy*- signing system of info-maps in the cities, tourism information system on website: tokajregion.sk and trade mark: 'Tokaj is the only one' are all the results of the Swiss- Slovakian project initiated by local department of tourism in cooperation with University of Lucerne),
- variety of scenic walking trails: beautiful walking paths around wineries, observation tower in Malá Tŕňa, wine museum in Trebišov, statue of Saint Urban in Čerhov),

[1] https://tokajregion.sk/en/explore-tokaj/

- access to historic and cultural sites: Greek-Catholic and Roman-Catholic churches located in all wine cities, Julius Andrassy mausoleum in Trebišov).

As for the second research aim was to detect the individual meaning fields of Tokaj wineries, so the investigation of mysterious customer was conducted in the most significant wineries located in Slovak Tokaj region, these are:

- J. & J. Ostrožovič winery (Velká Tŕňa),
- Macik Winery (Malá Tŕňa),
- Tokaj Company (Malá Tŕňa).

Result presentation. Warm-eyed meaning field – case study of 'J. & J. Ostrožovič Winery'

The meaning field of the tourists has been divided into tangible and intangible elements of value creation process. The first one represents facility potential of the analyzed winery that attracted tourists and are dedicated to carrying out professional and friendly wine service. On the other hand, the intangible values outlined the key interactions between researched winery and tourists. The Ostrožovič Winery was the first identified business model, which from the tourists' experiences point of view can be called 'warm' - warm-eyed meaning field (Figure 3).

Fig. 3: Tourists field of experiences in the 'J. & J. Ostrožovič Winery'

OI_{1-3} – outer interactions (outside the meaning field)

Source: authors' own elaboration

That is mainly because their stay there was characterized by the following experiences (Fig 3):

- inward orientation (restful and relaxing stay),
- comfortable atmosphere (high individualization, freedom in choices),
- tranquility during daily work hours,
- slow life in service (slow consumption, recreation etc.),
- spontaneous events arrangement,
- possibility of a long stay in winery house (more than 7 days),
- every day is "open" (loosely and adaptable in planned activities),
- experience co-sharing between owner, staff and tourists,
- long wine celebrations,
- self-service kitchen availability (e.g. tea, coffee, wine or small snacks between breakfast and dinners),
- positive and 'healthy' attitude of owners toward competitors (lack of a hostile attitudes towards nearby located wine companies),
- customer service problem resolving (making extraordinary wishes possible).

In the warm-eyed business model of Ostrožovič Winery the tourists felt very comfortable mainly because of the service delivery style was: very open, flexible, loosely arranged, heartful, kind and much personalized. The lady who prepared the daily breakfast was immensely kind and creative in tending to the needs of the tourists' less conventional dietary requirements (both were vegetarians). The traditional Slovak and local cuisine are based on meat; therefore, it was extremely difficult and unusual for her to offer a different meal creation.

Another reason why this meaning field is referred to as 'warm' is because of the hospitality base and the style of wine sale. All business processes are undertaken with the high level of respect toward the tourists' individual lifestyles and daily rhythms. Nothing is imposed on the daily structure of a client's activities or taken for granted. This approach makes for a comfortable and relaxing experience.

The staff emanated a very positive attitudes (willing to help, inquisitive about details and requirements), providing tourists with their own space and exuded happiness that also strengthened the whole atmosphere of a familiar and 'homely' stay (understanding of tourists' problems, nice and informal conversations).

Cold-Eye Meaning Field – Case Study Of 'Macik Winery'

The 'cold' meaning field diagnosed within the Macik' business model (Figure 4) is mostly a result of the commercial & selling orientation. It was very noticeable by the individual tourists and probably would not be by some groups or business client. The food service is only available for the groups, meaning that if you want to participate in degustation and afterward stay for -a- dinner, it is quite complicated unless you are an important client.

Wine shop design is very modern in comparison with the invitatory 'Tuscany' style in Ostrožovič, so it can be described as stylish, minimalistic and with predominantly 'whitish' features. The quality of service was perceived by tourists as medium. Mostly because of the inexperienced and quite rotatable staff (e.g. it was the third month for the young lady who was working there and she was in charge of the degustation), but also because of their staff's perceived lack of being integrated with the company (e.g. the young lady did not come from the village, neither did the girls from service and they appeared to make the owner nervous when the time of closing winery was coming up). Besides the owners and members of the winemaking family, nobody was able to take care of the business image and customer relationship management.

The call to confirm the booking before the visit was very formal and put the tourists in 'either-or' situations (visit winery on very strict rules, otherwise it is impossible). So, the tourists had to change plans and adopt to the service rules, without any possibility to achieve 'win-win' results. Therefore, no time and schedule flexibility were permissible, although the visit was during the 'out-of-season' period for the winery.

Fig. 4: Tourists field of experiences in the 'Macik Winery'

Legend:
IVC- intangible-based value creation (for the visitors)
MVC- tangible-based value creation (for the visitors)
OF_{1-3} – offered facilities (related with infrastructure potential)
OE_{1-7} – offered experiences (related with service delivery)
II_{1-7} – inner interactions (inside the meaning field)
OI_{1-3} – outer interactions (outside the meaning field)

Source: Authors' own elaboration

Regarding the winery's features with the tangible values one must definitely include the medieval wine cellar, compatibility of styles between wine house and rooms, as well as the creative offers possible to arrange up on the consumer's request (e.g. paragliding, river trip, bicycles, baths in barrels, agritourism works).

The short and rapid interview with the owner and manager (she was in a rush because of the approaching closing hours) was carried out in a formal business style with no attempt to build an informal relationship with the tourists. It confirmed that wine and service selling is the key competence of the winery, supported by the food and tourism offers.

Local-Eyed Meaning Field – Case Study Of 'Tokay & Co.'

Tokay Company is the most locally rooted producer in the Slovakian Tokay region, inheriting after the former state company the greatest wine cellars and distribution network (Figure 5).

Fig. 5: Tourists field of experiences in the 'Tokay & Co.'

Legend:
IVC- intangible-based value creation (for the visitors)
MVC- tangible-based value creation (for the visitors)
OF_{1-3} – offered facilities (related with infrastructure potential)
OE_{1-7} – offered experiences (related with service delivery)
II_{1-7} – inner interactions (inside the meaning field)
OI_{1-3} – outer interactions (outside the meaning field)

Source: Authors' own elaboration

Tokaj & Co. is the only wine producer that after commercialization kept a networking structure of ownership. There are five, unknown stakeholders and among them one possesses the greatest share. What was identifiable for tourists was that they were neither personally nor through family connected with the Slovak Tokay region. Wine production is for them the most important business field, which is profit oriented (focusing on a relatively good price to quantity ratio), thus, from a tourist's point of view it is dominated by the tangible-based experience.

Most of the intangible experiences were created spontaneously, which was sometimes a bit awkward for tourists who were not informed of the clear principles of service organization, especially of cellar visiting, wine ordering and limited ways of payments. There was also observed a significant number of rifts in HR investments and staff education, which made tourists disoriented in the service processes (e.g. cellar visit was combined with the degustation due to the major assistance and phone calls, otherwise it would be difficult to catch anybody from the winery, the service lady was apparently interrupted from her other home activities in order to open the wine cellar and wine-house etc.).

From all three researched producers, Tokaj & Co. cellars are rated as no 1. Dating back to the medieval times, with a large and extensive network of tunnels and the most historical cultural heritage they should be consider as having the greatest competitive advantage. Nevertheless, the quality of wine is generally lower than that of Macik or Ostrožovič Wineries. The wine bottles design is without certain idea and profiling direction, which is characteristic of a typical selling strategy aimed at anonymous customer (a quick shopper).

During the interview with the managers it was said that there are plans for a new factory investment near to the historical wine cellars. This confirms that there is a lesser interest in extending wine services facilities (wine tourism) and more importance on wine production. Currently the wine shop is located inside a somebody's private house that most probably is related to one of the owners' families.

Tokaj & Co. is supported by the local authorities and has favorable connections with local restaurants and hotels. In all nearby restaurants (e.g. Aqua Maria, Kolonia and more) only this company's wines were offered in the wine card to accompany your meal, while two other producers were hardly met. So, this can be considered as favoritism and unfair competition.

Conclusions and Discussion (Confrontation of The Wine Business Models in Tokay)

The differences in business model design of wine producers in the Slovak Tokaj region offers a diverse range of individual styles, experiences and types of wine tourism options. For long-term stay (a week or longer) the most suitable infrastructure as well as service possibilities were exhibited by two wineries: Ostrožovič and Macik (Table 1).

The competitive advantages shared by Ostrožovič and Macik only vary in the details of the consumer experience and target market profile. For those, who prefer more tranquility, freedom, space, flexibility and have more stringent dietary or health requirements, Ostrožovič seem to be ideal. But the ones who are interested in wine field working or search for a more active form of wine tourism, Macik winery has more to offer.

The business model of Tokaj & Co. turned out to not have the basic services on offer that tourists seeking for a longer staying or time spending. However, it is definitely the winner of the Tokaj region in terms of wine cellar heritage and worthy of booking a wine visit.

This research has shed considerable light on the tourists' experiences of a weekly observation and participation in the Slovak Tokaj wine route. The results are based on meaning field research techniques that are ready to explore after a one-visit testing and do not need to be verified through a repetitive data collection.

Summary

Consumer experiences understood as problem resolving skills of a company are the main constituents of the modern winery's business model according to the experience and engagement marketing approach. To find them out one has to be immersed in a value co-creation process (meaning field), by which tangible and intangible organizational capabilities can be authentically experienced. The analysis that assessing the service facilities and experiences of three wineries in the Slovak Tokaj region have exhibited their different business model's orientation within the scope of tourist's profiles, wine service delivery & wine sale strategy. The key competence of the Ostrožovič Winery's meaning field manifested as the relaxing stay Tokaj's combined with wine exploration, while the Macik Winery's one is directed on sporting activities for tourists and food design for professionals. In both of them wine facilities and production scale were on the comparable level but the service design was varied. The last visited winery with the largest production and lowest quality wine service was the Tokaj & Co. that can be also distinguished for the most historical tuff cellars, where tourists can feel like in an undergrounded labyrinth.

Abstract

Tourism and hospitality are increasingly recognized as one of the main impulses of economy, both in the European context and worldwide. The concept of sustainability has been widely debated socially and in the context of scientific research for the past two decades. When applied to the hospitality sector, investigation towards this topic is more recent and raises several issues that can be seen as challenges but also as sources of competitive advantage. In this article we seek to explore the concept of sustainability in the context of hospitality, making a theoretical review of the main lines of research and launching clues to those that may be the future lines of investigation in this context. The digital world has come to challenge companies, approaching everyone everywhere. Challenges that extend to all levels, not only economic, but also at a relational level, since the relationships themselves, and the way in which people relate and behave, have also undergone modifications.Two examples (best practices) of sustainability in communication will be presented, in specific contexts of hospitality and tourism (in Portugal). This research presents contributions to sustainability, tourism, hospitality and communication. At the end, guidelines for the future will be presented.

Keywords: Tourism, Hospitality, Sustainability, Communication, Trends

Introduction

Sustainability is a topic that is currently being discussed and constantly adapting, since it is related not only to an ecologically correct posture and strategy, but also economically viable and socially equitable. On the other hand, it is also a very complex concept, as it serves a set of interdependent variables, from the most diverse fields and disciplines, such as cultural, business, geographic sustainability, among others, which leads to the emergence of different interpretations about this. According to Hawken (2007) sustainability "is about stabilizing the currently disruptive relationship between earth's two most complex systems - human culture and the living world. The interrelation between these two systems marks every person's existence and is responsible for the rise and fall of every civilization" (Hawken, 2007, p.172). One of the theories on which the concept of sustainability rests relates to those who are its pillars of action, on which the concept rests. As previously mentioned, sustainability bases its action

on three aspects: economic, social and environmental, which are the so-called pillars of sustainability as it seeks economic prosperity, environmental quality and social integrity.

Therefore, the importance given by the media to the theme of ecology, sustainability has led to a growing concern among the population. This concern leads to greater environmental awareness, which ends up influencing the purchase, that is, they verify whether a product is ecological and sustainable. Consequently, companies need to act immediately to respond to this demand, which can use this factor as being differentiating and competitive. In this sense, Peneda de Oliveira and Sousa (2019) refers that communication professionals increasingly feel the challenge of integrating messages focused on corporate responsibility in their communication strategies, in a serious and creative way. New forms of communication have been modified and developed, in a world where information is made available in record time, it is important to know how to communicate and how to do it in a transparent perspective (Malheiro et al., 2019). Thus, the following sections will present a theoretical framework on the theme of sustainability and its relationship with current trends in online communication. Two (Portuguese) examples that illustrate the concern with sustainability (particularly in combating the new coronavirus in tourism and hospitality) will be presented and discussed.

Theoretical Background: sustainability and communication trends

Sustainability does not only comprise environmental issues, an idea that is in some way rooted, being much more comprehensive. This seeks that economic development occurs in coherence with environmental preservation and that allows the eradication of world poverty, based on a set of measures that respect nature and society. The tourism industry has the capacity to generate the movement of millions of people and, consequently, contribute to the entry of thousands of foreign currency in tourist destinations, which enable its development. However, uncontrolled growth in tourism can also cause serious damage, such as environmental and cultural degradation, the destruction of fragile ecosystems, the appearance of pollution, the generation of conflicts between tourists and the local population, overcrowding in receiving communities, among others (Hopkins, 2005). And it is due to these harms caused, and also for global well-being, that tourism must adopt sustainable measures, which will act as conservation tools and allow, for example, the preservation of important natural areas and wildlife, as well as as well as archaeological and historical sites; more efficient management of resources; improving the well-being of the community, through local investments and concern for its long-term sustainability, among others (Verbeke, 2000).

As previously mentioned, the concept of sustainability is based on three pillars: economic, environmental and social sustainability, which are considered fundamental for its development. In this way, three pillars were also defined for sustainable tourism, in order to demonstrate exactly to the tourist agents and other stakeholders what is intended with its practice. Regarding the economic pillar, tourism being an important activity that energizes the local economy, its main objective is to ensure the sustainability of operations in the long term and not its immediate profitability. In addition, it must contribute to the creation of new jobs, to the increase of income entry, both at national and local level, and above all to the equitable distribution of wealth, for example, by investing in less tourist destinations, favored, under development or not yet developed (Hopkins, 2005). The environmental pillar seeks preservation and respect for natural resources, since tourism affects and depends equally on them for the success of its activity. Thus, tourism needs to encourage the protection and conservation of these same resources and make tourists aware of the value they have, demonstrating that they are unique and that it is necessary to ensure their integrity for future generations (Moniz, 2009). Finally, the social pillar is dedicated to the conservation of the communities' cultural and historical heritage. It is essential for tourism to maintain the authenticity of these values and local customs, as it is also here that the attractiveness of various tourist destinations resides.

For instance, ecotourism is going to continue to expand and grow in importance as it is an essential strategy for the global plan of sustainable development. It has its base on the fundamental principles of sustainable tourism, integrating itself in the own development of this type of tourism as it is a

sustainable development tool that offers long-term social, environmental and economic benefits and given the proper priority in the economic development of the country (Hawkins and Lamoureux, 2001).

Thus, the latter must, for example, foster respect for local religion or culture, invest in the development of trade in local symbols, appeal to tourists for their responsible behavior, among others (Hopkins, 2005). In conclusion, it can be said that tourism is considered as one of the main agents responsible for major transformations that occur on a global scale, such as, for example, the emergence of new forms of displacement and new technologies, the transmission of cultural values, among others. But today the new challenge is the congruent integration of these three pillars, in order to be able to assist economic development, improve the quality of life of tourists and local communities and protect the environment and cultural heritage, all simultaneously. To carry out a sustainable tourism policy, stakeholders play an important role, since they both influence and are influenced by the activity of other tourist organizations, and their interrelationship is essential for the inclusion of sustainability in tourism. One of the sectors of tourism where this issue has been gaining relevance is hospitality. Legal motivations, market pressure, the sophistication of an increasingly infamous consumer and oriented towards sustainability issues have led companies in the sector to develop an increasing number of sustainability policies. In turn, marketing has proved to be an important tool for organizations in the struggle for this goal, which seek to associate the concept of sustainability with the brand it represents. Thus, sustainable marketing emerges, which uses traditional marketing methods in an attempt to assess the behavior of its potential customers, and to design a sustainable product that is suitable for them (Sloan, Legrand & Chen, 2009). It is in this sense that the following literature review seeks to systematize the conceptualization of sustainability in this context. In the end, the lines of action and challenges that the sector faces in this field will be identified and that may constitute a threat to its survival or an opportunity for the acquisition of competitive advantages.

Towards a comprehension of sustainability in tourism and hospitality

Tourism is increasingly recognized as one of the main impulses of economy, both in the European context and worldwide (Ferreira & Sousa, 2020). As a consequence of this expansion comes economic growth, increases in employment levels, social progress and the protection of natural resources when used with moderation (Pinto da Silva et al., 2019). Therefore, it is imperative in sustainable development to promote the satisfaction of the basic needs of the host community, favouring access to all opportunities that promote the well-being of society and facilitate its aspirations to a better life, without compromising coming generations (UN, 1987). So, sustainability should have a long-term perspective, avoiding the overexploitation of natural resources. At this point, we seek to address the way in which literature has focused on the theme of sustainability in the hotel industry, making reference to the measures that can be adopted by tourism agents to have a more sustainable enterprise. In addition, the competitive advantages arising from sustainable practices will be addressed, as well as some initiatives already put into practice to establish sustainability in this area. In hospitality industry where competition is increasing every day, it is necessary to create brand-new services or offer renowned services via diversified ways, to step forward from competitors. In this regard, it is important for companies to ensure that every innovative service should be sustainable (Ozturkoglu, Fari, & Saygili, 2019). In a recent investigation, Nair e Choudhary (2018), point out a set of social dimensions on which the concept of sustainability in hotels rests. The focal area of this research is 'social sustainability' and it comprises several aspects such as: social equity, liveability, health equity, community development, social capital, human rights, labour rights, place making, social responsibility, social justice, cultural competence, community resilience, and human adaptation as referred to the hospitality industry (James et al., 2015).

The hotel industry is considered as one of the main industries that has a negative influence on the environment, since it produces about 1 kg of waste, per night and per person, and around 180 kg of carbon (CO2), for each square meter quarter and a year. It also has a high water consumption, which averages 320 liters, per night and per person, among others (Sloan et. Al., 2009). In this way, the hotel industry has a great responsibility in adopting sustainable policies, which not only respect the environment but also promote the economy and social equity. On the other hand, it also has a greater financial capacity, than local commerce, for example, which allows it to invest in more sustainable

equipment and solutions. The strategies mentioned here are just a few examples of policies carried out by the hotel units, and there is room for the development of many others. It is up to the management of each hotel to identify the points where it is possible to improve its sustainability policy.

Sustainability policies in hospitality	Examples of good practice	Authors
Energy efficiency	Energy efficiency, type of construction, roof, lighting, air conditioning, electrical equipment	Sloan et. al. (2009); Werner (2006)
Waste management	Reduce the amount of packaging, choose environmentally friendly materials, promote good waste treatment, Choose reusable equipment over disposable equipment, use of recyclable batteries, donate food surplus	Sloan et. al. (2009); Werner (2006)
Water management	Efficiently designed distribution system that is preserved without failures or water leaks, choice of washing machines with less water consumption per cycle, use of rainwater, reuse of water, placement of flow control valves, or with aerators water, which introduce air into the water flow and reduce water consumption,	Sloan et. al. (2009); Werner (2006), Green (2010)
Hotels Eco design	Preservation of the surrounding natural and built environment, in order to integrate into the environment and not damage the predominant architectural feature, requalify degraded areas, encourage heritage conservation and even serve as a driving force for the local economy, using the sun as a natural source of light and heat, choice of materials that absorb, store and release heat have a high thermal mass and function as temperature regulators	Werner (2006), Ozturkoglu, Y., Fari, F. & Saygili, E. (2019).
Food and beverage management	Choice of local, safe, organic, seasonal foods, choice of organic wine	Oosterveer & Sonnenfeld (2012), Ozturkoglu, Y., Fari, F. & Saygili, E. (2019).
Efficient kitchen	Choosing the layout, the equipment you use and the actions of your employees.	Sloan et. al. (2009); Werner (2006)
Tourists' Awareness	Sensibilização dos turistas, promoção de comportamentos responsáveis	Belz e Peattie (2012); Sloan, Legrand & Chen, 2009; (Verbeke, 2000), Modica, L.A., Farmaki, A., Gursoy, D. & Zenga, M. (2020).

Energy Efficiency

This policy starts to be designed from the initial planning phase of the hotel project, since there are several aspects that can only be implemented in the construction phase. However, there are still several actions that can contribute to improving energy efficiency in the course of day-to-day activities, such as, for example, the purchase of high energy efficiency equipment or the appropriate choice of air conditioning parameters. Thus, the combination of these two factors, associated with a choice of mostly renewable energy sources, will maximize the overall sustainability of the building in the long term.

Waste Management

As mentioned above, the hotel industry is an industry that produces a large amount of waste, and as such it is essential to have a good management of it. Any industry concerned with the management of its waste must implement the policies known as the rules of the 3 R's, that is, reduce, reuse and recycle (Sloan et. Al., 2009). The reduce rule expresses the need to choose resources that minimize its impact on the environment and use only the minimum amount necessary for the hotel's operation, eliminating any expense that is not necessary. The reuse rule means that, whenever something is liable to be reused, once or several times, before being disposed of as garbage, it must be reused. The third rule, recycling, which is currently much debated, implies a differentiation between the different types of waste, so that it can be reused or correctly disposed of (Sloan et. Al., 2009). Good waste management, in addition to a better image, can also bring an additional economic advantage to the hotel, either through the savings obtained by eliminating waste, as well as gains obtained through the sale of used oils.

Water Management

The management of water consumption in hotels is a sensitive topic since restrictions on consumption could result in dissatisfied customers, but on the other hand water is a limited asset and as such should not be wasted. Although more than half of the water consumed in a hotel comes from the rooms, there is also a large amount that is used in the rest of the hotel's activities, such as the kitchen, laundry and common areas. Webster (Sloan et. Al., 2009) warns of the fact that any measure of water saving should not negatively affect neither the comfort of guests, nor the cleanliness and hygiene of the hotel. However, there are several measures that can be implemented and that contribute to reducing the consumption of this resource, without however neglecting the well-being of guests or the hygiene and general cleanliness of the hotel. There are measures that are more conventional and easy to implement, but also more innovative and complex concepts, among which measures can be highlighted (Green, 2010):

Guests can use the same towel and sheets for more than one day, if they are in good condition for use, in order to reduce the consumption of water used for washing. Thus, it is up to the hotel to raise awareness of this fact, and the vast majority choose to put a pamphlet in the room to explain this situation, and to ask the customer to place towels and sheets on the floor when they want them to be changed. However, in more luxurious hotels, this measure may not be well accepted. In addition to these measures, it is necessary to raise awareness and train all hotel employees, in order to also guarantee water savings in the normal day-to-day activities of the hotel. Thus, since water is an indispensable resource for man's survival and is disappearing due to its misuse, it is crucial to quickly adopt measures and attitudes that reduce its consumption. Thus, since the hotel industry is a sector that has a high consumption of water, it is of utmost importance that it also practices actions that allow the sustainability of water, having at its disposal a series of equipment and ways to achieve this. .

Hotels Eco Design

During the construction phase of a hotel and throughout its life cycle, there are several factors with a negative effect on the environment, such as the consumption of water, energy and fossil fuels, as well as emissions to the environment. However, due to technological advances and greater environmental awareness, it is possible to significantly reduce CO2 emissions and the environmental impact of building a hotel, through sustainable design or eco design. During the projection period of the hotel, it must take into account the preservation of the surrounding natural and built environment, in order to integrate into the environment and not harm the predominant architectural feature. In addition, depending on the construction site, the hotel will be able to requalify degraded areas, encourage heritage conservation and even serve as a driver for the local economy.

materials from local and environmentally responsible suppliers. To conclude, it can be said that the hotel sector has every interest in resorting to sustainable construction because it contributes to a better image of the hotel and, at the same time, it is economically advantageous. Therefore, despite requiring a larger initial investment, the option for this type of construction is largely offset by the higher

profitability in the medium and long term, in addition to increasing the life cycle of the building itself and reducing the investment risk.

Food and Beverage Management

More and more people are aware that the use and production of sustainable food and beverages also contribute significantly to global sustainability, with the hotel industry being an important driver due to the numerous meals it serves over a year. In this way, the author Walker (2012), defines sustainable food and drinks as the use of local products, since this way companies are able to reduce transport costs and contribute to the local economy. They must also pay attention to the entire production process, in order to guarantee their energy efficiency and a low CO2 emission. However, Sloan et. al. (2009) complements his definition with the fact that sustainable food production must necessarily respect natural resources, that is, it cannot consume these resources in an exacerbated way and that jeopardizes its regeneration time. The author even classifies sustainable foods and drinks as those that: are healthy and nutritious for consumers; provide a hygienic and safe environment for their producers and retailers; respect the limits of environmental resources and the safety and health of animals; and support for the local economy and culture, through the use of products and raw materials from the community where they operate.

Efficient Kitchen

In a hotel, the kitchen is considered to be one of the areas that expends the most energy, this is due to the fact that, for the most part, there is an energy inefficiency in the process of preparing food or in the storage equipment. However, this consumption can be reduced to a third, through the installation of efficient energy equipment and the correct training of employees, for example (Sloan et. Al., 2009). In this way, we can say that there are three main ways to ensure energy efficiency in a kitchen: through its layout, the equipment it uses and the actions of its employees.

Tourists' Awareness

There are several hotels that go further than achieving their energy efficiency to be considered sustainable, they also seek to attract the attention of tourists to the central need to adopt sustainable practices and attitudes. In this way, several initiatives started to emerge organized by hotels that seek exactly this awareness among tourists (UNEP & UNWTO, 2005). One of these initiatives consists of organizing guided tours around the hotel's surrounding space, in order to involve guests in the local community and the environment and to demonstrate the importance of preserving its cultural and natural traits (Lockyer, 2007). On the other hand, the organization of social events that support certain causes or charities, is a very sensitizing and wide-ranging action, since through the media they can easily spread the message and capture the attention of consumers, as for example, donate funds resulting from a particular event. But there are still small actions that can be developed by a hotel in the course of its activity that contribute to sensitize tourists, for example, through the placement of pamphlets in the rooms or in the various spaces of the hotel, that inform them about the sustainable activities that the hotel develops and the benefits they produce, in order to demonstrate its contribution to a better world and to encourage tourists to do the same (Lockyer, 2007). Thus, it can be seen that the sustainable initiatives carried out by the hotels are beginning to appear, although in small numbers, and that they have come to understand the need for their realization, as they are a sector that has direct contact with tourists and is easily manage to influence them.

According to Jackson (2006), consumers are the crucial element to achieve sustainable consumption, which the author defines as the use of products and services that satisfy the basic needs of society and provide him with a better quality of life, but at the same time, that minimize the use of natural resources, toxic materials, waste production and pollutants. That is, if consumers adopt sustainable habits, these attitudes will influence companies to create equally sustainable products and even acquire a similar attitude (Sloan et. Al., 2009).

On the other hand, practicing sustainable consumption also implies that each member of society carries out activities that contribute to this, namely the reduction of energy, water and waste consumption; the recycling; the use of public transport to replace private ones; consumption of local food; support for environmental protection projects; among others (Sloan et. al., 2009). However, there are a number of motivations that lead consumers to practice sustainable consumption that can be divided into four dimensions: personal well-being, ecology, ethics and lifestyle. To conclude, it is important to note that all consumers should seek to reflect on their consumption habits, in order not only to purchase sustainable products and services, but also to bring sustainability into their homes (Belz & Peattie, 2012).

Sustainability as a Competitive Advantage

Unfortunately, today, there are still many managers who only consider the initial investment of a venture, without checking other options that can become much more profitable in the long run, which is what happens with sustainability. A large part of the previously mentioned sustainable policies have a high acquisition value or require greater sensitivity on the part of managers, but in the long run, they are able to produce more benefits and even become a competitive advantage. Thus, according to Matias and Sardinha (2008), the adoption of sustainable measures generates mainly two advantages: cost reduction and differentiation in relation to the competition. Cost reduction is achieved through lower water consumption, more efficient management of energy and waste, among others, that is, through the reduction of waste and consumption. Differentiation occurs because, once the company offers a product or service considered "environmentally friendly" or contributes to the improvement of society's quality of life, it will stand out from the rest. In addition, this differentiation will contribute to a better reputation and, consequently, to a greater adhesion and loyalty of tourists, who are increasingly aware of the role of companies as social agents (Matias & Sardinha, 2008).

The fact that a new market segment has emerged, concerned with environmental and social issues, enhances new opportunities for the development of products and services, and, for this, companies must take full advantage of technological advances, which increasingly offers sustainable solutions. On the other hand, companies must also respect government regulations regarding environmental obligations, not only in order to subsequently avoid the cost of penalties, but in order to demonstrate their contribution to a modern and sustainable society. In short, it can be said that the competitive advantages arising from the practice of a sustainable activity result from the application of a set of measures, which require constant updating and adaptation to the new needs that arise.

Communicating with sustainability: best practices

"Haverá Tempo" - Turismo do Centro de Portugal

Turismo de Centro de Portugal launched, in March 2020, the "Haverá Tempo" campaign, called on the Portuguese to stay at home to contain the spread of Covid-19 and guaranteed that the region will be prepared to receive visitors after the pandemic. With this campaign, and according to the president of the Regional Tourism Entity of the Center of Portugal, he joined the enormous effort of the country in raising awareness and creating hope (figure 1).

Figure 1: "There will be time" campaign

Source: Turismo do Centro de Portugal (2020)

The campaign had as main platforms a video and images on social networks, accompanied by the hashtag #haveratempo, among others. The reaction, on the part of the public and followers, was quite positive, namely with regard to comments, reactions and shares through the social network Facebook. Analyzing the campaign promoted by Turismo do Centro de Portugal, it appears that the text of the promotional video states that "These are times like the ones we live in that force us to stop and then start again. Times that take away our freedom, but that also make us believe. Believe that we can, that we will win. There will be time to give wings to our dreams again, to embrace those we love, to smile without shadows". The video opens with the image of a person wearing a protective mask and follows some of the biggest tourist attractions in the region. "There will be time to start over, to travel, to run, to fly. Feel and vibrate again, with the wind, the sun, the rain. There will be time to sail and to be together again. Until then, we'll stay home. And as a whole, one, we will win". It should also be noted that under its Contingency Plan to deal with the outbreak, Turismo do Centro created a "sample" of 1,030 tourist spots, hotels, restaurants and attractions that it closely monitors. The objective was to follow the evolution of the pandemic, assess its impact on the sector almost at a minute and help find solutions.

"Estabelecimento Clean & Safe"

Turismo de Portugal will recognize companies in the Tourism sector that comply with the recommendations of the Directorate-General for Health to avoid contamination of spaces with SARS-CoV-2 (new coronavirus). Tourist Enterprises, Tourist Animation Companies and Travel and Tourism Agencies wishing to obtain the "Clean & Safe Establishment" seal must comply with the set of provisions contained in the «Declaration of Commitment» that will be available on the digital platforms of Turismo de Portugal concerning the registration of tourist companies: National Register of Tourist Enterprises (RNET), National Register of Tourist Entertainment (RNAT) or National Register of Travel and Tourism Agencies (RNAVT).

Figure 2: "Estabelecimento Clean & Safe"

Source: Turismo de Portugal (2020)

Only after companies have submitted the Declaration of Commitment on the aforementioned platforms, do they have the possibility to use the seal in question, either in their physical facilities, or in the channels and platforms for disclosure and sale. This measure, articulated with the Confederation of Tourism of Portugal (CTP) and with contributions from other associations in the sector, seeks to sensitize enterprises to the minimum procedures to be adopted and encourage the recovery of the tourism sector at national and international level, reinforcing confidence of everyone in the destination

Portugal and its tourist resources. The search for sustainability is thus operationalized through this Portuguese measure.

Final Considerations and Future Research

There is also a focus is also on the rising importance of a cared for destination image, vital for the success of every hotel unit in the different types of tourism, special relevance given to sustainable tourism.As previously mentioned, the tourism industry has the capacity to generate the movement of millions of people and, consequently, contribute to the entry of thousands of currencies in tourist destinations, which enable their development. However, uncontrolled growth in tourism can also cause serious damage, such as environmental and cultural degradation, the destruction of fragile ecosystems, the appearance of pollution, the generation of conflicts between tourists and the local population, overcrowding in receiving communities, among others (Hopkins, 2005). And it is due to these harms caused, and also for global well-being, that tourism must adopt sustainable measures, which will act as conservation tools and allow, for example, the preservation of important natural areas and wildlife, as well as as well as archaeological and historical sites; more efficient management of resources; improving the well-being of the community, through local investments and concern for its long-term sustainability; among others (Verbeke, 2000). But to carry out sustainable tourism, stakeholders play an important role, as they both influence and are influenced by the activity of other tourist organizations, and their interrelationship is essential for the inclusion of sustainability in tourism.

The current situation of tourism on a world scale brings the issue of sustainability to an even greater extent. At first sight, one might think that this has become the last concern of accommodation units that are struggling these days for survival. This study highlights the role of digital communication in changing consumer behavior in specific tourist and territorial marketing contexts. In this sense, the communication strategy used by Turismo do Centro de Portugal and by the Azores Tourism Association, reveals quite satisfactory results. The institutional communication strategy is strongly focused on social networks, in an attempt to capture the public's attention (domestic and foreign) and to convey the idea that “everything will be fine” in a “post-pandemic” scenario and that we will all have time to travel and to get to know the Portuguese tourist destination. In the present study, some real examples associated with the reaction to the new coronavirus were illustrated. The results show that online communication facilitated the interaction between the citizen / tourist and the brands, an aspect that is assumed to be very important in a context where the key is to inform, advise and prevent. The strengthening of the population's ties with tourism entities, a consequence of the messages used in the online context and the digital communication that was present on social networks. Consumers, tourists, visitors and the different generations (who also use social media more) like and appreciate the institution's type of communicational approach. This audience seems to be better able to understand the meanings of messages from publications and to understand that there is preventive work. The main focus of this initiative is to remember the importance of social detachment and “knowing how to wait” so that (in the future) everyone can again travel and spend their holidays in the tourist destination Portugal. Future studies should move towards corroborating the conclusions evidenced here, and it is recommended to use the quantitative methodology (ie questionnaire with consumers) in order to establish causal relationships between consumer behavior variables (and their relationship with the consumer). socially responsible marketing in tourism contexts). In an interdisciplinary perspective, the present study presents contributions to the area of marketing (digital communication) and tourism (with reaction to the covid-19 pandemic).

Lexicographic and Transfer Orders in A Set of Allocations

Arkadiusz MACIUK

Wroclaw University of Economics and Business, Poland
arkadiusz.maciuk@ue.wroc.pl

Abstract

Before the allocation of a predetermined number of indivisible and indistinguishable goods among agents with given claims, some boundary conditions are defined which such allocation should satisfy. If there are many such allocations, some additional constraints are necessary. The most frequent approach to solve this dilemma is choosing a specific method or algorithm of allocation, however another unsolvable dilemma emerges as to why a particular method should be chosen out of many other possible ones. This paper deals with a concept of performing the allocation by means of a compromise reached by agents participating in allocation based on the assumption that no agent or no coalition of agents can be favored. The compromise can be developed through subsequent reductions of the set of feasible allocations by maximal allocations under given relation of order, which favor at least one coalition. The identification of such allocation requires reviewing all possible permutations of agents and determining the relations of order that depend on the succession of allocation participants.
The paper analyzes two kinds of the relations of order, their properties and also how determining a given type of relation influences the reduction of the set of feasible allocations. The first type of relation are lexicographic orders which compare, in a given succession, the values of coordinates of vectors corresponding to allocations. The second type of relation are transfer orders where possibilities of relocating goods under given succession from a selected group of agents to remaining agents are considered. This relation has interesting properties, nevertheless, as shown in the paper, the methods to find its maximal elements require a great number of arithmetic operations and are inefficient given a great number of agents participating in allocation.

Keywords: Fair Allocation, Preference, Reduction of The Set

Introduction

The fair or optimal allocation of indivisible and indistinguishable goods or objects to a set of agents is a frequent and difficult problem. It emerges in many real world applications from different areas such as division of a bankruptcy estate, allocation of task to workers, choice of optimal strategy in a coalition game, and selecting electoral statute for legislative body.

In this paper models of fair apportionment of a given number of indivisible goods are considered based on the following assumption. A set of indivisible and indistinguishable goods are to be distributed among a set of agents, each of whom has got some entitlements, called also claims, which can be expressed numerically, and no monetary transfer is possible between agents. In other words, these allocations can be presented as vectors of natural numbers adding up to a given value, while the number of coordinates of vectors equals the number of agents. Moreover, it is assumed that the allocation process is centralized, that is:. it is either decided by a neutral arbitrator (or by computation), or through negotiations among agents always leading to a compromise.

One of key issues in this type of problems is how to correctly define the notion of fairness or optimality, and how to evaluate the degree of preserving it by a given allocation. Most of current papers focus on a specific and concrete criterion and a method to obtain the ensuing allocation. The strength of this approach is that is usually produces a clear unique solution, but its definite weakness is the arbitrary assumption of a concrete principle out of many possible criteria.

Literature Review

In order to avoid the arbitrariness one can proceed as follows. The first way is through the definition of a collective utility function (CUF) that aggregates individual agents' utilities. If this function is properly defined the arbitrator simply seeks the allocation maximizing the CUF. The second option is to define by means of a logical, naturally interpreted criterion, what is considered as fair or optimal. The examples of such criteria include: max-min fair share (MFS), proportional fair share (PFS), envy-freeness (EF), competitive equilibrium from equal incomes (CEEI) (Bouveret and Lemaître, 2016; Caragiannis et al., 2019; Conitzer et al., 2019; Golovin, 2005; Lipton et al., 2004; Segal-Halevi and Suksompong, 2019).

The allocation methods based on max-min fairness or envy-freeness are typically applied when preferences of agents are known and they are not necessarily equal: each player individually evaluates each good, and not necessarily in the same manner as other players. If the goods are indistinguishable and therefore the evaluations of goods are irrelevant these methods can also be applied. The similar dilemmas emerge when dealing with the area of bargaining games (Bateni et al., 2010; Goel and Krishnaswamy, 2018), cooperative matching games (Ito et al., 20160 and sequential forward selection (Padmaja and Vishnuvardhan, 2017). From many possible allocations one has to select the one that yields the most beneficial value of an objective function. If the objective function is known, then solving the problem comes down to concrete methods and it suffices to perform necessary computations. But it is not always clear how to define the objective function or the vector of pay-offs.

Barbera and Jackson (2006) and Koriyama et al. (2012) analyze the problem of selecting the electoral statute to political bodies such as the US Electoral College, the European Union Council of Ministers or the European Parliament, representing different regions, applying the collective utility function as the sum of utility functions of individual regions. Koriyama et al. (2012) assume in a simple and economically rational way that the coordinates of individual countries are positive functions with decreasing marginal values. Therefore they conclude that the optimal collective utility function is increasing and concave, hence the allocation of mandates should satisfy the principle of degressive proportionality. Correctness of such assumption can be confirmed by the analysis of the historical data regarding the composition of the European Parliament, which was elected according to this rule (Cegiełka, 2010). Nevertheless this assumption does not provide any rational argument as to which particular degressively proportional allocation should be selected. There may be many allocations satisfying the condition of degressive proportionality just like there are many increasing and concave functions. For example, there are millions of possible allocations of a given number of seats in the European Parliament among the member states of the European Union, which strictly satisfy the principle of degressive proportionality and all constraints implied by the Lisbon Treaty (Łyko and Rudek, 2013), and there are tens of proposed methods of allocation (Hamman, 2017; Dniestrzański, 2019).

Many authors introduce some additional criteria thereby allowing the unique selection of allocation or at least significant reduction of the set of solutions. These assumptions usually are contradictory. An example of such assumption is that the voters' preferences are independent random variables. This leads to the Penrose's square-root law stating that the optimal weights of individual entities participating in the allocation are proportional to the square root of their claims (Kurz, Maaser and Napel, 2017). It is worth emphasizing here that empirical research and common sense undermine the reliability of the assumption that decisions of agents participating in the allocation are independent (Gelman, Katz and Bafumi, 2004).

Another frequently applied assumption is trying to achieve proportionality of allocation in compliance with the rule that the closer an allocation is to the proportional allocation, the better are the interests of respective electoral groups represented. The conditions defining the manner of performing the allocation such as e.g. that each agent has to be allocated not more and not less than the predetermined numbers of goods -cause the feasible allocation to differ from proportional ones. Hence one has to select from the set of feasible allocations such allocation that is as close to proportionality as possible. Based on this principle, the Cambridge Compromise (Grimmett, 2012; Grimmett et al., 2017) and other

methods (Dniestrzański and Łyko, 2015; Cegiełka et al., 2018) were put forward as procedures to find the allocation.

This paper

The properties of another concept of fairness of allocation which is applied when the preference relation is not uniquely defined are discussed in this paper. One may then consider all the possible preferences in order to indicate the allocation which does not favor any agent or a coalition of agents. In organizations that associate agents with incompatible goals the compromise solutions are appreciated, based on cooperation and mutual concessions. Let us assume that all allocations satisfying given criteria can be determined. A set of such allocations will be called a set of feasible allocations. As mentioned before, in situations of this type it is not possible to uniquely define a collective utility function, so as a result, the set of feasible allocations can be very large. Nevertheless each relation of utility generates a preference, and for each preference one can indicate its maximal elements. They are valuable solely for a selected group of agents, i.e. they do not satisfy the criteria required to reach the compromise. One defines a relation of order in the set of feasible allocations and then one considers all possible permutations of agents participating in the allocation. Each permutation is associated with a preference relation, and each of them has got maximal elements. Thus in order to reduce the set of feasible allocations one has to exclude from it those which are maximal elements of one preference relation (Cegiełka et al., 2017). If such reduction does not give satisfying results, one can repeat the whole process to reach the desired goal.

Certainly, the effect determining of such subset of compromise allocations depends on the selected type of the order relation. This paper analyzes the properties of two types of order relations. The first type of relation are lexicographic relations Two given allocations are with each other in a lexicographic relation (i.e. one is "not worse" than the other) when the vectors of these allocations, preserving a proper succession, are not smaller lexicographically. Another type of relations are transfer relations where possibilities of relocating goods from a selected group of agents to remaining agents are considered under given succession (Cegiełka et al., 2017). This type of relation is a natural basis upon which the indices of the inequality satisfying the Pigou-Dalton transfer principle can be constructed (Maciuk, 2019). The effect of reducing the set of feasible allocations depends on the type of order relation defined. In Section 2 these relations are defined, while Section 3 presents their basic properties and shows how the set of maximal elements can be determined using these properties. The set of maximal elements for transfer orders is larger than for lexicographic relations, therefore the reductions in this case are more radical. Nevertheless determining such a set is more difficult and requires more arithmetic operations than determining the set of maximal elements in the case of lexicographic orders. In particular, finding maximal elements for lexicographic relations can be the first step of a procedure determining the maximal elements for transfer relations. The last section briefly compares the properties of these types of relations.

Problem Statement

The allocation s of indistinguishable and indivisible goods among n players can be equated to a n-dimensional vector whose elements are natural numbers, including zero and adding up to s. The term 'feasible allocation' indicates that this allocation fulfils additional conditions resulting from the issue under study, considering among other things the claims of shareholders (e.g. the condition that an agent with greater claims cannot be allocated less goods than an agent with smaller claims, and each of them is not allocated more than a predetermined number of goods). Let $\mathbb{D}_s$ denote the set of feasible allocations, $N = \{1,2,\dots,n\}$ – the set of indexes of agents, and $\Pi(N)$ – the set of permutations of the set N. A given feasible allocation is said to be not less in the relation of lexicographic order with respect to a given succession of agents than another allocation, if the vector of the first allocation is lexicographically not less than the vector of the other allocation with respect to a given succession.

Definition 1 (lexicographic order with respect to permutation π).

$d', d \in \mathbb{D}_s, \pi \in \Pi(N)$,
$d' \gtrsim_{\pi}^{lex} d \;\; \Leftrightarrow \exists t \; s.t. 1 \leq t \leq n \; \forall i \; s.t. 1 \leq i \leq t \; d'_{\pi(i)} = d_{\pi(i)}$ and $d'_{\pi(t)} \geq d_{\pi(t)}$.

The second type of studied relations includes the relations resulting from the possibility of transferring the goods between agents. A given allocation is not less than another allocation in this relation, if it is possible to transfer at least one single good from one to the other without violating the fixed succession.

Definition 2 (transfer order with respect to permutation π).
$d', d \in \mathbb{D}_s, \pi \in \Pi(N), \; d' \succcurlyeq_{\pi}^{tr} d \;\; \Leftrightarrow \;\; \forall k \in N \; \sum_{i=1}^{k} (d'_{\pi(i)} - d_{\pi(i)}) \geq 0.$

Both lexicographic relation and transfer relation are reflexive, transitive and weakly antisymmetric, i.e. they are order relations (Cegiełka et al., 2017). Lexicographic relation is a relation of linear order – each pair of relations has the property that either the first relation is in relation with the second relation or the second one with the first one. Transfer relation is different. For example, in lexicographic relation, under any succession of agents, it is always possible to compare the allocations (4,4,4) and (3,3,6): it holds either $(4,4,4) \gtrsim_{\pi}^{lex} (3,3,6)$, when there is index 1 or 2 in the first place of permutation, or $(3,3,6) \gtrsim_{\pi}^{lex} (4,4,4)$ when there is index 3 in the first place of permutation. They are also with each other in a transfer relation with respect to the succession $(1,2,3)$, but not with respect to the succession (2,3,1). In the case of permutation (1,2,3) one can interpret this in such a way that agent 1 transfers one good to agent 2, and agent 2 transfers two goods to agent 3: $1 \xrightarrow{1} 2 \xrightarrow{2} 3$. With permutation (2,3,1) this interpretation implies that agent 2 transfers a positive number of goods to agent 3, while agent 3 transfers a negative number of goods to agent 1: $2 \xrightarrow{1} 3 \xrightarrow{-2} 1$.

A maximal allocation is such an allocation that under a given succession, there is no better allocation, i.e. the allocation which is a maximal element of the order relation determined by a given succession of agents. It is the allocation that gives them the maximal number of goods, under given succession, beginning with the first one, then the second one, and so on.

Definition 3 (set of maximal elements for relation of linear and transfer order).
$\max \mathbb{D}_{s,lex} = \{d \in \mathbb{D}_s : \exists \pi \in \Pi(N) \forall d' \in \mathbb{D}_s d' \gtrsim_{\pi}^{lex} d \Leftrightarrow d' = d\}$;
$\max \mathbb{D}_{s,tr} = \{d \in \mathbb{D}_s : \exists \pi \in \Pi(N) \forall d' \in \mathbb{D}_s d' \succcurlyeq_{\pi}^{tr} d \Leftrightarrow d' = d\}$.

In a maximal allocation for transfer order each succeeding agent cannot transfer any good to the preceding agent without violating the allocation conditions. In particular, this means that the number of maximal allocations for transfer orders is not smaller than the number of maximal allocations for linear orders. Each lexicographic relation determined by a given succession of allocation entities, being a linear relation, has got exactly one maximal and one minimal element (i.e. the greatest and the smallest element of relation). On the other hand, in the case of transfer relation there may be more maximal or minimal elements.

Research Methodology

The trouble with the procedure determining maximal allocations for these relations is its computational complexity. Each permutation of the set of indexes can correspond to another relation, i.e. the number of relations may be equal to the number of permutation of an n-element set of indexes, i.e. $n!$, thus if one has to consider each of them, the procedure for large values of n will be inefficient. Therefore one has to apply any available steps to reduce the number of operations necessary to be performed. When the conditions determining potential divisions are fixed in such a way that there are some players who always are allocated the same number of goods or there is more than one player who always is allocated the same numbers of goods, then such players can be considered as insignificant for the subsequent analysis. For example, the rows of Table 1 present the set of all allocations of 75 goods among 8 agents with respective claims $P = [290, 230, 95, 92, 90, 30, 20, 10]$, satisfying the following conditions: agents with smallest and greatest claims are allocated fixed numbers of goods –3 and 20, respectively, and agents with smaller claims cannot be allocated more goods than those with greater claims, whereas

the succession of quotients of claims to numbers of goods has to be monotonic (so-called condition of degressive proportionality). In this case agents 1 and 8 are allocated the same numbers of goods, and agents 4 and 5 the same number as agent 3. Therefore, instead of considering the permutations of all eight agents, it suffices to consider the permutations of agents 2, 3, 6 and 7. It is worth noting that the reduction is significant – instead of considering 8! permutations which define the relations, it suffices to consider 4! cases, the number that is 1680 times smaller. In order to distinguish from initial indexes, these agents will be denoted in the remainder by letters A, B, C and D.

In a lexicographic relation determined by permutation $\pi = \big(\pi(1), \pi(2), \dots, \pi(n)\big)$ the maximal (minimal) allocation is characterized in such a way that an agent indexed by $\pi(1)$ is allocated the maximal (minimal) available number of goods. Hence, in the case of determining maximal (minimal) lexicographic orders, another available simplification is to reduce the set of allocations to the subset of allocations with a given coordinate that is of the greatest (smallest) possible value. In the case under study seeking the greatest element for all relations beginning with the index A can be reduced to allocations 9 and 10 (the smallest element – to allocations 1, 2 and 3).

Table 1: An example of the set of feasible allocations

#	1	2	3	4	5	6	7	8	+	–
	x	A	B	x	x	C	D	x		
1	20	16	8	8	8	6	**6**	3	D	ABC, BAC
2	20	16	8	8	8	**7**	5	3	C	ABD, BAD
3	20	16	**9**	**9**	**9**	5	4	3	BC, BDC	AC, AD
4	20	17	8	8	8	6	5	3		
5	20	17	**9**	**9**	**9**	4	4	3	BDA	
6	20	18	8	8	8	5	5	3		BCA

10	20	**19**	**9**	**9**	**9**	3	3	3	AB, BA	C, DBC, DC

Table 2: Examples of graphs of transfer relations for the set of allocations from Table 1

ABCD	ACDB	ACBD
		BCAD	BACD	CBAD

The remaining cases are similar. For relations beginning with the index B the set is reduced to allocations 3, 5, 8 and 10; for relations beginning with the index C – to allocation 2, and to allocation 1 for relations beginning with D. In the case of relations beginning with the index C or D one can stop seeking the greatest elements because there is no need to reduce the one-element sets. The greatest element of any lexicographic relation beginning with the index C is allocation 2 and for relation beginning with the index D – allocation 1. In the case of relations beginning with A one gets the one-element sets after introducing the second index: allocation 10 is the greatest element for relations determined by permutations beginning with AB. This is equivalent to the case when the agent indexed by A selects the most valuable allocation, while the agent B selects the most valuable allocation from allocations where A gets the largest part. In that case agents indexed by C and D have no choice, as the choice by the first two agents determined the unambiguity of allocation.

Determining a single allocation can be considered equivalent to labeling it. Allocation 1 has got a one-character label D, allocation 2 – label C, allocation 3 has got two different labels BC and BDC, and so on (see next-to-last column of Table 1). Therefore, determining the set of maximal elements for lexicographic relations is equivalent to identifying allocations that can be labeled. A similar procedure is applied to determine the set of minimal elements for lexicographic relations (see last column of Table 1).

A similar procedure to determine the set of maximal allocations for transfer relations is not possible because those relations may have more than one such element (see examples of graphs of transfer relations presented in Table 2). However, for that purpose one can employ the set of maximal elements of relations of lexicographic orders, because this set is a subset of the set of maximal elements of transfer orders.

Proposition. $\max \mathbb{D}_{s,lex} \subseteq \max \mathbb{D}_{s,tr}$.

Proof. It suffices to show that, given the succession $\pi \in \Pi(N)$, if the vector $d \in \mathbb{D}_s$ is the maximal element in lexicographic relation, then there does not exist a vector $d' \in \mathbb{D}_s$ that is greater than d in transfer order. Let us assume by contradiction that there exists such a vector, i.e. as $d'_{\pi(1)} \geq d_{\pi(1)}$, $d'_{\pi(1)} + d'_{\pi(2)} \geq d_{\pi(1)} + d_{\pi(2)}$, $d'_{\pi(1)} + d'_{\pi(2)} + \cdots \geq d_{\pi(1)} + d_{\pi(2)} + \cdots$ hold, but because it is the maximal element of lexicographic relation, it satisfies the inequalities $d'_{\pi(1)} \leq d_{\pi(1)}$, $d'_{\pi(1)} + d'_{\pi(2)} \leq d_{\pi(1)} + d_{\pi(2)}$, $d'_{\pi(1)} + d'_{\pi(2)} + \cdots \leq d_{\pi(1)} + d_{\pi(2)} + \cdots$. Hence $d'_{\pi(1)} = d_{\pi(1)}$, $d'_{\pi(2)} = d_{\pi(2)}$, …, or $d' = d$, thus resulting in a contradiction.

The proof of Theorem 2 also implies that each allocation "labeled" for lexicographic relation is the maximal element of transfer relation for the permutation corresponding to this label. For example, in the case under study allocation 9 has got label AC and is the maximal element of all relations defined by permutations beginning with AC. In the case of permutation ACDB it is the only maximal element, but for ACBD, besides allocation 9, also allocation 10 is the maximal element. This example also aptly illustrates the fact that one must not leave out any permutations -unlike in the case of lexicographic orders.

As a result, the first step in a procedure to determine the set $\max \mathbb{D}_{s,tr}$ can be division of the set $\mathbb{D}_s$ into $\max \mathbb{D}_{s,lex}$ and remaining allocations, whereas for the set $\max \mathbb{D}_{s,lex}$ labels of its allocations are determined and saved. Let $C \coloneqq \max \mathbb{D}_{s,lex}$, E – the set of labels of the set $\max \mathbb{D}_{s,lex}$, and $X = \mathbb{D}_s \setminus \max \mathbb{D}_{s,lex}$. Subsequently, all transfer relations $\succcurlyeq_{\pi}^{tr}$, at each step permutations of the set of indexes N, $\pi \in \Pi(N)$ and corresponding transfer relations $\succcurlyeq_{\pi}^{tr}$ are considered. For each of them $s \in \max \mathbb{D}_{s,lex}$, whose label belongs to π, is determined. Then the elements from the set $\mathbb{D}_s$ are compared with s to find those which are not in relation with it. If the set of such allocations is not empty, then they are compared with each other by relation $\succcurlyeq_{\pi}^{tr}$ and its maximal elements are determined. These elements are added to set C and deleted from set X. For example, in the set of allocations discussed above lexicographically maximal element of relation determined by permutation ABCD is allocation 9. Allocations 8 and 10 are not in transfer relation with it, while $10 \succcurlyeq_{\mathrm{ABCD}}^{tr} 8$ (see Table 2), therefore only allocation 10 is added to C.

Discussion

Methods resulting from preference relation such as relation of lexicographic order and relation of transfer order can be applied to conduct negotiations aimed at determining the allocation in conditions that are transparent and equal to all participants. These methods require the examination of all possible permutations of significant agents, thus increased computational complexity of procedures based on them. In the case of lexicographic relations, the procedure can be considerably streamlined for typical distributions of the set of allocations, yet in the case of transfer relations a procedure with this property is not yet available. If the set includes less than a dozen agents, the complexity is not a major problem, but in the case of larger sets transfer relations are not efficient. An open challenge for the forthcoming research is to find more efficient numerical methods that offer solutions possibly close to optimum.

Abstract

Gamification is a method for engaging learning in a fun way in different types of educational settings. Numerous recycling intention researches were conducted on the application of the Theory of Planned Behavior (TPB), a theory that explains why certain intentions or behaviours are formed. Self Determination Theory (SDT), a theory that explains the motivation of acting on a task through external and internal factors. This current study aimed to examine the recycling intention of participants before and after their gamified classroom experiences through educational crafting. This learning experience is called Edcraft Gamified Learning (EGL). A pre-survey and a post-survey were conducted with 14 participants who completed their EGL activities. The pre and post-survey analysis through Wilcoxon-signed rank was conducted. It is a non-parametric statistical test used to compare two similar pre and post samples of EGL. Results showed that the participants have no changes on their intention to recycle. With this data, an actual study will be conducted in the next stage of the research with more samples to participate in EGL. The current pilot study has surfaced with some suggestions to improve EGL on a larger scale.

Keywords: Gamification, recycling, educational crafting, Theory of Planned Behaviour, Self Determination Theory

Introduction

Gamification has been around for long before the appearance of video games; it applies gameful design into non-game settings to engage people in various types of activities. In the educational domain, teachers often employ games in the classroom [7], and in recent days, teachers have been applying game elements into their classrooms respectively to engage students.

The environmental problems have been a crucial issue which negatively impacted the natural ecosystem. This issue surfaced mainly due to irresponsible and selfish human activities who did not pay much attention to safeguard and protect their environment [8]. The purpose of this pilot study is to examine recycling intention among participants after experiencing the Edcraft Gamified learning class sessions.

Related Studies

Gamification and learning

In a recent study conducted by [1] showed that gamification is an effective way to quantify participants' academic performance, this leads to learning experience and engagement. Also, gamification in learning is a broad area to research on and it is yet conclusive [2], especially on the implementation of motivation in a game design learning environment. Besides, game-based design or serious game has been a famous implementation among the educators nowadays [5]. This had led to the motivation of this research in gamify

learning, to enable learners to think and visualise learning as a game and to reflect the knowledge that they learnt from the class, intervention or activity and to understand more about participants' expected outcome.

In gamification, badges and leaderboards are often implemented into non-game context [10] and the most prominent examples are Duolingo for language learning, Codeacademy and CodeCombat for computer programming learning. Using games in education has shown its success in the educational environment [13]. The freedom to retry has allowed the students to experiment without fear of failing and this has improved their engagement on learning [14].

Self Determination Theory (SDT)

Self-Determination Theory [9] is used as a theoretical support to enable a better understanding of the gamification mechanics in the context of motivating learning among participants. Besides, it is a type of motivation that drives behavior and performance [9]. The interpretation of motivation is an important factor to study the relationship between gamification and learning outcomes.

An educational research by Barna (2017) mentioned that "gamification research often focuses specifically on participants' performance like grades also in IT courses" [28], or on behavioural outcomes like tasks on schedule.

Figure 1: The spectrum of "self-determination and motivation within self-determination theory". Adapted from [16] and [17]. Image source: "https://academy.sportlyzer.com/wiki/motivation/self-determination-theory-intrinsic-and-extrinsic-motivation/"

Intrinsic Motivation

In the SDT model, enjoyment, challenge, pleasure and interest are the intrinsic motivation factors that can engage performance or behaviour.

Ryan and Deci (2000) define the intrinsic motivation as "an activity that characterizes its inner satisfactions rather than other outcomes externally". It does not cause by other external stimulations, pressure or rewards to get intrinsically motivated, get challenged and feel of engagement.

Intrinsic motivation facilitates "the behavioral regulation representing engagement in an activity for the sheer pleasure and satisfaction" [19]. Moreover, the behavior from intrinsic motivation is closely related to the "enjoyment, engagement in a task, or the capacity of the task to provide opportunities for cognitive and social development" based on Deci and Ryan's study.[21].

It is perceived that some individuals were not engaging themselves into a particular activity because they did not enjoy the activity. Boosting up the inner motivation or intrinsic motivation could eliminate the said attitude. With the complementary of any external rewards, players feel more enjoyable and excited in the said task and will keep them engaged to perform the activity.

Extrinsic Motivation

Extrinsic motivation is more apparent in the reward and achievement context. Extrinsic motivation can be in the form of grades, a promotion and social reciprocity. This type of motivation is not necessarily rewarding in a physical way.

In real-life practice, the applications of gamification are not an intention or extreme video games; intrinsically motivating game-like experiences is most widely accepted explanation for the behavioral impact from gamification elements, for example, leaderboard, badges and points [17, 18] that will be included in the current study.

By providing a suitable push factor by an extrinsic motivation, it is perceived that reasonable performance and goal can be achieved within a period.

Autonomous and Controlled Motivation

Few studies from [22] have confirmed that SDT constructs and predicts the future intention. The current work builds upon previous research by (Turel, 2016)"incorporating a measure of Autonomous Motivation (AM) and Controlled Motivation (CM) intended to clarify the exact revelators of behavioral intention".

AM is a self-determined behavior. It works as an intrinsic oriented goal and is defined as a behavior that engages with intrinsic goals or outcomes and discoveries of self-behaviour from an individual. [24]

With AM intact, a sense of choice can be felt by the individuals, as well as self-recognition, interest, and satisfaction. Therefore, behavior of a task is more likely to persist. They are personally motivated by the need to feel self-driven without the external factors and autonomous reasons or actions. [24, 25]

CM also engages an individual's behaviors for externally influenced reasons such as extrinsically motivated elements such as rewards, in form of money, consumable credits, points or perceived approval from others or to avoid any external penalisation and guiltiness [25].

Usually, the engagement of individuals in the behavior for "controlled reasons often has a sense of restriction and pressure when engaging such behavior" and are only motivated when engaging with the external factor [24, 25].

If the external reinforcing agent is removed, action will not be attached with the task. Individuals who are motivated through control-motivated are less self-regulated.

Amotivation

[15] explains that amotivation is a form of motivation that does not involve personal feelings. Amotivation, is the lack of interest, enthusiasm, emotion, or concern towards an action and is more closely related to goal-directed behaviour [20]. In a study from [16], they found that amotivation predicted students' physical activity intention, that it shows the strong relationship of Amotivation and intention.

At the ends of the opposite side of motivation is amotivation, a state where engagement of an activity does not regulate from intention; intrinsic motivation, an opposite behavioral regulation displaying of engagement in an activity with the ignorance of pleasure and satisfaction[19].

The Theory of Planned Behavior (TPB)

The TPB by Ajzen [11] stated that "each behavior is positively influenced by behavioural intention that will be predicted by attitudes (i.e., preferences beliefs), subjective norms (i.e., perceptions that others would approve), and perceived behavioural control **(PBC)** (i.e., difficulty to perform a particular behaviour)".

Research Conception Framework and Edcraft Gamified Learning (EGL) Gamification Design

This study's main objective is to study the intention of recycling, and it is referred to "an individual's self-commitment to engage in recycling behaviors" [29]. Throughout the study from (Park, 2014), "recycling intention has seen by drawing variables and models from social psychology". Theory of Planned Behavior (TPB) proposed by Ajzen as the main theory used to study the intention of recycling, numerous researches from TPB has also shown the improvement of the recycling of E-waste. This proves the effectiveness of TPB in recycling and learning.

Figure 2: Research conceptual framework

The main idea of the research model (Figure 2) is to achieve intention by the end of the EGL activity. This research framework adopts SDT and TPB into the EGL gamification design for recycling learning activity, where SDT is to study the motivation on the gamification design. SDT is an important theory to investigate in numerous gamification research and it is based on the spectrum of self-determination, categorised from autonomous motivation to controlled motivation and to amotivation as explained in Section II – Related studies. The keywords of the SDT spectrum are selected to match with this study such as pleasure, fun, enjoyment and satisfaction for intrinsic motivation and value, competition, reward and control for extrinsic

motivation.

Whereas TPB is widely used for recycling related behavioural theory to test on the attitude, social norm and perceived behaviour control that affect intention of recycling.

This research aimed to test how game elements which are related to self-determination theory can improve the recycling intention.

Study Design and Flow of EGL Pilot Study

EGL activities were conducted in two piloted sessions. First, it was piloted to young participants and the second session was piloted to elder participants, in a "level 1 & level 2" gamified class setting. Before starting the game, the participants were required to answer a pre-survey, then followed by watching a video about the objective of EGL with footage of the current waste problems.

Next, the participants watched a tutorial video that guided them to craft a "level 1 craft" out of unused plastic. The participants were given 2 hours to make their own craft according to the tutorial video. During the session, they were also guided by mentors. Once the first level was done, participants were ranked by judges and proceeded to the level 2. In this level, they replicated the process of crafting by creating a more difficult and challenging craft. After "level 2" craft creation, the participants were asked to fill in a post-survey questionnaire. The participants were then ranked by the appointed judges, and the winners will earn a beautiful badge as a reward. As for the data collection, the pre and post survey consist of five-point Likert scales from left to right, strongly "agree, agree, neutral, disagree and strongly disagree" given to the participants in paper form during the EGL activity, the pre-survey questionnaire will be given right before the activity started, it is the state when they have little to no impression on the activity and post-survey is right after the activity and completed the EGL experience.

Figure 3: Badges for the winners as a reward.

Descriptions of The Study, Data Analysis and Findings

Participants

There were 14 participants involved in the two piloted EGL sessions. First EGL has 6 college students between 19 to 29 years old and the second session are 8 elderly persons aged between 50 to 60 years old. The questionnaire surveys consist of 4 major aspects, namely the recycling awareness, SDT, gamification,

TPB on "attitude, subjective norm, perceived behavioural control and intention" to recycle. Overall, all 14 participants attempted the survey items, and the dependent variable to be examined is on their intention to recycle.

Data collection

Pre-survey is a prior survey before EGL, it is comparable to the Post-survey data to compare with the difference of result, specifically on before and after for the intention to recycle. In the first EGL, a competition was held where level 1 and level 2 craft was made for the participants to follow.

Post Survey is a survey given after the participants completed EGL intervention.

Figure 2: The first pilot study session with 6 participants between age 19- 29.

Figure 3: The second pilot study session with 8 participants between age 50- 65

To determine the differences between pre-survey and post-survey, Wilcoxon signed rank test was used as a hypothesis testing tool, allowing the test to acquire an assumption from the test object population. Wilcoxon signed rank test compares the two independent groups' mean to find out whether there is statistical evidence that the related population means are significantly different. Wilcoxon signed rank test is a non-parametric test.

Analysis and Findings

A paired t-test and Wilcoxon signed rank test are normally used when a survey was conducted twice (pre and post survey each) to the same group of the participants. The paired t-test can show whether the mean (average) of Dependent Variable (versus the grouping variable) has changed between the first and second time the participants took the survey.

Since the current study involved a small piloted sample size, therefore it is not advisable to run the normality test for a small sample size; the parametric test such as paired t-test is inappropriate in this context. Instead, we decided to use the equivalent non-parametric test, namely the Wilcoxon signed-rank test to compare two sets of scores from the 14 samples.

Table 1: EGL pre and post survey on "intention to recycle" based on "Wilcoxon signed-rank test".

Ranks				
		N	Mean Rank	Sum of Ranks
intention_post - intention_pre	Negative Ranks	2[a]	6.50	13.00
	Positive Ranks	7[b]	4.57	32.00
	Ties	5[c]		
	Total	14		
a. intention_post < intention_pre				
b. intention_post > intention_pre				
c. intention_post = intention_pre				

According to the data, after EGL class, there were 2 participants with lesser intention in recycling recorded through the data, while 7 participants have recorded a positive intention to recycle, and 5 participants have recorded no changes in their intention to recycle upon completing EFL.

Table 2: EGL Wilcoxon test statistics

Test Statistics[a]	
	intention_post - intention_pre
Z	-1.130[b]
Asymp. Sig. (2-tailed)	.258
a. Wilcoxon Signed Ranks Test	
b. Based on negative ranks.	

Table 2 shows the "Asymp. Sig (2-tailed)" value, which the "p value" > .05 for the null hypothesis test of "equivalence of means for pre and post survey on 'Intention to recycling' " ; the hypothesis alternative is, "There are differences for both pre and post survey on the intention for recycling". The result can be interpreted as non-significant for the Wilcoxon signed-rank test, which means that the hypothesis null cannot be rejected, and hence there is no difference of "Intention to recycle" after completing their EGL classes with two levels of crafting game.

Discussions and Conclusion

This is a pilot study of the EGL and it will be further expanded with more samples for actual study with more consideration (or precaution) surfaced through this pilot study. Among the precaution measures are: coaching the participants whenever they are in trouble to avoid drop out; the difficulty of the craft activity should be

suitable for novice and not to give much pressure to the participants; also the period of the activity should be conducted during the participants' leisure time to avoid drop out or lack concentration and interest in the activity.

Results of intention (to recycle) for pre and post survey in EGL activity shows no difference based on the analysis, mainly due to the precaution measures weren't well established for this pilot test activity. From these statistic result and potential precaution measures, it is believed to be able to give a positive result on the actual study.

Abstract

Foreign and domestic investors have shown different trading strategies in stock markets. For stock markets with foreign investor activity, however, previous studies indicate that they are exposed to risks related to volatility dan liquidity, especially during financial crisis. The purpose of this study is to analyze the characteristics of foreign and domestic investors regarding industry indexes. Using foreign and domestic investors 2013-2018 daily trading (buy and sell) data, we calculate daily Net Investment Flow (NIF) for each group of investors for each industry. We use vector autoregression (VAR) to estimate feedback trading behavior based on the relationship of daily industry index return and daily investor NIF. VAR estimation indicates that both foreign and domestic investors apply different feedback trading strategies for each industry index return. Foreign investors tend to react with positive feedback trading with shorter lags, while domestic investors tend to use negative feedback trading with longer lags. There is also an indication that domestic investors' trading affects industry index movement, but we could not observe the same effect from foreign investors. The findings of this research offer new evidence regarding foreign and domestic investor behavior regarding industry indexes.

Keywords: feedback trading, financial behavior, stock market, stock return.

Introduction

For the last few years, there's been a constant increase of trading activity in Indonesia Stock Exchange (IDX). This increase is not undesirable; IDX has continuously conducting a campaign to encourage local investors to trade in stock market actively. Since 1988, however, IDX has allowed foreign investors to trade and make transactions in stock market. In 2018, IDX reported that foreign investors are accounted for 52% of total investors in the stock market (CNN Indonesia, 2019). Interestingly, foreign investors net transaction has decreased quite significantly since 2013 despite market composite index continuous improvement over the years. Using IDX daily trading transaction data in 2010-2019 (Fig 1), we can see that in the last four years, there has been a decline in foreign investor percentage transaction volume compared to domestic investors'. Although occupying more than half of market participant numbers, foreign investors seem to trade less over the years compared to domestic investors.

Fig 1. Comparison of foreign and domestic investor daily transaction in IDX 2010-2019

In 2019 The Indonesia Central Securities Depository (KSEI) mentioned that foreign investors ownership of Indonesian stock is 51,46% of the total market (CNN Indonesia, 2019), which leads IDX stock market to be exposed to higher liquidity risk, especially during financial crisis (Arshad et al., 2019; Naufa et al., 2019). Previous studies in this similar topic have shown that foreign investors' activity is related to market volatility, information publicity, and return (Vo, 2017; Martharini, 2018; Omay and Iren, 2019). Moreover, it is proven that foreign investors in IDX have superior knowledge based on their historical experience, which leads domestic investors' tendency to pseudo-herd in mimicking their trading strategy (Setyawan and Ramli, 2016).

Fig 2. IDX Indexes return comparison 2013-2018

This research tries to expand the understanding of foreign and domestic investors' trading activity relationships with different industry indexes in the market. A study by Hong et al. (2007) showed that investors could use industry indexes to predict market index for a short period. This research is supported by Lee et al. (2013), who concluded that there is a correlation of industry index, primarily financial and service industry to market index in Asian countries. Observation of IDX trading data in 2010-2019 (Fig 2) shows that there's been a difference in performance for different industry indexes in IDX compared to the market-wide index. This study tries to comprehend analysis of the previous research in IDX, which indicates that foreign and domestic investors deploy different feedback trading behavior (Martharini, 2018) by using industry indexes instead of IDX composite index.

Using foreign and domestic investors trading data during the 2013-2018 period, we found that foreign and domestic investors show different feedback trading strategies in response to industry indexes return. Our VAR estimation data shows that foreign and domestic investors react differently to each industry indexes movement. In general, domestic investors tend to use negative feedback trading strategy while foreign investors use positive feedback trading strategy. Based on the lags, foreign investors also react in a shorter period compared to domestic investors.

Literature Review

Studies comparing foreign investors and domestic investors' performances are still inconclusive. Some studies indicate that foreign investors perform better (Johnson et al., 2009; Oh et al., 2008), while some showed the opposite (Agarwal, 2009; Choe et al., 2005). However, using data from 32 countries, Ferreira et al. (2017) concluded that domestic institutional investors perform as well as foreign institutional investors on average. A specific study in Indonesia Stock Exchange (Agarwal et al., 2009; Dvořák, 2006) suggested that domestic investors gained higher return than domestic investors in IDX (previously JSX), not because of a difference of information, but foreign investors aggressiveness in trading that affected their overall performance.

In the era of global investment, emerging economies become an interesting destination for investors from developed economies to diversify their portfolio, earning higher returns with lower risks (Vo, 2017). However, these investors can significantly affect market liquidity as it trades in large amount and create a trend of price movement (Peranginangin et al., 2016; Onishchenko and Ülkü, 2019). In Indonesia, domestic investors consider foreign investors to be better informed and have better trading strategies (Setyawan and Ramli, 2016). With the information on trading activities in IDX are accessible for market participants, foreign investors trading may affect domestic investors. Hence, studies regarding foreign investors in emerging economies are necessary.

Feedback trading is one of the many behaviors that can be observed between foreign and domestic investors trading characteristics. It is a form of noise trading where investors make investment or trading decision based on market noise (Koutmos, 2014). Investors responses to these noises can be classified as positive or negative feedback trading. Positive feedback trading (momentum trading) happens when net investment flow is positively related to increasing return. In contrast, negative feedback trading occurs when an increase of return affect net investment flow negatively (Phansatan et al., 2012). A study in IDX (Martharini, 2018) also indicates that foreign investors and domestic investors in Indonesia display contrast behavior regarding feedback trading. Foreign investors tend to use positive feedback trading strategy, especially for short term trading, while domestic investors tend to use negative feedback trading strategy. However, a rather new study using trading data from Korea, Taiwan, Thailand, and Finland indicates that some foreign investors are shifting from return chasing investment patterns and positive feedback trading in regards to market return (Onishchenko and Ülkü, 2019). Evidence from IDX also indicates that feedback trading in IDX investors led to herding behavior (Setyawan and Ramli, 2016).

As mentioned previously, some industries in IDX stock market give better performance than the other and even better than the overall market index. Previous studies have shown that industry return could predict market return as far as two months period and industry indexes are related to the market index, although some industry index has a better impact than the others, depends on the country (Lee et al., 2013; Hong et al., 2007). Investors' limited capability to process all complex information in the market causes lag of information diffusion from asset market to stock market. This finding might indicate that there is a difference in investors' trading activities in each industry sector and whether industry indexes movement can affect investors' behavior. A study in Asian stock markets shows that there's a tendency of different herding behavior within industry indexes, some more than the other, depends on the market. For some Asian markets, investors herd more within the industry than within domestic markets (Zheng et al., 2017). Therefore, it suggests that investors behave differently in regards to industry indexes.

Evidence shows that investors behavior and market performances may vary between industries, and there is an indication that foreign and domestic investors may behave differently in each industry market. Since both foreign and domestic investors in IDX has shown tendencies of different reactions to market return with positive or negative feedback trading, the evidence also suggests different market indexes may affect investors' tendency of feedback trading. This study tries to extend previous studies regarding foreign and domestic investors feedback trading behavior by analyzing foreign and domestic investors' trading activities in regards to industry indexes movement. For this research, we propose the following hypotheses:

Hypothesis 1: Industry indexes affect foreign investors trading behavior in IDX.

Hypothesis 2: Industry indexes affect domestic investors trading behavior in IDX.

Data and Methodology

For this study, we use daily volume trading data acquired directly from The Indonesia Capital Market Institute (TICMI), a subsidiary of IDX. The data consists of Foreign Investors (FI) and Domestic Investors (DI) daily buy and sell data for each company during 2013-2017. We have categorized these data based on nine industry indexes in IDX, as shown in Table 1. We also use daily closng price of industry indexes during the same period, which were acquired from Thomson Reuters Datastream.

Table 1: List of industry indexes and codes

Industry Index	Code	Number of Companies
Agriculture	AGRI	19
Basic industry	BASIC-IND	71
Consumer goods industry	CONSUMER	48
Finance	FINANCE	91
Infrastructure, utilities, and transportation	INFRASTRUC	63
Mining	MINING	47
Miscellaneous industry	MISC-IND	44
Property, real estate and building construction	PROPERTY	68
Trade, services, and investment	TRADE	136
Total		587

To analyze feedback trading behavior, we use bivariate Vector Autoregression (VAR) to model the relationship between net investment flow (NIF) of foreign and domestic investors trading and industry indexes returns. VAR model has been widely used for similar studies (Vo, 2017) and especially relevant in analyzing the relationship between foreign investor with stock returns in emerging market (Ülkü, 2015). On top of that, since both the trading transaction and market return can affect both ways, VAR is used to accommodate the lack definition of dependent and independent variable between the market return and trading activity.

$$NIF_{i,t} = \frac{NVBuy_{i,t} - NVSell_{i,t}}{NVBuy_{i,t} + NVSell_{i,t}} \quad \text{(Eq. 1)}$$

$$NIF^{g}_{i,t} = \alpha_1 + \sum_{j=1}^{k} \beta_1 Return_{i,t-j} + \sum_{j=1}^{k} \beta_2 NIF^{g}_{i,t-j} + \varepsilon_0 \quad \text{(Eq. 2)}$$

$$Return_{i,t} = \alpha_2 + \sum_{j=1}^{k} \beta_3 NIF^{g}_{i,t-j} + \sum_{j=1}^{k} \beta_4 Return_{t-j} + \varepsilon_0 \quad \text{(Eq. 3)}$$

We calculate NIF of each investor groups using Eq. 1, where *i* indicates the investor groups (domestic or foreign) and *NVBuy* and *NVSell* are net volume of buy and sell respectively on day *t*. This formula is a modification from Phansatan et al. (2012) which used value as an indicator of net investment. We opted to use volume, as Vo (2017) has indicated that volume is closely related to information acquisition and investors' return. We use Eq. 2 and Eq. 3 for VAR model

estimation of investors NIF and industry indexes return, where *g* indicates investors group (domestic or foreign), *i* indicates the industry index, and *t* indicates the day of trading observed. Optimum lags k for each VAR is estimated using a few different methods as explained in Table 2. We chose the most selected lag by five criteria used in EViews 10.

Results and Discussion

Table 3 presents the descriptive statistics from investors NIF and return of each industry indexes. Some industry indexes return was negative during the period, which indicates a decrease in performance in these industries. Foreign NIF is negative for most industry indexes, showing that foreign investors tend to sell instead of buy during 2013-2017. On the contrary, we can see domestic NIF is positive for all industry indexes, indicating an increase in domestic investment flow.

Table 3: Descriptive statistics of daily return and NIF for industry indexes

Industry Index	Variables	Mean	Median	Maximum	Minimum	Std. Dev.

To accommodate space, we present the VAR estimation result for return industry indexes and investors NIF in four separate tables, two tables for each investor group. As we can see in Table 4 and Table 5, VAR estimation result indicates industry index return affects domestic investors trading in various lags. For lag (-8), we see that positive return in FINANCE affect NIF positively,

while negative return gives the opposite effect for NIF in AGRI and TRADE. For lag (-7) positive return index in INFRASTRUC affects domestic NIF positively, and a day later in lag (-6) negative return leads to positive domestic NIF. Moving to lag (-4), positive return in AGRI leads to negative NIF, a contrast to previous observation in lag (-8). Similar to this, domestic NIF in FINANCE is still growing despite negative index return FINANCE in lag (-3). Finally, the positive return in lag (-1) industry PROPERTY affects domestic NIF negatively. Generally, there is no apparent feedback trading behavior for industry BASIC-IND, CONSUMER, and MINING.

These results show that domestic investors in IDX showed different feedback trading behavior regarding index return for each industry index in the form of negative feedback trading.

On the other hand, as we can see in Table 6 and Table 7, index return affects foreign NIF in shorter lags. Negative return of FINANCE index on lag (-5) affects foreign NIF negatively while positive return on lag (-1) leads to positive foreign NIF. Positive return of MINING index on lag (-4) affects foreign NIF negatively, and we can observe negative return of PROPERTY and TRADE indexes that affects foreign NIF on lag (-2) positively. For lag (-1) we can see positive return of indexes BASIC-IND, FINANCE, INFRASTRUC, and PROPERTY leads to positive foreign NIF as well. In contrast, negative return of MISC-IND index leads to positive foreign NIF. The estimation shows no apparent feedback trading in AGRI and CONSUMER industry. The result indicates that foreign investors in IDX showed different feedback trading behavior regarding index return for each industry index in the form of positive feedback trading.

Fig. 3 : Impulse Response of Domestic and Foreign NIF to Indexes Return

We can also observe that domestic NIF affects index return for industry MINING and PROPERTY on lag (-4) and lag (-5). We cannot observe the same finding for foreign NIF on industry index return. Interestingly, return of CONSUMER index doesn't affect both foreign and domestic investors trading. Using impulse response function from Fig. 3, we can see that generally, a shock to industry index return will cause a rather high impact on foreign NIF and gradually decrease around day 6 where it tends to stay constant, unaffected. Domestic NIF, however, is more volatile against the shock of industry index return, although most of them are affected negatively. We can see that all domestic NIF will be affected adversely at first before gradually reaching the zero line (unaffected). For some industries (BASIC-IND, FINANCE, INFRASTRUC, MINING), we can see the shock of index return leads to positive domestic NIF around day 5-7. This result indicates that although showing a similar

pattern, domestic investors show a different reaction to each industry indexes.

Conclusion

Based on IDX daily foreign and domestic investors trading data during 2013-2018, we found that lagged returns affect both foreign and domestic investors' trading behavior differently. Domestic investors tend to show negative feedback trading behavior with longer lags, while foreign investors tend to respond to the industry index with positive feedback trading in shorter lags. We also observed that neither foreign or domestic investors trading were affected by the consumer goods industry index. Another interesting finding was domestic investors' trading affects industry indexes returns, while we cannot observe the same effect from foreign investors.

Related to the purpose of this study, we found that during 2013-2018 there is an indication of feedback trading behavior within the industry level in IDX. Both foreign and domestic investors showed various feedback trading strategy regarding lagged industry return; therefore, we can conclude that industry indexes in IDX affect both foreign and domestic investors' trading behavior.

These findings support previous studies regarding feedback trading in IDX (Martharini, 2018; Setyawan and Ramli, 2016) and bring new evidence regarding investors' behavior within IDX industry indexes. Although the previous study has shown that industry indexes lead to different herding behavior, this study focuses on trading behavior using net investment flow and index return to model the relationship. The findings of this research give implications for international stock market investors and portfolio investment about how investors trade within the industry level and how foreign and domestic investors' trading activity affects one another.

The findings of this research provide an analysis of a general perspective of foreign and domestic trading activities. Future research regarding this topic should analyze trading behavior or pattern on specific events, such as Ramadhan or financial crisis, that significantly affect the stock market. We also suggest that more in-depth analysis regarding movement of the stocks, whether stocks sold by foreign investors transferred to domestic investors or stay within the group, and vice versa.

Abstract

In modern conditions of management and strict state regulation of pharmaceutical activity, the problem of using the internal audit system in the organizations of the pharmaceutical market is acute. In addition to the system of state control, independent control — external and internal audit — became widespread. In these conditions, taking into account the peculiarities of pharmacy organizations, it became necessary to develop organizational principles and methodological approaches to the implementation of internal audit of pharmacy organizations.
This study develops the theory of internal audit in pharmacy organizations. It allows on the basis of a documentary study of the regulatory aspect in the field of internal audit of pharmacy activities to substantiate organizational and methodological approaches to optimizing the conduct of internal audit. The article sets forth the basic principles of internal audit taking into account classification features that can improve the management of a pharmacy organization. The basic principles of the internal audit of pharmacy organizations can be divided into professional and ethical. In the course of the study, we added the following principles of the internal audit of a pharmacy organization to the list of ethical principles and professional principles of auditors, which can serve as an example in the development of local documents for internal audit in any organization: appropriateness, principle of practical benefit, consistency, logical harmony - to ensure clarity of wording, integrity and clarity of presentation, orientation on the interests of owners (the auditor should understand that he protects the interests of owners from internal economic violations).

Keywords: Internal Audit, Pharmacy Organization, Principles Of Internal Audit.

Introduction

The activities of pharmacy organizations are very specific and strictly regulated by regulatory documents. These organizations carry out retail trade in medicines, storage, transportation, manufacture and dispensing of medicines for medical use in accordance with the requirements of current legislation. In this regard, all sorts of risks arise.

Studies have shown that in practice a formal internal audit is carried out in the organization, while the applied methods of internal audit in the organization do not cover the entire process of pharmacy organizations. During the internal audit, its principles are not fully applied, which leads to inefficiency in the application of audit procedures.

Materials and Methods

The object of the study is the pharmacy organization of various forms of ownership and legal status, carrying out pharmaceutical activities.

The subject of the study is the stable, stably repeating premises, cause-effect relationships and the consequences of a single process of industrial specialization of the regions and the territorial division of labor with the accompanying process of industrialization in the aspect of their connection with the efficiency of social production.

The theoretical basis of the research is scientific developments and works of foreign authors such as A. Apcherch, E. Atkinson, J. Brimson, R. Garrison, K. Drury, D. Ryan, J. Foster , as well as Russian scientists P.S. Bezrukikh, N.A. Breslavtseva, S.A. Boronenkova, V.B. Ivashkevich, O.B. Vakhrusheva, M.A. Vakhrushina, O.N. Volkova, T.V. Zyryanova, T.P. Karpova, V.E. Kerimov, A.N. Kondrakov, E.I. Kostyukova, M.I. Kuter, , E.ALisovich., Ya.V. Sokolov, V.I. Tkach, Z.V. Udalova. Scientists such as M.A.Azarskaya, V.D. Andreev, S.M. Bychkova, Yu.A.Danilevsky, M.V. Melnik, O.A. Mironova, S.V. Pankova, V.I. Podolsky, N.A. Remizov, B.N. Sokolov, N.N. Khakhonova. contributed to the study of the development of the methodology and methods of internal control.

Research into the problem of internal audit in pharmacy organizations was carried out by scientists: Yakushev V.I., Grishin A., Kovalenko S., Lebedinets V.

The need for research is caused by the need for the administrative apparatus of pharmacy organizations to create an internal audit system.

The methodological basis of the study was the principles of a systematic and regional approach to the study of pharmaceutical regulatory mechanisms, including pharmacy organizations, the fundamental works of domestic and foreign experts in the field of auditing, legislative and regulatory acts of the Russian Federation, statistical and departmental documents of the RF Ministry of Finance, the RF Ministry of Health and Social Development, and International Standards audit activity.

Research Results and Discussion

When organizing an internal audit of pharmacy organizations, attention should be paid to the features of their activities.

Compared with other organizations, a pharmacy organization has its own peculiarity - it performs two functions simultaneously:

- social (providing the population with goods of a pharmaceutical assortment);
- economic (profit as an economic entity).

Therefore, the presence of an internal audit in a pharmacy organization is rather a necessary measure than just the desire of management, since pharmacy activity is, first of all, a socially oriented activity.

Features of pharmacy organizations, depending on the type, conditions, specifics of activity, include the following functions fully or partially in accordance with the main tasks:

- production, control and dispensing of medicines to the population according to prescriptions of medical workers who have the right to prescribe them;
- sale to the population of finished medicines permitted for over-the-counter sale, as well as hygiene items, patient care, dressings, medical instruments, veterinary products and items, children's, medical and diet food, cosmetics (parapharmaceutical products), medical equipment and etc.;
- sale of medicines and medical devices to medical, preventive and other institutions;
- procurement of medicinal plant material in the form of its purchase from the population;
- the provision of necessary first emergency medical care (first aid kit corresponds to the car first-aid kit);
- advising customers on the choice of medicines and other pharmacy products, disseminating sanitary and hygienic knowledge and popular information about medicines to the public;

- informing medical workers about the medicines available in the pharmacy, the receipt of new medicines and their administration;
- a systematic study of the demand of the population of the served region for medicines in order to determine the need for medicines.

Having studied the features of the activities of pharmacy organizations, we highlighted the features of internal audit in pharmacy organizations: the specificity of activities, since this industry has special social significance, accordingly, the internal control system is legally regulated, which must be checked by an internal audit system; the organization of activities directly affects the formation of accounting (financial) statements, the accuracy of which is verified by the internal audit service.

Based on the foregoing, the following tasks should be included in the internal control system of pharmacy organizations:

- verification of compliance with the storage conditions of drugs during transportation and delivery;
- checking the formation of the price of medicines in accordance with state regulation;
- organization of loading and unloading operations upon acceptance of the goods, taking into account its protection from the effects of environmental conditions;
- verification of shipping documents, including quality documents;
- conformity assessment of accepted goods shipping documentation on the assortment, quantity and quality, compliance with special conditions;
- verification of certificates of conformity for medicines and declarations for dietary supplements;
- checking the correctness of electronic document management;
- verification of acts of reconciliations of suppliers with the data of the accounting service;
- implementation of pharmacovigilance (monitoring the effectiveness and safety of drugs in circulation in the Russian Federation);
- andothers.

When checking, the internal auditor should be guided by the principles of managing pharmacy organizations and international audit standards (ISAs), the requirements of owners for internal audit, which are established by the internal documents of the pharmacy organization.

Therefore, the auditor of the internal audit service should build its work based on ethical principles.

The Code of Professional Ethics of Auditors defines: “The auditor must comply with the following basic principles of ethics: honesty, objectivity, professional competence and due care, confidentiality, and professional conduct.” Code - a set of rules of conduct that explains how the auditor should act in various situations. Therefore, observing ethical principles, the auditor should: [4]

- act openly and honestly in all professional and business relationships;
- avoid relationships that may distort or affect his professional judgment;
- maintain knowledge and skills at a level that ensures the provision of clients or the audit organization in which he works with qualified professional services based on the latest practice and legislation;
- act in good faith in accordance with applicable professional standards in the provision of professional services;
- be aware of technical, professional and industry achievements;
- act in accordance with the requirements of the assignment (contract), carefully and in a timely manner;
- take reasonable measures to ensure that persons working under his supervision in a professional capacity, have appropriate training and proper leadership;
- inform customers, audit organizations or other users of professional services of the limitations inherent in these services;

- ensure the confidentiality of information obtained as a result of a professional or business relationship, and not disclose this information to third parties who do not have appropriate and specific powers, except when the auditor has a legal or professional right or an obligation to disclose such information;
- not use confidential information obtained as a result of professional or business relations to obtain any advantages by him or third parties;
- maintain confidentiality outside the professional environment, bearing in mind the danger of unintentional disclosure of information to persons with whom he is in close business relations or close relationship;
- maintain confidentiality of information disclosed to him by a potential client or audit organization;
- maintain confidentiality of information within the audit organization;
- take reasonable measures to ensure that persons working under his supervision in a professional capacity, and persons from whom he receives advice or assistance, have due respect for his obligation to maintain confidentiality of information;
- maintain confidentiality after the end of the relationship between the auditor and the client or audit organization;
- comply with the requirements of applicable regulatory legal acts and avoid actions that may discredit the audit profession;
- notgive scornful comments about the work of other auditors or to make unreasonable comparisons of their work with the work of other auditors. [4].

The independence of the audit evaluation means the expression of the opinion of the auditor without attention to the influence of biased factors in the audit process. The auditor should prepare conclusions only on documented facts of economic activity, regardless of the opinion of the head, whether it be written or oral. The auditor should understand that during the examination errors may be identified that will affect the conclusions, therefore, sufficient audit evidence should be obtained, which should come first in the audit. Oral statements cannot serve as audit evidence. This is only possible subject to professional principles.

In accordance with International Auditing Standard 200 “The main objectives of an independent auditor and conducting an audit in accordance with international audit standards” (entered into force on the territory of the Russian Federation by Order of the Ministry of Finance of Russia dated 24.10.2016 N 192n), the auditor should observe the following principles:

1. Professional skepticism.

Professional skepticism is necessary for a critical assessment of audit evidence. It includes the need to cast doubt on conflicting audit evidence and the reliability of documents and responses to inquiries and other information received from management and those charged with governance.

2. Professional judgment.

A distinctive feature of professional judgment is that it is developed by an auditor, whose professional training and qualifications in themselves are already helpful in developing the skills and abilities necessary for the formation of reasonable judgments.

3. The sufficiency and appropriateness of audit evidence.

Audit evidence is required to justify the audit opinion. It is cumulative in nature and is mainly obtained as a result of applying audit procedures during the audit. However, they may also include information obtained from other sources, such as previous assignments or in-house quality control procedures for the purpose of considering proposals from new customers and continuing relations with existing customers.

The sufficiency and appropriateness of audit evidence are interrelated. Sufficiency is a measure of the amount of audit evidence. The amount of audit evidence needed depends on the auditor's assessment of the risks of misstatement, as well as the quality of such audit evidence.

Proper character is a measure of the quality of audit evidence; that is, its relevance and reliability to confirm the conclusions on which the audit opinion is based.

We have added the following principles to the list of ethical principles and professional principles of auditors for the internal audit of a pharmacy organization, which can serve as an example in the development of local documents for internal audit in any organization:

expediency;
principle of practical benefit;
consistency;
logical harmony - ensuring clarity of wording, integrity and clarity of presentation.
orientation on the interests of the owners (the auditor must understand that he protects the interests of the owners from internal violations);
making rational decisions according to the audit;
friendliness and loyalty towards employees; the responsibility of the auditor for the consequences of his recommendations and conclusions on the results of audits;
promoting the growth of the effectiveness of pharmaceutical activities.
improving the audit methodology (the auditor should strive to improve the audit system and develop his own professionalism, that is, to constantly learn);
compliance with local regulatory documents (internal audit should primarily be based on internal audit documents);
forecasting (the auditor in the course of inspections, based on experience and professional judgment, should assume and prevent the occurrence of errors on the ground);

knowledge of pharmacy activities (in order for the auditor to be able to provide quality judgments, he needs to know the structure, organization, regulation and other aspects of pharmacy activities);

systematization of information (since the internal audit is ongoing, it should systematize the receipt of evidence in order to rationally allocate resources and allow for an operational audit).

Based on the foregoing, we can distinguish the main principles of internal audit, which are presented in table 1.

Table 1: The main principles of the internal audit of the financial statements of pharmacy organizations

Ethical	**Professional**	
	Regulated by International Standards	**Regulated by Internal Documents**
independence;	Reasonable confidence	Proprietary orientation
honesty;	Professional skepticism	Improvement of audit procedures
objectivity;	materiality	Compliance with local regulations
Professional competence and integrity;	Custom scan	forecasting
confidentiality;	Division of responsibility	Knowledge of pharmacy
Professional behavior	uniformity	Systematization of information

Based on the foregoing, it follows that the internal auditor must adhere to all types of principles in his work, including ethical, regulated by the Code of Professional Ethics, professional, regulated by international audit standards, as well as specific ones that meet the characteristics of the organization. This is especially urgent in small businesses, because, as a rule, in such organizations, employees communicate closely and have friendly relations, in which case the internal auditor especially has to adhere to the principles of objectivity, independence, honesty, professional behavior, professional skepticism, differentiation of responsibility and orientation on the interests of owners. In accordance with the requirements of the Federal Law "On Auditing", the International Auditing Standards, the

preparation of working documents is a prerequisite for audit organizations, as well as for internal audit.

The cases recommended by us allow documentary coverage of all stages of the internal audit of the pharmacy organization and confirm the implementation of analytical procedures. Table 2 presents the structure of audit cases.

Table 2: The structure of cases of internal audit

Case Number and Name	Name of Working Documents
Case No. 1 “Working documents at the stage of organizing the work of internal auditors”	The order of the head of the organization to conduct an internal audit of the unit or facility
	Creation of a working group
	Independence of the internal auditor

	Other information

Thus, making a conclusion from all of the above, it can be said that the internal auditor must adhere to all types of principles in his work, including ethical ones regulated by the Code of Professional Ethics of auditors, professional ones regulated by ISAs, as well as specific ones that meet the characteristics of a pharmacy organization.

Conclusion

The organization of internal audit in pharmacy organizations depends on their types and takes into account the characteristics of activities, key tasks at a certain stage of business development. The

effectiveness of the internal audit in pharmacy organizations depends on strict observance of the audit principles and the formation of the case system: “Working documents at the stage of organizing the work of internal auditors”, “Working documents at the planning stage of the internal audit”, “Collection of audit evidence by internal auditors”,“ Working documents at the stage of completion of the internal audit. ”

Abstract

The article identifies the problems of a comprehensive assessment of the results of managing innovative systems from the perspective of a systematic approach for the participants of the systems, describes the methodological approach to assessing the effectiveness of innovative systems from the perspective of the theory of human capital development, substantiates the possibility of achieving the goal - improving the quality of life of the population by increasing the quality of human capital. It is proposed in the article to use the resulting indicator - the quality of life of the population to assess the effectiveness of the innovation policy of the territories, an algorithm of the influence of innovation on the target indicators of the main components of the economic development of the territory with an expanded description of its stages is presented, factorial two- and three-dimensional models of the influence of the main components of the economic development of the territory on the quality of life of the population are developed, recommendations are given on the development of the innovative policy of territorial innovative systems.

Keywords*:* Innovation System, Human Capital, Quality Of Life Of The Population, Management Positioning Map.

Introduction

The modern model of socio-economic development, developed by the governments of the countries, is largely due to changes in the economic role of innovations, directions and mechanisms for the implementation of innovative processes laid down in official legislative documents and regulations for the sustainable growth of economies. Russia is objectively integrated into the global economy and the global scientific and technological space [Barro, R.J., 1996], [The Global Competitiveness

Report, 2018], [Fleurbaey, M., 2019]. But the level of this integration is not high enough yet. For the period 2010-2019, Russia, according to the Global Innovation Index, succeeded and rose from a place in the middle of the rating to a place in the first third of the rating of the countries observed. However, in 2010 Russia took 9th place in the ranking of the world economies of developed countries according to the UN data, by 2018 Russia's position fell to 11th, which indirectly confirms the long-term stagnation of the Russian national innovation system (NIS). Russia's GDP growth rate in 2018 amounted to 2.3%, with a global value of 3.0%. A peculiarity of managing the innovation sphere in Russia is predominant and insufficiently effective financing from the federal budget. Under the conditions of objective budgetary constraints, two interrelated tasks should be solved - actively attracting business funds to the field of science and innovation and increasing the profitability of relevant types of activities and sectors of the economy. All of the above does not provide impulses to the development of the Russian national innovation system (NIS) on the part of business. It should be noted that the Russian NIS is distinguished by the presence of gaps between science, education and business, a weak level of network cooperation as the basis for innovative growth in leading countries. The level of innovative activity of organizations oriented to international markets and directly determining the global competitiveness of the Russian economy is only 0.2 -0.3% from 2016 to 2018. According to the strategy of innovative development of the Russian Federation for the period until 2020, it was planned to increase this indicator to 2%. This task was set based on the high quality of human capital available in Russia, which is estimated to be higher than the general level of innovation activity (The Global Innovation Index) - 46th place, and in terms of the Global Qualified Professionals Index (The Hays Global Skills Index) - 27th place). All this testifies to the underutilization of the country's intellectual potential.

The aggregate indicator of the level of human development in the country according to the United Nations Development Program (UNDP) is the human development index, which is interpreted as a synonym for the concepts of "quality of life" or "standard of living". Between 2016 and 2019 Russia maintains a stable position in the international rating of human development at the level of 49-50 places among 188 countries. This situation indicates a stagnant state of the implementation of the state policy of socio-economic development of the country [Gokhberg, L, 2017] [Data on international ratings, 2020].

In recent years, a large number of regulatory documents have been developed in the Russian Federation aimed at achieving new qualitative and quantitative indicators of sustainable economic development. For example, the goal was set - to enter the top five leading economies in the world. Despite the fact that institutional conditions were created to achieve ambitious goals, this did not significantly change the competitiveness of the country's economy at the international level.

In this regard, the relevance of the research topic lies in the scientific and practical importance of the formation and development of technologies for managing innovative systems of various levels within the framework of the concept of competitiveness of territories, allowing for the long term to create conditions for sustainable economic growth, ensuring an increase in the quality of life of the population in all its aspects [Meissner, D., 2019]. In the world and domestic practice, with the abundance of available points of view regarding the problems of developing innovative systems, there is still no consensus on the categorical apparatus that would show all participants of these systems the importance of innovation as a necessary condition for improving the quality of life of the population.

In our opinion, ensuring the existing needs of participants in innovative systems interested in obtaining reliable information resources on the results of the effectiveness of applied technologies for managing innovative systems cannot be achieved for several reasons. They are associated with the lack of complete, reliable, timely, accessible statistical information in the context of objects of research; the lack of a methodology and a comprehensive assessment of the results of managing innovative systems from the perspective of a systematic approach; the lack of an approach to taking into account the influence of the level of innovative development of systems of various levels on the achievement of one of the national goals of the country - improving the quality of life of the population while maintaining macroeconomic stability.

Materials and Research Methods

The purpose of the study is the development of a methodological approach to assessing the effectiveness of innovative systems from the perspective of the theory of human capital development.

The object of research is the innovation system of the Russian Federation, which implements the state innovation policy.

The subject of the study is the factors of human capital development in the context of innovative systems of various levels within the framework of the concept of improving the quality of life of the region's population.

The methodology of work is based on foreign scientific works (G. Becker, I. Ansoff, P. Drucker, S. Kuznets, R. Nelson, D. North, R. Solow, C. Freeman, J. Schumpeter, S. Young and other authors) and domestic scientists (V.V. Ivanova, V.L. Makarov, G.G. Malinetsky, T.E. Kuznetsova, L.E. Mindeli, L. Gokhberg and other authors) dedicated to the formation and development of human capital, development of innovative systems and assessment of the effectiveness of their management to ensure innovative development and increase competitiveness of socio-economic systems.

The methodological basis of the study was a complex of general scientific and special methods of cognition. In the course of the study, such general scientific methods were used as: analysis, synthesis, generalization, historical, graphic method; special methods of cognition: formal-logical method and specific sociological.

Research Results and Discussion

An analysis of the definitions of "innovation system" proposed in scientific papers as applied to the research topic allows us to state that the innovation system can be considered as a set of subjects and objects of innovative activity that interact in the process of creating and selling innovative products and carry out their activities within the framework of the innovation policy pursued by the state. Given the current state innovation policy, it is assumed that all territories should be considered as innovation systems. The innovation system is characterized by a certain structure, its degree of orderliness and connections in accordance with the concept of open innovation. According to this concept, the innovation system is represented vertically as a three-level system (national, district, subject), and horizontally it is defined as an innovative platform that unites participants taking into account their mutual interests, within which innovation is synthesized using a dynamic and adaptive mechanism that generates, consuming and transforming innovation into innovative products.

In addition, the innovation system is influenced by environmental factors, which include market, infrastructure, cultural, knowledge and institutional conditions [Sveiby, K.E., 1997]. In these conditions of development of innovative systems, there is an objective need to study the specifics of innovative processes in the framework of the formation of the information society to justify their impact on the final result according to key indicators characterizing the achievement of the goals of the system. To assess the effectiveness of the innovation system, a level of competitiveness is used, which shows the degree of effectiveness of the creation, transfer and maintenance of customer value [Suvorova, A.P., 2017].

When exploring approaches to the formation of state innovation policy in the framework of the sustainable development model, it is necessary to proceed from the priority of the national goal - ensuring the quality of life of the population, which is determined by three aspects: the well-being of the population, the accumulation of human capital, and the level of human development. The well-being of the population is characterized by the achievement of a certain level of provision of the population with tangible and intangible goods. It is customary to distinguish three qualitative levels of well-being of the population: the first - sustainable satisfaction of the primary human needs, ensuring a normal level of life; the second is the achievement of material wealth, in which there is a saturation of primary needs; the third is the optimal, individually-oriented type of satisfying human

needs [Santalova, M.S., 2016]. The accumulation of human capital in terms of its ability to reproduce social capital, which can be characterized by the state of public health, educational, professional and cultural parameters [Rudenko, S.A., 2019]. The concept of "human development" as an indicator of the quality of life of the population is assessed in cross-country comparisons and is characterized by the possibility of fulfilment of a person through demographic, medical, environmental, and intellectual conditions of their existence and personal fullfillment, as well as the possibility of integrating individuals into society [Alimova, E.F., 2010].

The concept that combines the effectiveness of the innovation system with its results is the theory of intellectual capital. Despite a significant amount of research on intellectual capital, this theory is still considered to be undeveloped due to the lack of a unified understanding of the essence of this capital and approaches to its assessment. Researchers define different categories of human and intellectual capital [Novgorodov, P.A., 2017]. Most researchers interpret the category of intellectual capital as potential, which implies the possibility of obtaining a useful result through the use of this capital. Another fairly common approach to the essence of the category of intellectual capital is its understanding as a resource, and only a small part of researchers consider such capital as a result.

Moreover, all scientists engaged in research on the concept, essence and structure of intellectual capital are unanimous in their opinion that human capital is a structural element of intellectual capital.

In our opinion, the formation of intellectual capital as a result is preceded by the formation of resources, as well as capacity building and use (Figure 1). The resources should include human and labor resources as the physical presence of the population in a certain territory. The potential includes: firstly, the part of the population involved in the production of goods and services is economically active population; secondly, human capital, as a person's potential ability to generate income, which is ensured by an increase in the level of education, qualifications, employee health, and the formation of innovative skills and competencies. The result is intellectual capital, considered as qualifications, competencies, technologies, intellectual property, corporate culture and communication channels that can create added value and provide competitive advantages, high quality of human life. In the categories considered, a hierarchical vertical is clearly traced, the categories are interdependent, with each previous category being the basis for the next category. Each subsequent level of capital formation is formed by the increment of certain components, allowing you to go to the next stage of formation of intellectual capital [Sasani, Ali, 2012].

The basis of the hierarchy of constructing categories are human resources, as a set of qualities and characteristics of a person, which is the source of his ability to work of a certain kind. The scheme presented in Figure 1, in our opinion, combines all the categories we have examined into a single process of reproduction of this capital, which is reflected by the upward arrow from human resources to the top of the pyramid - intellectual capital. The reverse arrow in Figure 1 directly illustrates the process of reproduction of intellectual capital from resources.

Fig. 1: The relationship of the categories that form the intellectual and human capital

For the intensive growth of the country's intellectual capital in order to ensure a high quality of life for the population, at each stage of the reproduction process, managerial innovative solutions are necessary within the framework of an innovation system of different levels [Suvorova, A.P., 2019]. Thus, since 2007, in accordance with Federal Law of December 29, 2006 No 256-FZ "On Additional Measures of State Support for Families with Children" [Federal Law, 2006], in order to create conditions providing families with children with decent life standards, they are building up human resources through increased fertility. At the stage of the formation of labor resources in Russia, for example, a migration policy is implemented that focuses on attracting highly qualified specialists and educational migrants [President of the Russian Federation, 2012]. The pension reform of 2019-2028, providing for a gradual increase in the retirement age, also contributes to an increase in the mass of labor resources [Federal Law, 2018]. All of the above measures of state policy allow us to form the resource base of intellectual capital.

The next stage of reproduction is related to capacity building based on the formed labor resources. The increase in the economically active population is facilitated by the implementation of state policy in the field of employment. However, it is human capital that is the fundamental potential of Russia's innovative growth through the formation of intellectual capital. The mechanisms that ensure the growth of competitiveness of the domestic national innovation system were laid down by the state in the Strategy for Innovative Development of the Russian Federation in 2012 [Government of the Russian Federation, 2011]. The state played a leading role in ensuring the implementation of innovation policy, creating an innovative field, using the development of the institutional environment and a system of tools and regulators, including support for the interaction of science and business, innovative infrastructure of universities, the creation of technological platforms, the development of innovative development programs for companies with state participation and others. Achieving the goal of the quality of life of the population is ensured by many factors (table 1), the main of which is improving the quality of human capital, which, in turn, is achieved through the sustainable development of institutions of the innovation system at various levels.

In order to implement the social functions of innovation and increase the degree of public involvement in the innovation process, improving the quality of human capital contributes to the formation of a creative class that, through the development of innovative thinking and culture through entrepreneurial initiatives, leads to the construction of a knowledge economy and a transition to the resulting level - intellectual capital. In Russia, it is possible to single out areas of the economy where

significant increments of intellectual capital have occurred: nuclear energy, space, and weapon technologies. The direct development of innovative systems in the given institutional conditions occurs through an increase in intellectual capital (Figure 2).

Fig. 2: Intellectual Capital Development Model

In order to identify the opportunities (potential) that allow ensuring the quality of human capital to meet the needs of the reproduction of innovative systems of different levels, it is necessary to determine the factors of the institutional environment for the development of innovative systems that determine the requirements for the quality of human capital and also affect the quality of human capital (table 1).

Table 1: Factors of the institutional environment for the development of innovative systems

Innovation system levels	Factors determining the requirements for the quality of human capital	Factors affecting the quality of human capital
National	Strategic national goals and development goals Current level of innovation development Level of technological development Legal regulation	Income and expense policy Health care system Education system Priorities for scientific and technological development Labor market Population policy Migration policy Pension system

		Living conditions Inequality and poverty Family, motherhood and childhood Criminality Level Ecology Partnership for sustainable development
District	District Development Strategy	Inequality and poverty Partnership for sustainable development
Subjective	Subject Development Strategy Level of technological development Features of institutional development	Income and expense policy Education system Priorities for scientific and technological development Population policy Entrepreneurship support Ecology Infrastructure development Partnership for sustainable development

Assessment of factors affecting the quality of human capital should be carried out: firstly, in order to study the impact of innovation on the possibility of ensuring an increase in the quality of life of the population of the territories; secondly, to determine the existing differences in the level of innovation within the framework of the concept of competitiveness of territories; thirdly, to justify the impact of innovation on the achievement of target indicators of the main components of the economic development of the territory.

Studying the impact of innovation on ensuring an increase in the quality of life of the population at each of the three levels is difficult due to objective reasons due to the lack of statistical information by factors. In accordance with the sustainable development goals of the countries, the Federal State Statistics Service (Rosstat) in the Russian Federation developed a project of the list of national indicators of sustainable development goals [Rosstat, 2020], [Sustainable Development Agenda, 2020]. Data collection on the levels of aggregation of official statistical information should be carried out according to national and subject innovation systems. In fact, the published collection "Sustainable Development Goals in the Russian Federation" [Rosstat, 2019] reflects information on indicators of achieving the sustainable development goals in the Russian Federation both for internal use (for the national innovation system) and international comparisons between countries. Data presented in the collection allow us to assess the current state of the dynamics of sustainable development of the country. It is not possible to compare the results of achieving the sustainable development goals with other CIS countries, BRICS and some OECD countries, since the point data for individual indicators are presented from 2015 to 2019.

In Russia, a number of national and federal projects (programs) have been developed and are being implemented in accordance with Decree of the President of the Russian Federation dated May 7, 2018 No. 204 "On National Goals and Strategic Tasks of the Development of the Russian Federation for the Period until 2024" [President of the Russian Federation, 2018]. Rosstat drew up a collection of methods for calculating indicators of national projects (programs), calculated as part of the implementation of this decree [Rosstat, 2018]. The study of this document allowed us to ascertain that the proposed indicators are calculated by industry ministries and Rosstat at the federal level as a whole for the Russian Federation on an annual basis. Thus, the problems of the methodology of statistical support for the adoption of managerial innovative decisions, which should form the invariance of all participants in the perception of innovative systems of different levels of the current state of innovative development and the quality of life of the population do not allow successfully implement public policy in this area.

The existing theory and practice of assessing the socio-economic development of territories of any level allows us to judge that in most cases the emphasis is on either the economic or social

component of economic development, thereby limiting the coverage of existing problems in these areas of development.

In our opinion, to justify the impact of innovation on the achievement of target indicators of the main components of the economic development of the territory, it can be represented by the following stages:

- assessment of the level of innovative development of territories;
- assessment of the quality of life of the population of the territory;
- assessment of the level of economic development of the territory;
- building a two-dimensional model “Quality of Life - Innovation”;
- building a three-dimensional model “Quality of life - Level of economic development - Innovation”;
- development of directions of strategic management decisions based on the analysis of the obtained model results.

In international practice, different approaches are used to assess the level of innovative development of territories. In practice, the index method is most often used, which allows you to calculate innovative indices by forming a system of indicators for the development of innovative processes and their regulation within the framework of regional innovation systems. In the practice of assessing the level of innovative development of the United States, the Portfolio innovation index (PII) technique is used [Statsamerica, 2009]. Based on the Portfolio innovation index, more than 3,000 areas within the United States are analyzed and five groups of territories are identified. With the aim of informing the innovation policy at the regional level, the European Commission applies the regional innovation development rating development model Regional Innovation Scoreboard (RIS) [Hollanders, H., 2019]. The structure of the Regional Innovation Scoreboard and Portfolio innovation indexes is such that they combine both innovation resources and their results.

In the domestic practice of assessing the level of innovative development of the territory, a methodological approach is applied, developed by the Association of Innovative Regions of Russia together with the Ministry of Economic Development of the Russian Federation in 2012 [AIRR, 2012]. The AIRR model includes a system of indicators grouped in 4 blocks: research and development, innovation, socio-economic conditions of innovation and innovation activity in the region. According to the authors of the approach, the rating reliably reflects changes in the innovative development of the economy of the constituent entities of the Russian Federation, since it is scientifically substantiated and built primarily on the basis of official statistics and is used as a tool for managing the regional innovation system. The results of assessing the level of innovative development of the territory allow the regional authorities to obtain the necessary information for making strategic decisions regarding the further development and improvement of innovative systems and the dynamics of changes in all directions reflected by indicators. One of the important components of the Association’s work is the exchange of regional experience in creating a favorable economic, social, legal, educational and creative environment for the development of innovations. In addition, the work of the Association contributes to the effective innovative development of its members, built on the recognition of various models of scientific and technological growth of the regions. Despite the practice-oriented nature of the AIRR methodology for assessing the level of innovative development of territories, the results of regional assessments are weakly related to the achievement of one of the national goals countries - improving the quality of life of the population.

To assess the quality of life of the population of the territory, data from the Russia Today International Information Agency, the largest Russian information provider for an international audience, are used. The agency draws up ratings of the constituent entities of the Russian Federation on various aspects of the country's socio-economic development and is one of the authoritative experts in this field [Agency "Russia Today", 2020].

Assessment of the level of economic development of the territory is carried out by the Federal State Statistics Service on a regular basis and can be used by researchers to assess different parties.

To assess the effectiveness of managing a regional innovation system aimed at achieving the national goal of improving the quality of life, by building an innovative institutional environment, a strategic toolkit — a management map — in the form of the matrix model "Quality of Life - Innovation" can be used. Such a model can be represented in the form of a coordinate system in which the X-axis shows the indicators of the rating of innovative development of regions, and the Y-axis shows the indicators of the quality of life of the population of the constituent entities of the Russian Federation, the factor sign is the innovativeness of the subject, and the resultant sign is the quality of life of the population.

As an information base for building the map, we used the ratings of innovative development of the AIRR regions for 2016-2018 and the ratings of the regions of the Russian Federation in terms of quality of life for 2016-2018 of MIA Russia Today. The object of the research is the innovative systems of the Central Federal District and the Siberian Federal District, since they are two types of development of the economic systems of the Russian Federation, namely, industrial and raw materials.

Management cards "Quality of Life - Innovation", based on data for 2016-2018, are presented in Figures 3, 4.

Fig 3. Map "Quality of life - Innovation" for the regions of the Central Federal District, 2016-2018

Fig 4. Map "Quality of life - Innovation" for the regions of the Siberian Federal District, 2016-2018.

The management card is designed on the basis of a systematic approach, which allows us to argue that any single problem - improving the quality of life - should be tied in conjunction with solutions to another problem - the level of innovative development of the region - focused on achieving the best socio-economic results, namely increasing the competitiveness of the region.

The position of the region on the management map allows us to assess the effectiveness of the innovation policy pursued by the regional authorities in dynamics and the competitiveness of the region in its impact on the quality of life of its population. The positioning of the region is determined by the minimum values on each coordinate axis, since the management map is based on rating estimates. Three authors zones of regional positioning: leading regions are "green", middle regions are "yellow" and weak regions are "red", which allows was visually assess the degree of success of the innovative development of the territory.

The approach used makes it possible to conclude that the innovation policy pursued by regional authorities has a significant impact on the level of innovative development of the territory with the ability to achieve the goal - to ensure a high quality of life for the population. Thus, the top 4 in terms of innovative development, through which a high standard of living of the population of the Central Federal District is ensured, is Moscow, Moscow Region, Voronezh Region and Kaluga Region. The green zone regions remain stable during the period under review. The arrows on the management map show the direction of the change in the position of the region from 2016-2018. For example, the

Tula region from the “yellow” zone in 2016 moved to the “green” in 2017-2018. However, improving the quality of life was provided not by increasing the innovative activity of the region, but by other factors. Note that for a full analysis of the effectiveness of the state innovation policy of the region, it is necessary to use additional factor attributes to analyze the socio-economic situation of the territory and study the assessment of their impact on the quality of life of the population. In the Central Federal District, the quality of life of the population in most regions for the period under review decreased, which indicates the insufficient attention of the authorities of this level to the issue of innovative development of the district.

An analysis of the positioning of the regions of the Siberian Federal District on the management map made it possible to conclude that none of the regions fell into the green zone, despite the presence of two large scientific and technical centers in the Tomsk and Novosibirsk regions and large reserves of natural raw materials. Note that in this district, the position of almost entities remains stable, maintaining positions in the "red" zone. The exception is the Krasnoyarsk Territory, which has improved its position in the ranking of innovative development of regions by 12 positions, but remained within the "yellow" zone. Presented on the two-dimensional matrix model “Quality of Life - Innovation”, the relationships and the mutual influence of the levels of innovation of the region and the quality of life of its population can be used by regional authorities to develop alternative options for strategic development.

In our opinion, the most complete idea of the possibility of strategic innovative development is provided by the construction of the three-dimensional model “Quality of Life - Level of Economic Development - Innovation”. The three-dimensional model includes the indicator "Gross Regional Product (GRP) per capita", which allows you to evaluate the economic component of socio-economic systems. In this model, the factor signs are “innovative development of the region” and “GRP per capita of the region”, and the resulting “quality of life of the region’s population”. By analogy with the two-dimensional model, three zones of regional positioning are distinguished: “green” - leaders, “yellow” - medium, “red” - weak.

The three-dimensional models “Quality of Life - Level of Economic Development - Innovation”, constructed for the Central Federal District and the Siberian Federal District for 2017, are presented in Figures 5 and 6.

1- Moscow, 2 - Belgorod region, 3 - Bryansk region, 4 - Vladimir region, 5 - Voronezh region, 6 - Ivanovo region, 7 - Kaluga region, 8 - Kostroma region, 9 - Kursk region, 10 - Lipetsk region 11 - Moscow region, 12 - Oryol region, 13 - Ryazan region, 14 - Smolensk region, 15 - Tambov region, 16 - Tver region, 17 - Tula region, 18 - Yaroslavl region

Fig. 5. Three-dimensional model “Quality of life - Level of economic development - Innovation” for the regions of the Central Federal District, 2017

1-Republic of Tuva, 2-Republic of Khakassia,
3-Altai Territory, 4-Krasnoyarsk Territory, 5-Irkutsk Oblast, 6-Kemerovo Oblast, 7-Novosibirsk Oblast, 8-Omsk Oblast, 9-Tomsk Oblast

Fig. 6. Three-dimensional model “Quality of life - Level of economic development - Innovation” for the regions of the Siberian Federal District, 2017

With the introduction of another factor in the model for the Central Federal District, only Moscow and the Moscow Region, Voronezh Region and Kaluga Region moved to the “yellow zone” as the leading regions. Thus, only Moscow and the Moscow Region provide high quality of life for the population of these territories with production volumes. If in the two-dimensional model only four

regions were represented in the “red” zone, then in the three-dimensional model their number increased to eight. The same trend continues for the regions of the Siberian Federal District.

So, a three-dimensional model using an indicator of the economic component of socio-economic systems allows a more objective assessment of the influence of model factors on the quality of life of the region’s population. This model, built over several years, allows us to analyze the dynamics of changes in the positioning of the region and, based on its results, allows us to develop alternative options for strategic management decisions by regional authorities. Of course, the factors of the model should be considered as opportunities for software solutions in the development of the territory and improving the quality of life of the population.

Communication and mutual influence of the level of economic development, the level of innovativeness of the region and the quality of life of its population, presented on two- and three-dimensional models, can be used in the development of managerial decisions within the framework of the development strategy of the region as a whole. Depending on the choice of management methods and models, managerial relations in the implementation of innovative activities and interaction mechanisms of participants in the innovation system, the regional leadership may generate solutions to the problems identified. For example, it is recommended to use information and institutional management methods to influence the awareness of participants in the innovation system; for choosing the direction of strategic changes in the region’s policy, it is necessary to determine the position of the region Compared with other regions - competitors and study the experience of the leading regions and closest competitors on the basis of benchmarking techniques.

Conclusion

The presented study reveals a relevant topic for the Russian Federation in the study of factors of development of human capital in the context of innovative systems to improve the quality of life of the population. The relevance of the topic is explained by the fact that the dynamics of the economic and innovative development of the country does not allow achieving the national goals declared by the state and the expected results of development strategies. One of the reasons for Russia's lagging behind the leading countries of the world is revealed - the underutilization of the country's intellectual potential.

The study of approaches to the formation of state innovation policy in the framework of the sustainable development model showed the inadequacy of a systematic study and full analysis of the process of reproduction of intellectual capital in order to increase it. In the work, a model for the development of intellectual capital in the conditions of innovative systems of different levels was proposed.

The factors of the institutional environment for the development of innovative systems have been identified that determine the requirements for the quality of human capital, as well as affect the quality of human capital in order to identify opportunities for moving to another level - intellectual capital.

It is proved that the assessment of factors affecting the quality of human capital cannot be fully realized due to the problem of the methodology of statistical support for making innovative management decisions. The classification of regions by positioning of regions in the innovation field is formed. The algorithm presented in this paper for assessing the impact of innovation on achieving the target indicators of the main components of the economic development of the territory will allow regional authorities to use the results in the development of managerial decisions in implementing the regional development strategy.

This problem is seen as a promising area of scientific and applied research.

Abstract

Knowledge is the competitive advantage of companies. Its source are the experts who are embedded in the work environment and have technical knowledge - built mainly on the basis of procedures, documentation and professional experience. The turnover of experts causes a loss of company know-how. Therefore, it is important to formalise technical knowledge in order to use it further, in such as the training of new staff, in supporting decision-making and in the drawing of conclusions from it. To this end, mathematical algorithms are used to organise, classify, infer and optimise it.
On the basis of an analysis of the literature and a case study, an approach has been modelled which allows expert knowledge to be preserved and the level of knowledge to be predicted and also, the most important areas to be indicated which build it by means of functions. The model consists of the following elements: (1.1) a closed list of choices, which describe the area of the knowledge, (1.2) a questionnaire template, for acquiring the knowledge, (1.3) formalised and acquired expert knowledge which is stored in the knowledge base, (2.1) the Bayesian Network learned, (2.2) the level of knowledge in the enterprise, resulting from the clustering of acquired technical knowledge which is (3.1) the input data for the GMDH (Group Method of Data Handling) and (3.2) the model for forecasting technical knowledge. Finally, this model is implemented in a real case study conducted by the Research and Development department of a manufacturing company.

Keywords: Technical Knowledge; Technical Knowledge Modelling; The Bayesian Network; The GMDH Method

Introduction

Due to the growing phenomenon of the frequent turnover of employees, in companies, it is necessary to retain knowledge in the company and then to forecast its level, in order to determine which source might be missing, within the company, for the implementation of further projects or orders. Therefore, companies need to acquire the knowledge of their workers. Expert and technical knowledge is understood as the knowledge that specialists have, in their company which constitutes the competitive advantage of that company (Patalas-Maliszewska, Śliwa and Kłos 2019). It is formalized, using forms which can be stored and retrieved later, for use by new employees; however, expert knowledge that is closely related to tacit knowledge, is very difficult to acquire and describe formally.

Currently, the following methods and tools are used (Śliwa, Patalas-Maliszewska, 2015; Patalas-Maliszewska, Śliwa, 2017): filling in knowledge acquisition forms (Fazlagić, 2014); making audio-video recording showing actions taken by an experienced worker (Patalas-Maliszewska, Dudek,

2016); talking to experts, engaging experts from external companies, reporting workers' observations; brainstorming, thus comparing knowledge with that already held by workers; registering logs generated in the course of the creative work of an expert and showing the process by visualisations, holograms and the cyber-world etc.

Next, in order for acquired, expert knowledge to be of use to an enterprise, it needs to be formalised, correctly classified and finally forecasted. It is then necessary to design a solution which will enable any expert knowledge, so extracted, to be put into practice. An example of the algorithms used, in order to model knowledge, are the genetic algorithm (Prakash, Chan and Deshmukh, 2011), GMDH (Group Method of Data Handling) (Farlow, 1984; Witkowski, 2002), artificial neutral networks (Patan, Korbicz and Mrugalski, 2002) and data mining techniques (Zhang and Wu, 2010). Accordingly- and with a somewhat limited assumption of trust- comes the selecting of corresponding methods, depending on the conditions of their implementation (Kriegel, Schubert and Zimek, 2017). In our approach, those algorithms used to model knowledge were selected; these are the Bayesian Network and the GMDH Method. According to Van Hulse and Khoshgoftaar (2009) modelling with a simple, statistical algorithm appears to be more effective and reliable than do complex methods. This is confirmed, even in the case of a resistance to the impact of noise or imbalanced data. The Bayesian Network is widely used in statistical, decision-based analysis, where new knowledge is taken into account when making decisions. An example of such usage is in economic analysis (Salles et al, 2019) and reliability tests in the automotive industry (Hadorn, Pohl and Bammer, 2010; Torres-Jiménez et al, 2015). The GMDH algorithm is a solution with which the models organise themselves by creating polynomials and select those with the best prediction criteria. The issue of estimating the value of knowledge, using the Bayesian Network and the most important elements of expert knowledge, using the GMDH Method, within an enterprise, refers to research conducted on the process of the exploration and transformation of data and information, especially in the context of using the classification algorithm and artificial neural networks or the genetic algorithm, in order to predict decision variants, that is, to evaluate the effectiveness of cleaner production (Li et al, 2017b), to understand the causes of the failure of electronic products (Kang et al, 2017) or to understand discrepancies in the desired design (Baykasoglu, Özbakir and Kulluk, 2011).

The present authors have attempted to develop an approach to modelling the level of technical knowledge on the basis of an R&D department, in a production enterprise, in order to determine the most important elements of the technical knowledge within that department. It also endeavours to define the type of this knowledge, which is missing in the company, in order to process further projects or orders The model consists of the following elements: (1.1) a closed list of choices, which describe the knowledge area, (1.2) a questionnaire template for acquiring the knowledge, (1.3) formalised and acquired expert knowledge which is stored in the knowledge base, (2.1) the Bayesian Network learned, (2. 2) the level of knowledge in the enterprise, resulting from the clustering of acquired expert knowledge, which is (3.1) the input data for the GMDH Method and (3.2) the model for forecasting expert knowledge. Finally, this model is implemented in a real case study from the Research and Development department of a manufacturing company.

Review of the Literature

The modelling and forecasting of knowledge can be treated as an approach that not only allows knowledge to be analysed but also to be inference-based on accumulated knowledge, along with a simulation of future phenomena.

Forecasting the level of knowledge in a company means decreased risk, faster access to the necessary information and a base for optimal decisions. This translates into the minimisation of the expenditure taken up in solving problems. It is important to make decisions in an enterprise using the knowledge assessment algorithm, which could (Śliwa, 2018):

- support the management's decision-making processes by assessing the knowledge level expected.
- take into account knowledge resulting from constant assumptions and dynamic expert knowledge.

- be a reliable way of reasoning, based on statistics, for example.
- be a coupling of decision (mathematical) rules with a unique knowledge base.
- allow exceptions, conditions and rules, etc., for managed knowledge, to be declared.
- support the decision-maker with a clear and graphic representation of the availability of the knowledge resources in a company.

The level of technical knowledge results from a combination of the incidence of a codified knowledge base, developed standards and a competent team. The higher the incidence of constituent elements then the higher, also, is the level of estimated knowledge. This assessment may indicate areas of a high degree of employee competence. It can also be the basis for tracking the direction of the growth of knowledge in an enterprise, compared to the previous level, or to the assessment of the knowledge resources, present in a work team dedicated to a task. An interpretation of the level of knowledge may support the management in the form of ready-made conclusions, rules of conduct or the guidelines previously defined by experts. At the same time, "*acquiring knowledge*" is understood as the obtainment of an answer to a question posed in conditions of uncertainty in a complex environment.

Classification algorithms, as well as those operating as independent learning systems, are helpful in understanding and inference, on the basis of collected and formalised technical knowledge by recognising the pattern in images or audio-visual materials (Hall, Phan and Whitson, 2016). Its purpose is to use mathematical models, based on the forecasting data analysed (Kuhn and Johnson, 2013; Janardhanan et al, 2019) which supports decision-making processes. Modelled knowledge, created as the final product of the inference algorithm, is perceived as a new enterprise resource.

Knowledge mapping is also useful to represent the knowledge. It is based on the definition of a set of batch information, its properties and mutual relations (Pan, Wang and Liu, 2007). Knowledge maps, which are the easiest, can represent two-dimensional knowledge matrices which are chosen depending on the location of the map (Wachowiak, 2009). The technique is often used for the quick diagnosis of knowledge in organisations, for example when indicating sources of knowledge while conducting work in the enterprise department; it is also used for tracking processes.

Semantic nets represent the logical structure of knowledge. Semantic terms are selected in relevant clusters and describe the properties and features of the object tested (Kurtz et al, 2014). Semantics and the ontological approach are also used in the analysis of audio materials, in such as construction risk knowledge management in BIM (Ding et al, 2016) or as a document search system that describes the indicated documentation by ontological multi-level network.

Classification and the Regression Tree (one dependent, variable, qualitative and one or more, explanatory variables / independent variables), are developed by split nodes, where the nodes are in one class. Tree branching can be limited by node distribution rules or the optimal size of the tree can be controlled through a complexity parameter. Regression trees are used to perform tests, whose target quantitative value describes the degree of achievement of the variable explained, as opposed to the class label, which treats the problem as binary (Li et al, 2017a). Classification trees are used for assessing events with distribution probability, such as to indicate the cause of errors, to recognise patterns in Earth Science (Zaremotlagh and Hezarkhani, 2017) and also to indicate regressive ones for assessing reliability and estimating levels of a searched variable (Fenton and Neil, 2014).

Algorithm which allow the assessment of knowledge is e.g. Bayesian Network. It is used for classifying objects by the statistical probability of their distribution, presenting the process of dependencies, as well as when making decisions in uncertain conditions with data and expert knowledge (Fenton and Neil, 2012; 2014). Examples of use are in diagnosing learning diseases in such as robots, which are able to adapt to a changing environment in diverse knowledge (Wu and Bell, 2003).

Understanding knowledge includes intelligent algorithms that have the ability to estimate static systems, automatic control systems and optimisation systems when creating new solutions, such as

the replication process and independent creation, based on analysed data and then updating and adapting complex mathematical models. Mentioned here is the GMDH Algorithm.

Genetic algorithms (GAs) are used to study knowledge and optimise intelligence (Prakash, Chan and Deshmukh, 2011; Kuah, Wong and Wong, 2012). Further iterations in the development of the algorithm include evaluation, selection and reproduction to find the best-matched function obtained from the choices available (Chakraborty et al, 2017). In estimating knowledge, GA allows the optimal combination of attributes, affecting a function, to be examined, i.e. the level of knowledge.

Population chromosomes - a chromosome being a single polynomial - are exchanged in one iteration. The GMDH algorithm presents the relation of a dependent variable, Y, to some independent variables X1, X2,...,Xm and is used to construct a higher order, regression type model. The basic GMDH model is a quadratic polynomial of two variables, usually consisting of many layers (Prakash, Chan and Deshmukh, 2011). Examples of the use of GMDH, when forecasting knowledge, are applying it in order to select the features, as outlined by the customer (Xiao et al, 2017). Moreover, a hybrid GMDH was employed to establish a model in order to estimate the heat capacities of Ionic liquids (Rostami et al, 2019). The result of the algorithm's operation is a polynomial which is the model of the object.

Based on a review of the literature, a model to predict technical knowledge was formulated (Fig. 1). It was assumed that the technical knowledge, present in the enterprise - that is, where the sources are expert, from R&D, Technology, Production, Quality departments and others - is built by two kinds of knowledge, namely:

- tacit, understood as education, training, work experience, gained from years of work and the number of patents and completed projects etc.
- explicit, present in formalised sources, such as, technical documentation, reports, knowledge base, the Internet, books, journals.

Interviews with experts, in the area of technical knowledge examined, allowed definition of a closed list of elements describing their *know-how* from R&D (STEP 1.1). Cyclically, this increases during the implementation of new activities in the enterprise, such as, conducting a new project, laboratory work, results and new research. The use of a dedicated questionnaire (STEP 1.2) will allow it to be acquired and formalised (STEP 1.3) and then allow the Bayesian Networks to be learnt (STEP 2.1). A network, thus modelled, on the designed rules, shows the relationships between the elements of technical knowledge. As a result of classification, the level of knowledge is estimated (STEP 2.2). Implementing data, gained from the Bayesian Network into the GMDH Method (STEP 3.1) allows the function of the level of knowledge to be described (STEP 3.2). On this basis, the most important components that affect its level will be indicated, which in fact is new technical knowledge in the enterprise studied (STEP 1.3).

Fig 1. A prediction model for knowledge levels

The proposed model (see Fig. 1) was implemented in the R&D department. The manufacturing company in question, produces small elements of car pneumatics for several key clients; it has a series of repetitive tasks for which fixed elements of expert knowledge are used when developing a project.

Materials and Methods

As discussed in the introduction, the main objective of this paper is to develop a prediction model for the knowledge level in a manufacturing enterprise. This study was conducted with the participation of employees of R&D, a medium-sized, Polish automotive industry production company, making pneumatic components for braking systems. In order to be able to define this approach the following elements are developed.

STEP 1.1, STEP 1.2, STEP 1.3: Formalised and acquired expert knowledge which is stored in the knowledge base.

To collect the expert knowledge in the company, it was proposed that '*knowledge acquisition'* forms be completed. Before that, a closed list of choices was defined (STEP 1.1), according to the following areas: (1) domain: structure, technology, material, functionality, research, (2) sub-domain: e.g. in structure domain: construction, geometry, thread, (3) keywords: e.g. prototype, 3D model, pattern, 3D printing, (4) completed activities: client feedback, additional studies, external consultation, internal consultation, (5) documents used: technical documentation, literature, website, customer feedback, report, (6) documents created: technical documentation, procedure, audio-video recordings, report, model, patent, (7) connected departments: technology, maintenance, purchasing, sales, production.

For this, a dedicated knowledge questionnaire was created (STEP 1.2) and used, whereby using the direct interview method, experts selected responses from a closed list. This included questions about completed R&D projects related to the product's "valve" (STEP 1.3). The experts, who answered, were selected, according to the criteria of their general experience and for their years of work in the company analysed.

STEP 2.1, STEP 2.2: The level of knowledge in the enterprise, resulting from the clustering of acquired expert knowledge using the Bayesian Network.

The Bayesian Network (equation 1) is the so-called conditional probability - *'a posteriori'* of event A (belonging to specified class A) on condition of the occurrence of event B (possessing the properties specified as B) (Król, 2014; Constantinou, Fenton and Neil, 2016; Śliwa, and Patalas-Maliszewska, 2017).

$$P(A_i \setminus B) = \frac{\left(P\left(B \setminus Ai\right) P\left(Ai\right)\right)}{\left(P\left(B\right)\right)} \tag{1}$$

The analysis of events with the use of Bayes in the network construction, is based on determining the probabilities in nodes, which have ascending vertices, otherwise referred to as parents. It is assumed that the occurrence of an event is directly related to its state, also known as an alternative. The conditional probability table (CPT) is characterised by the sum of knowledge A states, for the state bi which belongs to the knowledge alternative vector B and their sum is 1 (*equation 2*). These states are mutually exclusive.

$$\sum_{i=1}^{n} P(A = a_i \mid B = b_i) = 1; \forall b_j \in sp(B) \tag{2}$$

where:

A, B - random variables (*nodes*),
B - a vector of knowledge states (*alternatives*),
a_i, b_i - states of variables *(nodes*),
sp(B) - states set,
i, n ϵ N.

The model of expert knowledge externalisation is based on the assumption that new knowledge is acquired through the Bayes Network (i.e. classification). This means that in order to obtain benefits for the enterprise, the codification of expert knowledge - by means of a form and slogans describing it, is necessary. This, on the other hand, functions in the algorithm as an a posteriori probability. Therefore, the basis is to determine the probability in the input nodes, in the CPT table, as q.v. equation 3:

$$P(X = T) = \frac{x}{t \times u}, P(X = F) = 1 - P(X = T) \tag{3}$$

where:

x - number of occurrences of element X in the database,
t - number of entries in the knowledge base (*completed forms*),
u - the number of potential X-type speeches,
T - State 1 (True),
F - State 0 (False).

In the Bayes Network, designed, dedicated rules were used to determine the probability in selected nodes. Learning the network is enabled by the implementation of the knowledge base, which is the result of formalised technical knowledge. By using the Bayesian Network, it is possible to obtain the

value of the level of expertise in the company. It allows one to determine whether or not a company has sufficient expertise to conduct new projects/orders, in a given area.

STEP 3.1, STEP 3.2: Gaining new knowledge using the GMDH Method

Employing this method, allows the most important type of expert knowledge in the company, to be defined, in order to process further projects or orders. Determining the structure of the object, using the GMDH algorithm, involves iterative repetition of a specific sequence of operations, leading to an evolutionary result structure (Prakash, Chan and Deshmukh, 2011; El-Alfy and Abdel-Aal, 2011; Xiao et al, 2017). This process is completed when the optimum level of complexity is achieved. In order to determine the population of polynomials (equation 5) for an object with m inputs x_1, x_2, ..., x_m, m ϵ N and one output y, a matrix is created in the form (equation 4):

$$X = \begin{bmatrix} x_{11}, x_{12}, \ldots, x_{1m} \\ x_{21}, x_{22}, \ldots, x_{2m} \\ \ldots \\ x_{t1}, x_{t2}, \ldots, x_{tm} \\ \ldots \\ x_{n1}, x_{n2}, \ldots, x_{nm} \end{bmatrix} \tag{4}$$

in which columns 1...m represent independent variables x_1, x_2, ..., x_m, m ∈ N; y represents the vector of output values: $y = [y_1, y_2, \ldots, y_t, \ldots, y_n]^T$, n ϵ N.

It is assumed that the columns of the X matrix are linearly independent. The input data is divided into training (1,2, ..., t) and testing (t + 1, ..., n) data. The training data will be used to construct the object model, while the test data will be used to evaluate partial models. In the first step, for each pair of independent variables $<x_p,x_q>$, p = 1, 2,..., m–1, q = p+1,..., m, m ϵN, an approximation polynomial of general form, namely Iwachnienko, is formed (equation 5):

$$y^* = A_{pq} + B_{pq}x_p + C_{pq}x_q + D_{pq}x_p^2 + E_{pq}x_q^2 + F_{pq}x_p x_q \tag{5}$$

Polynomial coefficients (equation 5) are determined for t training observations using the LS method, i.e. from the condition (equation 6):

$$S_R = \sum_{i=1}^{t} (y_i - y_i^*)^2 = \min \tag{6}$$

where:

$$y_i^* = A_{pq} + B_{pq}x_{ip} + C_{pq}x_{iq} + D_{pq}x^2{}_{ip} + E_{pq}x^2{}_{iq} + F_{pq}x_{ip}x_{iq} \tag{7}$$

In total, m (m – 1) polynomials are created. Every polynomial yi* (equation 7) is evaluated for all observations in the X matrix. The values calculated are placed in separate columns of the auxiliary Z matrix.

In the second step, for each column j = 1,2, .., m (m – 1), m ϵ N of the Z matrix, the regularity criterion is determined from the formula (equation 8):

$$r^2{}_j = \frac{\sum_{i=t+1}^{n} (y_i - zi_j)^2}{\sum_{i=t+1}^{n} y^2{}_i} \tag{8}$$

where:

i – the i-th observation of the X matrix.

j = 1,2,..,m(m−1) is the j-th column of the Z matrix

The coefficient obtained is an assessment of the quality of a given polynomial. The input values of the matrix (see equation 4) were probability values obtained from the Bayesian Network (STEP 3.1). In STEP 3.2, the best polynomials are selected with the lowest value of the coefficient. This process is repeated until the r_{min} value decreases. After the process is completed, the best of the previous generation polynomials is selected. The result of the algorithm is a polynomial being the object model.

Thanks to the use of the GMDH Method, it is possible to define the most critical expert knowledge for the implementation of new projects/orders and to build a prediction model for the knowledge level of a manufacturing company. The application of the algorithm enables the acquisition of new knowledge in the company.

A prediction model for the knowledge level of a manufacturing company

To measure expert knowledge in the enterprise, a dedicated decision model was built, *viz.,* the Bayesian Network (STEP 1.2, Fig. 1). The level of technical knowledge, referred to as a “K” node is, according to the definition, the specialist knowledge held in the minds of employees (Szwarc, Bach-Dąbrowska and Bocewicz, 2018). For this purpose, a network of dependencies was created on the basis of choices there defined: the area of "key words" (elements Ci), gathered in “sub-domain” (SBij), and those in larger thematic “domain” (Bi). Bi nodes, together with the area Gi ("Documents created during the implementation of the project") and Fi ("Sets of used documents") together with subordinate elements Fi ("Documents used to solve the task") constitute the input for node O ("Ready-made templates"). At the same time, area N ("Competent team") was defined, which is built by Di nodes "Connected departments”, to which knowledge in the IT system was made available, Ei nodes ("Activities carried out” while solving the design task) and Ii - "Worker who answered” which is the R&D department employee solving the design task.

In STEP 1.3, a questionnaire was used to formalise the technical knowledge of the R&D employees. The questionnaires then had to be completed and the data thus obtained entered into the knowledge base. Each response was identical to the node assigned to it in the Bayesian Network. The Bayesian Network was taught (STEP 2.1) based on 5 questionnaires. This was the basis for conducting research experiments, i.e. Test 0 and its variances:

- Test 00_v1 – implementation of 10 questionnaires: 5 obtained from the company and 5 the same, with the modification, with nodes E1, E2, E3 always being chosen in the Ei group.
- Test 00_v3 – implementation of 10 questionnaires: 5 obtained from the company and 5 the same, with the modification, with node I2, always being chosen in the Ii group.

On the basis of the answers obtained, the probability of the occurrence of particular choices, for the nodes belonging to the group, was determined: Bi, Bij, Ci, Di, Ei, Gi, Ii, Fi. The values in CPT table for nodes from the group Fi, O, N and K were determined, based on their own rules. They were built on the basis of dependencies and weights, which were defined in co-operation with the R&D department of the company in question. Methods for determining the conditional probability of the nodes for State 1, are presented below.

The rule for nodes Fi (equation 9):

$$P_{(F_i=1(true))} = \sum_{1}^{3}(S_{Fi'} \times P_{Fi=1(true)}) \quad .(9)$$

where:

$S_{Fi'}$ – the alternative state in Fi node (1 True/0 False), for Fi node i {1, …, 3: n ϵ N},
$P_{(Fi=1(true))}$ - the probability of the occurrence of Fi node in the base.
The rule for node N (equation 10):

$$P_{(N=1(true))} = (0.25\sum_{1}^{5} S_{Ei'} \times P_{(Ei=1(true))}) + (0.15\sum_{1}^{5} S_{Di'} \times P_{(Di=1(true))}) + (0.6\sum_{1}^{3} S_{Ii'} \times P_{(Ii=1(true))}) \quad (10)$$

where:

$S_{Ei'}$ - the alternative state in Ei node (1 True/0 False), for Ei node i {1, …, 5: n ϵ N},
$S_{Di'}$ - the alternative state in Di node (1 True/0 False), for Di node i {1, …, 5: n ϵ N},
$S_{Ii'}$ - the alternative state in Ii node (1 True/0 False), for Ii node i {1, …, 3: n ϵ N},
$P_{(Ei=1(true))}$ - the probability of the occurrence of Ei node in the base,
$P_{(Di=1(true))}$ - the probability of the occurrence of Di node in the base,
$P_{(Ii=1(true))}$ - the probability of the occurrence of Ii node in the base.

For example, a method for determining the conditional probability of the O node for State 1 (True) is presented by equation 11 (Śliwa, 2018):

$$P_{(0=1(true))} = (0.65 \times \sum_{1}^{9} \frac{S_{Gi'} \times w_{Gi}}{\sum_{1}^{9} w_{Gi}}) + (0.35 \times \sum_{1}^{3} \frac{S_{F_i'} \times w_{F_i}}{\sum_{1}^{3} w_{F_i}}) \quad (11)$$

where:

$S_{Gi'}$ – state of alternative in Gi node (1 True/0 False); for Gi node i {1, …, 9: n ϵ N},
$S_{F_i'}$ – state of alternative in F_i node (1 True/0 False), for F_i node i {1, …, 3: n ϵ N},
W_{Gi} – the materiality level of the resulting document is determined, based on the application of the AHP method (Analytic Hierarchy Process),
w_{F_i} – the weight assigned to the type of document used (w_{F_i} takes the scale: 1 minor -2 medium -3 major).

Each test required the network to be developed for the "valve" product to be learnt manually. This means: (1) determining the probabilities of each choice on an external spreadsheet and (2) the manual implementation of the results, as calculated, into CPT tables for each node in the Bayesian Network as built into the GeNIE programme. Table 1 presents part of the CPT table for the O node. Calculations for all nodes required the application of individual rules.

Table 1: part of the CPT table for O node, built onto a spreadsheet

Node	**State of node (alternative)**							
G1	1	1	1	1	1	1	1	1
G2	0	0	0	0	0	0	0	0
G3	0	0	0	0	0	0	0	0
G4	0	0	0	0	0	0	0	0
G5	0	0	0	0	0	0	0	0
G6	0	0	0	0	0	0	0	0
G7	0	0	0	0	0	0	0	0
G8	0	0	0	0	0	0	0	0

G9	0	0	0	0	0	0	0	0
F_1	0	0	0	0	1	1	1	1
F_2	0	0	1	1	0	0	1	1
F_3	0	1	0	1	0	1	0	1
P(O=0)	0,8005	0,7421	0,6838	0,6255	0,6255	0,5671	0,5088	0,4505
P(O=1)	0,1996	0,2579	0,3162	0,3746	0,3746	0,4329	0,4912	0,5496

The parameters of the experiments are included in Table 2. The results of the research of the experiments are the measurement of the probability in the target node with its level of knowledge, K, here, in the R&D department. This was done by declaring the occurrence of selected knowledge parameters representing network nodes. For tests 00_v1 and 00_v3, similar combinations of observed knowledge were tested for comparison. The selection of individual nodes with a declaration of their status (State 1 = True and State 0= False) is possible only when the knowledge represented by the node appeared at least once in the questionnaires assigned to a given test.

Table 2: conditions of the experiment and the levels of expert knowledge estimated by the Bayesian Network

Research	**The level of expert knowledge before the test P(K)**	**Observed nodes P("X")**	**The level of expert knowledge when tested with the Bayesian Network (K)**
Test 00_v3 (q. 1-5 + q. 1-5, where node I2 was always chosen)	0.27	D1, D4, E1, E2, I1	0.34
		D1, D4, E1, E2, I1, O	0.85
		E1, E2, E3	0.29
		N	0.51
		C61, C30, B48, B5, E2, F2, D4, G2, G7, I1	0.45
		D1, E2	0.27
		I1	0.32
		I2	0.32
		I1, I2	0.38
Test 00 _v1 (q. 1-5 + q. 1-5 where node E2 was always chosen)	0.38	D1, D4, E1, E2, I1	0.39
		D1, D4, E1, E2, I1, O	0.90
		E1, E2, E3	0.39
		N	0.51
		C61, C30, B48, B5, E2, F2, D4, G2, G7, I1	0.50
		D1, E2	0.39
		I1	0.38
		I2*	0.38
		I1, I2*	0.38
Test 0 (q. 1-5)	0.38	D1, D4, E1, E2, I1	0.39
		D1, D4, E1, E2, I1, O	0.90
		E1, E2, E3	0.39

		N	0.51
		C61, C30, B48, B5, E2, F2, D4, G2, G7, I1	0.50
		D1, E2	0.38
		I1	0.38
		I2*	0.38
		I1, I2*	0.38

** Empty node; never chosen in the questionnaires*

The knowledge described by the following parameters was observed: Connected departments (D1 – Technology dep., D4 – Sales dep.), Activities carried out (E1 - Customer feedback, E2 - Additional research) with the worker who answered, being I1. View of the Bayesian Network designed, is shown in Fig. 2. The results of the experiments conducted are summarised in Fig. 3. Further studies did not take into account the level of knowledge obtained from Test 0, because this data constituted the basis for the considered Tests 00_v1 and 00_v3.

Fig. 2: A graphical model of the Bayesian Network, made in GeNIE

Fig. 3: The level of expert knowledge when tested with the Bayesian Network (K): (a) chosen nodes (State 1): D1 D4 E1 E2 I1 at Test 00_v1, there P(K)=0.39; (b) chosen nodes (State 1): D1 D4 E1 E2 I1 at Test 00_v3, there P(K)=0,34; (c) chosen nodes (State 1): D1 E2 at Test 00_v1, there P(K)=0.39; (d) chosen nodes (State 1): D1 E2 at Test 00_v3, there P(K)=0.28, made in GeNIE

In order to present the 10, most important parameters that affect the change of state in the K node, i.e. P(K=State1), a sensitivity analysis was undertaken (Fig. 4). In GeNIE software, the algorithm proposed by Kjaerulff and van der Gaag (2000) was implemented. The analysis supports validation of the probability parameters of the Bayesian Network [HELP Genie]. Each parameter presented below, is described by the exact relation of states that conditionally affect its value. The green bar shows a positive change, i.e. an increase in the level of knowledge (State 1) and the red bar – a negative change. The analysis was carried out assuming the observation of a 10% change for the knowledge level node. The location of those areas that affect the increase in the level of knowledge, in the company, can serve as a guide for the management, by showing which areas, in particular, need to be developed.

Fig. 4: Sensitivity analysis (Tornado analysis) for the K node "Level of knowledge", made in GeNIE

The level of knowledge of a completed project is the result of the combined presence of a codified knowledge base, a competent team and ready-made templates. The higher the occurrence of component elements and the higher the level of knowledge estimated, the better reflected is the increase in knowledge within the enterprise. However, it has been noticed (see Table 1) that the level of knowledge does not change, despite further development of the knowledge base. Further research in the company studied will allow us to determine the maximum value for the level of knowledge. Using the GMDH Method and based on the research results (see Table 2), the type of knowledge in the company is determined (equation 12, 13), which is crucial to the successful completion of further projects and orders (Patalas-Maliszewska, Śliwa and Kłos, 2019).

$$K^{T}_{00_v3} = [0.34; 0.85; 0.29; 0.51; 0.45; 0.27; 0.32; 0.32; 0.38] \quad (12)$$

$$K^{T}_{00_v1} = [0.39; 0.90; 0.39; 0.51; 0.50; 0.39; 0.38; 0.38; 0.38] \quad (13)$$

Each K_i is associated with indicators that describe the frequency of the response data from the knowledge questionnaire, stored in the individual nodes of the Bayesian Network. A KCO (Knowledge Classification Output) map is provided to present the relationship between formalised knowledge and the outcome of the estimated level of knowledge (see Table 2); equation 14 was based and built on the responses given in the knowledge questionnaires.

$$KCO = \begin{bmatrix} D11 & D41 & E11 & \ldots 1 & I11 & I21 \\ D12 & D42 & E12 & \ldots 2 & I12 & I22 \\ \ldots & \ldots & \ldots & \ldots & & \\ D1n & D4n & E1n & \ldots n & I1m & I2m \end{bmatrix} \quad (14)$$

where:

n, m ϵ N and D1,… ,I_m – elements of the nodes within the Bayesian Network, that is, the formalised knowledge, based on the knowledge questionnaires (Patalas-Maliszewska, Śliwa and Kłos, 2019).

The model proposed by the present authors makes it possible to estimate the most important elements of expert knowledge, in order to complete further projects and orders successfully. The Bayesian Network data regarding the product "valve", in all the variations of the GMDH algorithms, was investigated where designated, using the Consulting IT computer system (Patalas-Maliszewska, 2013) (Fig. 5).

Fig. 5: Variations of the Group Method of Data Handling (GMDH) algorithm, for expert knowledge in a manufacturing company

As a result, the best possible polynomials were obtained, with the algorithm evolution process being completed on the second iteration (equation 15, 16):

a) model KT_{00_v3}:

$$KT_{00_v3} = -0.01 - 4.88 \times B48 + 5.88 \times C30 - 0.47 \times B48^2 - 0.81 \times C30^2 + 1.29 \times B48 \times C30 \quad (15)$$

where:

K - the level of knowledge, forecast in the enterprise
B48,C30 - the most important elements of expert knowledge, namely: B48 – functionality of the product “valve”: “thread sealing”, C30 – structure of the product “valve”: “glue”.

b) model KT_{00_v1}:

$$KT_{00_v1} = 0.28 + 0.21 \times F8 + 0.06 \times G2 + 0.38 \times F8^2 - 0.09 \times G2^2 + 0.42 \times F8 \times G2 \quad (16)$$

where:

K - the level of knowledge, forecast in the enterprise,
F8, G2 - the most important elements of expert knowledge, namely: F8 – the documents used: "reports”, G2 – the established documentation: “procedures”.

As a result of the research, it was found that critical expert knowledge for the implementation of a new project for the product “valve” is knowledge regarding:

- According to model KT00_v3: functionality of the product “valve”: “thread sealing” and its structure “glue”. Therefore, the decision should be made to expand the knowledge questionnaire for this part, so that, in the case of those employees who have such expert knowledge and who leave, or who are otherwise absent from work, do not, thereby, cause the company to lose this knowledge.
- According to model KT00_v1: the documents used: "reports” and the established documentation: “procedures”.
  Therefore, the decision should be made to initiate activities aimed at providing more detailed documentation regarding completed projects / orders in order to not lose expert knowledge from the company.

The resulting models allow new elements of specialised knowledge about the company, to be acquired that should be stored in the company. The use of these models is aimed at formulating recommendations for company managers in the context of developing tools to acquire detailed specialist knowledge, defined in this way.

Discussion

Due to the proposed prediction model for the level of expert knowledge, it is possible to receive expert knowledge using a knowledge questionnaire and then, using the established rules in the form of the frequency of responses, formulate a knowledge base, in order to build the Bayesian Network. The application of the Bayesian Network, a given state in the node, was assigned through an analysis of features, that is, through the probabilities of the elements of knowledge which build up this node. The Bayesian Network allowed, a priori, the classification to the states or alternatives assigned to this node, according to the size of the knowledge element selected. As a result of the operation of the Bayesian Network, a formalised knowledge base is obtained, based on which, and using the GMDH method, new knowledge about the most important elements influencing the success of the new project or order can be obtained.

The limitation in the proposed approach, is the need to define the rules for acquired specialist knowledge in order to formalise it. In addition, knowledge should only be obtained from specialists who actually do the job. Obtaining incorrect answers in knowledge questionnaires may lead to key elements of knowledge being wrongly obtained.

The use of the proposed model allows decision making to be supported when selecting the most important elements of knowledge that should be acquired and stored in a company. The use of the prediction model of the level of expert knowledge is helpful in:

- selecting an expert, from among the employees, to share the most important knowledge with the other employees.
- selecting the area of expert knowledge, in order to improve the competences of employees, in relation to the most important knowledge needed in a company.
- defining a key expert worker based on the value of the model.

The proposed model is currently implemented in a medium-sized, Polish manufacturing company. Currently, implementation has been partly completed with regard to the definition of the most important area of pre-requisite knowledge. Our model will be extended by the algorithm for automatic data acquisition from expert workers, as part of further research.

Conclusions

This work introduces the methodology for managing technical knowledge. For this purpose, a model for forecasting the level of knowledge was presented, along with a definition of the function. The solution presented is dedicated to activities carried out in the R&D department of a production company in the SME sector. Each time, the solution requires adaptation to the specifics of the enterprise, i.e. the formulation of elements describing the selected area of knowledge. Determining the level of knowledge enables prediction using the Bayesian Network. By contrast, the GMDH algorithm affords better understanding of classified knowledge and indicates areas that are key to the further increase of the company's know-how. Both tools support management in decision-making; when used together they create a synergy effect.

The novelty of our approach is the ability to estimate the level of technical knowledge and its most important elements in a company, in the absence of any involvement of experts, therein. Employees are only required to complete a general knowledge questionnaire and then, thanks to the use of our model, it is possible to determine what kind of knowledge area requires more detailed answers to be collected from the relevant employees who carry out the work, specific to the knowledge area identified.

In further work, is planned to expand the model with a dynamic knowledge questionnaire. Completing forms by workers will allow for continually update and expanding the knowledge base, which is very important for correct work of presented solution.

Abstract

The assumptions of the Fourth Industrial Revolution have the digitisation of enterprises, as their objective. One of the factors that drive it is the use of XR technologies: augmented reality (AG), virtual reality (VR) and mixed reality (MR). Building a dedicated virtual environment supports knowledge management in terms of its formalisation and transfer. AR technologies in manufacturing companies are used in research and development departments and also in production and maintenance departments. This publication describes the concept of using augmented reality as support for quick changeovers, in line with SMED (Single Minute Exchange of Die) assumptions. The motivation was the desire to increase competitiveness in an existing automotive industry enterprise by using modern, IT applications to support business processes, while gaining technical knowledge and saving it in digital form. The solution developed is based on the definition of a closed set of keywords, which are also related to the graphic representation – the 3D model. The defined set contains the names of the machines, the instrumentation, the tools and the actions necessary to carry out the changeover. As a result of gaining expert knowledge, the dedicated iSMEDs system enables intelligent instructions to be built, based on a template assigned to a group of products. The implementation of such a solution may impact upon the ever faster and safer implementation of changeovers, the elimination of human error and a reduction in internal training time.

Keywords: Augmented Reality, SMED, Production Enterprise, Technical Knowledge

Introduction

In research conducted by Lindemann et al. (2010), Pillay and Barnard (2019), it was emphasised that the development of enterprises depends on expert and technical knowledge. Industry 4.0 assumptions determine the increase in demand for specialist engineers. On the one hand, they should have key competences, on the other, they should be able to use modern information technologies, as AgrotecPolska (2012) mentioned. There are still too few such experts; they have high requirements in relation to employment conditions and their 'turn-over' rate is quite frequent. Hence the need to preserve their knowledge, facilitate remote work and get new employees into their duties more quickly without causing machine downtime and the use of unnecessary resources.

According to report of World Economic Forum (2019), technological megatrends in the sphere of production include connectivity, intelligence and flexible automation. According to the Australian Government Department of Industry (2019), four key factors driving the development of enterprise digitisation can be identified:

- the increasing amounts of data, computing power and their connectivity,
- the analytical capabilities of Business Intelligence (BI) applications,

- new forms of human-machine interaction, such as touch interfaces, augmented reality and virtual reality systems,
- improvements in the transmission of digital instructions to the physical world, e.g. through robot work, 3D printing.

With regard to this, one important role is to promote the use of extended reality (XR) to preserve knowledge in an enterprise. XR is another dimension of human experience of the physical and virtual environment, from observation to immersion, as described Chuah (2018). A network of enterprises has been located in the world, which are model units using solutions in line with the demands of Industry 4.0. They are called lighthouses. As proved in the report of the World Economic Forum (2019), some of them explicitly list reality modelling – and there: augmented reality, mixed reality and virtual reality - as being among the five, most important technological solutions they use:

- The Bayer Pharmaceuticals Division in Garbagnate, Italy, admits that due to the use of mixed reality, changeover time has decreased by 30%.
- Johnson & Johnson DePuy Synthes in Cork, Ireland, state that training in virtual reality caused a fivefold increase in the retention of information by employees regarding work safety in a given environment,
- Phoenix Contact in Bad Pyrmont and Blomberg, Germany, states that the use of mixed reality in maintenance facilitates more effective time management and reduces errors,
- Schneider Electric in Le Vaudreuil, France declares that mixed reality causes a 20% decrease in the time required for diagnostics, maintenance and repairs.

Modelling reality as a support for knowledge management in an enterprise

Based on taxonomy, presented by Milgram and Kishino (1994), the real world stands out, while the other is completely virtual (VR), that is, a world in which the environment and actions between virtual objects are completely modelled, without access to external stimuli (Metry, 2018) [14]. The following are defined between these worlds: augmented reality (AR), which allows one to display objects modelled in the real environment, and which are “connected” to it by markers (i.e. specific shape, GPS data); and extension of virtual reality - augmented virtuality (AV) - by adding information, objects, obtained from the environment, expand the effect perceived in the modelled environment - i.e. implementation of the weather effects, mentioned by HITLabNZ (2018). Metry (2018) describes the intermediate element as mixed reality (MR), where virtual objects interact with the real environment, that is, there is manipulation of objects in both environments and the solids seen by man are spatial. Based on the definitions presented, the range of knowledge about the environment, generated by the model, was also distinguished (Fig. 1).

Fig. 1: Representation of a virtual continuum and knowledge of the environment; own study based on research by Milgram and Kishino (1994)

Modelling completely virtual reality means using more time and work resources. According to Milgram and Kishino (1994), the more knowledge remains in the real world - and thus in the consciousness of the people - the more it is dispersed and the less it is systematised [16]. Its opposite is an environment described by functions depicting relations between objects. This is also how the knowledge management support process, in a modern enterprise, can be understood - according to Baran, Ryszko, Szafraniec (2014) and Pedlowski (2012): as formalising technical knowledge - non-system principles that allow one to succeed in solving the engineering problems encountered, usually existing in the mind. However, obtaining tacit knowledge is difficult because it is based mainly on observation or independent action. In an enterprise, it means preparing recordings of actions taken and preserving photos of the surroundings (VR, AR, MR) with comments or voiced notes. In further use, procedures or actions should be described in words, using (in the case of visualisation) geometric models, or, in the case of intelligent decision support systems by using logical relationships or mathematical models (Śliwa, 2018).

Amadi-Echendu (2007), among others, mentioned that an expert is a basic source of technical knowledge [2]. In an enterprise, the engineers generate models and graphic visualisations built in CAD and CAM applications; these define the parameters and the rules for the working and production environments. This is the foundation of using AR and MR techniques. The recipient of knowledge, in this form, focusses on the reference of visualisation in relation to the real environment, which does not need to be modelled and which gives certain boundary conditions (Fig. 2).

Fig. 2: XR technologies as a medium supporting the formalisation and transfer of knowledge in an enterprise; own study

The direction of the transfer of knowledge is from the expert to those employees subjected to immersion, which means, with reference to Rose, Nam and Chen (2018), the possibility of experiencing extensive, vivid stimuli, surrounding and matching such as user movement.

However, this concept is usually associated with the user's immersion in the VR environment. In a company, as Śliwa and Patalas (2016) mentioned, a source of formalised knowledge (explicit knowledge) documents, instructions, procedures are indicated. The specialist defines in them:

- a sequence of actions,
- programmes for machines,
- audio-visual tips, hints and comments,
- key indicators (KPIs), parameters, alerts,
- quick access paths to related and archived sources of knowledge,
- conditions for complying with the assessment of a process, product, etc.

It is also possible to exchange knowledge between employees as a result of a conversation, the sharing of comments about the real and virtual environment. These methods are mainly used when implementing a remote service, using AR or MR technology. As is well known, feedback communication promotes faster problem solving and learning.

The dynamics of the actions, taken in an enterprise, require the use of techniques for the rapid and repeatable transfer of knowledge, mainly in the case of training and the imparting of instructions.

XR Applications in the Production Department

With reference to Bridgwater (2018) and Michalos et al. (2018), in a production company, VR is most often dedicated to research and development activities, as an unreal training environment model, support for R&D design processes, numerous prototype visualisations, and also for workplace analysis and design. A technology that has a number of practical applications and is cheaper in relation to VR is AR. As presented by Rusek and Pniewski (2017), the most common advantage of implementing such a system is higher employee productivity, a reduction of the potential number of errors, a reduction of the time needed for training, as well as optimal employee utilisation, In this case, the user focusses on the reference visualisation relative to the existing environment; this allows him to more effectively fulfil his duties and minimise unnecessary movements in accordance with Lean methodology. The disadvantages refer directly to the limitations of technology; it is possible to reduce comfortable working when using additional equipment - goggles, reliability, battery life, communication range. The problem is also the limited viewing angle of the modelled image, which forces a physical distance from the real object. For example, the leader of equipment to MR technology, Microsoft Corp., in HoloLens goggles, provides 52 degrees diagonally – as was

described by Robertson (2019) in tech-article. The uses of AR glasses in the area of production, including technology and maintenance are:

- assembly of components using the instructions (Lang et al, 2019),
- operating machines with a preview of work instructions,
- determining communication paths, safety zones, in relation to machines and devices,
- monitoring; controlling working time and employee efficiency (Dataconsult, 2019),
- access to security procedures and as a problem solving platform,
- verification of quality parameters,
- mapping of areas of the most common faults assigned to a machine,
- remote co-operation with the service,
- programming machines and devices, e.g. trajectories of robot movements,
- verification of technical documentation, instructions related to the machine and device,
- retooling machines based on virtual instructions, diagrams,
- verification of the parameters of spare parts (e.g. date of last replacement) and their availability in stock,
- planning repairs and verifying the path of the installation with simultaneous collision detection.

In addition, in a modern factory, the virtual environment can provide broadly understood support for decision making by the management, by reading documentation from ERP systems, verifying the BOM structure of products, production plans. It can support the performance of audits in the production hall and the response during the review of messages, parameters, alerts, statistics or performance indicators (KPI).

Modelling reality as a support for SMED

As presented in chapter 1, production enterprises using modern information technologies, most often cite measurable benefits resulting from the automation of work related to maintenance. This suggests, that smooth machine changeovers, can result in big savings. Usually, these operations are carried out by experienced machine operators who have knowledge about the machinery and devices and who have many years of experience regarding quality requirements. They are able to choose the right manufacturing equipment and tools. During a large diversification of products, instructional support is necessary. Incompetence, when re-tooling can cause:

- a malfunctioning item which means the need to adjust the machine's settings which is both a waste of time and material,
- the possibility of damage to tools,
- possibility of damage to the machine: loss of axles, damage to bearings, damage to tool magazine sockets.

One of the Lean Tool, Single Minute Exchange of Die (SMED) techniques are commonly used to reduce changeover times, i.e. to eliminate waste and unnecessary operations (Monteiro et al, 2019). The SMED methodology begins with an analysis of the changeover process, distinguishing between internal operations which may cause interference on the production line and external operations, which can be carried out, outside the machine and which have no bearing on the flow of production. Based on Sousa et al (2018), it is continued by three main stages:

1st stage: separation of internal and external operations, including the preparation of a checklist necessary for the rig;
2nd stage: transformation of internal operations into external operations, through the use of indirect clamping devices and the standardisation of their functions;
3rd stage: streamlining the setting up of changeovers with particular emphasis on internal operations.

The implementation of SMED also means continuous improvement and monitoring of the process. Numerous studies, such as the example given by Moreira and Pais (2011), indicate that the implementation of this technique brings measurable benefits, such as savings of 2% of the sales value in a metal industry company. Another case is confirmed by an 83% decrease in the time necessary to carry out re-tooling operations in the furniture industry.

The concept of the practical use of AR in the SMED

The concept of a dedicated IT system, using AR technology, or the Intelligent SMED system (iSMEDs) so-called, can help in the efficient implementation of activities identical to SMED when monitoring the changeover process. The basic assumption is to support the current work of machine operators by displaying them in AR / MR technology virtual instructions, based on short commands, supported by virtual 3D graphics. This would shorten machine retooling time. In addition, this system would serve lower-level management staff while maintaining specialised knowledge, monitoring the efficiency of changeovers and implementing internal training.

The system's functions would overlap with the assumptions postulated in SMED methodology, i.e. preliminary operations from stage 0 (*definition of activities*), stage 1 (*definition of checklists*) along with monitoring the time of quick changeovers. Such a solution would allow the automatic re-tooling of instruction machines using universal templates. It is assumed that iSMEDs use both (Fig. 3): knowledge from *external sources* as: specialised database (CAD bib), producers' bib, Internet and *internal sources* of knowledge as: ERP systems, technical documentation, own CAD 2D/3D models of products, self-developed machines, infrastructure (places). The basis is therefore the definition of actions taken during retooling (1), necessary equipment for retooling (2), preparation of programmes for CNC machines (3), the statistics monitoring the changeover (4), definition of a closed list of machines, equipment, tools, materials available in the enterprise, associated with 3D models (5), and workers' feedback for instructions (6). Keeping statistical records would also enable the measurement of the performance of individual employees and the time taken to complete tasks while learning with the selected instruction.

Fig. 3: Function diagram of the Intelligent SMED system; own study

When building instructions in iSMEDs, specialists would use markings for internal and external operations that would be initiated through a colour distinction in the interface. Operations of a given type would be grouped together and the time taken to carry out a particular action would be measured according to the change (execution) of command in the intelligent instruction. In addition, the employee would be shown a communication path which he should follow after downloading the

individual tooling. Improvement in the changeover means revision and development of instructions through the use of new solutions and acquired experience. Therefore, it is important to involve all employees, including the operator, who would be able to add comments to individual steps of the instruction. This would be the basis for a justified modernisation of the changeover by an authorised unit, i.e. a technologist.

Applying the iSMEDs concept requires the implementation of individual steps:

Step 1a. Development of a list of components, grouped together, according to their shared characteristics, where retooling is carried out in a similar way, that is, where their production takes place on similar machines. CNC programme overview. Preparation of a list of objects used in a company for changeover and their storage locations. This information is taken from the information system present in a company.
Place$_i$
Component's group$_i$ = {component$_i$, with the set of features (material$_i$: basic type of bar, forging, other materials); manufactured on the machine$_i$; using device$_i$; tool$_i$; .....}.

Step 1b. Integration of iSMEDs with a representation of places (3D or 2D picture) and a database of 3D models of products and objects used in the enterprise for retooling: a database of tools, devices and machines.
3D models database = {2D/3D place$_i$; 3D component$_i$; 3D machines$_i$; 3D device$_i$; 3D tool$_i$; 3D material$_i$}.

Step 2. Recording, e.g. using a camera built into the AR glasses, for retooling individual product groups (step 1a) by an experienced employee. The operations should be accompanied by voiced comments taking into account, especially, the equipment and tools required for assembly and use.

Step 3. Observation of the changeover process. Setting up a set of command sequences for standard changeover steps (formalisation of technical knowledge) dedicated to specific product groups (step 1a).
Sequences should be universal enough to be able to insert the names of necessary elements and places associated with the 3D object model, into the assigned set of activities. Association of identification tags for objects (if required) and places.

Step 4. Development of the tooling control system.
• Method 1: using the technology installed in AR / MR glasses, which allows one to scan the necessary tools prepared for the change of station and unchecking them on the virtual list.
• Method 2: using a defined list of control questions with confirmation.
The tooling used is in the defined database of 3D models (step 1b).

Step 5. Proposal and implementation the rules, which allow simple statistics to be kept for specific instructions:

- monitoring the average changeover time using the developed instructions,
- monitoring the efficiency of changeovers carried out by a given production employee (work efficiency assessment),
- statistics on the training of production workers (e.g. the number of completed re-tooling operations).

Step 6. Linking the activity sequence template (step 3) - there marking the operation as internal and external (step 2) - with statistics (step 5) to individual groups of details (step 1a).
Step 7. Install the instructions based on the template (step 6) for individual products (step 1a). Associate the names of objects and places with the graphic representation (step 1b).

Step 8. Implement the virtual instructions from the SMED in AR / MR technology, for employees.

An important improvement would be the implementation of voice control in iSMEDs in order to accept individual operations carried out with interactive instruction cards, especially for step 4.

Case study

The company under consideration is a producer of the pneumatic components used in the braking and suspension systems of commercial vehicles. The company manufactures diversified products from its permanent assortment and adds new projects from time to time. The problem is the lack of modern IT solutions supporting management of the knowledge of the production and technology employees. In addition, the company has high staff turnover. Description of the company's specifics is presented below:

- Enterprise size: SME.
- Industry: automotive. Production of connectors, blocks, pneumatic valves found in the braking system of trucks over 3.5t. Production and assembly take place in the enterprise.
- Production volume: serial and high volume depending on the product type.
- Machine park: 15 CNC machines with bar feeders; average changeover frequency *per* week: 2-4x per machine.
- Production mainly includes: semi-finished products constituting the basis for the finished product, mainly small, turned brass elements.

Currently, selected specialists (*2 employees with 15 and 8 years of experience working with CNC*) are involved in retooling in the machine park. Changes made by other operators take much longer and require consultation with experienced staff.

The case study presents a definition of the lists of necessary objects and the sequence of activities associated with re-tooling the machine for selected groups of products - straight connector bodies.

Step 1a
Component group: bodies of straight connectors turned from a round bar

Characteristics:
Tip type I: plug socket ØXX,
Tip type II: undercut thread, MX or GX,
Versions of tip I: Ø6, Ø8, Ø10, 12
Versions II: M12, M16, G1.8", G1.4"

Components:
The list of products meeting the given criteria was generated from the ERP system (Table 1).

Table 1: components building the group: bodies of straight connectors turned from a round bar (combinations of terminals I and II); own study

Body	Index	Body	Index	Body	Index	Body	Index
Ø6/M12	0M0612	Ø8/M12	0M0812	Ø10/M12	0M1012	Ø12/M12	0M1212
Ø6/M16	0M0616	Ø8/M16	0M0816	Ø10/M16	0M1016	Ø12/M16	0M1216
Ø6/G1.8"	0G0618	Ø8/G1.8"	0G0818	Ø10/G1.8"	0G1018	Ø12/G1.8"	0G1218
Ø6/G1.4"	0G0614	Ø8/G1.4"	0G0814	Ø10/G1.4"	0G1014	Ø12/G1.4"	0G1214

Fig. 4: Illustrative model of component groups: bodies of straight connectors turned from a round bar; own study

Machines: STAR1, STAR2, STAR3; each of these has a bar magazine - feeder.
The machine is selected based on the production plan available in the ERP system.

Instrumentation:
a) expansion sleeves and contracting collet for fixing the rod into the machine tool holder, with diameters appropriate for the diameter of the processed bars: Ø16, Ø18, Ø20, Ø22,
b) three-jaw chucks, in the diameter range appropriate for the rods being machined, chuck I - range 10-20, chuck II - range 20-30,

Material:
Cleaning materials, Compressed air gun,
Input material: Mo58 brass, round bar with diameters: Ø16, Ø18, Ø20, Ø22
Information from the ERP program, from the technology card.

Programmes (called component index numbers): 0M0612, 0M0616, 0G0618, 0G0614, 0M0812, 0M0816, 0G0818, 0G0814, 0M1012, 0M1016, 0G1018, 0G1014, 0M1212, 0M1216, 0G1218, 0G1214.
Information from the ERP program, from the technology card.

Machining Tools:
Turning tools: QS-SVJBR 12 3C, QS-SVJBR 16 3C, QS-SDJCR082XHP-M
Parting-of turning tool: DGTL 12B-1.4D30, DGTL 10B-1.4D20, DGTR 16B-1.4D30, DGTL 16B-2D32
Threading turning tool: SER 0808 H11, SEL 1010 H11, SER 1010 H11, SEL 1212 F16
Special turning tool: 266RG-16VM01A001EE 7015, 266RG-16VM01A002EE 7015, MATL 3-MM01F-040-A 1105, MATL 3-MM01F-050-A 1105
Standard drills: WØ4,2, WØ6,2, WØ8,2, WØ10,2
Multi-cut drill: WG06, WG08, WG10, WG12
Face mills: FØ8, FØ10, FØ12
Boring straight, internal turning tool: WTG6, WTG8, WTG10, WTG12
Information from the ERP program, from the technology card.

Support tools:
M4 Allen key, M6 Allen key, Transport trolley

Places:
Storage location for instrumentation: Machine room, zone A - collet rack
Storage location for machining tools: machine hall, common area - tool cabinet (for CNC tools)
Storage location for support tools: machine room - mobile tool cabinet
Storage location for material: material warehouse

Step 1b
Downloading 3D models representing the elements from step 1a from internal and external databases and documentation (Fig. 5 and Fig. 6.).

A) B)

Fig. 5: A) STAR20 CNC machine and B) mobile tool cabinet; own study

Fig. 6: External threading toolholder; own study

Step 2
Retaining the sequence of operations of the STAR1 machine changeover for the production of 0M0812 component.
Employee identification: Jan Kowalski
Total changeover time: 15 min 30 sec.
Image Recording

Step 3
Observation of recording, ordering activities.

An example of the changeover of the STAR1 machine for the 0M0812 component.

√	Material: rods Ø18 Mo58		

Step 5

Development of statistics measurements:

- Measurement of changeover time from step 3 (retooling point 2) to the initial turning of the component.
- Total measurement of implementation time for external changeovers.
- Total measurement of the time for internal changeovers.
- The retooling counter carried out within the same group of details: straight connector bodies by employee 1.

The other steps - viz., 6, 7 and 8 - link the template to each component in a group named: bodies of straight joints turned from a round bar, then, build a ready-made, retooling instruction for the 0M0812 component (see Step 3) and implement it in the company, within the iSMED system.

Discussion and summary

The original concept of the IT system supports operation in the SMED area by the possibility of building and using intelligent machine setup instructions in augmented reality technology. The virtual instructions created in iSMEDs include:

- displaying the command and graphic equivalent of the activity visualisation (3D models),
- distinguishing between internal and external operations,
- checking prepared equipment,
- possibility of adding a comment to a particular instruction card,
- preservation of statistics on work with instructions,
- ability to record work with instructions, to make templates and analyse employees' mistakes.

The idea of the iSMEDs system is based on the definition of universal steps; however, developed machine retooling templates for individual products are the company's *know-how*.

The proposed concept requires refining the system's architecture and integration methodology with knowledge sources - the ERP system, 3D object databases. In addition, according to the research work of Patalas-Maliszewska (2012), integration with current resource management systems, of the presented solution, will also allow achievement of the company's strategic goals in the context of a *learning and growth* perspective.

It is recommended to specify a quick verification method for necessary equipment at the workplace. This is possible by scanning and comparing with the reference model, using a code or tag assigned to a part, or confirming by voice. It is also necessary to indicate the degree of interaction required, which will suggest which technology would be a better solution: AR or MR, as well as conducting performance and cost-effectiveness tests of the system, in the enterprise in question.

The expected benefits of applying the system are: fast execution of setups with instructions; faster implementation of machine operators; support in the implementation of operator training; the opportunity to improve and evaluate employees based on monitoring time and the possible creation of standard template instructions for rapid implementation, based on acquired technical knowledge. The advantage of using AR / MR in an enterprise is the presence of the user at the coal face; awareness of the real environment and the possibility of interaction; also freeing employees' hands and reducing the need to prepare and archive paper documents, which are replaced by a digital image.

Further work relates to the increased automation of analysis and to the preservation of knowledge in the initial white stage SMED. It is recommended to develop building and analysing audio instructions through ontology definitions and the assessment of acquired knowledge; this refers to the research presented by Patalas-Maliszewska, Krebs and Dudek (2017). Also useful could be video analysis - through the ability to automatically link objects, registered in the image, with objects used by the employee. Another important aspect is the development of XR functionalities related to control by defined movements of the eyeballs or blinking, which technology was presented by Fogliatto and Fagundes (2003). This kind of solution, viz., the registering of eye movements, give the possibility of precisely measuring the distance between the objects under observation and any quick glance at the related documentation.

XR technologies support many business processes, from development, through to production-technological and organisational activities. Virtual object models and rules of conduct embedded in the reality of a company can be classified as formalised knowledge and collected in internal databases. The solution is a medium for transferring technical knowledge in a repetitive and structured manner. The use of XR in production companies impacts on the elimination of human error, on better control and on increasing the efficiency of processes and product quality. The case studies described in the literature of companies that have successfully implemented AR solutions - especially for retooling machines - are proof of the huge potential and the need to popularise it in the SME sector.

Abstract

In the 1990s, ice wine was added to the popular products of wine makers in the Czech Republic, who receive awards at international wine competitions. Although the Czech Republic is not one of the world's wine powers in terms of viticulture, wines from Bohemia and Moravia are considered to be of high quality and are currently successful at many of the world's wine competitions. Ice wine is considered by experts to be a real delicacy, characterized by a very sweet taste, full body, high extract, most often with fruit and honey tones or with tones of caramel, and a relatively low alcohol content. Ice wine is not intended for everyday drinking. It is drunk alone as an aperitif or consumed together with sweet desserts. The oldest known mention of the production of ice wine comes from the pen of the Roman philosopher Pliny the Elder, who lived in the first century AD. He noted that some wine makers were waiting until the grapes froze to make wine. Grapes for ice wine are most often harvested early in the morning, when there is the greatest frost. It is necessary for these grapes to be in the vineyard for at least two days at a temperature of not more than -7 degrees Celsius before being harvested. The aim of this article is to express the current state of ice wine production in the Czech Republic and the main problems related to its production, especially in the conditions of ongoing climate change.

Keywords: ice wine, wine growing and viticulture, wine production, climate change

Introduction

The wine industry is undoubtedly an economic sector in which the Czech Republic can compare with the major economies. The beginnings of wine growing in Moravia reach back to the 2nd century. Vineyards were planted by Roman soldiers on the south-west slopes of the Pálava hills. At the time of the Great Moravian Empire (833-906), wine was part of the way of life of the ancient Slavs. In the Middle Ages, a great many vineyards were established by monasteries. In the 13th century, the wine trade brought large profits to the nobility in certain areas.

Viniculture in Bohemia is connected with the Middle Ages. According to legend, wine came to Bohemia as a gift for Prince Bořivoj and his wife, Ludmila, on the occasion of the birth of their son, Spytihněv. The gift came from no-one else but Svatopluk, the Prince of Great Moravia. The couple took such a liking to the wine that they had the first vineyards planted in Mělnicko. Charles IV was a great supporter of wine-making and had grapevine seedlings brought from France. Burgundy varieties became traditional, in our country called Rulandské (pinot) (Kraus et al., 2010).

Nowadays, wine from Czech Republic is a synonym of quality. Wines of many Czech wineries win awards at competitions in France and other wine superpowers. However, the story of wine-making is not only successes and the tasting of wine from new harvests. To give an example, the Thirty Year's War caused the destruction of half of the vineyards on Czech territory.

The issues of vine-growing and wine-making in the Czech Republic are dealt with in the articles of the following authors: Tomšík et al. (2016), Kraus (2010) and Gosch (2005). The economic significance, position and performance of vine-growing and viticulture within the economy are also dealt with in the works of agricultural economists and journalists such as Horáková (2008), Kütner (2016), Poliačik (2016, 2019, 2020), Pánková (2019) and others.

The aim of this article is to express the current state of ice wine production in the Czech Republic and the main problems related to its production, especially in the conditions of ongoing climate change.

Material and Methods

Methodology

The main method used in writing this paper was to describe the production of ice wine and the problems currently related to it in the Czech Republic. Time series analysis was used to express the development of the grape harvest in the Czech Republic.

Vine-growing for the production of wine constitutes one of the major areas of agriculture of the Czech Republic, and in recent years it has been qualitatively improved. Of the total wine production in the Czech Republic, two thirds are white wine and one third is red wine. These ratios correspond to the ratio of vineyards planted with white and blue varieties. The total area of vineyards in the Czech Republic is over 18,700 ha. The share of the Moravian wine-growing region in the total area of vineyards in the Czech Republic is 96.4%, whereas the share of the Bohemian wine-growing region is a mere 3.6% (Kostovčík et al., 2020).

The vine-growing area of Moravia includes approved territories for vine-growing in the area of the historical country of Moravia. It is formed by four vine-growing sub-areas, Mikulov, Velké Popovice, Slovácko and Znojmo, and it includes 312 vine-growing municipalities. Chládková (2006) states that this vine-growing area is due to its prerequisites predetermined to produce white wines of a good quality. Moravian area can also be used for red wines producing. A typical taste of Moravian wines combines earthy genuineness with savoury fruitful characteristics. Because of the new technologies of wine production, the features of Moravian wines are changing. These technologies supply them particularly with refinement (Chládková, 2006).

Vine-growing regions include the approved areas for growing vine in the historical land of Bohemia. It consists of two vine-growing regions, Mělník region and Litoměřice region, and includes 66 vine-growing villages. The vineyards are located around the rivers of the Elbe, Vltava and Berounka on the southern protected slopes. As reported by Kraus (2010), the vine here gives fairly good yields; however, the quality of wines varies. Despite this fact, many excellent wines, which gain their quality from lying in historically interesting and perfect for aging wine cellars, are successfully grown (Kraus et al., 2010).

This classification of areas was established in May 2004 in connection with the new arrangement of vine-growing regions, which was brought by the Act no. 321/2004 Coll. on viticulture and wine-making and its implementing decree no. 324/2004 Coll.

Harvesting grapes in the Czech Republic

In 2019, domestic wine makers had problems with pests during the grape harvest, which contributed to a year-on-year decline in yield of 20 to 30 %. Wine makers therefore assume that they will harvest from 73,000 to 83,000 tons of grapes, which is the smallest amount in the last three to four years.

Fig. 1: Harvesting grapes in the Czech Republic (in thous. tons) (Ministry of Agriculture CR, 2020)

Starling raids in 2019 were more destructive than in the previous year (Château Valtice, 2020). The cost of the damage can reach millions of Czech crowns. Wine makers in the Czech Republic most often protect the harvest using gas cannons, which drive starlings away with noise. However, blasting cannot be used in all vineyards and it is expensive, as are the nets protecting the most valuable vineyards abroad. In 2019, wine makers in the Czech Republic also struggled with the overpopulation of voles. The voles attacked the roots of the vines and some of the ripe grapes, causing damage of up to hundreds of thousands of crowns in some places. Voles are naturally killed by small carnivores or birds of prey (Vinařská unie ČR, 2019).

The decline in the harvest is also due to the high comparison base from 2018, when 104,000 tons of grapes were harvested. The vineyards needed to rest after such an extraordinary performance. Nevertheless, wine makers in the Czech Republic are not going to raise prices. According to them, nothing significant is happening; they still have a supply of wine from the extremely successful harvest of 2018. They are also satisfied with the quality of the 2019 vintage. The Ministry of Agriculture, which makes an optimistic estimate of the harvest at around 90,000 tons of grapes, therefore is not considering compensation for wine makers (Pánková, 2019).

Results

Ice wine is considered by experts to be a real delicacy, characterized by a very sweet taste, full body, high extract, most often with fruit and honey tones or with tones of caramel, and a relatively low alcohol content. Ice wine is not intended for everyday drinking. It is drunk alone as an aperitif or consumed together with sweet desserts.

History of Ice Wine Production

The oldest known mention of the production of ice wine comes from the pen of the Roman philosopher Pliny the Elder, who lived in the first century AD. He noted that some wine makers were waiting until the grapes froze to make wine. Another, more accurate description of ice wine appears only at the end of the 18th century, in the German region of Franconia. At that time, early and hard frosts came suddenly, and unfortunate wine makers tried to press the affected grapes before giving them to cattle for food. Gradually, the production of wine from frozen grapes developed into an interesting and relatively complex procedure.

However, a greater expansion of the production of ice wine did not occur until the 20th century; of course, in those wine regions where early frosts can be expected. The cradle of this wine is therefore in Central Europe, especially in Germany and Austria. Currently, however, the largest producers are Switzerland, Slovenia, Croatia, Hungary, Moldova and Slovakia. Wine makers from the Czech Republic have been producing this delicacy since the 1990s. Canada joined the large European producers in 1983 (Poliačik, 2019).

Harvesting Ice Wine

According to the law, grapes for ice wine can only be harvested at a maximum frost temperature of -7 °C (-8 °C in Canada), while harvesting at -10 °C is considered ideal. Waiting for such weather conditions brings many pitfalls. As the vast majority of grapes from the vineyards have already been harvested, and at the same time other options for sustenance are narrowing, hungry birds and various game are very happy to find these islands of abundance (Poliačik, 2019).

However, the real wild card is the weather. When it is rainy and warm, it creates an ideal environment for various diseases. For example, if wine makers wait until the end of December for the harvest, which is not unusual, the chance of disease is very high.

As soon as the daily temperatures start to go below 0 °C, preparations for the harvest begin. Wineries have people in the vineyards who measure the temperature, mainly in the morning. Grapes for ice wine are most often harvested early in the morning, when there is the greatest frost. Wine makers will determine how long to wait for this day; some will hold on until January. When the perfect time comes, the team at the ready sets off.

The deadline for wine makers from Château Valtice is Christmas. At this time, thawing occurs regularly, so they begin to harvest in any case. The grapes are then used to make wine with the "selection of raisins" attribute (Château Valtice, 2020).

After harvesting, the grapes must be processed very quickly, as they must not thaw at all during pressing. Thus, the grape juice does not melt throughout the production process. During fine pressing, water remains in the form of ice inside the press, while a thick and very sweet, concentrated must flows out. The Czech Wine Act requires that this must have a sugar content of at least 27 °NM, which is usually not a problem. The price of producing high quality must is a very low pressing yield - around 20 percent. The must ferments very slowly, and a high sugar residue always remains in the wine. The wine does not ferment to more than 8-9 % of alcohol, but it has a higher acid content and a very high extract (usually more than 50 g/l) (Poliačik, 2019).

The production of ice wines requires late varieties that are resistant to rotting or falling grapes. The most commonly used varieties are Ryzlink rýnský, Ryzlink vlašský, Chardonnay, Sauvignon and Veltlínské zelené.

Ice Wine Price Research

In order to express the value of ice wine production, a survey was carried out of the prices of these special wines on a given segment of the wine market in the Czech Republic. The subject of the research was the prices for which the ice wines are offered to consumers through e-shops, i.e. the prices including the tax burden. As Table 1 shows, the prices of individual varieties of ice wines are differentiated not only according to type, but also according to the winery.

Table 1: Prices of ice wines from selected wineries

Variety	Winery	Price (CZK)	Volume (l)	Price for 1 dcl (CZK)
Ryzlink vlašský	Vinařství Mikrosvín Mikulov	799.00	0.375	213.07
Veltlínské zelené	Vinařství Mikrosvín Mikulov	679.00	0.375	181.07
Ryzlink vlašský	Vinařství Mikrosvín Mikulov	665.00	0.375	177.33
Sauvignon	Vinařství Krist	539.00	0.375	143.73
Ryzlink rýnský	Vinařství Krist	539.00	0.375	143.73
Rulandské modré	Vinařství Krist	539.00	0.375	143.73
Pálava	Vinařství Krist	539.00	0.375	143.73
Pálava	Vinařství Vajbar	449.00	0.2	224.50
Veltlínské zelené	Vinařství Vajbar	399.00	0.2	199.50
Veltlinské zelené	Rodinné vinařství Špalek	404.00	0.2	202.00
Rulandské bílé	Réva Rakvice	412.00	0.2	206.00
André	Réva Rakvice	412.00	0.2	206.00
Ryzlink rýnský	Réva Rakvice	412.00	0.2	206.00
Cabernet Moravia	Vinařství Proqin	469.00	0.2	234.50
Cabernet Sauvignon	Vinné Sklepy Maršovice	419.00	0.2	209.50
Rulandské šedé	Šebesta	469.00	0.2	234.50
Chardonnay	Vinné Sklepy Maršovice	419.00	0.2	209.50
Frankovka	Maňák	379.00	0.2	189.50
Cabernet Sauvignon	Vinné sklepy Lechovice	399.00	0.2	199.50
Frankovka klaret	B/V vinařství Ratíškovice	429.00	0.2	214.50
Frankovka	Maděřič	439.00	0.375	117.07
Merlot barrique	Maňák	439.00	0.2	219.50

Ice wines are offered in packages of either 0.375 liters or 0.2 liters; therefore, a conversion to 1 dcl is necessary for price comparability. For example, the popular Ryzlink rýnský variety from the Réva Rakvice winery is sold at 206 CZK for 1 dcl, while from Krist Winery this variety is sold at only 143.73 CZK for 1 dcl, i.e. about a quarter cheaper. Of the samples of ice wines selected by us, the highest price, 234.50 CZK for 1 dcl, was stated for the Rulandské šedé variety from the Šebesta winery. On the other hand, Frankovka from the Maděřič winery was sold for the lowest price, 117.07 CZK for 1 dcl. The price is not affected by whether the varieties are white or red, but especially by

the quality of the wine of the given vintage. The average price of the examined sample of ice wines in the Czech Republic was 191.75 CZK for 1 dcl, which is approximately the same price at which the consumer can buy identical varieties of late harvest wine in retail chains in packages of 0.75 l. Due to the high price, ice wine is not intended for normal consumption, and consumers therefore tend to buy it for special occasions. It is drunk mainly alone as an aperitif, or consumed together with sweet desserts.

Discussion

Wine makers from the Czech Republic have several years of experience in foreign competitions, so they know which wines to send to have a chance of success. Along with their victories, their self-confidence increases, and more and more wine makers from the Czech Republic apply to wine competitions abroad. However, these are not the most important reasons for their increasing success, because:

- The main reason why wine makers from the Czech Republic win medals in important competitions is that their wines are of better quality than many wines from the wine powers and renowned world wineries.

- At the same time, participation in prestigious competitions is becoming easier and easier for wine makers. In the Czech Republic, the Wine Fund and the National Wine Center especially are responsible for this. The portfolio of international competitions which wine makers can enter with the support of the fund is constantly expanding. The support is not only financial, however, but also organizational, with the National Wine Center currently in charge (Vinařský fond ČR, 2020).

The international wine competitions in which Moravian and Czech wine makers participate are carefully selected. Above all, attention is paid to seriousness and prestige. Most of the selected international competitions take place under the auspices of the OIV (Organisation Internationale de la Vigne et du Vin). If this international organization associates its name with a competition, it very strictly oversees the fairness and high quality of the competition. Thus, such events rank among the most prestigious competitions in the world (Poliačik, 2020).

Even though the production of ice wine in the Czech Republic has been permitted officially only since 1995, domestic wine makers are very successful with their ice wines. For example, Ryzlink rýnský 2013 from Vinné sklepy Lechovice won the gold medal at the prestigious Sélections Mondiales des Vins competition in Quebec, Canada in 2016. The winery celebrated the same success with Ryzlink rýnský at the Terravino Mediterranean International Wine and Spiritý Compétition in Israel in 2019. At the Vinagora world competition in 2015 in Hungary, Tramín červený 2010 from Znovín Znojmo won the gold medal and the title of National Winner. Neuburské 2001 from the Château Valtice winery became a champion at the world competition in Panama in 2003, where it was declared the best wine of the century (Poliačik, 2019).

Conclusion

Although the Czech Republic is not one of the world's wine powers in terms of viticulture, wines from Bohemia and Moravia are considered to be of high quality and are currently successful at many of the world's wine competitions. The oldest known mention of the production of ice wine comes from the pen of the Roman philosopher Pliny the Elder, who lived in the first century AD. He noted that some wine makers were waiting until the grapes froze to make wine.

However, a greater expansion of the production of ice wine did not occur until the 20th century; of course, in those wine regions where early frosts can be expected. The cradle of this wine is therefore in Central Europe, especially in Germany and Austria. Currently, however, the largest producers are Switzerland, Slovenia, Croatia, Hungary, Moldova and Slovakia. Wine makers from the Czech

Republic have been producing this delicacy since the 1990s. Canada joined the large European producers in 1983.

According to the law, grapes for ice wine can only be harvested at a maximum frost temperature of -7 °C (-8 °C in Canada), while harvesting at -10 °C is considered ideal. Waiting for such weather conditions brings many pitfalls. As the vast majority of grapes from the vineyards have already been harvested, and at the same time other options for sustenance are narrowing, hungry birds and various game are very happy to find these islands of abundance.

The production of ice wines requires late varieties that are resistant to rotting or falling grapes. The most commonly used varieties are Ryzlink rýnský, Ryzlink vlašský, Chardonnay, Sauvignon and Veltlínské zelené.

Even though the production of ice wine in the Czech Republic has been permitted officially only since 1995, domestic wine makers are very successful with their ice wines. For example, Ryzlink rýnský 2013 from Vinné sklepy Lechovice won the gold medal at the prestigious Sélections Mondiales des Vins competition in Quebec, Canada in 2016.

The lack of water, not only in rivers but also in the soil, is also reflected in the anticipated future harvest of grapes in the Czech Republic. According to the Czech Hydrometeorological Institute (2020), the drought in the Czech Republic is currently worse than it was in mid-April 2019 and 2018. If it does not rain in the near future, it will have a negative impact on agriculture. Not only agricultural crops in the fields, but also vines are at risk.

New landscape of the Industry 4.0 trends in the ICT sector after the COVID 19 epidemic[1]

Katarzyna JASIŃSKA

Wrocław University of Economics, Wrocław, Poland
katarzyna.jasinska@ue.wroc.pl

Abstract

Technological progress has contributed over the centuries to the development of so-called industrial revolutions. One of such revolutions is the Fourth Industrial Revolution (Industry 4.0), in which we are now living. It is the development of ICT that has contributed to its definition as a concept within which technologies and the physical world not only coexist but intertwine. Given that currently, the coronavirus epidemic has shaken the global economy and practically all sectors have fallen. Therefore, the question naturally arises how Industry 4.0 trends in the ICT sector are shaping in the face of the crisis. The purpose of the article is to try to answer this question. The first part of the article defines the ICT sector, then presents its evolution and discusses the concept of Industry 4.0. The next part characterizes the main trends in the Industry 4.0 area in the ICT sector. These trends became the basis for empirical research conducted in the Polish ICT sector, the results of which are further presented. The last part of the article presents the summary and conclusions.

Introduction

The development of technological technology is one of the most important phenomena for the growth of a modern economy. In the era of the fourth industrial revolution (Industry 4.0), the ICT sector plays a key role. Enterprises and public investments invest in the implementation of new technological systems. These investments are not limited to individual processes, but fully integrated environmental technologies. Trends identified in the Industry 4.0 concept, such as: Internet of Things (IoT), intelligent factories, intelligent installations, artificial intelligence (AI) systems and analysis of large data sets translated into real enterprise strategies, and solutions in this field are not widely used only in enterprises, but also by individual users. In the most developed national implemented programs providing support in the adaptation of solutions used in enterprises, e.g. various clusters and Industry 4.0 programs focused on the development of digitization of selected transport branches, e.g. e-health, e-education and e-offices. The picture of technological development was current at the beginning of 2020. Currently, however, the coronavirus epidemic has shaken the global economy and practically declines have been recorded in all sectors all sectors. Therefore, the question naturally arises how industry 4.0 trends in the ICT sector are shaping in the face of the crisis. The purpose of the article is to try to answer this question.

The chosen goal is part of the economic analysis conducted by various institutions in the face of crisis phenomena [IDC 2020; KIGEiT 2020]. However, it should be emphasized that the available studies perform the functions of reports and do not constitute scientific papers.

The first part of the article defines the ICT sector, then presents its evolution and discusses the concept of Industry 4.0. The next part characterizes the main trends in the Industry 4.0 area in the ICT sector.

[1] The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

These trends became the basis for empirical research conducted in the Polish ICT sector, the results of which are further presented. The last part of the article presents the summary and conclusions.

The ICT Sector

The ICT sector is defined in many ways [OECD 2011; Central Statistics Office 2010; PARP 2017; Zuppo 2012]. The large number of definitions of the ICT sector, and thus the diversity in the area of reporting data on it, is related to the relatively short time that has elapsed since it was recognized as an autonomous economic discipline by institutions involved in the classification of economic activities.

ICT as an autonomous sector in Europe began to be talked about only in the early 1990s in the context of separating economic activities related to advanced technologies. It was not until 1998 that OECD member states agreed on a common definition of the ICT sector [OECD 2002]. The basis for defining the ICT sector is product isolation specified in the International Standard Industrial Classification of All Economic Activities [United Nations Statistical Commission, 2002].

The condition for classifying an enterprise as ICT production is the production of products that must be designed to perform the functions of information and communication, including transmission and display, or must use an electronic system to detect, measure and / or record physical phenomena or control a physical process. However, the condition for qualifying service activities as being within the ICT sector is the provision of services for electronic information processing and communication [United Nations Statistical Commission, 2002]. According to this separation, ISIC defines the ICT sector as a set of enterprises conducting production and service activities, which consists in intercepting, sending and displaying data and information by electronic means [OECD 2011].

In the simplest way, the ICT sector is understood as a combination of the IT sector (Information Technologies) and the telecommunications sector. In practical terms, the use of the term ICT is somewhat discretionary. And as it depends on the specific company, e.g. telecommunications operators, all activities not related to telecommunications activities, e.g. equipment resale or integration activities, are classified as ICT activities. It should be emphasized that the issue of including a specific entity in the ICT sector is interpreted differently even by the sector participants themselves. However, over the past nine years, entity awareness has increased in this regard. According to my own research conducted from March to December 2011 on a group of 40 ICT enterprises and 104 respondents - 80% of surveyed employees of telecommunications operators (42 out of 53 persons) claimed that their companies are not ICT enterprises and 50% of surveyed employees of ICT equipment producers claimed that they do not carry out activities related to ICT (8 out of 16 people)2 [Jasińska, Szapiro, 2014]. Currently, based on a survey conducted in 2020, by interviews with representatives of 20 ICT enterprises, it can be seen that all respondents asked confirmed that their enterprises are representatives of the ICT sector (about half of the respondents participated in both the 2011 survey and the 2020 survey). It should be emphasized that these studies vary in scale, so the results can only speak of a certain trend in the perception of belonging to the ICT sector. The study will be described in more detail in the next part of the article.

[2] *Data provided on the basis of a survey consisting of a telephone interview with 30 experts from ICT enterprises and a survey of a group of 90 experts from enterprises in the ICT sector (in total, the study was conducted on 104 different people - 16 of whom took part in both the survey and the interview). The purpose of the interview and survey was not to create the definition of the ICT sector. The application presented by the author is an additional application in relation to the chosen research goal. During the first contact with a group of respondents, it turned out that some of them (48%, i.e. 50 out of 104 people) did not want to participate in the survey, claiming that they were not participants in the ICT sector.*

The evolution of the ICT sector and Industry 4.0 contept

Over the past 50 years, the following breakthrough ICT technology periods have been observed [Lombard 2009; Schwab 2017] :

- The Third industrial revolution (Industry 3.0) erupted in the 1970s and was connected with automation processes, thanks to the use of new computer technologies. Within the third industrial revolution, the following periods can be mentioned:
  - The first stage, covering the years from 1975 to 1995 (the period from the development of the second Moore and Ethernet law to the success of mobile telephony in the USA), in which the so-called three big blasts occurred, namely: the introduction of digital telephony, Internet take-up, and the beginning of mobile communication..
  - The second stage, covering the years 1995–2004 (the period from the Netscape debut on the stock exchange to the Google debut on thereupon) is called transitional or otherwise referred to as the "second fetal life of the network". During this period, Internet browsers developed, and the network became the basis for providing services and content, as well as many surprising uses.
  - The third stage, covering the years following 2004; the so-called second life of the web (Web 2.0). During this process, new phenomena occurred: e.g. the emergence of a new type of user being a network node, which not only downloads content, but also publishes it. Other phenomena from this period are the emergence of free services, conditioned by the spread of new business models of advertisers. Combining value chains, where companies search for new ways of functioning is another significant phenomenon (e.g. equipment suppliers take over the role of service providers, and service providers are struggling to grant new frequencies, which is associated with acquiring the key value for the enterprise - the final recipient).
- The Fourth Digital Revolution (Industry 4.0), which has been observed since 2014, concerns building interdisciplinary systems by integrating physical and digital layers [Lasi et. al 2014; Rifkin 2011; Czyżewski et. al, 2017]. Klaus Schwab and World Economic Forum characterized this term by a range of new technologies that are fusing the physical, digital and biological worlds, impacting all disciplines, economies and industries [Schwab, 2017]. In the Industry 4.0 solutions are: smart factories, cyber-physical systems, self-organization, new systems in distribution and procurement, new systems in the development of products and services, adaptation to human needs, and corporate social responsibility. Industry 4.0 focuses on the end-to-end digitalization and creation of complex digital ecosystems with value chain partners. In contrast - Industry 3.0 was focused on the automation of single machines and processes [PwC 2016]. In Industry 3.0 opportunities are limited by parameters of technology and IT infrastructure. The fourth industrial revolution is connected with completely new solutions in which technology becomes a part of complicated systems, societies, or even human bodies. The most important trends in Industry 4.0 are presented in Table 1.

Table 1: The most important trends in Industry 4.0

Trend	Description
Big Data and Analytics	The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making

	The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making The trend is growing due to the increase in the amount of data in the company's services and their general availability. These data should be analyzed and made based on their decisions at runtime. The application of artificial intelligence and machine learning algorithms is the subject of many projects in the ICT sector [Rüßmann 2015]
Autonomous Robots	utonomous robots can complete given task precisely and intelligently within the given time limit and also focus on safety, flexibility, versatility and collaboratively The trend associated with the replacement of human work by robots in connection with progressive automation. Autonomous, robotic systems not only do the work for a man, but also make decisions for him. Thanks to this, given task can be implemented precisely and intelligently within the given time limit and also focus on safety, flexibility, versatility and collaboratively. Examples of applications are autonomous vehicles and drones [Rüßmann 2015]
Simulation	Simulations will be used more extensively in plant operations to leverage real-time data to mirror the physical world in a virtual model, which can include machines, products, and humans, thereby driving down machine setup times and increasing quality The trend associated with the development of virtual reality and its wide industrial and military applications. Simulations are used in data processing operations when used to calculate the physical world in a virtual model. Virtual reality currently allows reversing of real conditions, in which it is possible to conduct e.g. training in various fields. [Schuh et al. 2014]
Horizontal and Vertical System Integration	The trend is developing in connection with the progressive integration of ICT systems to create a coherent environment is one of the main assumptions of Industry 4.0. The Industry 4.0 paradigm concerns: the level of integration in the entire value creation network, vertical integration and networks of production systems and comprehensive engineering throughout the product life cycle [Stock, Seliger, 2016; Schuh et al. 2014]
Internet of Things	Is one of the fastest growing trends. It applies to equipping devices and commonly used items with communication modules to transfer their functionality to the network. IoT solutions include: Internet of Everything (IoE) which consists of Internet of Service (IoS), Internet of Manufacturing Services (IoMs), Internet of People (IoP), an embedded system and Integration of Information and Communication technology (IICT) [Neugebauer et al. 2016]
Cyber security and Cyber Physical Systems (CPS)	Decentralization and autonomous behavior of the production process are main characteristics of CPS. The evolution of CPS mainly depend on the adoption and reconfiguration of product structures Supply Networks considered as Collaborative Cyber physical systems which are used in Manufacturing systems as well as different cyber physical systems like city traffic control and control systems he trend is developing due to the need to secure ICT systems that are becoming more open and accessible to a large number of users. It is particularly important to secure Collaborative Cyber Physical systems that connect the real world with the technical one. These systems are widely used in the production and control of road traffic [Ivanov et al. 2016]

	With the increased connectivity and use of standard communications protocols that come with Industry 4.0, the need to protect critical industrial systems and manufacturing lines from cyber security threats increases dramatically. As a result, secure, reliable communications as well as sophisticated identity and access management of machines and users are essential
The Cloud	Cloud-based IT-platform serves as a technical backbone for the connection and communication of manifold elements of the Application Centre Industry 4.0 The trend is developing due to the need to secure ICT systems that are becoming more open and accessible to a large number of users. It is particularly important to secure Collaborative Cyber physical systems that connect the real world with the technical one. These systems are widely used in the production and control of road traffic [Ivanov et al. 2016]
Additive Manufacturing	With Industry 4.0, additive-manufacturing methods will be widely used to produce small batches of customized products that offer construction advantages, such as complex, lightweight designs. High-performance, decentralized additive manufacturing systems will reduce transport distances and stock on hand A growing trend in connection with the smart-factory concert. Additive-manufacturing methods are used to produce small batches of customized products that offer construction advantages, such as complex, lightweight designs. [Rüßmann 2015; Landherr et al. 2016]
Augmented Reality	Augmented-reality-based systems support a variety of services, such as selecting parts in a warehouse and sending repair instructions over mobile devices. Industry can use of augmented reality to provide workers with real-time information to improve decision making and work procedures. Workers may receive repair instructions on how to replace a particular part as they are looking at the actual system needing repair Trend related to the development of cyber-physical systems. Augmented-reality-based systems can support a variety of services or production systems, by displaying various information about objects without the need for special search. Workers in factories may receive repair instructions on how to replace a particular part as they are looking at the actual system needing repair [Rüßmann 2015]

Source: Own study based on [Rüßmann et al., 2015; Landherr et al. 2016; Neugebauer et al. 2016; Ivanov et al. 2016; Stock, Seliger 2016; Schuh et al. 2014; Vaidya 2018]

The trends presented in the Table1 show the complexity of the Industry 4.0 concept. A lot of tehnological phenomena are included into Industry 4.0. World Economic Forum predicts that will occur until 2025 and have a significant impact on the development of the economy are indicated. These include: 80% of people with a digital presence on the Internet, 5% of products made in 3D, 10% of cars in the US being unmanned cars, 90% of people having access to unlimited data storage, 10% of people wearing clothes connected to the Internet, 1 trillion sensors connected to the network, 30% of corporate audits carried out using artificial intelligence, 90% of the population using a smartphone, and 90% of the population with Internet access [WEF 2015]. The quoted data show the scope of challenges posed by ICT projects, and represent huge prospects for the development of the sector.

These activities, however, require significant capital, and even under stable conditions are subject to great risk. The question then arises whether these perspectives will not be significantly disturbed in connection with the crisis associated with the COVID-19 epidemic.

It should be emphasized that the emerging crisis is not the first situation of this type that can be observed during the last twenty years. The first of such events, strongly related to the ICT sector itself, was the crack in 2000 of "Internet bubble", which caused an avalanche of bankruptcies of ICT enterprises (e.g. the American operator Worldcom). This led to an overall decline in stock exchange rates and collapse in non-ICT industries as well. It is estimated that this crisis has led to the elimination of around one million jobs worldwide and decapitalization of the US stock market by around $ 2 trillion. After only a few years, the ICT sector - mainly due to telecommunications - has overcome the collapse. Another crisis that began in the US in mid-2007 due to the risky use of sub-prime mortgage loans on the financial market, hitting the entire global economy also had an impact on the ICT sector being analyzed [Lombard 2009]. The decade was even named by Angela Merkel as the "lost decade", which in her opinion meant that it takes 5 to 10 years to restore economic growth before 2008 [http://www.ekonomia24.pl/artykul/…, date downloads: 21.11.11]. Nowdays, Compared to 2019, Thomas Meyer, IDC's CEO in Europe, emphasizes that the stagnation in the ICT sector during the 2007-2008 crisis was significantly greater [IDC 2020].

Industry 4.0 trends in ICT Sector– Research Results

Trends indicated in the Table 1 were verified in empirical studies that was conducted from April 10-17, 2020 and involved in-depth interviews with 52 managers representing 20 companies from the Polish ICT sector. Share of respondents in the knowledge broken down by type of enterprise is presented in Figure 1-2.

Figure 1: Share of companies surveyed broken down by type of enterprise

Figure 2: Share of respondents in the knowledge broken down by type of enterprise
Source: own study

Respondents were asked if the chosen trend described in Table 1 was significant for their company before the coronavirus epidemic. Then they were asked whether the area of the given three was related to the implementation of projects, sale of products or provision of services. Respondents were later asked to explain scope of changes taking place within Industry 4.0 trends after the coronavirus epidemic.

Results are presented in Table 2

Table 2: Results of the research

Trend	Description
Big Data and Analytics	The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making The collection and comprehensive evaluation of data from many different sources production equipment and systems as well as enterprise and customer-management systems will become standard to support real-time decision making 19% of respondents indicated that in their enterprises the trend played a significant role in the pre-epidemic strategy. The respondents, however, expect decreases in orders. Currently, about half of the big data projects implemented by companies have been frozen. At the same time, over half of the respondents expect resumption of projects in the near future. They relate in particular to financial risk analysis. The projects, whose

	implementation was sustained, concerned modules supporting decision making and robot control in the scope of production support. Respondents also indicated that big data analyzes are used to model the course of an epidemic (one of the surveyed companies made infrastructure available to a scientific unit for this purpose).
Autonomous Robots	utonomous robots can complete given task precisely and intelligently within the given time limit and also focus on safety, flexibility, versatility and collaboratively The trend was very significant for the majority of respondents - 67%. Most enterprises also implemented projects in this field (57%) or provided services based on the work of robots (12%), 2% of the respondents provided services for providing autonomous robots for hours. In the long run, respondents even expect an increase in interest in the services they offer, because they enable the replacement of human work with a device, which allows for savings in the client's company (25%). However, most of the respondents expect a change in the scope of ongoing projects (54%). These changes relate to deferring part of the expenses for the future and focusing primarily on providing basic functionality. As an important perspective, the respondents indicated - the supply of robots to provide assistance services in hospitals at patients (transfer of patients, distribution of medicines and medical measurements).
Simulation	Simulations will be used more extensively in plant operations to leverage real-time data to mirror the physical world in a virtual model, which can include machines, products, and humans, thereby driving down machine setup times and increasing quality The trend was recognized by 32% as important, but it did not have a great impact on the current activities of the respondents. Only two companies from the surveyed offer services or products related to simulations (training simulators based on VR). The projects implemented by the companies were high-budget. Company representatives expect significant drop in orders in this type of simulators. However, one of the development companies was developing indirect cost simulation software at the client's company. Despite the epidemic, the project is still being continued.
Horizontal and Vertical System Integration	The trend was not considered particularly significant by the majority of respondents (62%). It should be emphasized that the understanding of what horizontal and vertical integration is was different. The necessity of multi-level integration of services provides and products of implemented projects was taken for granted. Taking into account the scope of conducted activities - 32% of respondents had in their strategy implementation of projects typically associated with the integration of devices and applications. None of the respondents had ever heard of the term "Horizontal and Vertical System Integration". Over half of the respondents assume significant changes in the area of integration strategy and expect significant decreases in orders in this respect. In response to what, integrators and operators are trying to develop their own cloud-based products, instead of implementing individual implementations.
Internet of Things	The trend was identified by 90% of respondents as very significant. 82% of respondents said that their strategy includes the development of IoT-related products or services, as well as implementing projects in this area. 71% of respondents confirmed that they would continue the IoT strategy also after the outbreak, but would partially change its scope. The number of implemented projects dropped significantly. The respondents estimate the decrease even at the level of 70% of the value of project portfolios, which mainly applies to smart city, POS TV and smart-building implementations. Telemedicine systems and systems for monitoring the movement of

	machines and people have gained enormous importance. 8% of respondents see a development perspective in this respect.
Cyber security and Cyber Physical Systems (CPS)	Decentralization and autonomous behavior of the production process are main characteristics of CPS. The evolution of CPS mainly depend on the adoption and reconfiguration of product structures Supply Networks considered as Collaborative Cyber physical systems which are used in Manufacturing systems as well as different cyber physical systems like city traffic control and control systems Over half of the respondents indicated that this is an important trend for their company (51%). 41% of the respondents had in their strategy directly included the development of the cyber-security area (e.g. creation of the Security Operation Center). 35% of respondents expected significant decreases in cyber security. At the same time, the importance of audit and RODO consulting services has increased. In the case of the CPS-related trend, the respondents pointed to its limited significance, only to specialist suppliers, e.g. in the production sector. Only a representative of one of the surveyed companies confirmed the implementation of the CPS project. This project was frozen in connection with the coronovirus epidemic. With the increased connectivity and use of standard communications protocols that come with Industry 4.0, the need to protect critical industrial systems and manufacturing lines from cyber security threats increases dramatically. As a result, secure, reliable communications as well as sophisticated identity and access management of machines and users are essential
The Cloud	Cloud-based IT-platform serves as a technical backbone for the connection and communication of manifold elements of the Application Centre Industry 4.0 90% of respondents considered the trend significant and had in their offer services, products or implemented projects in this area. Cloud was a very important element of business strategy. 81% of respondents said that the trend would develop undisturbed even after the epidemic in the context of the provision of SaaS services, although 70% expect a decrease in orders from the private cloud area.
Additive Manufacturing	With Industry 4.0, additive-manufacturing methods will be widely used to produce small batches of customized products that offer construction advantages, such as complex, lightweight designs. High-performance, decentralized additive manufacturing systems will reduce transport distances and stock on hand None of the surveyed companies had a trend in strategy or implemented this type of project. The trend was considered by the respondents as insignificant
Augmented Reality	Augmented-reality-based systems support a variety of services, such as selecting parts in a warehouse and sending repair instructions over mobile devices. Industry can use of augmented reality to provide workers with real- time information to improve decision making and work procedures. Workers may receive repair instructions on how to replace a particular part as they are looking at the actual system needing repair The trend was considered important but translated only into the strategy of two of the surveyed enterprises. None of the companies has implemented a

	project in this field yet. One of the enterprises saw prospects for the development of this type of systems in exhibition applications. However, this trend was abandoned due to the epidemic. Subjects were skeptical about its further development, putting it off into the distant future.

The data presented in Table 2 indicate that a large part of trends is subject to continuation, however their scope changes. However, significant pessimism has been identified in predicting the future of the sector. A surprising conclusion was the respondents' declarative rejection of continuing the Industry 4.0 development strategy in general, which, however, did not correspond to their actual activities, as is indicated by the launch of numerous projects. This discrepancy may be related to a strong focus on ongoing activities and rejection, even at the mental level, of commitment to development issues. At the same time, based on the statements of the respondents, it can be concluded that after a temporary shock related to the advent of new conditions, a new distribution of forces on the market and a new type of segmentation are forecasted. After this period, which is estimated to last for 1-2 years, there will be a further perspective of growth with the emergence of new trends. Probably it is the ability to adapt to these future trends, and not the crisis itself, that will be decisive in relation to maintaining the competitive advantage of existing leaders.

Summary

The development of information and communication technologies is one of the most important elements related to the Fourth Industrial Revolution. Trends identified within this concept stimulated the development of virtually all branches of the economy and influenced the development of various social phenomena. Due to the coronovirus epidemic, this picture was disturbed both in terms of the impact characteristics of trends and the continuation of the development of technologies themselves. In response to this problem, the article attempts to characterize the changes occurring within industry 4.0 trends in connection with the economic crisis caused by the COVID-19 epidemic. The goal of the article has been achieved. Changes occurring in the area of Industry 4.0 trends have been characterized by presenting the results of in-depth interviews with 52 managers representing 20 companies from the Polish ICT sector. Research has shown that virtually all companies will continue their pre-epidemic activities in the Industry 4.0 area. However, the scope of activities carried out will be different and minimized in some areas.

It should be emphasized that a significant limitation of the conducted research was a very large focus of the respondents on solving current problems, which hindered the discussion on the further development of companies. In addition, the Polish ICT sector is local and the impact of some Industry 4.0 trends is noted with some delay. Although the conducted research does not meet the conditions of representativeness, the presented conclusions seem to be of a directional nature.

Further research into the impact of the economic crisis caused by the coronovirus epidemic seems to be of interest from a scientific and practical economic point of view.

Abstract

The health crisis has led to a financial crisis and the various stock markets are also suffering from the virus. The consequences for the economy and individual investments are real. Therefore, our article tends to explain the relationship between the spread of the Coronavirus and the financial market behavior. To this end, we use the Non-linear Autoregressive Distributed Lag (NARDL) model. Our results, then, show that the financial market is negatively impacted by the spread of Coronavirus. Also, we note that the impact of positive and negative variations in new cases and deaths caused by COVID-19 have an impact on the values of market indexes.

Keywords : Covid-19, NARDL, Stock markets

Introduction

Stock returns always tend to spread to major events. Several studies explain these effects on financial markets, sports events (Buhagiar et al., 2018), news (Li, 2018), environment and events (Guo et al., 2020), and political matters (Bash & Alsaifi, 2019; Shanaev & Ghimire, 2019). The appearance of the new coronavirus has caused a pandemic of respiratory disease (COVID-19) for which vaccines, targeted therapies, and treatment are not available (Wang et al. (2020)).

The epidemic has caused great concern for public health worldwide. At the same time, the economic consequences are increasingly worrying, as families need to remain at home to slow the spread of the infection. In several articles, it is well indicated that the coronavirus epidemic could affect sectors such as travel, tourism, entertainment, hotels, and airlines. The fact that the spread of this epidemic has been rapid with an unforeseen rate, forced the world to undergo the lockdown and stop activities in several sectors. At the beginning of March 2020, COVID-19 had infected more than fifty times more people than the epidemic of SARS, and the situation is expected to worsen (Abadi et al., 2020). The impact of this economic "downturn" can cause damage in supply chains, household demand, and corporate financial stability.

As a result, governments and central banks have dramatically scaled up operations, and many economists are predicting a deep Coronavirus-induced recession (Schwartz, 2020). Thereby, policymakers, businesses, and market players are trying to revise growth expectations in the short,

medium, and long term. Due to the uncertainty surrounding the global COVID-19 pandemic, stock markets around the world have experienced sharp declines. According to a World Economic Forum article, two of the largest single-day declines in the history of Dow Jones Industrial Average and S&P 500 took place in March 2020, during the COVID-19 epidemic.

Previous studies suggest links between risks to human health and price equity. Unlike other different global financial markets, the literature has revealed that Chinese financial markets remain strong and stable regardless of the current COVID-19 pandemic. Xin Huan (2020, p. 1) reported this different and significant opinion on the world financial market, insisting that "the Chinese financial market remains generally stable compared to foreign markets despite the spread of the new Coronavirus (COVID-19)." However, in the United States, the market experienced turbulence, enough to push the main benchmarks to close in the red. On February 25, the S&P 500 Index fell 3%, the Dow Jones 3.2%, and the Nasdaq Composite closed down 2.8%.

The value of government bonds increased when central banks lowered benchmark interest rates and unveiled large bond-buying programs (Smialek and Irwin, 2020). Although the US Federal Reserve has also committed to buying corporate bonds, the S&P corporate bond index declined in value due to the increased credit risk among investors. Many products have also declined in value, particularly petroleum and natural gas. Gold, on the other hand, has increased in value and the US dollar strengthened against several foreign currencies.

Investors' fear is quite evident as the CBOE Volatility Index (VIX) rose 11.3% to close at 27.85, clearly indicating panic. In Morocco, the main index of the Casablanca Stock Exchange MASI lost 21.6% of its value between February 28 (last trading session before the appearance on Monday, March 2 of the first case of Coronavirus in Morocco) and March 20. Moreover, the literature on investing in an epidemic can be roughly divided into two parts. Indeed, the value of a company results from all the expected future cash flows discounted in the present to take into account time and uncertainty.

In the financial markets, a wide range of individuals meet, sophisticated and naive, obstinate and without convictions, to play a game with high stakes: the game of prices.

Thanks to a mixture of fundamental value factors and a simple dynamic of supply and demand, asset prices are emerging. The stock market is an incentive survey on expected future results. It is precisely in complex and rapidly changing situations that the Stock Exchange provides particularly useful information. However, we lack answers to some of the most basic questions about how pandemics affect the financial markets. Reinhart (2020) argues that there is "no historical episode that can provide insight into the likely economic consequences of the global Coronavirus crisis".

This study, therefore, provides one of the first large-scale empirical analyzes of the impact of the pandemic on the financial markets. This article aims to show how Coronaviruses have an impact on market indexes. We consider different periods (depending on the start of the epidemic in each country). We examine three categories of data, namely new case announcements and mortality rates, as well as several indexes from deferent country's (USA, Italy, Spain, France, China, and Morocco). For this purpose, we use the Non-linear Autoregressive Distributed Lag (NARDL) model, which allows us to explain the impact of the announcements of new cases and the number of death cases on the closing values of the flowing indexes (MASI, CAC40, IBEX35, S&P 500 FSTE CHINA A50 and FTES BIM).

Data And Descriptive Statistics

In this section, we describe the datasets used in this article. We obtain data on daily cases of COVID-19 from status reports on Coronavirus disease (COVID-2019), which have been being published daily since December 31, 2019, based on information provided to WHO (World Health Organization). The data relates to stock market indices were extracted from website investing.com and Yahoo finance. Nevertheless, the durations taken from each country are different because the starting periods of the epidemic are different. The data is structured on 6 panels: from 29/01/2020 until 15/05/2020 for the CAC40 index (FRANCE), from 21/01/2020 until 15/05/2020 for the SP500 index (USA), from 31/12/2019 until 15/05/2020 for the FTSE CHINA A50 index (CHINA), from 24/02/2020 until 15/05/2020 for the FTES_MIB index (ITALY), from 03/10/2020 until 15/05/2020 for the MASI index (MOROCCO), and from 02/11/2020 until 15/05/2020 for the IBEX35 index (SPAIN).

Figure 1: Evolution of the closing values of the MASI, CAC40, IBEX35, S&P 500 FSTE CHINA A50 and FTES BIM indices

Figure 2: Announcements of new COVID 19 cases

Figure 3: Announcements of deaths caused by COVID 19

We discover that the figures linked to the spread of the Coronavirus outside of China generate higher volatility in the financial markets, compared to those reported for China. Additionally, financial volatility increases with the number of countries affected.

Methodology

Given the objectives of this study, a linear model has two drawbacks. First, it cannot be used to test asymmetric uncertainty effects. Second, our data may contain other inherent non-linearities.

Bloom (2009) argues that at the micro-level, most companies operate near their hiring and investment thresholds and that a small positive VIX shock can affect hiring and investment, while a small negative shock may have no impact.

Moreover, asymmetric models can work better with equity data than symmetric models. Among autoregressive models, asymmetric non-linear methods can provide a better adjustment to the volatility of returns (Curto and Pinto, 2012; Dakhlaoui and Aloui, 2016).

Given these caveats, a linear model can impose unrealistic limitations and possibly lead to biased inferences (Katrakilidis & Trachanas, 2012). Recently, non-linear VAR models have been widely used to model the change of regime between the two phases of the economic cycle. In a second approach, quantile regression (QR), was applied to model the impact of uncertainty at different levels (quantiles) of a result variable reflecting the health of the economy. This article claims that the NARDL model is well suited for modeling the asymmetric impact of uncertainty. The NARDL model has three main advantages (Lahiani, Hammoudeh, and Gupta, 2016) which are directly relevant to our study.

First, it distinguishes between short and long-term asymmetries. This allows us to look for specific characteristics (for example, an overshoot) in the immediate reaction of index prices to uncertainty shocks.

At the same time, we can characterize the long-term equilibrium relationship between uncertainty and index performance. Secondly and in a related way, the methodology makes it possible to test the responses of the dependent variables regarding positive and negative changes in each of the explanatory variables (Lahiani et al., 2016).

This permits us to construct and represent the line of asymmetry. Consequently, the NARDL method is flexible to the dynamics of cointegration between variables. It can support multiple data sets of different integration orders and can be used to test linear and non-linear cointegration.

Recently, the NARDL model has been widely used to model the price asymmetry of basic products (Atil, Lahiani, and Nguyen, 2014; Bildirici & Turkmen, 2015; Kumar, 2017), energy policy (Hammoudeh, Lahiahi, Nguyen, and Sousa, 2015; Ndoricimpa, 2017), and other areas (Apergis & Cooray, 2015; Katrakilidis & Trachanas, 2012).

While it has already been used to model the price of stocks (Kisswani and Elian, 2017; Raza, Shahzad, Tiwari, and Shahbaz, 2016) and the impact of uncertainty (Gupta, Lahiani, Lee and Lee, 2018), to our knowledge, ours is one of the first NARDL asymmetry models studying the relationship between the index uncertainty and COVID-19.

Our study will test the following hypotheses

Hypothesis 1 (The damping effect of uncertainty): positive (negative) shocks cause a decrease (an increase) in the values of the indices.

Hypothesis 2 (Repressed growth potential): negative uncertainty shocks lead to greater long-term adjustments in index prices than positive shocks.

Hypothesis 3 (overshoot): negative uncertainty shocks lead to a short-term overshoot of index price adjustments.

NARDL Basic Methodology

We consider long-term asymmetric regressions of the form

$$X_t = \beta^+ UV_t^+ + \beta^- UV_t^- + u_t \qquad (1)$$

Where β^+ and β^- are the associated long-term asymmetric parameters, u_t is an i.i.d. with zero mean and finite variance, and UV_t is a decomposition of the following form:

$$UV_t = UV_0 + UV_t^+ + UV_t^-$$

With UV_0 equal to the initial uncertainty value UV_t^++ and UV_t^- representing the partial sums of the positive and negative changes in the uncertainty of the dependent variables (MASI, CAC40, IBEX35, S&P 500 FSTE CHINA A50, and FTES BIM) given by

$$UV_t^+ = \sum_{j=1}^{t} \Delta\, UV_j^+ = \sum_{j=1}^{t} max\,(0, \Delta UV_j)$$

$$UV_t^- = \sum_{j=1}^{t} \Delta\, UV_j^- = \sum_{j=1}^{t} mix\,(0, \Delta UV_j)$$

NARDL model (p, q) derived from the equation. (1) can be rewritten as follows:

$$X_t = \sum_{j=1}^{p} \varphi_j\, X_{t-j} + \sum_{j=0}^{q} (\theta_j^+ UV_{t-j}^+ + \theta_j^- UV_{t-j}^-) + \epsilon_t \qquad (2)$$

Where φ_j is the autoregressive parameter, θ_j^+ and θ_j^- are the delays asymmetrically distributed and ϵ_t is a homoscedastic process *i.i.d* with mean zero. The asymmetric error correction equation can be specified as

$$\Delta X_t = \rho \Delta X_{t-1} + \theta^+ UV_{t-1}^+ + \theta^- UV_{t-1}^- + \textstyle\sum_{j=1}^{p-1} \gamma_j\, \Delta X_{t-j} + \sum_{j=0}^{q-1} \left(\delta_j^+ UV_{t-j}^+ + \delta_j^- UV_{t-j}^-\right) + \epsilon_t \qquad (3)$$

Where

$$\rho = \sum_{j=1}^{p} \varphi_{j=1} - 1 \; et \; \gamma_j = -\sum_{i=j+1}^{p} \varphi_j \; , pour \; j = 1, \dots, p-1,$$

With δ^+ and δ^- short-term positive and negative adjustments to the changes in the explanatory variable $\llbracket UV_t$. We emphasize that the equations. (1), (2), and (3) are connected by:

$$\beta^+ = -\frac{\theta^+}{\rho} \; and \; \beta^- = -\frac{\theta^-}{\rho}$$

We implement Eq. (3) NARDL model (Shin, Yu, and Greenwood-Nimmo, 2014) in four steps. First, the error correction model is estimated via standard OLS. Second, the Banerjee, Dolado, and Mestre (1998) t-test and the Pesaran, then Shin and Smith (2001) F-test, which each apply a boundary test approach to search for long-term asymmetric relationships between the magnitudes of the variables, are used to test the null hypothesis (no cointegration) against the alternative hypothesis (cointegration). More precisely,

$$H_0: \theta^+ = \theta^- \; against \; \rho \neq \theta^+ \neq \theta^- \neq 0$$

Third, the Wald test is used to detect long and / short term asymmetries. The null hypothesis (long-term symmetry) is tested against the alternative hypothesis (long-term asymmetry). Similarly, the null hypothesis (short-term symmetry) is tested against the alternative hypothesis (short-term asymmetry).

In mathematical terms, we test:

$$H_0: \beta^+ = \beta^- \; against \; H_1: \beta^+ \neq \beta^-$$

$$H_0 = \sum_{j=0}^{q-1} \delta_j^+ = \sum_{j=0}^{q-1} \delta_j^- \; against \; H_1 = \sum_{j=0}^{q-1} \delta_j^+ \neq \sum_{j=0}^{q-1} \delta_j^-$$

Finally, the asymmetric cumulative dynamic multiplier effects of the unit change in UV_t^+ and UV_t^- on X_t , are calculated as:

$$m_h^+ = \sum_{j=0}^{h} \frac{\partial X_{t+j}}{\partial UV_t^+} \; , m_h^- = \sum_{j=0}^{h} \frac{\partial X_{t+j}}{\partial UV_t^-} \; , \quad h = 0, 1, 2, \dots \tag{4}$$

Where

$$m_h^+ \to \beta^+ \; et \; m_h^- \to \beta^- \; in \; the \; case \; h \to \infty$$

Long-term symmetry is implied by equality between long-term multipliers

$$L_{UV^+} = \frac{\theta^+}{-\rho} \; et \; L_{UV^-} = \frac{\theta^-}{-\rho}$$

Hypothesis Tests

The methodology gives us the tools necessary to test hypotheses 1 to 3. Since the long-term multipliers satisfy the hypotheses, they represent the adjustments in the price of long-term equilibrium indices following positive (negative) uncertainty shocks.

Hypothesis 1 indicates that positive shocks lead to lower prices, while negative shocks lead to higher prices. This happens if and only if both L_{UV^+} and L_{UV^-} are negative and significant.

Hypothesis 2 indicates that the impacts of negative shocks outweigh those of positive shocks. This can only happen when the Wald test indicates significant long-term asymmetry. (Otherwise, the difference in magnitude observed between the long-term adjustments the positive and negative uncertainty shocks may be due to chance.)

If Wald's test is significant, then we can classify long-term asymmetry as negative, which means that stock prices have a stronger reaction to decreases in uncertainty ($L_{UV^+} | L_{UV^-}$) or positive. Accordingly, this implies that they respond more strongly to the decrease in uncertainty.

Hypothesis 3 indicates that during the reversals, the prices of the indices show a short-term overshoot. This can only happen if the Wald test indicates significant short-term asymmetry.

When the Wald test is positive, we use the dynamic multipliers m_h^+ and m_h^- to reconstruct the line of asymmetry and determine if its short-term behavior displays the basic characteristics of the overrun.

Result and Discussions

The bounds test procedure requires that no I (2) variable can be involved. We, therefore, perform unit root tests on time series. The results of the unit root tests: ADF (Augmented Dickey-Fuller), and PP (Phillips-Perron) are at level. Additionally, the first difference of the logarithms of the stock market indices values and the announcements of new contagions and deaths are presented in table 2. Moreover, the unit root tests indicate that the different series are I (0) or I (1) and no series is, therefore, I (2). Thus, we can proceed with the bounds test and estimate by applying general procedures to reach the final specific model.

Cointegration Test

The results of the cointegration test are presented in Table 3. Based on these results (F-Bounds Test), the four variables, namely the logarithms of the closing values of stock market indices, the announcements of new cases, as well as the number of cases of death, have long-term relationships. The F-Bounds Test shows significant relationships at the 1% level for CAC40, S&P 500, and LMASI. For LFTES MIB and LIBEX35, the F-Bounds test shows significant relationships at the 10% level. While the F-Bounds of the LFTSE CHINA A50 indices are not significant. This rejects the hypothesis of the existence of a long-term relationship between the variables in the series.

Table 3: Cointegration testing

F-Bounds Test				
Index	**F-statistic Value**	**Signif**	**I (0)**	**I (1)**
CAC40	8.009223	1%	3.29	4.37

LMASI	5.178341	1%	3.29	4.37
LIBEX35	3.414096	10%	2.2	3.09

Before studying the long-term and short-term links between the indices and the different repressors, we first judge the adequacy of the dynamic specification. This is done based on various diagnostic statistics including, LM statistics and the test ARCH of heteroscedasticity. The results of these tests are presented at the bottom of Table 4.

Table 4: LM statistics and the test ARCH of heteroscedasticity

Our model surpasses all diagnostic tests suggesting the absence of autocorrelation and heteroskedasticity at a level of significance of 1% for all stock market indices.

Long- and short-run asymmetries

Table 5 summarizes the results of the Wald test for long and short-term asymmetry, respectively. The results (Table 5) suggest the existence of long-term symmetry for the LFTSE CHINA A50 index.

For the negative and positive shocks of the CAC40 and S & P500 indices, the null hypothesis according to which the variables in the series are symmetrical is rejected, which means that in the short and long term, the positive and negative partial sum of the squares is significantly different from each other and supports asymmetric behavior. For the FTES MIB, MASI, and IBEX35 indices, the null hypothesis is accepted in the long term but rejected in the short term.

Table 5: Long- and short-run asymmetries

Indice	Wald statistic	F-statistic	Proba	χ^2 Statistic	Proba

Combining our results with time series estimation, we detected evidence of asymmetric effects of increases and decreases in indices caused by new case announcements as well as numbers of deaths caused by COVID-19 in all countries; these match the indices dung beetles of our study, except China (LFTSE CHINA A50 index) which seem to differ in its reaction to new cases and deaths caused by COVID-19.

NARDL Estimates

Table 7 presents the results of the NARDL model estimates. Based on these results, we note that the estimated coefficients related to new case announcements and cases of death caused by COVID-19 are representative. Based on the AIC information criteria and Wald symmetry tests, we have selected the NARDL offset specification for each index. Therefore, the results of the long-term dynamics are presented in Table 6. They, accordingly, show that the long-term coefficients of positive and negative variations of new case announcements and death cases are negative. Consequently, the increase in COVID-19 cases has a direct negative impact on the financial market.

The results of the NARDL model estimation for the different indices indicate that new cases and death cases affect negatively the evolution of the index values. For the CAC40, the coefficients of positive and negative variations of the LCASFR and LDEATFR variables are negatively significant which confirms the negative impact of the shocks caused by COVID-19. The same results are confirmed for the S & P500, LFTES MIB, MASI, and LIBEX35 indices. Only the LFTSE CHINA A50 index is of non-significant results. This may be because China has well-controlled the situation of COVID-19, and it has well-kept the economy in general in a more stable state than other countries. We should also be aware that the countries most affected by COVID-19 have stronger shocks than the others who have had good control over the situation from the start of the epidemic.

Nonlinear Dynamics

Figure 4 presents the dynamic effects of positive and negative variations of COVID-19 on the various stock market indices. Based on FIG. 4, an asymmetric response of the stock market indices values to the positive and negative variations of the new cases of COVID-19 are confirmed. The CAC40, S & P500, and LIBEX35 results show an asymmetric and statistically significant response of the shock and negative index values for new cases and deaths caused by COVID-19. For the LFTES MIB indices, the dynamics are asymmetrical only for new cases of COVID-19. However, for MASI, the dynamics are asymmetrical only for cases of death, while for the LFTSE CHINA A50 index, the dynamics are more symmetrical. Thereby, coefficients are not significant in the results of modeling estimates.

Figures 4: Non-linear dynamics of the explanatory variables of the models

The empirical results debated above have important insinuations for investors as well as analysts and policymakers. First, we note that the impact of positive and negative variations in new cases and deaths caused by COVID-19 affects the values of the indices. Second, we prove that the stock market values are very sensitive to positive, and negative shocks that occur by COVID-19. Overall, our results confirm that in the case of an epidemic, the financial market has negative reactions linked to the evolution of the epidemic, which confirms the first hypothesis. The second and third hypotheses are also confirmed since the wall test has shown significant asymmetric impact for the short and long time runs. The last hypothesis substantially helps investors adapt their investment strategies to these changes and lends itself to a more effective decision-making policy, as it helps them to mitigate the negative impact of unforeseen events.

Conclusion

This article examines the dynamics between stock market indexes on the one hand and new cases and deaths caused by COVID-19 on the other hand, using the closing values of a set of stock market indexes. One of the contributions of our analysis to the existing literature on the relationship between the price of indices and COVID-19 consists of using the nonlinear cointegration approach called (NARDL). This approach makes it possible to examine the possible asymmetry in the short and long term. The study used data relating to the CAC40, S & P500, LFTSE CHINA A50, LFTES MIB, MASI, and LIBEX35 indices. The second contribution of this study is to examine the dependence of the values of the stock market indices on fluctuations due to epidemic situations.

Abstract

Corporate social responsibility in creating competitive advantage is currently the topic of many studies and analyses. The purpose of the paper is to provide an answer to the following research question posed by the author: Can a micro-enterprise strengthen its position in the market and achieve a market advantage by functioning according to the CSR concept? If so, how were particular fields of the enterprise's functioning designed? In order to obtain an answer to the posed research question, the author presented a method in which the Better Land online environmentally-friendly drugstore, by functioning based on corporate social responsibility principles, strengthened its market position and then achieved competitive advantage.

Keywords: Corporate Social Responsibility, Competitive Advantage, A Micro-Enterprise

Introduction

One of the objectives of enterprise management is the achievement of competitive advantage in the market. An enterprise can achieve it when it proposes its customers products or services that meet their expectations in a better way than the competition's offer. When will an enterprise be able to offer the most expected products and services to its customers? When it precisely gets to know its customers, including who they are, what are their values, what they expect from the enterprise and its products. The knowledge about customer needs and expected methods of meeting them allows for translating them into real profit. The key to success for contemporary enterprises is focusing on the customer and his or her expectations, and on building and maintaining lasting, long-term relations with him or her. Relations will constitute the basic determinant for survival, development and building competitive advantage in enterprises that will effectively respond to customer needs and expectations. Currently, it is the customers, by becoming prosumers, who increasingly pressure enterprises for them to also take into account long-term negative effects of their activity when focusing on their functioning. Corporate social responsibility (CSR), which engages enterprises in social activity, means meeting customer needs with simultaneous consideration of the expectations of other enterprise stakeholders: employees, suppliers or local communities. Furthermore, CSR allows an enterprise to achieve many benefits, which include, among others, building lasting relations with social and business partners, improving the company's credibility among its stakeholders, building a positive company image, increasing customer loyalty and consequently achieving competitive advantage.

Literature Review

The subject literature does not clearly define the CSR term. The most often referred definitions are definitions proposed by the International Organisation for Standardisation. According to the ISO 26000 standard, CSR is the "responsibility of an organisation for the impacts of its decisions and activities on society and the environment, through transparent and ethical behaviour that:

— contributes to sustainable development, including health and the welfare of society;
— takes into account the expectations of stakeholders;

— is in compliance with applicable law and consistent with international norms of behaviour; and
— is integrated throughout the organisation and practised in its relationships." The 6 core subjects listed by ISO 26000 include: human rights, labour practices, the environment, fair operating practices, consumer issues, community involvement and development (ISO 2010). The European Commission defines CSR as "the responsibility of enterprises for their environmental impact" (European Commission 2011). The deliberations in this paper are mainly based on research specifying that CSR is a product differentiation strategy (Navarro 1988, Bagnoli and Watts 2003, Siegel and Vitaliano 2007). This strategy, based on distinguishing oneself from the competition with features important for recipients, such as quality or uniqueness, can be focused on the product, sales system or customer service system (Pierścionek 2007). The differentiation can concern, for example, the product or brand model, product features, post-sale service, sales network, company philosophy, etc. The product's or service's distinctness does not necessarily have to be ascertained in a tangible manner, it can also be developed solely in the awareness of the recipients. The desired effect can also be achieved through effective marketing used for the given product or service. The implementation of this strategy improve customer loyalty, thereby providing enterprises with a greater bargaining power. A greater enterprise bargaining power results from its ability to sell at higher prices or to a greater degree products with CSR features (see, for example, Creyer and Ross 1997, Augeretal, 2003, Pelsmacker, et al. 2005, Elfenbein and McManus 2010, Elfenbein et al. 2012, Ailawadi et al. 2014, Hilger et al. 2019, Albuquerque, Koskinen and Zhang 2019). A product differentiation strategy may allow companies to establish lasting relations also with representatives of the Z generation, just entering the labour market, for whom values such as corporate social responsibility, ecology or environmental protection are very important (Korombel, Ławińska 2019a; Korombel, Ławińska 2019b; Ławińska, Korombel, 2019a; Ławińska, Korombel, 2019b). By using the product differentiation strategy, enterprises have a positive impact on the environment by providing diversified highest quality products.

Research Objectives and Methodology

The purpose of the publication is to obtain answers to the following research questions: Can a micro-enterprise strengthen its position in the market and achieve a market advantage by functioning according to the CSR concept? If so, how were particular fields of the enterprise's functioning designed? In order to obtain the answers to the posed questions, the author studied a Polish enterprise with registered seat in Leszno, the owners of which are Małgorzata Jackowska Poloch and Paweł Poloch. The marriage runs an environmentally-friendly drugstore in the form of an online shop, the offer of which includes reliable environmentally-friendly products or products that enable living in an ecological, healthy and economical manner. It is also a place for ecological inspiration, motivation for personal development and making changes in the local community. The information provided on the website of the Better Land online environmentally-friendly drugstore [Web-1], the company's Facebook page [Web-2] and other websites specifying the Better Land company was subject to analysis. The study was conducted in the first quarter of 2020.

Findings

Better Land History

Better Land is the biggest environmentally-friendly drugstore in Poland, offering environmentally-friendly products or products that enable living in an ecological, healthy and economical manner. It was established by Małgorzata Jackowska Poloch and Paweł Poloch in 2009 due to their passion for ecology, environmentally-friendly style of life and for creating innovative undertakings that change the reality for the better. Małgorzata was the originator of the business. Being an active participants of a forum devoted, among others, to environmentally-friendly cleaning agents, she noticed a huge interest of female forum members in reusable sanitary napkins which were then not available in Poland in the quantity that would meet the demand of Polish women. The women were sewing the product at home and sold it online, however the demand substantially exceeded the supply. This observation contributed to the establishment of the company and online shop, which was run solely by the owners at the beginning. The marriage started the manufacturing and sales of state-of-the-art reusable sanitary napkins under the Soft Moon brand in 2010. The first Soft Moon reusable sanitary napkins were sewn by women sewing and selling their products online. Then, the sewing of the reusable sanitary napkins

was commissioned to the Polish company called NAYA. The Better Land - the biggest in Poland professional shop with reusable sanitary napkins - was also established in 2010. Better Land encouraged KokoSi and Pupeko to sew reusable sanitary napkins (Web-1). In time, the drugstore's product offer was expanded with food stuffs, environmentally-friendly washing liquids, feminine hygiene products, cosmetics for children and menstrual cups. The owner, Małgorzata Jackowska-Poloch, was the first cup advisor in the world, providing advice to selecting menstrual cups (Web-1). In 2018, Better Land won the competition for the best environmentally-friendly online drugstore, which was organised among the Uroda i Zdrowie [Beauty and Health] magazine readers (Web-3). In the same year, Better Land also received an award in the popularity contest of Ulica Ekologiczna [Ecological Street] for the Lady Cup menstrual cup (Web-4). Over the years, Better Land and the products offered by it were repeatedly awarded in the Puchary Zero Waste [Zero Waste Cup] popularity contests (Web-5). Currently, the Better Land online shop's offer, including several thousand products (including, among others, cleaning agents, hygiene products, food stuffs, kitchen accessories, child clothing, books, office accessories), is one of the most developed offers of environmentally-friendly drugstores in Poland.

Better Land's Functioning Principles

Better Land is a part of business managed by Małgorzata i Paweł Poloch. Aside from the Better Land environmentally-friendly drugstore, they also run a wholesale business with environmentally-friendly products and are working on establishing a foundation (fig. 1).

Fig. 1: Three pillars of the activity conducted by Małgorzata i Paweł Poloch

Source: own elaboration

Better Land Philosophy

The Better Land owners have clearly defined views on their values and objectives, as well as the methods of achieving them. The main priority is the will to change reality for the better, not only by applying and propagating an environmentally-friendly life style, but also by executing and creating innovative undertakings. The company's philosophy, focused on changing the world for the better, was presented by the owners in several points (figure 2).

WITH BETTER LAND WE CHANGE THE WORLD FOR THE BETTER!

Stop Consumption	When running a shop, it is difficult to remain authentic, but everyone that knows us also knows that we do not persuade customers to make purchases by force. We tell them how to make the product on their own, how to buy something that will make buying more of something else unnecessary!
Stop Corporations!	We know for a fact that NETWORKS and CORPORATIONS WILL NOT SAVE THIS WORLD, and that the world would be better without them. Corporations and networks will be painted green in the front and will be eyeing people like us, but from the back door they will be introducing plastics, crank up the economic situation and use cheap labour, thereby destroying culture and loyalty. Network will say: we have products for Vegans, but they also have 1,000 others that featured the use and harming of animals during the manufacturing process.
We support bottom-up initiatives!	Systematically! You don't have to be a freak and you cannot get discouraged. Therefore, we support! It was a dream come true that we were able to support HelloWielo. Of course, it was also publicity for us ☺
We bet on relations!	We know that it is necessary to bet on relations with children and everyone who surrounds us. Talk, talk and talk some more. Otherwise, the voice will be given to people with bad intentions towards the Earth or that are indifferent towards it. Check out our bookshop section occasionally. As you know, we are educators and ecologists: we offer communication and values, the following of which make respect for the Earth and people become NATURAL.
We bet on honesty!	We know that you have to speak your mind, call things the way they are, but also admit mistakes and imperfection. It would be difficult to develop and change otherwise.

Fig. 2: Better Land Philosophy

The most important values of Better Land are presented in figure 3.

Fig. 3: Better Land Values

Source: elaboration based on (Web-1)

Objective and strategy

The elements of Better Land's strategy include not only increasing sales volumes, but also supporting good brands, education and changes aimed at minimising environmental impact. The objective is to be the leading centre of environmentally-friendly drugstore goods. On the other hand, the objective of the Soft Moon brand created by Better Land is to market the highest quality reusable sanitary napkins, hygienic pads, nursing pads and other accessories for women. The brand's mission is to support women self-esteem. Each product makes us remember about the greatest features of women - wisdom, sensibility, beauty. The brand's vision is: "we believe that we will support women with our products during days important to them: childbirth, lactation, period and when they need it. Because each one of us is a goddess. Each one of us is exceptional" (Web-1).

Recruitment Process

At the beginning of 2020, the company was employing 30 persons: 15 persons hired on an employment agreement and 15 persons hired on a contract of mandate. Contracts of mandate mainly apply to students, mother wanting to earn extra money and subcontractors. The owner conducts a long and multi-layered job interview, expecting the future employees to have a passion for ecology and follow values related to ecology. It is a necessary condition during recruitment for the company's key positions. The leave system forces employees to plan their two-week leaves until the end of April of each year. Such an early leave declaration allows for determining the substitutes' timesheet well in advance. Each employee receives a 30% discount for purchases and each hired woman receives a gift in the form of a menstrual cup or a set of environmentally-friendly sanitary napkins.

Selection of products for the shop's offer

The shop owners and employees are very committed to environmentally-friendly and Zero Waste activities. They test all the products they want to include in the shop's offer themselves. Only the products that pass their verification, i.e. are effective and of high quality, can be included in the drugstore's range of products. Better Land promotes brands that have real achievements in terms of environmental protection or in supporting people in need. The consistence of the approach and the fact that not all, not even the most popular brands can become part of Better Land's offer, is confirmed by the company owner: "*We seek honest manufacturers who not only can demonstrate the quality of their products, but also speak openly about the manufacturing, invite us to their laboratories, tell us about their work (…) - We don't want to market products from other continents if a similar product can be found in Europe. We rather choose small Polish workshops, the product quality of which is really high*

(…) – The message is important for us. If a manufacturer declares something and then keeps his word, he gains our trust. The case is similar for distributors. Activities in the scope of CSR, environmental protection and supporting good initiatives are important to us. Thus, our co-operation with the German Hydrophil, which not only has high-quality hygienic products, such as bamboo toothbrushes, but is also transferring a portion of its profits to a foundation dealing in providing access to water to Southern countries. (…) – I think we will always seek even more environmentally-friendly, ethical and healthy solutions. We are ecologists. The well-being of our customers is as important for us as the well-being of our planet. We believe that we can change much by our action. Join us!" (Web-3). In the given interview, Paweł Poloch emphasises: *"I check how long is the manufacturer in the market or where he is from. It is also important for us whether the given manufacturer really follows the values he declares. We don't co-operate with companies that are environmentally-friendly, because they want to make a profit on it. It is really clear – from business relation to the method of preparing a pallet, packaging, everything really. I know from experience that those who only declare being environmentally-friendly close their activity sooner or later."* (Web-6). Customers can also choose the "Zero Waste and high capacity" category in the shop's offer. This category means the ability to purchase chemical raw materials in large quantities sold in recycled and reusable packaging.

Sales Process

Better Land never used the dropshipping system. The sales process assumes that each product offered on the website is available in the Better Land's warehouse. The products are shipped immediately after the payment is credited or when the customer sends a payment confirmation. This allows us to substantially shorten the product delivery time - the purchased goods most often reach the customer the day after shipment. Each order is monitored and insured. It is necessary to note that since the beginning, Better Land has virtually never bought or used new packaging for its shipments. As much as 95% of the shipments are packaged in recycled packaging. The packaging is collected once a week from local wholesalers and stores, such as pharmacies, stationery shops and grocery shops. On the other hand, parcel paddings are made by Better Land or the company uses or the company uses the paddings sent to the company in parcels along with the ordered goods (the company uses films, foams and paper). Such a system not only enables minimising shipment costs, but also contributes to environmental protection. In 2019, Better Land estimated that the zero waste approached applied to its packaging process allowed for saving and refraining from purchasing 60,000 cardboards – so many cardboards would have to be bought in a traditional packaging process. In some cases, it is necessary to use adhesive tape and stretch film for product packaging. The company makes every effort to minimise the use of these materials and declares their complete elimination in the near future. Nearly 90% of all shipments is transported to logistics centres by bikes. The use of parcel pick-up stations and personal collection in the post office are also promoted (Web-1).

Conducting educational activity and providing financial support

Better Land is actively taking part in activities aimed at protecting the environment and local entrepreneurship. The company's flagship campaigns include, among others, the following:

1. *Appreciate local shops and regional products* – the company owners argue that there is huge strength and good in local diversity. They make an appeal and encourage to support small shops and thereby the local business, which should become competitive against commercial networks that fill the world with wastes. They link it with care for the environment and culture as well as decent employment. The quantity of wastes generated daily by a single commercial store is incomparably higher than the wastes generated by a single small shop, even if both shops had the same turnover. The Zero Waste principle will take action faster in the case of a small shop.
2. *Buy in Polish shops - support the Polish economy!* – in this campaign, the owners make an appeal to appreciate the Polish products and services as well as to promote them in social media.
3. *If you can, choose sunscreens that guarantee not being harmful to living organisms in water reservoirs* – the owners point to the huge problem related to the pollution of seas and oceans

with sunscreens and oils of swimmers, posing a direct hazard to the organisms living in them. They make an appeal to choose sunscreens certified to be neutral to seas and oceans.

4. *We say stop to the removal of particulate filters in passenger cars.* The particulate filter is a damper component, the removal of which causes substantial environmental pollution, lung diseases and cancer. The component is removed by vehicle owners for savings. The actions taken by the company lead to over a dozen press articles and TV programs. These included: Onet.pl, Nowoczesny Warsztat.

The drugstore's owner, Paweł Poloch is also actively engaged in the development of a democratic school in Poland. Until 2013, he was the co-creator of the first social democratic school in Poland called Trampolina [Trampoline] and took part in the establishment of the Democratic Education Foundation, the activity of which contributed to the formation of further democratic schools around Poland. In the opinion of the foundation members, a young man or woman knows quite well what he or she needs. Therefore, he or she should be able to decide for him or herself. Paweł Poloch emphasises that "*This will allow to prepare the child for the challenges of the contemporary world. Moreover, the child is learning responsibility thanks to the ability of making decisions on his or her own.*" (Web-7). Currently, Paweł Poloch is supporting the activity of the members of the democratic schools' initiative groups, propagating the functioning of democratic schools and supports close parenthood. Better Land's support for many organisations is a very important element of its functioning. The aid takes various forms, not only financial by transferring a portion of the profits, but also support in projects and undertakings. A portion of the profits is transferred, among others, to the Giving Birth Humanly Foundation, Bullerbyn Foundation for the organisation of the EUDEC event - the biggest and most important educational event in Poland, or for the organisation of the nationwide Close Parenthood Conference. The list of companies receiving support from Better Land is very long.

Building Relations

Communications with the customer are very important for Better Land owners. The Better Land owner's telephone number is available on the shop's website all the time. Paweł Poloch states that *"I still didn't remove my telephone number from the website. And, of course, it has its down sides, because my telephone is ringing all the time and I can't ignore it. Maybe on the other side there's a desperate mother, the child of whom has a very dry skin and all of the medicine used thus far were ineffective? Maybe the caller has a psoriasis problem and is helpless against it? We try to help such people."* Close contact with the customers does not only mean helping them in choosing the products, but also on listening to their comments and suggestions. Małgorzata Jackowska-Poloch admits that "*We get to know a lot of the products sold today from our customers. We listen to them and try to respond to their needs. People are knowledge repositories for us"* (Biokurier.pl 2019). The important role of the customers in the company's functioning is also visible in Paweł Poloch's statement during the interview. The Better Land owner responded as follows to the question of what should be the focus of a person that wants to open an environmentally-friendly drugstore: *"Contrary to popular opinion, the green industry is not the easiest. I am observing enthiusiastic establishments of environmentally-friendly shops that are closed after some time. Knowledge about the sold goods and actual interest in the green industry are surely important. Competencies related to customer services, sales, marketing, knowledge of the law related to sales, etc., are also important. However, the ability to recognise and adapt the products to customer needs is key. We provide aid in this scope to both our wholesale and retail customers. It is therefore worth having a good business partner. I think that we are such a partner for our recipients. If they ask, we always provide them with honest feedback. Companies that are open to criticism grow very well, they improve their offer and approach. It is also important to be resilient and happy of what you are doing, and I wish this to all of my partners. We have to remember that the green industry has really great customers. I love to listen. They have extraordinary knowledge and are eager to provide various ecological trivia. They also have problems that we try to solve together."* (Web-6)

The Better Land owners, in response to the question of customers on *What to do to be even more environmentally-friendly?*, formulated special recommendations for them (figure 4).

Packaging segregation!
It is very important to adequately segregate used materials. Waste sorting is very important as well.

Relay segregated packaging for further recycling!
For example, you can search your neighbourhood for a shop that deals with sending goods in packages. If it is conducting a responsible business, it will surely take you packaging and use it again. Do you have many paddings or cardboards? You can always send them to us! We will use them in our shipments.

Buy products in bulk packaging!
Rarely buy the products you use constantly. In other words, buy as much as you can at once. This way, you save time, money, consumables and generate less CO_2.

Buy consciously thoughtfully!
It is worth taking the vendor's advice on the product you want to buy, if it meets your expectations. Call us!

Order the shipment to a parcel pick-up station or personally at the post office. Such a parcel is cheaper and more economically-friendly if the customer picks it up by bike or foot.

Fig. 4: Recommendations formulated by Better Land owners *What can we do to be more environmentally-friendly?*

Source: own elaboration based on (Web-1)

Respect for other people is very important for Better Land owners when building relations with customers. This was confirmed with a situation that occurred during the shop's functioning *"A woman called once with complaints and she yelled at our pregnant employee who was concerned with the entire situation. Paweł did not trivialise this. He called the customer and told her that her behaviour was unacceptable and he does not wish her to talk to his employees that way"* (Biokurier 2019).

Better Land owners also try to keep close relations with their suppliers. This allows them to notice when something is not right and the co-operation must be stopped. This results from the fact that the company takes responsibility for what it sells and wants to deliver high quality products. Each co-operating company is under observation – it receives support from Better Land when necessary or the co-operation is stopped when it is not based on Better Land owners' values. Shop owners effectively pressure manufacturers and suppliers to make zero waste changes. It were the comments of Better Land owners that made the Italian Anthyllis brand, among others, to decide to market children products in glass packaging (Biokurier 2019).

Summary

The Better Land enterprise achieved success – from the time of its establishment in 2010, it consequently strengthened its market position to achieve competitive advantage. Currently, it is the largest environmentally-friendly drugstore in Poland and employs 30 persons (at the beginning, only the owners were managing the drugstore). The Better Land brand is recognised and respected among customers and by many websites or organisations, which is confirmed by numerous awards and

distinctions. A number of factors contributed to this. The owners, even before the company's establishment, had a very clearly defined need to change the world for the better, which they aptly expressed in the *Better Land* name. The shop owners' passion for an environmentally-friendly life style and for developing initiatives that change the world for the better are reflected in their business. The Better Land environmentally-friendly drugstore is not only an online shop with environmentally-friendly products, but also a place of education with ecological inspirations and incentives for self-development, taking care for the natural environment and local community.

Table 1: CSR in the Better Land business fields

Element of company functioning	Description
Philosophy	Clearly specified, covering socially responsible activities
Values	Clearly specified, covering socially responsible activities
Objective and strategy	Transparent, strongly correlated with corporate social responsibility
Recruitment process	Executed personally by the owner. Persons are employed based on similar values and their passion for ecology and environmental protection.
Relations	They are a very important element of the company's functioning. Relations based on trust, they are built with all of the company's stakeholders.
Process of selecting products for the offer	Very restrictive, scrupulous selection of products for the shop's offer. The drugstore's offer can only include high quality products manufactured by socially responsible entities.
Sales process	Consumer-friendly prices, very quick processing of orders and scrupulous selection of products checked in terms of quality and expiry date prior to shipment. Each transaction is monitored and reaction to a complaint is instantaneous. Complaints are most often recognised for the customer's advantage. The limitation of the negative environmental impact is executed through zero waste for shipment packaging which is most often acquired from the local community.
Social objectives	Large engagement in the development of the local community through substantive and financial support of environmental protection initiatives. The educational activity is executed on a broad scale, through propagation and co-creation of democratic schools and financial support of the foundation, among others. Propagation of the environmentally-friendly concept, healthy and economical life style.
Environmental protection	It is a priority, which is included in the philosophy, vision, strategy and selection of products in the shop's offer, in choosing business partners, educational activity and activity supporting local initiatives.
Profit division	Most profits achieved on commercial activity is allocated for developing other initiatives focused on innovations, social problems and improving reality.

Source: own elaboration

The concept of corporate social responsibility, with which the company owners identify, constituted the foundation for formulating the company's objectives and strategy. This in turn allowed for translating the CSR principles on the methods of achieving the objectives specified in the strategy and on particular processes (table 1). The functioning according to the CSR concept greatly contributed to strengthening the Better Land company's position in the market and achieving competitive advantage. Virtually all of the enterprise's fields of activity were designed to enable implementing the CSR principles. The CSR allowed Better Land to diversify its products, the sales process and building relations with stakeholders. The CSR allowed Better Land to differentiate its services from those of its competitors – customers choosing Better Land can be certain that the company, in every area of its operation, operates on the market in a socially responsible manner.

Abstract

This research aims to study the application of industrial environmental management in shipyards. first, by identifying parameters that affect the implementation of industrial environmental management obtained based on literature studies. Second, analyzing the situation in the sample shipyard by using predetermined parameters, namely the production process, company management and environmental management. Third, formulate a strategy for implementing industrial environmental management in shipyards. Based on the analysis conducted, it was identified that the shipyards that were sampled by researchers had deficiencies in several aspects viz. energy saving activities, use of water resources, waste management, and lack of several aspects of existing environmental standards. The overall rating of the PROPER criteria raised is still in the red category. These deficiencies are then analyzed by researchers to formulate strategies to meet the parameters of the application of industrial environmental management.

Keywords: Management, strategy, knowledge, industry, Shipyard

Introduction

The environment is a place occupied by living things together with living and non-living objects in it (Haryanto MP, 2018). From this understanding, it can be concluded that the environment consists of two components, namely components (biotic) and components (abiotic) and within these two components there is a reciprocal relationship that can influence and the dependence of one another. This means that living things will affect the environment, and likewise with changes in the environment it will affect the lives of living things.

Industry is the activity of the economic branch of a company or business entity of the like where a person works. Large industries are companies that have 100 or more workers. A small industry is a company that has 5-19 workers. Home Industry is a household handicraft business that has 1-4 workers. The current industry is a company that has workers between 20-99 people (BPS, 2012). An advanced industry is an industry that develops by implementing a system of sustainable development (sustainable development) which is a strategy in ensuring the sustainability of the lives of future generations by paying attention to aspects of the sustainability of resources and care for the environment (Chen, et al., 2015).

The aim of sustainable development is to achieve ecological, economic, political, social and cultural success and prosperity with the principle of participatory equity with all forms of diversity in an integrated manner with a long-term perspective by optimizing existing resources in a sustainable manner (Harris, 2000). The parameters contained in sustainable development support the development of Indonesia that wants to achieve the MDGs (Millennium Development Goals). By contemplating a

sustainable development system the environmental management strategy in the shipyard industry can be applied by analyzing the initial conditions of the shipyard.

Over the years environmental degradation has increased in all areas including in the maritime industry, characterized by climate change, increased airspace, and disturbance to ecosystems due to decreased biodiversity of flora and fauna, including social problems caused (Wihaji, Achmad, & Nadiroh, 2018). In the maritime industry, the shipyard industry is one of the main supporting factors that become a reference to developments in the maritime world. Then there will be more shipyard industry in Indonesia over time. The shipyard industry not only handles the field of ship building, but also is engaged in ship repair, maintenance and modification.

Shipbuilding is an industry in which the process of transformation of inputs in the form of materials (fiber glass, wood, steel, rubber, etc.) becomes a whole that can be in the form of ships, or offshore buildings and other floating structures. Shipyard industry is an industry that is classified as Product Oriented or Job Shops production (Storch, 1995). Product oriented or job shop production suati can often also be referred to as an industry that works based on quantity or volume orders. The type of shipyard that does the construction of new ships is always in accordance with orders from the owner While the orientation of new buildings and repairs is a multi-function shipyard that is able to make new shipbuilding as well as maintenance / repair and modification of ships (Ahyati, A. 1996).

The shipyard industry can build various ships for government agencies in Indonesia, individuals and others including shipbuilding orders from abroad. Its products can be produced among other things: tankers, passenger ships, cargo ships, etc. Because it causes the shipyard industry to be an industry that uses quite large natural resources. On the other hand, the limitations of the availability of natural resources and the limitations of the carrying capacity of the environment in receiving industrial waste and emissions, so to develop an industry that is guided by the sustainability of economic, social value and protection of environmental quality must be done immediately.

Picture 1: Shipyard PT.X

(Source: Researcher, 2019)

Based on RI Law No.32 of 2009 concerning Environmental Protection and Management article 1 paragraph 3 that sustainable development is a conscious and planned effort that integrates environmental, social, and economic aspects into development strategies to ensure environmental integrity and safety, ability, welfare, and quality of life of present and future generations, living in harmony with the natural surroundings, with fellow humans (Marthinu & Nadiroh, 2018). Because of this the application of environmental management in the shipyard industry must be applied because the shipyard industry plays an important role, especially in terms of repairs and construction of stinky ships (Abdul & Heri, 2016). Industrial confusion management is management which in the production process prioritizes the effectiveness and efficiency of sustainable use of resources so as to harmonize the development of the shipyard industry.

Methods

The research method used in this study is a qualitative method with a focus on aspects of the production process, company management, environmental management. the production process is an aspect which explains therein everything related to the process of production, including supporting materials and raw materials, the use of energy and water, technological processes, products, work environment and human resources. The aspect of company management is an aspect in which all business fields that have been carried out by the company management in leading to the concept of sustainable industry include management systems, rewards and efficient production. The aspect of environmental management is an aspect in which all fields of business that have been carried out by the company in the framework of environmental and waste management include the fulfillment of quality in the environment of the shipyard industry.

The analysis of the initial conditions of the shipyard industry is carried out by researchers based on the implementation of environmental management of the shipyard industry. Shipyard which is used as material for the implementation of environmental management of the shipyard industry is one of the shipyards in Indonesia that has been serving projects from the government and the private sector, hereinafter referred to as shipyard X. Shipyard X is included in the most basic shipyards located in Indonesia with land that is in Indonesia. quite extensive, quite a lot of employees and included in the pilot private shipyards in Indonesia.

Result and Discussion

In the aspect of the production process it is known that there is no effort made by shipyard X in the use of raw materials / auxiliary materials from waste but the raw materials used do not use raw materials that are prohibited in their use. Shipyard X strives in optimizing and minimizing the use of raw and auxiliary materials which have been carried out strictly for the use of raw materials. Verification from the planning stage to its use must be undertaken before making an order or taking raw materials at warehousing. In the energy aspect, shipyard X has no incentive to use new renewable energy (EBT). But in the shipyard there are efforts in carrying out energy efficiency by means of an appeal to divisions that use high energy.

The use of energy for industry has been restricted. In Shipyard X, the majority of energy use uses electricity, so the limit is the maximum energy usage per year. In the use of water, shipyard X has no effort in implementing programs related to the maintenance of the existence, nature and function of water resources. In addition, there is no implementation of the water quality management program and there is no audit of water use by the shipyard which causes the use of water in the shipyard to become uncontrolled.

Likewise with the human resources who work on shipyard X have never gotten an increase in capacity for HR related to clean production, environmental management, K3, energy conservation, 3R, total quality management, six sigma, and so forth. The application of K3L to shipyard X is in accordance with Kepmenaker No. 51 of 1999 which has been carried out despite the disadvantages such as the level of humidity in the workroom and lighting. In Galangan X, there is no specific policy from top management regarding the application of production efficiency. So that the production process at this shipyard is running as is.

The development program in shipyard X regarding the implementation of CSR has been routinely implemented and managed every year. Galangan X divides the CSR program into two parts, namely the partnership program and Community Development. For the Environmental Development program, Galangan X has increased competencies with scholarships, training, becoming sponsors of sports such as football, opening places for students or students, field work practices, medical improvement for mosques. As for the partnership program, Galangan X does this by providing or providing capital to SMEs, equipment assistance for SMEs and also monitored its progress every 2/3 months to support the shipping of Galangan X will fully support.

The parameters regarding the quality standards of liquid waste, gas and dust are already owned by Galangan X, although not given in full, especially regarding the parameters of liquid waste. Evaluations regarding the fulfillment of environmental quality standards are also carried out every six months. Integrated business in Shipyard X related to segregation, reduction (minimization), handling (handling), utilization, treatment of waste and emissions in the shipyard environment is still lacking or nonexistent. Likewise with proper activities which are a mandatory agenda of the Ministry of Environment and is a policy of the government to improve the performance of the company's environmental management which has been followed by Shipyard X.

Equipment at Shipyard X that requires electrical energy does not get technology updates. This has an impact on electricity consumption being higher than the same equipment with newer technology. Shipyard X does not have a special program on saving water use. This causes no control on its use. In addition, there is also no audit regarding water use. There is no training to increase human resource capacity related to the results of clean production, environmental management, energy conversion, K3, 3R, total quality management, six sigma, and so forth. For the application of HSE, there are also many obstacles, namely lack of supervision. So some workers do not comply with K3L well. Lack of policy from top management towards efforts to implement shipyard industry management. This can be seen from planning to production activities as usual or not in accordance with applicable regulations.

Table 1: Investment value of implementing an environmental management strategy

Aspect	Strategy	Investment Value (Rupiah)	Savings (/Month)
Energy	Solar Panel	2.065.500.000,-	114.276.000,-
Air	Saving Machine	375.000.000,-	11.210.000,-
Industrial Environment	Green roof	1.000.000.000,-	
Heavy Equipment	Usage Time		
	Planting	87.500.000,-	
Total Investment		3.528.000.000,-	125.486.000,- /Month

For the application of an environmental management strategy to be more economical, the return on investment should not exceed 15 years. 15 years is the ideal time because the company will benefit from the investment already spent. One way to make the investment return time faster then what needs to be done is to impose a portion on the production results, namely the ship. Loading of this ship can be different from other shipyards. It really depends on the capacity of the shipyard. The increase in ship prices is due to some strategies that have no impact on savings. The strategy does not have an impact on the savings obtained because the strategy focuses on environmental management such as the use of green roofs, planting and making biopori holes. The increase in ship prices is expected not to reduce the shipyard's competitiveness because it directly has an added value in environmental management. Besides this value does not really affect the overall price of the ship whose value is much higher.

Conclusion

This research shows that the management of the shipyard industry environment needs to be implemented. Starting with regulations from the government that must be met with sanctions that will be accepted if not implemented. The importance of lighting the industrial environmental management in shipyards is because several shipyard companies in Indonesia have implemented strict regulations but still do not get maximum results like shipyard A which always gets a red PROPER every year. Knowledge about industrial environmental management in shipyards needs to be deepened as one way to change behavior in shipyard activities. Thus, shipyard industry activities related to environmental security will be a ladder to a sustainable shipyard industry.

Fourth Industrial Revolution from The Perspective of Generation Z Representatives - Evaluation of Selected Aspects

Joanna GAJDA

Czestochowa University of Technology, Czestochowa, Poland
joannagajda@vp.pl

Abstract

The paper comprises a theoretical and an empirical part. The theoretical part includes an attempt at analysing the main premises of the fourth industrial revolution based on studies of Polish and foreign literature. Next, characteristics of Generation Z are presented. Generation Z has already marked its presence on the labour market and will become its driving force in the years to come.
The primary goal of the empirical part is to identify the remarks, forecasts and expectations guiding the employees that belong to Generation Z with respect to certain aspects of professional work in the era of the fourth industrial revolution.

Keywords: Fourth Industrial Revolution, Generation Z, Labour Market.

Introduction

Technological progress is an inseparable element of a society's development and exerts impact on the sphere of socio-economic life. If transformations in technology permeate a number of areas of life and exert a positive mark on production (starting from technology and ending with new products and commodities) or on consumption (within a broad meaning, understood as overall behavioural aspects), then we can talk about a revolution. Along with introduction of the term industrial revolution to literature for the first time in 1884, after discernment of the first one of 1760, four revolutions have been listed to date (Olender-Skorek 2017, p. 38). Nowadays, we are dealing with the fourth industrial revolution, which has changed basically every aspect of life. Three prior ones were primarily limited to industry (Bulak 2020, p. 78). There is no unanimous answer as to the degree to which the society will be able to make use of the opportunities brought by the fourth industrial revolution. A positive approach to changes and readiness to implement them is of key importance. The purpose of the paper is to analyse the fourth industrial revolution and to present expectations of representatives of Generation Z with respect to changes that are related to 4.0 economy in the realm of professional work.

Concept and Essence of Fourth Industrial Revolution

In relation to the growing proliferation rate of ICT, the approaching phenomenon of the fourth industrial revolution is talked of more and more frequently. It constitutes a compilation of three independent elements: the real world of production machines, the virtual world and the information technology. The phenomenon is becoming increasingly clear and the already happening industrial transformations initiated by new technologies are called the era of Industry 4.0 (Industry 4.0 or, less frequently, Digitisation 4.0), (Olender-Skorek 2017, p. 41). The characteristic feature of the new revolution is quality and speed of information flow, which often causes numerous problems related to the analysis of a huge quantity of information. The factor distinguishing man in such difficult situation is the ability to design machines which are going to help with this process and which support or even substitute man. This is the core of this revolution. Entities that are involved in production more and more frequently decide to introduce higher automation in their companies as machines are capable of processing greater volumes of data than people. This calls for an increase in the demand for qualifications and digital competence along with specialisations when ensuring high flexibility and production efficiency in a rapidly changing technological environment.

J. Gracel and M. Makowiec singled out four technological trends that drive the Fourth Industrial Revolution and significantly contribute to the changes on the labour market. The first refers to an enormous increase in the quantity of data, computing capacity and connectivity. The second trend is related to the emergence of analytical tools from the Business Intelligence segment that offer the possibility of processing data and drawing conclusions on their basis that facilitate decision making in business, without the necessity of relying on intuition. The third trend encompasses new forms of interaction between man and machine (tactile interface, augmented reality or virtual reality). The fourth trend is a facilitated process of transferring digital instructions to the physical world (advanced robotics and 3D printing), (Gracel, Makowiec 2017, pp. 105 – 125).

This context features a question about the employment prospects at the time of the fourth industrial revolution. Nowadays, forecasts related to the appearance of Industry 4.0 are diverging. Some mention reduction of work positions or FTEs, which means that a specific number of positions will be liquidated, whereas other predict an increase in employment.

Sceptics voice fears with a vision of factories dominated by robots installed on a mass scale. Work automation is slowly pushing professions the performance of which relies, to a significant degree, on routine and repetitive activities, out of the market. Smart software is an element supporting the manufacturing process of a new product (W. Schmitz 2015, p.6). This situation carries an increased risk of unemployment caused by maladjustment of qualifications to the requirements of created work positions and induces the necessity of adapting to the changing conditions in the environment (Bulak 2020, p. 83).

According to positive forecasts, machines will not replace man in specialist situations. They will not be capable of meeting the demands in the sphere of creation or construction of new inventions. A positive impact of 4.0 industrial revolution is pointed out with respect to the formation of such work environment where man plays the key role. There is talk about maintaining or even increasing employment. J. Bendkowski, relying on studies of numerous companies with respect to opportunities and threats brought by the fourth industrial revolution, notes the positive impact of this concept. Boston Consulting Group forecasts an increase in employment by 6% in the perspective of the next 10 years. Growth in employment is related to a high demand for qualified employees (Bendkowski 2017, p. 25). It follows from the analyses of Roland Berger that in spite of reduction in employment caused by the advent of the fourth industrial revolution, one should expect a positive net effect for employment. It is anticipated that as a result of implementation of approx. 50% of 4.0 industry solutions in the Western European countries, 8.2 million work places will be lost by 2035, which may be neutralised by creation of almost 10 million new ones (Götz, Gracel 2017, p. 224).

Enterprises are becoming increasingly aware of the fact that their competitive advantage is significantly determined by proper selection of highly qualified personnel. Activities aimed at raising qualifications of the employed personnel become necessary, and this will definitely result in an increase in outlays on trainings that the employers will be forced to make.

However, serious limitations in the implementation of changes related to the fourth industrial revolution concern no possibility of ensuring proper training of employees and difficulties with sourcing persons that have adequate knowledge for companies. Along with the arrival of digital transformation, employers are going to face a number of challenges, for example in the area of setting up new positions and searching for talents for 4.0 economy (7). The progress that is made in the area of technology, related to the creation of virtual reality or in the area of artificial intelligence, is not without impact on a change in the competence model of employees. Today, one cannot doubt that competence models may be assigned to a specific group of positions or specialisation. Major issues include the necessity of developing competence as part of another area than the one to which the performed work refers. One may notice permeation of numerous professions and the fact that competence of one professional profile turns out to be necessary in another one. When examining the issue of work skills, it must be stressed that both hard competence (technical and cyber-technical), as well as soft one (creativity, ability to reason logically and analyse data) become essential (1). According to McKinsey, transformation towards industry 4.0 induces the necessity of development of

specialisations resulting from performance of advanced technological processes and should cause an increase in professional activity, which may be stimulated by establishment of new platforms conducive to the formation of competence, as well as the possibility of remote performance of work (Mc Kinsey 2016). 4.0 economy will impose the requirement of adjusting to changing conditions, readiness to expand knowledge and acquire new professional experiences on the employees. It follows from the above that a linear professional path will cease to exist. A future employee will be characterised by a capacity for multitasking. Using the experiences and knowledge from various disciplines as a result of a change in the profession, he/ she will be capable of performing various projects (4).

Generation Z: Characteristic Traits

Employees who belong to Generation Z have been marking their presence on the labour market for a while. It is assumed that Generation Z are persons born after 1994, i.e. in years influenced by a rapid technological progress (Gajda 2017, p. 161). Since early years, they had the possibility of using computers with Internet access. Thus modern technologies are their natural environment. The world without the Internet is abstract for them. For Zets, the cyber-space has its reference to the real space which results in the fact that they do not feel hesitant about posting information about themselves on-line (Pandit 2015, pp. 17-18). Representatives of Generation Z experience difficulties with functioning outside of the Internet, which is manifested by the loss of contacts with people surrounding them and lack of ability to focus attention, as well as neglect of everything outside of the Internet (Stillman, Stillman 2017). On account of being constantly on-line, they narrate their lives on social networking media, they communicate via messengers and willingly read e-books. Based on the observations of representatives of this generation, it may be concluded that they are capable of performing several tasks simultaneously. Holding a conversation whilst simultaneously composing an e-mail is not problematic for them. They are characterised by the ability to divide attention. Furthermore, they are considered a generation that cannot focus on one task for an extended period of time and in relation to this, it is quite difficult to attract their attention sufficiently strongly to prevent them from doing something else (Gocłowska 2019). Due to this, the concept of multi-tasking is frequently applied to this generation. It is to be noted that multi-tasking that consists in moving from one task to another one is sometimes incorrectly understood as the ability to divide attention (Suchorabski 2017). Some researchers warn against work in a multi-tasking mode, claiming that it offers only a semblance of efficient work. The opponents of multi-tasking indicate that even if somebody is a productive person, it is impossible to focus attention on several things at once for an extended period of time and due to this, the quality of performance of each of them drops. Facing a number of tasks and wishing to perform them at the same time, it is impossible to carry them out accurately. Reality often shows that employers set increasing demands for subordinates. As a result of a rapid development of technology, people do not keep up with the changes that are taking place (Grzegrzółka 2018). In spite of it, they are trying to reach for various solutions in order to adjust to the current market conditions. Thence the idea of applying multi-tasking as a tool used for more efficient boost of the employee's potential.

More optimistic authors claim that the use of multi-tasking at work may turn out to be valuable. It will allow the young generation for efficient functioning in the reality that surrounds it, where quick and efficient flow of information is necessary and tasks required by the employer have to be performed reliably and precisely. According to the proponents of multi-tasking, for Generation Z to face the requirements set for it, it needs the ability to select among difficult tasks, tasks requiring concentration and minor partial tasks with a smaller degree of difficulty which do not require greater attention from them.

In compliance with an expert opinion, representatives of Generation Z would like to fulfil their dreams about a stellar professional career immediately, without any effort. They often find it difficult to cope with the vision of a long-term pursuance of individual professional career step by step (Dolot 2018, p. 290). They cannot be bound to a company for an extended period of time if their expectations have not been fulfilled and if they were not guaranteed the space for independence and realisation of own ideas. They are willing to commence work not only in Poland, but also abroad, as

knowledge of foreign languages facilitates their mobility. What the older generation sees as a threat is an object of fascination for Generation Z and a field for experiments. They do not attach great importance to stability at work, they are searching for variety and flee from routine (Hysa 2016, p. 390).

Study Methodology

The study was carried out between June 2018 and March 2019 among persons working in Poland in the Silesian Province. The goal of the study was to identify the observations, forecasts and expectations guiding the employees that belong to Generation Z with respect to certain aspects of professional work in the era of the fourth industrial revolution.

For study purposes, an on-line survey form (CAWI) available through a browser and completed independently by study participants, was used. Every participant received an e-mail invitation with a link to the survey and individual one-time access to the survey. A questionnaire was used in the study which consisted of closed-ended or semi-open ended questions (multiple-choice answers) and socio-demographic details. 820 invitations were sent to survey participants; the survey was anonymous and voluntary; 734 correctly completed surveys were sent back.

$\chi 2$ independence test was performed for the study sample. Based on the test, it was assessed whether the character of responses to the questions asked depended on age, education and industry in which the respondents were currently working. The zero hypothesis (H0) indicates absence of important dependences among presented variables, whereas the alternative hypothesis (H1) indicates presence of existing dependences. The test was carried out for a level of significance of α=0.05.

The results of analyses are presented in tables below.

Table 1: Description of Survey Sample

Age	18-20	21-23	24-26
Education			
Vocational	4%	3%	2%
Secondary	8%	6%	3%
Bachelor's degree	0%	8%	15%
Master's degree	0%	0%	50%
Industry			
IT	1%	6%	18%
Production	4%	3%	9%
Logistics	1%	4%	15%
Commerce	6%	5%	28%

Results of Survey

The fourth industrial revolution related to a dynamic development of technology in combination with other socio-economic and demographic changes will leave its mark on the labour market in the course of the nearest decades. The tables below present remarks, opinions and forecasts of Generation Z employees with respect to changes that are related to economy 4.0 in the realm of professional work.

Table 2: Opinions of Generation Z with respect to prospects of employment in the era of economy 4.0

	Liquidation of jobs	Keeping employment on the same level	Increase in employment of highly qualified labour force
Age			
18-20	48%	37%	58%
21-23	60%	37%	62%
24-26	20%	6%	53%
χ^2	93.90	120.69	3.82
Hypothesis	H1	H1	H0
Industry			
IT	11%	31%	88%

χ^2	56.72	22.57	111.00
Hypothesis	H1	H1	H1

Source: author's own study.

The received study results will be presented on the basis of occurrence of statistically significant dependencies between the forecasts and expectations of young respondents in the area of the fourth industrial revolution and variables pertaining to age, education and industry in which they work. One of the factors differentiating the received results is the respondents' age. Persons representing Generation Z aged 21-23 clearly articulate their opinions (60% of indications) forecasting that in the course of the next decade, due to automation and digitisation of production processes, jobs may be liquidated, whereas employees who do not occupy specialist positions will be the most affected. IW Köln studies confirm the findings above and lead to a conclusion that in the case of Germany, one-tenth of enterprises expects that development of 4.0 industry will in reality contribute to a reduction in the number of jobs. The fourth industrial revolution encourages changes in the area of business management and sets the requirement of expanding own competence and acquiring a competence mix for the employees (soft and hard). Based on the survey above, it is impossible to determine precise consequences in the context of professional work (2).

An identical level of indications is observed among persons aged 18-20 (37%) and persons aged 21-23 with respect to employment staying on the same level. According to their remarks, the factor conditioning retention and further guarantee of work places on the hitherto level is investing in skills of employees which will allow for avoiding disruptions on the market in a long-term perspective. Similar findings follow from studies carried out by E. Voss and H. Riede. In the on-line survey for ETUC devoted to the effects brought by 4.0 economy, the most important possibilities indicated by the highest percentage of respondents (45%) included, in the first place, establishment of new work places (engineers/ IT specialists, scientists, network specialists, etc.). It is worth drawing attention to the fact that such possibility was pinpointed most frequently by study participants in Southern Europe (51%) and less frequently in Central and Eastern Europe (38%). The ETUC survey revealed significant differences among countries with respect to perception of possibilities on the national level: 56% of respondents in France and 50% of respondents in Spain indicated the potential of digitisation related to the creation of jobs as one of the most important opportunities, whereas in Denmark this opinion was shared by only 22% of respondents (Voss 2014, pp. 15 – 16).

It was noted that a variable significantly correlating with responses in this part of the survey is the industry where the respondents work. Positive impact of the fourth industrial revolution on the labour market is indicated by young people from the logistic industry (93% of indications) and IT (88% of indications), who expect an increase in employment of highly qualified labour force. They believe that extensive employment prospects are opening up for graduates of electrical engineering, automatics, robotics and electronics; furthermore, such employment is going to be stable and more and more attractive financially. According to the opinions of 57% of representatives of the young generation from the production industry, the level of employment will diminish. They explain this conviction by the fact that robotisation and automation of manufacturing processes is going to translate to a growth in productivity and simultaneously will contribute to emergence of situations where enterprises will have smaller demand for employees. IT industry employees (31% of indications) perceive a possibility of keeping the employment on an unchanged level, provided the requirement of qualification raise is fulfilled. There are substantial differences in views in the context of the discussed aspect between employees from the IT industry (31% of indications) and commercial industry (1% of indications) on the level of 30 percentage points. The optimism of IT industry employees in the context of changes on the labour market in the era of economy 4.0 should not be surprising, as it follows from the fact that they are practising the profession of IT technicians. According to young respondents from the IT industry, the greatest field of knowledge used as part of the fourth industrial revolution is information science, given that the majority of solutions relies on it.

Taking the next criterion from the list into account, namely education, it must be claimed that respondents with vocational education (62% of indications) as opposed to persons with master's degree (21% of indications) perceive a possibility of reduced employment in a 4.0 enterprise. Anxiety about the future at work results from a conviction that simple work will be performed by robots, whereas modern manufacturing systems will require the employees to acquire new skills. Respondents note disappearance of certain simple tasks performed manually and emergence of new jobs that require competence that has been rarely encountered to-date. A low percentage of people with secondary education (12% of indications) and tertiary education (11% of indications) as compared to the group of respondents with vocational education (32% of indications) believe that employment will be kept on the same level. The results above testify to low awareness of employees with vocational education about challenges that are brought by the technological progress. Opinions of well-educated respondents do not instil optimism as they assess their skills as insufficient. According to the assessment of respondents with master's degree (67% of indications) and respondents with bachelor's degree (66% of indications), only employees with an interdisciplinary approach to technology will find their place in a 4.0 enterprise, e.g. employees who have knowledge and practical skills from various areas of engineering and technical sciences.

Table 3: Opinions of Generation Z with respect to the role of man in a 4.0 enterprise

	Cooperation between man and machine	Machines (robots) will fully replace humans	Qualified employees will assume control over all operations in an enterprise
Age			
18-20	91%	46%	65%
21-23	59%	37%	40%
24-26	76%	11%	14%
χ^2	31.00	87.31	124.37
Hypothesis	H1	H1	H1
Industry			
IT	94%	12%	31%
Production	85%	39%	38%
Logistics	70%	26%	34%
Commerce	61%	14%	11%
χ^2	70.26	44.48	49.67
Hypothesis	H1	H1	H1
Education			
Vocational	62%	28%	30%
Secondary	69%	36%	32%
Bachelor's degree	68%	25%	30%
Master's degree	82%	11%	19%
χ^2	22.91	43.59	13.88
Hypothesis	H1	H1	H1

Source: author's own study.

The received results showed that employees aged 18-20 (46% of indications) took a positive stance towards a hypothesis claiming that in the future, the majority of routine and repetitive tasks will be performed with the use of artificial intelligence without the participation of people. They believe that robots will start to push people out of such industries as: production, transport, agriculture, trade and mining. On the other hand, it is noticeable that as many as 65% of respondents aged 18-20 are optimistic with respect to the forecast that even though machines are quicker and more efficient than man, they will not be able to dominate man and push him out of the labour market. In line with their expectations, robots will not find employment in places where creativity and establishment of contacts with people is necessary. A high percentage of respondents from the 18-20 age group (91% of indications) and among persons aged 24-26 (76% of indications) express a conviction that man creates robots to have support in rapid analysis of huge amount of information and in solving other complex problems. Representatives of IT industry (94% of indications), production (85% of indications), logistics (70% of indications) agree that robots (machines) have the task of supporting people in their work and will not cause a reduction in FTEs. The received results indicate a convergence of views with respect to the discussed issue among people with secondary education (69%), bachelor's degree (68%) and vocational education (62%). They believe that in spite of the

announcements of rapid growth in the number of robots in the future, they will not exist without people. An analogous situation takes place in the case of answers given by respondents with vocational education (30% of indications) and respondents with bachelor's degree (30% of indications) about the relations between man and machine (robot). These relations rely on employee personnel with high qualifications who are responsible for decisions and control of all activities in an enterprise, whereas machines handle exclusively precise performance of activities.

Review and analysis of studies in domestic and English-language literature induces a conclusion that one of the effects of technological revolution will be a higher level of cooperation between man and machine. So far, it has been feared that machines will fully replace man in a smart factory (8). Meanwhile, new opportunities are mentioned that man faces in the era of economy 4.0. Growing demands in the era of economy 4.0 contribute to the creation of new areas of application of robots intended for direct cooperation with man, assisting man in physical, precise or even hazardous work. Direct cooperation of man and robot carries a number of benefits. Man's intelligence and potential are a great supplement for the machine's precision and speed (9).

Conclusions

The approaching fourth industrial revolution related to a dynamic development of modern technologies brings changes in the area of work. Trends related to economy 4.0 (artificial intelligence, automation, robotics, advanced data analyses) redefine the employee market. For a number of years, diverse opinions have been heard about the impact of the "industry 4.0" concept on the employment policy. Some forecast growth in employment in the next 20 years as a result of expansion of artificial intelligence, whereas others foresee a deficit of qualified employees, which entails difficulties with staffing certain work positions.

As part of the adopted goal, an attempt was made at discerning the opinions of representatives of Generation Z with respect to the employment prospects in the era of technological transformation. The completed studies have shown that representatives of Generation Z are self-confident young people who can boldly present their views and expectations in the context of changes taking place in the area of work under the impact of economy 4.0. The advantage of the procured empirical results is specification of the aspects of professional work related to the functioning in industry 4.0 that the youngest generation of employees is aware of.

The survey carried out among employees that belong to Generation Z leads to the following conclusions:

- 60% of persons aged 21-23 anticipate that in the course of the next decade, jobs will be liquidated on account of automation and digitisation of production processes, whereas employees without high professional qualifications will be most affected by loss of work;
- 37% of persons aged 18-20 and 37% of persons aged 21-23 expect retention of employment on an unchanged level;
- 93% of persons from logistics industry and 88% of persons from IT industry expect a growth in employment of highly skilled labour force, as broad employment prospects are opening up before them (stable and financially attractive);
- 57% of persons from production industry expect that as a result of robotisation and automation of manufacturing processes the level of employment will be downsized;
- 31% of IT industry employees perceive a possibility of keeping employment on an unchanged level if the requirement of raising qualifications has been fulfilled;
- 62% of respondents with vocational education forecast the possibility of reduction in employment in a 4.0 enterprise as a result of performance of simple tasks by robots;
- 12% of respondents with secondary education and 11% with tertiary education foresee retention of employment on the same level;
- 46% of persons aged 18-20 expect that a major part of routine and repetitive work will be performed with the use of robots without the participation of man;

- 65% of respondents aged 18-20 are optimistic with respect to the forecast that machines will not be capable of dominating and pushing man out of the labour market (where creativity and ability to enter into relations with other people is concerned);
- 94% of employees from the IT industry, 85% from the production industry and 70% from the logistic industry believe that robots will not contribute to a reduction in FTEs, as their task is to support people at work;
- 60% of respondents with secondary education, 68% with bachelor's degree and 62% with vocational education claim that without the presence of man at a work place, robots do not have a reason to exist;
- 30% of people with bachelor's degree and 30% with vocational education believe that relations between man and robots at a work place should rely on cooperation (responsibility for decisions and controls over activities is taken by man, whereas a machine is responsible for precise performance of operations).

The above conclusions justify that in adapting to new trends, enterprises should make efforts to reorganize employment and efficiently use the opportunities created by digital transformation for business, to include employees in decision-making processes. Such action should bring a positive effect in the form of elimination of routine associated with the performance of work, but above all an increase in self-efficacy among employees (10).

Abstract

The article is devoted to analysis of the Russian economy socio-economic conditions. Considerable attention is paid to assessing the economic indicators group: physical volume index of gross regional product, per capita gross regional product, state debt, energy intensity of gross regional product, retail trade turnover; and the social indicators group: the unemployment rate of the population aged 15-72 years; the number of fatal industrial accidents victims; level of participation in the workforce; the share of employees of organizations with accrued wages is lower than the cost of living of the able-bodied population. As a result, a multidimensional grouping of the Siberian Federal District regions by the socio-economic status level is presented. The interregional inequality in the studied district is revealed, the circle of problems and economic development courses is defined.

Keywords: Socio-Economic Situation, Gross Regional Product, Cluster Analysis, Siberian Federal District, Regions, Integrated Assessment.

JEL Classification Codes: E7.

Introduction

The Siberian Federal District importance is very great for the whole country due to its geopolitical position. в силу которого The region is not only an integrating link between the Far Eastern economic region and the European part of the country, but also a "bridge" between foreign Europe and the Asia-Pacific region. Therefore, the study of the Siberian Federal District socio-economic situation is a very urgent task. In terms of resources, Siberia and the Far East are the richest territories to which the increased attention of Russian and foreign investors is riveted (Malyshevskaya T.E., 2018). The Siberian Federal District role is becoming very significant for Russia and the world. In this regard, tracking trends in the socio-economic sphere, identifying the main risks and threats to the Siberian

Federal District economy, identifying measures to reduce their negative impact are very relevant from both a scientific and a practical point of view.

This study is devoted the socio-economic indicators dynamics assessment that reflect the state and development characteristics of the Siberian Federal District and its subjects. The purpose of the research is the Siberian Federal District regions ranking in the aggregate of socio-economic indicators.

Materials and Methods

The methodological tools formation of the research is determined in the context of the two principles implementation. The first principle is a theoretical study of the phenomenon essence. The basis of this principle are the theoretical differentiation of the object and the essential perception of the object. The second principle reveals the analytical features of the investigated phenomenon. The implementation of this principle is based on the application of statistical and econometric analysis methods that allow us to study the multiple elements of a holistic system based on the multifactor model construction; grouping data by a related attribute; conducting an integral indicators assessment.

The information and empirical base of the study includes legislative and regulatory documents of federal and regional significance, data of the Federal State Statistics Service for the Siberian Federal District (SFD). The results of the study are also based on data obtained in the process of the scientific work carried out by the authors and conclusions made (Rosstat, 2020; RIA-Analytics 2020).

The Results

A spatio-temporal study of the socio-economic situation of the territory should begin with an economic group of indicators, such as the index of physical volume of gross regional product, gross regional product per capita, state debt of the Siberian Federal District, energy intensity of gross regional product, and retail trade turnover. The volume of GRP in the Siberian Federal District for the entire period under review decreased by 3.9%, and compared with the previous year, increased by 0.04%. Considering the dynamics of the physical volume GRP of the Siberian Federal District in the regional context, we note that the volume of GRP in the Siberian Federal District increased in 2018 compared to 2007 only in the Tyva Republic – by 0.45%. The GRP volume decreased most significantly in the Altai Republic – by 6.54%, in the Novosibirsk Region - by 4.71% and in the Omsk Region – by 4.22%. Compared to 2017, the largest increase in GRP can be observed in the Irkutsk region – by 2.03% (Fig. 1).

Fig. 1: Dynamics of the physical volume index GRP by the Siberian Federal District regions in 2007-2018, %

The cumulative T-criterion for a number of dynamics of the index of physical volume of GRP in the Siberian Federal District for 2007 - 2018 amounted to 3.04, which indicates the absence of a trend. With a probability of 82.6% in 2019, 97.00% in 2020, it can be argued that the index of physical volume GRP in the Siberian Federal District will decrease (Fig. 2).

Fig. 2: Dynamics of the physical volume index GRP in the Siberian Federal District in 2007-2018, %

GRP per capita in the Siberian Federal District for 2007-2018 decreased by $ 1,123.1 (18.55%) and amounted to $ 7,177.9. The maximum GRP per capita was observed in 2013 – $ 9,003.3, the minimum – in 2009 – $ 5,535.0.

In 2018, leaders in per capita GRP are such regions as the Krasnoyarsk Territory – $ 10,867.4, the Irkutsk Region – $ 8,162.3 and the Tomsk Region – $ 8,087.9. The most lagging regions for this

indicator are the Republic of Tyva – $ 3,028.5, the Altai Republic – $ 3,674.9 and the Altai Territory – $ 3,773.2. Most in 2018, compared with 2007, GRP per capita increased in the Republic of Khakassia – by $ 1,799.5 (38.3%), in the Irkutsk region – by $ 1,759.7 (by 27.5%) and the Novosibirsk Region – by $ 1,602.1 (by 29.6%) (Fig. 3).

Fig. 3: The dynamics of GRP per capita in the context of the Siberian Federal District regions in 2007-2018, USD

The cumulative T-criterion for a number of GRP dynamics per capita in the Siberian Federal District for 2007-2018 amounted to 2.09, indicating the absence of a trend. With a probability of 49.0% in 2019 and 24.0% in 2020, it can be argued that GRP per capita will increase (Fig. 4).

Figure 4: Dynamics of GRP per capita in the SFD for 2007-2018, thousand us dollars

The public debt volume for the period from 2007 to 2018 increased by 2.69 billion US dollars (2.38 times) and amounted to 4.65 billion US dollars, which is less than the same indicator in 2017 by 1.61

billion US dollars (by 25.70%). The maximum amount of government debt was recorded in 2013 – 8.43 billion US dollars.

In 2018, the leader in terms of state debt in the Siberian Federal District is the Krasnoyarsk Territory – 1 651 058.1 billion US dollars. This indicator in the Krasnoyarsk Territory increased in 2018 compared to 2007 by 1 586 837.3 billion US dollars. The smallest amount of government debt in such regions as the Altai Republic is 23 989.1 billion US dollars, Altai Krai is 30 734 billion US dollars and the Tyva Republic is 31 525.0 billion US dollars (Fig. 5).

Fig. 5: Dynamics of the public debt volume by Siberian Federal District regions in 2007-2018, billion US dollars

The cumulative T-criterion for a number of dynamics of public debt in the Siberian Federal District for 2007-2018 amounted to 8.97, indicating a trend. The forecast value of the indicator in 2019 amounted to 7.15 billion US dollars, in 2020 – 7.52 billion US dollars (Fig. 6).

Fig. 6: The public debt volume dynamics in the Siberian Federal District for 2007 - 2018, billion US dollars

The GRP energy intensity in the Siberian Federal District for the period under review decreased by 273.22 kg of standard fuel/ 10 thousand rubles (62.77%) and in 2018 amounted to 162.08 kg of standard fuel/ 10 thousand rubles.

In 2018, the largest value of GRP energy intensity in the Siberian Federal District can be observed in the Kemerovo Region – 348.56 kg of standard fuel/10 thousand rubles, the Republic of Khakassia – 269.50 kg of standard fuel/ 10 thousand rubles and the Tyva Republic – 267.71 kg of standard fuel/ 10 thousand rubles. The lowest value of GRP energy intensity in the Siberian Federal District can be observed in the Novosibirsk Region – 72.31 kg of standard fuel/ 10 thousand rubles. and Tomsk Oblast – 95.22 kg of standard fuel / per 10 thousand rubles. To the greatest extent, energy intensity decreased in 2018 compared to 2017 in the Republic of Khakassia – by 66.66 kg of standard fuel/ 10 thousand rubles. and the Irkutsk region – by 59, 66 kg of standard fuel/ 10 thousand rubles. (Fig. 7).

Fig. 7: GRP energy intensity dynamics by Siberian Federal District regions in 2007-2018, kg of standard fuel/ 10 thousand rubles.

The cumulative T-criterion for a number of GRP energy intensity dynamics in the Siberian Federal District for 2007-2018 amounted to 14.49, which indicates the presence of a trend. The predicted value obtained by the method of analytical alignment with a linear function in 2019 amounted to 137.24 kg of standard fuel/ 10 thousand rubles, in 2020 – 112.40 kg of standard fuel/ 10 thousand rubles. (Fig. 8).

Fig. 8: GRP energy intensity dynamics in the Siberian Federal District for 2007-2018, kg of standard fuel/ 10 thousand rubles

Retail turnover for 2007-2018 decreased by 6.41 billion US dollars (12.84%) and amounted to 43.52 billion US dollars. It is worth noting that the highest value of the indicator was observed in 2013 – 80.07 billion US dollars, the minimum – in 2015 (41.85 billion US dollars). The largest retail turnover in 2018 was in the Krasnoyarsk Territory – $ 8.5 billion and the Novosibirsk Region – $ 8.0 billion, and the smallest in the Republic of Altai and the Tyva Republic – $ 0.4 billion. USA in both regions. To the greatest extent, retail trade turnover decreased in 2018 compared to 2007 in the Kemerovo region – by $ 2.8 billion (31.6%) (Fig. 9).

Fig. 9: Retail trade turnover dynamics by Siberian Federal District regions in 2007-2018, billion US dollars

The cumulative T-criterion for a number of retail trade turnover dynamics in the Siberian Federal District for 2007-2018 amounted to 3.79, indicating the absence of a trend. With a probability of 56.5% in 2019, 81.1% in 2020, it can be argued that retail sales will decrease (Fig. 10).

Fig. 10: Retail trade turnover dynamics in the Siberian Federal District for 2007-2018, billion US dollars

In the social indicators group for the Siberian Federal District, the unemployment rate of the population aged 15-72 years, the number of people injured in fatal accidents at work, the level of participation in the labor force, the number of people with cash incomes below the subsistence level, the share of organizations employees with accrued income are analyzed wages below the subsistence level of the able-bodied population.

The population unemployment rate aged 15-72 years for the entire period under review in the Siberian Federal District decreased by 0.80 percentage points (by 10.96%) and in 2018 amounted to 6.5%. The maximum unemployment rate was recorded in 2009 – 10.2%.

From 2007 to 2018 the unemployment rate ages of 15 - 72 years decreased in almost all Siberian Federal District regions, with the exception of the Altai Republic, where the increase was 25.8%. The greatest decrease in unemployment is observed in the Krasnoyarsk Territory (by 35.53%) and in the Khakassia Republic (by 21.21%). In 2018, a high unemployment rate aged 15-72 years was recorded in the Tyva Republic (11.20%) and Altai Republic (14.80%) (Fig. 11).

Fig. 11: Unemployment rate Dynamics by Siberian Federal District regions in 2007-2018, %

The cumulative T-criterion was 5.10, which is less than the critical value 5.49, therefore, there is no tendency in the series of the unemployment rate dynamics the Siberian Federal District. With a probability of 69.9% in 2019 and 90.9% in 2020, we can say that the unemployment rate will decrease (Fig. 12).

Fig. 12: The unemployment rate dynamics aged 15-72 years in the Siberian Federal District in 2007-2018, %

The number of injured in accidents decreased to 470 people (71.58%) and represented in 2018 186 people. In the regional context, the decrease in the number of fatal industrial victims accidents in 2007-2018 occurred in the Altai Territory (by 73.77%) and the Kemerovo Region (by 82.67) (Fig. 13).

Fig. 13: The number of the fatal accidents at work victims number dynamics in the Siberian Federal District regions in 2007-2018, people

The cumulative T-criterion was 12.47, which is more than the critical one, equal to 5.49, therefore, there is a tendency in the number of the fatal accidents at work victims number dynamics in the Siberian Federal District. The predicted value of the indicator obtained by the method of analytical equalization based on a linear function in 2019 amounted to 129.46 people, in 2020 – 95.21 people. (Fig. 14).

Fig. 14: The number of the fatal accidents at work victims number dynamics in the Siberian Federal District in 2007-2018, people

The participation in the workforce level of the Siberian Federal District population for 2007-2018 decreased by 0.30 percentage points (by 0.30%) and amounted to 66.90%. The maximum participation in the workforce level was observed in 2016 – 68.2%. An increase in labor force participation for the entire period under review is observed in the Omsk Region – by 5.8%, the Novosibirsk Region – by 3.81%, the Tyva Republic – by 2.84% and Khakassia Republic – by 0.47%. In all other the Siberian Federal District regions this indicator tends to decrease. Negative demographic trends are primarily due to the lack of comfortable conditions for economic activity and population living in Siberia (Fig. 15).

Fig. 15: Dynamics of the participation in the workforce level of the population by the Siberian Federal District regions in 2007-2018, %

The cumulative T-criterion for a number of dynamics of the participation in the workforce level of the Siberian Federal District population for the period from 2007 to 2018 amounted to 6.39, which confirms the presence of a trend. The predicted value obtained by the method of analytical alignment with a linear function amounted to 67.70% in 2019 and 67.78% in 2020 (Fig. 16).

Fig. 16: Dynamics of the participation in the workforce level of the population by the Siberian Federal District in 2007-2018, %

The population share with cash incomes below the subsistence level for the entire period under review decreased by 3.17 percentage points (by 14.36%) and amounted to 18.88% in 2018. The population share with cash incomes below the subsistence level in 2018 compared with 2007 increased in Kemerovo – by 54.17%, Irkutsk – by 5.29% and Tomsk oblasts – by 35.04%, the Republic of Tyva – by 11.19% and in the Krasnoyarsk Territory – by 15.83%. It should be noted that in all other subjects of the Siberian Federal District there is a decrease in the indicator in question (Fig. 17).

Fig. 17: Dynamics of the population share with cash incomes below the subsistence level in Siberian Federal District regions in 2007-2018, %

The cumulative T-criterion for a number of dynamics of the population share with cash incomes is below the subsistence level in the Siberian Federal District for 2007-2018 amounted to 2.48, indicating the absence of a trend. With a probability of 69.9% in 2019, 90.9% in 2020, it can be argued that the share of the population with cash income below the subsistence level in the Siberian Federal District will decrease (Fig. 18).

Fig. 18: The dynamics of the population share with cash incomes below the subsistence level in the Siberian Federal District for 2007-2018, %

The organizations employees share with accrued wages is lower than the subsistence minimum of the able-bodied population decreased by 8.88 percentage points (by 52.83%) and amounted to 7.92% for the period from 2007 to 2018. From 2007 to 2018 there was a reduction in the organization employees share with accrued wages below the minimum subsistence level of the able-bodied population in all subjects of the Siberian Federal District. It is necessary to highlight the Khakassia Republic and Altai Republic, where the decrease was 92.23% and 75.38%, respectively (Fig. 19).

Fig. 19: The dynamics of the organization employees share with accrued wages below the subsistence level of the able-bodied population in the Siberian Federal District regions for 2007-2018, %

The cumulative T-criterion for a number of dynamics the organizations employees share with accrued wages is lower than the cost of living of the able-bodied population, the minimum in the Siberian Federal District in 2007-2018 dens to 11.29, which confirms the presence of a trend. The predicted value obtained by the method of analytical equalization based on a linear function filled to 7.20% in 2019 and 6.67% in 2020 (Fig. 20).

Fig. 20: Dynamics of the organization employees share with accrued wages below the subsistence level of the able-bodied population in the Siberian Federal District for 2007-2018, %

To predictive model of changes in the socio-economic situation of the Siberian Federal District, we took the amount of government debt (billion US dollars) as an effective indicator (y). This is due to the fact that currently the most important is the implementation of a balanced credit and financial policy aimed at phasing out the dependence of the country or the federal district on external credit borrowing and strengthening international positions. The following indicators were assigned to factor signs: X_1 – the investments share in fixed assets of GRP (%); X_2 – the share of investments in machinery, equipment, vehicles in the total investment in fixed assets (%); X_3 – the index of production by

economic activity "Mining" type (%); X_4 – Industrial Production Index (%); X_5 – Producer Price Index by Economic Activity "Industrial Product Manufacturing" (%); X_6 – the unemployment rate of the population aged 15-72 years (%); X_7 – the number of fatal industrial accidents victims (people); X_8 – level of participation in the workforce (%); X_9 – the share of population with cash incomes below the subsistence level (%); X_{10} – the share of organization employees with accrued wages below the subsistence level of the working population (%); X_{11} – GRP physical volume index (%); X_{12} – GRP per capita (thousand US $); X_{13} – Retail Turnover (Billion US $); X_{14} – Energy intensity of GDP (kg of standard fuel/ 10 thousand rubles); X_{15} – the share of domestic spending on research and development in GRP (%); X_{16} – The share of high-tech and knowledge-intensive industries in GRP (%); X_{17} – costs of technological innovation organizations (million US $); X_{18} – developed advanced manufacturing technologies (units); X_{19} – information on the use of intellectual property (units).

An analysis of the correlation matrix showed that the most significant factors are X_{13} and X_{17}. Thus, a regression model was obtained that describes the change in public debt in the Siberian Federal District, taking into account, two factors of influence – Retail Turnover (X_{13}) and the costs of technological innovation of organizations (X_{17}):

$$y = 2{,}677 - 0{,}035\ X_{13} + 0{,}002\ X_{17}.$$

The regression model is significant according to the F-Fisher criterion, since the calculated value was 24.71 with a critical value of 4.26. Consequently, the change in the Retail Turnover in the Siberian Federal District has the opposite effect on the effective attribute, that is, with the increase in revenue from the sale of goods to the population, the volume of public debt decreases. The amount of expenses on technological innovation of organizations directly affects the size of the state debt of the Siberian Federal District, i.e. increased costs may affect debt growth (Fig. 21).

Fig. 21: Graphical interpretation of the regression model of the Siberian Federal District socio-economic status

To analyze the socio-economic situation and establish the ranking of regions in the Siberian Federal District, a multidimensional ranking method was used. For each indicator, ranks were calculated, according to the summary value of which ranking was carried out.

Then, all regions were divided into groups according to the following principle:

- total rank above 120 - 1 group (regions with the highest socio-economic level);
- total rank from 100 to 119 - group 2 (regions with an average socio-economic level);
- total rank below 99 - 3 group (regions with a low socio-economic level).

So, in 2007, there are 5 leading of the Siberian Federal District regions in terms of socio-economic status. The Novosibirsk region can be distinguished by a significant margin from other regions, and a high socioeconomic level can also be noted in the Krasnoyarsk Territory, Tomsk Region, Kemerovo Region, and Irkutsk Region. The average level for the values of indicators can be observed in the Omsk

region and Altai Territory. The lagging regions in 2007 were the Altai Republic, the Khakassia Republic, and the Tyva Republic. In 2018, 4 leaders – Krasnoyarsk Territory, Irkutsk Region, Tomsk Region and Novosibirsk Region. Unlike 2007, the Novosibirsk Region is no longer the undisputed leader and is in the last position in the group of regions with the highest socio-economic level. The regions with an medium indicator level include the Khakassia Republic, the Omsk Region, as well as the Kemerovo Region, which in 2007 was in the group of regions with a high socio-economic level. The most lagging regions in 2018 include the Altai Territory, the Tyva Republic and Altai Republic (Fig. 22).

Fig. 22: Multidimensional grouping of the Siberian Federal District regions in accordance with the socio-economic level in 2007-2018.

We will also conduct a cluster analysis of the regions of the Siberian Federal District by socio-economic level in 2007 and 2018 and compare it with the results obtained by the multidimensional grouping method (Table 1).

Table 1: Grouping of the Siberian Federal District regions by the distant neighbor method in 2007 and 2018

Clusters	2007	2018
1 cluster	Krasnoyarsk Territory, Tomsk Region, Republic of Khakassia, Irkutsk Region and Kemerovo Region	Krasnoyarsk Territory, Irkutsk Region, Novosibirsk Region, Tomsk Region
2 cluster	Novosibirsk Region, Altai Territory, Omsk Regio	Khakassia Republic, Altai Territory, Omsk Region
3 cluster	Altai Republic, Tyva Republic	Altai Republic, Tyva Republic

The cluster analysis results by the distant neighbor method in the Siberian Federal District regions in 2007 and in 2018 confirm the situation with the presence of three main clusters, which have almost the same composition of the regions ranking position in terms of socio-economic level in a particular cluster.

The Conclusion

It can be noted that during the study period there is an increase in inter-regional inequality in the studied district. The economic level of more developed regions is growing faster than in other Siberian Federal District regions. One of the main factors that determine the prospects for socio-economic development of the Siberian Federal District is the huge resource potential of this region, including mineral deposits. An important factor in the economic development of the Siberian Federal District is its high production, scientific, technical, and scientific and educational potential. However, the Siberian Federal District

economy in modern conditions is uncompetitive in many types of products. Factors that hamper the economic development are: a qualitative deterioration in the raw material base, high transport costs due to the remoteness from the densely populated and more developed European Russia and the industrially developed Europe countries and the Asia-Pacific region, low population density in Siberia itself and insufficient level of development of transport infrastructure, increased consumption of fuel and energy resources for production and social needs due to harsh climatic conditions i, the lack of effective measures to attract investment at the regional level. To create a favorable economic environment, it is necessary to implement a number of measures for the development of the economy, competently implementing strategies in the priority areas of the Siberian Federal District development.

Business Model Innovation and Internationalization Strategies: The Case of Flixbus

Luka BUNTIC, Mate DAMIC and Eva PERICA

lbuntic@efzg.hr, mdamic@efzg.hr, evaperica@gmail.com
Faculty of Economics and Business, University of Zagreb, Croatia

Abstract

The impact of globalization has led to a significant rise of born global companies. In order to achieve competitive advantage on the global market these organizations aim to develop unique business models which are hard to replicate for their competitors. Some of these organizations pursued the strategy of establishing a strong local presence to ensure success of their future internationalization. FlixBus can be seen as one of these organizations. This start-up company's revolutionary business model has initiated a disruption of the bus industry in the global market, completely changing the landscape for traditional bus transport service providers. The aim of this exploratory study is to analyse the FlixBus case through the perspective of business model innovation as a tool for internalization. The aim of this exploratory study is to analyse the FlixBus case through the perspective of business model innovation as a tool for internalization.

Keywords: Business Model Innovation, Internationalization, Disruption, Franchise

Introduction

Global importance of the bus industry can be observed in terms of providing cost effective transportation services to general population and enabling the mobility of people in and between countries. Cost effectiveness of buses as a means of transport is especially important in less developed countries. The industry itself is highly regulated in many countries. Bus operators often need to compete and gain approval from local authorities in order to operate different lines. Less profitable lines often mean that the service providers will operate at breakeven point. The entrance of FlixBus to the market, however, completely changed the landscape and perspective of the whole industry.

German company FlixBus is part of the FlixMobility GmbH group. Through this case study, we will analyse the business model, structure and selected internationalization strategies of FlixBus. From 2013 to 2015 they covered 71% of the German market and in 2018, they covered 90% of the German market (The Economist, 2018). They currently offer over 400,000 daily connections with 2,500 travel destinations and 2,000 buses available. They employ over 1000 people in 27 countries and have over 300 partners and 7000 professional drivers in their partner network.

The data has been collected from the Flixbus official press releases, Bundesanzeiger (official government financial service), and Crunchbase (database for innovative global companies). Financial reports were analysed for FlixMobility group in 2015 and 2016. Our research method follows grounded theory approach and comparative case study (Eisenhardt, 1989). Ravenswood (2011) implies how theory building from case studies suits new areas of research with little extant literature because it does not rely on previous literature. Moreover, we conducted non-structural interview with FlixBus Global Communications Manager for better understanding the subject of this case study.

FlixBus Case Study

The peculiarity of the FlixBus business model is based on the fact that the company does not own a single bus nor employ any professional drivers. The FlixBus business model integrates local partners providing passenger transport in the markets in which they operate. FlixBus has currently over 1000 employees in its affiliates and management. They have over 300 partners (carriers) and over 7000 professional drivers in their network. With their activities, they provide over 10,000 jobs. They also record over 400,000 daily routes to over 2,500 destinations in 30 countries. From 2013 to 2019 they achieved over 100 million passengers in their network (FlixBus, 2020).

A quality partnership is one in which experience and learning can be measured. These two components can be potential sources of competitive advantage for businesses. Thus, in addition to learning through their own experience, organizations can learn from the experiences of other organizations (Kedia and Lahižri, 2007). FlixBus business model seems to have both of these components. FlixBus's partners own a bus fleet worth around 600 million € and employ over 7,000 professional drivers (FlixBus, 2020). The source of their competitive advantage are low operating costs. This enables them to offer low prices while maintaining a high quality of service.

In designing their innovative business model, FlixBus analysed the traditional bus industry where they planned to pursue their disruptive activity. At that time, very few tech companies operated in medium and long-distance travel market, while competition was already present in the short distance market with companies such as Uber or Lyft. FlixBus used the franchise strategy enter the market. Based on the franchise agreement, they planned and organized transport routes. The company was also responsible for marketing and sales activities, pricing (price algorithm by managing over 100 million tickets on a daily basis), supply and demand analytics and customer support. They created a platform model to influence the development of their customer network. Through interactive access today, users are able to purchase tickets online and leave feedback. FlixBus system tracks over 2500 buses in real time.

In the franchise model, FlixBus clearly emphasizes the rules of conduct for professional drivers and the maintenance of a partner bus fleet. They retain approximately 25 - 30% of the price of tickets sold for their services. On the other hand, local partners are responsible for providing end-to-end customer service - passenger transportation and covering operating costs. Partners are usually local small and medium-sized enterprises with registered passenger transport activity. In franchise, financial risks, as well as other costs, are significantly reduced with brand development. The franchisee will assume significantly less costs and risks of setting up an international franchise, which will also create a good incentive for the franchisee to build a profitable business as quickly as possible, or to continue expanding into new markets. The franchisee thus becomes a participant in the global market and a representative of the global enterprise, at a much lower cost than if he had developed a product or a brand himself (Hill, 2013).

FlixBus shows characteristics of a start-up corporation (Davila and Epstein, 2014). On one side, they combine the start-up's ability to develop an innovative idea and disrupt the traditional industry, while having a strong and established organization in terms of scalability of a business model and execution of operational plans. Spremić (2017) explains how digital transformation of a business takes place when a company makes radical changes in its most important business activities such as strategy in the short term, structure, business processes, business model and organizational culture. In the business transformation, the new business model may represent a competitive advantage in the market. The business model innovation (BMI) design facilitates business scalability and, through strategic sustainability, seeks to avoid business risk (França et al., 2017). FlixBus owes its rapid growth and internationalization process to business model scalability and successful internationalization strategies. Scalability involves developing a business model that can be customized in any local market, regardless of customer size or segment. FlixBus' scalable business model has enabled them to become a leader in the mobility market with successful financial and operational indicators together with the development and growth of a business partner network. FlixBus's long-term goal is to dominate the bus market

globally and to implement environmental reform that would significantly contribute to less pollution in the markets in which they operate.

BMI is considered to be an effective and efficient form of innovation. Primary function of BMI is to perform two important functions: create value and collect value. Good ideas or technologies have been proven to be inferior to a good business model (Chesbrough, 2007). Based on the example of FlixBus, we can conclude that there is no revolutionary idea in the way passengers are transported, but rather that innovation relates solely to the business model. We can justify the assumption that FlixBus business model is well designed and represents a competitive advantage for the company. Intense competition in the global marketplace has been influenced by changing market conditions. Such conditions force companies to adapt their business models and operating activities more often and more thoroughly, as innovations based solely on new products and targeted at local markets are no longer enough to maintain a competitive position in the market. Competitors can copy products relatively easily, and local markets have never been more accessible than they are today (Taran et al., 2015).

It is much more difficult for competitors in the same industry to emulate or replicate an entire system of activities than just one new product or a process. It should be emphasized that competitive threats often go beyond the boundaries of the industry in which the enterprise operates (Amit and Zott, 2012). If we were to compare the business of FlixBus with that of other companies in the industry, at first glance, we would not notice significant differences. However, a detailed analysis would determine that the difference comes precisely from the BMI, which is difficult to replicate. By investigating the bus industry separately through the FlixBus phenomenon, we can conclude that the company has gained a competitive advantage with its BMI, which has been very difficult to replicate for other companies. After the disruption of the local market, the organization has expanded through the internationalization process and has achieved significant success globally.

Internationalisation Strategies

Companies that base their operations on new technological platforms, often face challenges in their development process, as they rapidly enter the process of internationalization with the innovation of products or services (Onetti et al., 2012). Internationalization is dependent on the business model, which determines how to enter the international market. It also determines the level of operational activities on international markets. Internationalization combines innovative, proactive and risky behaviour in order to create added value to organizations on international markets. By pursuing growth opportunities and increasing the volume of business operations, companies face uncertainties and risks that require adapting internal routines and external processes to new environments. This strategy requires capital intensive action (Schwens et al., 2018).

Also, emerging economies mature, and advanced technology becomes more and more important for global competitiveness. In these conditions, firms have the ability to innovate and affect future growth with the internationalization process (Holmes Jr et al., 2018). The growth of the international market and the growing importance of emerging economies offer new opportunities for development, which more and more companies are choosing to take advantage of. The decision to internationalize may be due to a previous event or process, such as a rapid increase in competition in the domestic market, product maturity, access to resources, establishing relationships with international customers, flexibility, re-configuring the value chain or improving usiness image (Dominguez, 2018). Innovation and internationalization are processes that can be interconnected. Internationalization and innovation in the business model are influenced by the local market and the relationships between competitors on this market. New ventures in the high-tech industry should exploit the interrelationships between innovation and internationalization and are likely to design their strategy and business models accordingly (Onetti et al., 2012).

The literature describes internationalization as a slow and incremental process in which an enterprise gradually acquires knowledge in order to compete in international markets. Knowledge is a valuable resource because it enables companies to execute an internationalization strategy with greater

efficiency. It can be flexibly combined with other assets abroad. Knowledge-intensive firms may be better able to adapt to new environments compared to firms that rely more on capital (Schwens et al., 2018). However, they also face the risk of technological obsolescence at the moment when knowledge-based resources are dispersed, or competitors replicate innovative products. The ownership rights of these companies are difficult to determine and enforce in international settings, therefore, companies that are abler to protect their knowledge will be more successful.

FlixBus was founded as a start-up company in Munich, offering local bus transportation to customers. With the deregulation of the German bus industry market in 2013, they introduced three bus routes. Until then, Deutsche Bahn AG, more specifically the German Railways, had a monopoly on the market. In 2015, they merged with MeinFernbus, their competitor with similar business model, mostly focused on the platform economy. Main motive for the merger and acquisition strategy is the knowledge sharing with the aim of improving the business model of the company. These strategies and processes have been simplified with the development of digital technology (Vendrell-Herrero et al., 2018). A merger is a process where at least two companies combine to form a new legal entity. This merger brought FlixBus closer to internalization.

FlixMobility and MeinFernbus were two largest start-up companies in the bus industry in Germany just before the merger. Both companies began their journey by competing in the local market, MeinFernbus in Berlin and FlixBus in Munich. The objective they wanted to achieve through the merger was to create a pan-European transportation network. MeinFernbus was founded in 2011 and by the time of the merger, the firm had 40 routes, 135 destinations and over 10 million passengers carried. FlixBus had 90 routes, 148 destinations and approximately four million passengers (General Atlantic, 2015). With its well-designed business model, they won the award for the best start-up in 2014 by the Bayerischer Gründerpreis, the prestigious Bavarian business award.

FlixBus and MeinFernbus had 170 local partner bus carriers at the time before their appearance in foreign markets. The liberalization of the German market helped them at that moment to create an organization generated 10,000 jobs in the upcoming period of three years. The main investor who supported the merger of the then two competitors in the German bus industry was General Atlantic (FlixBus, 2015). They were also financially supported by Holtzbrinck Ventures and UnternehmerTUM. General Atlantic is one of the leading investment groups providing capital and strategic support to fast-growing companies. They have approximately 35 billion euros investment value in their portfolio. If we analyse their portfolio, we can see a lot of companies in various fields creating the disruption in the industries. They certainly played a major role in developing the internationalization strategy for the FlixBus. Main objective of internationalization for FlixBus was to establish wholly owned subsidiaries in strategic locations in order to achieve the strategy of creating a pan-European network in the bus industry. Through wholly owned subsidiaries they gained full control of their operations in foreign markets and did not have to disclose their technology to other companies, which also reduced the risk of creating competition among potential partners.

In 2015, the process of internationalization of FlixBus began. In Table 1 we can observe the speed and impact of the internationalization process. The biggest growth of FlixBus occurred in January 2016 when a wholly owned subsidiary of FlixBus CEE was established to cover Central and Eastern Europe (Flixbus, 2016).

Table 1: Speed of internationalization process in the EU countries in one year

Month and Year	Whole Owned Subsidiary	Bus Routes
May 2015	France	Yes
August 205	Italy	Yes
November 2015	Netherlands	Yes

December 2015	No	Austria, Switzerland, Belgium, Luxembourg, Sweden, Denmark
January 2016	Croatia, Slovenia, Poland, Czech Republic, Hungary, Slovakia, Romania	Yes
March 2016	No	Great Britain, Spain

Source: Author; FlixBus (2020)

Companies that wish to have a direct operational presence in the international market and to have complete control over their operations usually establish a wholly owned subsidiary. Subsidiaries can either be established or bought. In the second case, most of the companies will buy their existing partners or resellers. When a business is purchasing its local supplier to gain direct control of delivery, a process of vertical integration occurs. It requires the highest commitment due to all the risks involved – financial, economic and political. (Carpenter and Dunung, 2012). Moreover, from the point of view of capital investment, setting up a wholly owned subsidiary is generally the most expensive way of entering international markets. Businesses opting for this strategy must bear full capital costs and risks of setting up international operations. The level of risk is lower if the company acquires an already established organization in the local market (Hill, 2013).

In 2015, FlixBus agreed on a strategic co-operation with the Austrian Blaguss Group, a company owning a luxury bus fleet with many years of experience in the bus industry. In 2016, FlixBus has taken over Megabus Europe, owned by the Stagecoach Group. Megabus was founded in 2006 and has been one of the pioneers of change in the bus industry. As a low-budget company, they have started offering long-distance, online transportation services for as low as a dollar. Over a ten-year period in the business, they sold over 22 million tickets in over 120 cities across North America. The reasons for the acquisition were the environmental awareness and standards of Megabus and the high level of service on their platform. Today, FlixBus' vision and business are focused on creating green technology that is environmentally friendly. Also, this merger began the idea of electric buses. In 2018 FlixBus launched a new project of electric buses on long-distance journeys on the German, the French and the US market. After the acquisition, Megabus continued to operate, but under the management of FlixBus. The analysis showed that after acquisition, Megabus was capable to increase ticket sales by almost six times, while the cost of their services decreased. In the same year, FlixBus took over Postbus, which was a subsidiary of the Deutsche Post DHL Group (Deutsche Post DHL Group, 2016). Deutsche Post Mobility Group also launched Postbus after deregulation of the German bus industry. However, despite the high quality of service, they were unable to respond to the competitive presence of Flixbus, which dominated the market overwhelmingly because of its BMI that was hard to replicate.

In 2017 FlixBus started to operate in Portugal and Poland, in 2018 in the USA and in 2019 in Turkey. Their first cross-border conenection occurred in 2020 from France to Morocco. Future internationalisation strategy focus is targeting the markets in South America and Asia.

FlixBus' new corporate vision emphasizes smart and green, i.e., environmental mobility for every individual who has the opportunity to experience the world through their travels. In other words, FlixBus aims to offer every citizen their business travels at affordable prices, and through that experience take care of the environmental standards of its buses. In 2019, FlixBus took over Eurolines SA, a travel agency founded in 1971. Their network is considered to be the most extensive in Europe with over 500,000 possible routes between cities. In addition to booking tickets and organizing group travel, they also offer accommodation in hotels and apartments. According to the last available consolidated report from 2016 for the FlixMobility GmbH group, a positive impact of the internationalization processes on the business result can be seen. In one year, company revenues rose from 25.5 million € to 131 million € in the EU countries.

Source: Author; Bundesanzeiger (2020)

The impact of BMI on the choice of a company internationalization strategy has not been sufficiently explored in the academic literature. This exploratory paper based on a case study of an individual company may provide guidelines for future research. Flixbus's innovative business model enabled the organization to capture a somewhat overlooked market niche of mid and long-distance transport. So far, there has not been much competition on global market for the organization, and main competitors are predominantly large companies which still base their services on economies of scale instead of new business models. However, we have not fully demonstrated the impact of BMI on the choice of strategy for the internationalization process. Our analysis provided an overview of business model as well as current and past strategic choices related to FlixBus internationalization. We still lack insights into possible future trends related to the changes in FlixBus business model.

Conclusion

Early internationalization of a company helps develop an international identity and, consequently, the enterprise is likely to repeat the steps that led to internationalization in other markets if it already has a brand that is recognizable to customers. FlixBus can be seen as an example of this. On the other hand, companies entering the internationalization process at a later stage must change their pre-existing routines that have been established during the period of activity in the local market. Businesses with outdated business models are becoming inert, and if they do not embrace the wave of digital transformation in their industries, they can easily die out.

Essentially, the business model will specify the most important business activities of the company. The ultimate goal of each model is to create the value that customers or clients receive. Another important goal is to collect value, that is, to monetize the business model. By analysing the FlixBus platform, we concluded that it is based on technology and customer experience at the highest level. The organization uses the advantage of operating partnerships, which provided them with a greater possibility to develop a scalable platform. Scalability involves developing a business model that can be customized in any local market, regardless of customer size or segment.

The scalability of FlixBus' business model has enabled them to become leaders in the mobility market with successful financial and operational indicators and the development and growth of a business partner network. FlixBus's long-term goal is to dominate the bus market globally and implement environmental reform that would significantly contribute to less pollution in the markets in which they operate. To sum up, FlixBus has successfully integrated its BMI into the platform model and the concept of sharing economy. In doing so, they made a radical innovation in the traditional industry on the global market. Successful internationalization strategies enabled rapid business growth and current business

success. However, it would be interesting to see what the future will bring and in which way will the FlixBus business model evolve or will it be exceeded by a more competitive business model.

This paper sheds light on the understudied issue of using business model innovation as a tool for internalization. Contrary to organizations that are born global or incumbent multinational corporations, our case study shows how business model innovation can be used as another way of expanding on global markets. The findings of our research can be generalized and the method used is transferable for similar studies in the future.

Abstract

The article is devoted to the broadly understood issue of the effectiveness of banks. The study focuses on financial changes that took place in the banking sector of Ukraine in the period 2013-2018. The article presents the results of the analysis of changes in financial ratios used in the study of the financial effectiveness of banks. Therefore, the analyses included such values as the average of selected indicators, minimum, maximum, as well as references to the values of indicators in selected countries of Central and Eastern Europe and the European Union. The authors also thoroughly interpreted the changes in the value of indicators from the point of view of the effectiveness of individual analysed objects. The analyses presented in this article constitute the first stage of research on the financial effectiveness of banks in Ukraine. The research hypothesis adopted in the conducted research: The difficult political and economic situation in Ukraine was not without an impact on the condition of the banking sector. The article uses a critical analysis of the literature on the subject and indicator analysis as the research method. There was also conducted a comparative analysis of changes in the size of selected financial performance indicators over the years 2013-2018.

Keywords: financial security of banks, benchmark analysis of banks, financial efficiency, financial ratios of banks

Introduction

The growing economic and financial relations between the EU and Ukraine mean that aspects such as the country's economic development, institutional development issues, as well as stability and development opportunities for the financial system are becoming increasingly important from the point of view of Ukraine's potential future accession to the EU. Relations between the EU and Ukraine under the European Neighbourhood Policy and the Eastern Partnership are constantly developing. The Association Agreement between the European Union and Ukraine, covering a deepened and comprehensive free trade zone, entered into force on September 1, 2017. Considering the financial resources flowing from the EU to Ukraine, all of the above results in an increased interest in what is happening in the Ukrainian banking sector.

The former finance minister and president of the Hungarian stock exchange Lajos Bokros (2001) pointed out in one of his statements that the financial sector is a kind of symbol of general development phenomena in the economy. It should, therefore, be noted that the stabilisation of the financial system, the efficiency of its assessment by the efficiency of financial markets, and thus primarily the banking sector, plays a key role in assessing the changes taking place in the Ukrainian economy. All this undoubtedly helps EU authorities to determine not only the scale of Ukraine's

adaptation to the requirements of the modern global banking system, but it also helps in creating new directions of change.

It must be remembered that in today's economies, it is the financial system that assesses decisions made by enterprises and consumers. As Wojtyna (1997) point out the legal legitimacy of financial system, the scope of the employed institutional solutions, and social awareness of his role are all important criteria for changes taking place in the transforming socio-economic and political systems of this part of Europe.

In the context of the above considerations, therefore, it seems justified to have a more detailed interest in the financial situation and efficiency of banks operating in the Ukrainian banking sector. The aim of the article is to analyze and evaluate the financial effectiveness of 15 leading banks in Ukraine, measured by ROA and ROE ratios in 2013-2018 shown against the background of the political and economic situation in Ukraine. The research hypothesis adopted in the conducted research: The difficult political and economic situation in Ukraine was not without an impact on the condition of the banking sector.

The article uses a critical analysis of the literature on the subject and indicator analysis. There was also conducted a comparative analysis of changes in the size of selected financial performance indicators over the years 2013-2018. The necessary empirical data were collected using BankFokus database, data from the International Monetary Fund (IMF), the World Bank (WB) and the European Central Bank (EBC) and the financial statements of banks.

The political and economic situation during the period 2013-2018

In 2013-2018 Ukraine struggled with many serious problems. The political and economic situation during this period was extremely difficult. The main external factor influencing the situation of Ukraine was the conflict with Russia. This conflict in all its aspects, i.e. from the military confrontation in Donbass, through the issue of Crimea's membership to those related to gas, had an impact on the country's economic situation. There was a political crisis at the beginning of 2014. The occupation of Crimea and some areas of Donetsk and Luhansk oblasts resulted in a deep crisis in the economy.

Ukraine has experienced serious political, security and economic challenges. As the most significant events affecting these areas of state functioning, after the establishment of Maidan, which led to the overthrow of the previous president in November 2013, World Bank Group (2017) identified:

1) events in Crimea and Sevastopol in March 2014 which led to the adoption by the UN General Assembly of resolution 68/262 confirming Ukraine's territorial integrity;
2) the outbreak of conflict in the Donetsk and Lugansk regions of eastern Ukraine;
3) the presidential, parliamentary and local elections in 2014-2015.

As the paper developed by: the National Bank of Ukraine (NBU), the National Securities and Stock Market Commission (NSSMC), the National Commission for Regulation of Financial Services Markets (NCFS), the Deposit Guarantee Fund (DGF) and the Ministry of Finance of Ukraine (2020) highlighted, in 2014-2016 "Ukraine faced a triple crisis as the combined impact of a banking crisis and a currency crisis exacerbated a crisis in the real sector of the economy". 2014 and 2015 are the years in which several waves of significant depreciation of the hryvnia occurred in Ukraine.

Stephan Barisitz, Mathias Lahnsteiner (2017) points out that the effects of the armed conflict in the eastern part of Ukraine, which hit the economy through direct and indirect channels, such as the loss of export capacity of industry or the effect of confidence, had the greatest impact on the economy in 2014 and 2015. In 2016, economic activity began to recover, but the political and geopolitical environment remained unstable.

Among the internal problems faced by Ukraine, moral hazard, the high level of corruption and crimes, including financial crime, should be mentioned. From the point of view of their impact on the banking sector, a group of crimes directly related to the area of bank operations emerges as particularly important. Kurilo, Klochko, Timchenko, Gulyk (2017) emphasize that crimes in banking sphere are the very serious problem in Ukraine. The authors show that there are many types of crimes that include:

1) illegal actions with documents for transfer, payment cards and other means of access to bank accounts, electronic money, equipment for their production - article 200 of the Criminal Code of Ukraine;
2) legalization (laundering) of income from crime - article 209 of the Criminal Code of Ukraine;
3) making the bank insolvent - article 2181 of the Criminal Code of Ukraine;
4) causing to become bankrupt - article 219 of the Criminal Code of Ukraine;
5) violation in maintaining a database on depositors or reporting procedures - article 2201 of the Criminal Code of Ukraine;
6) financial documents and financial organization reports falsification, non-disclosure of the financial institution's insolvency or grounds for revocation (cancellation) of a financial institution's license - article 2202 of the Criminal Code of Ukraine;
7) fraud with financial resources - article 222 of the Criminal Code of Ukraine;
8) illegal collection or using sensitive information - article 231 of the Criminal Code of Ukraine;
9) commercial or banking secrets disclosure - article 232 of the Criminal Code of Ukraine.

The problem of financial crimes was presented in detail by the Chairman of the Council of the Independent Association of Ukrainian Bank - Roman Shpek - at the corporate security conference. As Shpek (2017) shows, the most common types of financial crimes consist: crimes in the credit process, financial resources fraud, falsification of related documents with these types of fraud, illegal actions with mortgaged property as well as intentional non-enforcement or obstruction of execution of court decisions.

In order to improve the situation of banks as well as to protect the rights of consumers in connection with high level of crime, appropriate actions and mechanisms were taken, such as the Comprehensive Program of Ukraine Financial Sector Development Until 2020 approved on 18 June 2015 by the Board of the National Bank of Ukraine. As Afanasyeva, O., & Kammel, A. J. (2017) indicate, according to the assumptions of this program, all Ukrainian obligations under the EU-Ukraine Association Agreement had to be resolved, ensuring the creation of a well-functioning financial sector in line with EU standards. NBU (2019) indicated that the most important areas of activities undertaken under the program were: ensuring financial stability, building institutional capacity of regulators as well as consumer and investor rights protection. The provisions of the Program indicate that the condition for the reforms to be effective is the implementation of the following comprehensive changes regarding:

- regulators of the financial sector, i.e. enhancing the institutional capacity of the regulatory authorities and the Deposit Guarantee Fund, and establishing conditions for effective supervision and remedies that promote sustainability of the financial sector as well as improve the credit and investment prospects of the country;
- financial sector participants (of different forms of ownership), i.e. removal of "dead weight" and problem institutions from the market, improving the financial soundness and solvency of the participants, restoring and increasing trust to the market players, fostering development, transparency and competition in all segments, which will ensure equal opportunities for all participants in the financial sector.

Fig. 1. shows the number of fraud with financial resources (article 222) and illegal actions with documents for transfer, payment cards and other means of access to bank accounts, electronic money, equipment for their production (article 200).

Fig. 1: Number of registered criminal offenses under Art. 222 and Art. 200 of the CC of Ukraine

Source: own elaboration based on Pohoretskyi, Serhieieva and Toporetska (2019); Klochko, Kurylo, Kvasha, Zahynei, Logvinenko (2020).

While figures show that fraudulent activities related to financial resources have indeed decreased, the number of illegal activities using documents for transfers, payment cards and other means of accessing bank accounts, electronic money and equipment for their production decreased only between 2014 and 2016 and then increased sharply between 2017 and 2018.

The signing of the Association Agreement between the European Union and its Member States, of the one part, and Ukraine, of the other part (OJ L 161, 29.5.2014, p. 3–2137) was extremely important from the point of view of building the basis for positive changes in Ukraine. This agreement entered into force on 1 September 2017. According to the content of the contract, the principles which constitute essential elements of the Association Agreement between the parties include respect for democratic principles, the rule of law, good governance, human rights and fundamental freedoms. It was concluded that the fight against various forms of trans-national organised crime and terrorism as well as the promotion of sustainable development are also important for building EU relations with Ukraine.

One of the important aspects that were a manifestation of the efforts aimed at improving the situation in Ukraine was also the Deep and Comprehensive Free Trade Agreement (DCFTA). This agreement is part of the EU-Ukraine Association Agreement and was entered into force on 1 January 2016. According to the observations of the European Parliament (2017/2283(INI)), the DCFTA provides a solid basis for economic development and modernisation of Ukraine.

Table 1 and Fig. 2 present the main indicators characterizing the economic situation in Ukraine in 2013-2018.

Table 1: Gross domestic product, capital investment and inflation in Ukraine in 2013-2018

	2013	2014	2015	2016	2017	2018
GDP (mln USD)	179,572	130,571	90,489	93,313	112,125	130,857
Capital investment (mln UAH)	249873,4	219419,9	273116,4	359216,1	448461,5	578726,4
Inflation	-0,24%	12,07%	48,70%	13,91%	14,44%	10,95%

Table 1 shows the value of GDP, capital investment and inflation, while Fig. 2 expands these values by the employment rate.

Fig. 2: The employment rate in comparison with GDP in Ukraine 2013-2018
Source: tradingeconomics.com.

The values of the employment rate are presented in comparison with GDP. As the data presented show, after the crisis and the difficulties encountered by Ukraine in earlier years, the economic situation in Ukraine began to stabilize from 2016.

Ratio analysis in research on the effectiveness of banks

Nowadays, the most popular method of analysing a bank's financial situation is the ratio analysis. The basis of such analysis are the financial amounts disclosed by banks in key financial statements such as balance sheet, profit and loss account, and cash flow. The results of a skilfully conducted indicator analysis can provide interested parties with numerous relevant pieces of information regarding the standing of the bank. Such skilfully used information may enable banks to take appropriate corrective action in advance, so that the negative consequences of "market and economy corruption by the bank" can be reduced and, in exceptional cases, ruled out.

Literature studies indicate several groups of indicators significant from the point of view of the bank's financial situation, among which Zabawa (2011) and Kochaniak (2010) lists the group of profitability indicators, margin indicators, financial result burden, and employment efficiency. According to another literature source Iwanicz-Drozdowska (1999), the following indicators are marked as financial indicators enabling a proper assessment of the bank's financial standing: efficiency, liquidity, solvency, stock market, and asset quality.

Market analysts dealing with analyses of the banking sector point to certain accepted market standards, in which the basis for assessing financial performance of banks are mainly the following indicators mentioned by Iwanicz-Drozdowska (2005): profitability, margin, financial result burden, as well as employment efficiency. For that reason, these groups of indicators are the main focus of the analysis of the financial standing of key banks in Ukraine.

The analysis of the values of individual ratios can be performed from the point of view of the group of the surveyed banks (which provides an opportunity to assess selected banks against the background of the group, e.g. Lithuanian banks, Polish banks) or time. Since the presented results are only part of the research on the financial efficiency of key banks in Ukraine, the presented article focuses on the analysis of the indicators obtained over time, taking into account the period 2013-2018. This approach allowed comparison and assessment of changes in the effectiveness of individual banks over time.

Considering the availability of unit data in the BanksFocus database, the following indicators, mentioned by Kochaniak (2010), were used in the study: ROA and ROE. In the conducted analysis,

according to the indications of Kochaniak (2010) the scientist researching the topic, the relation between selected indicators, i.e. the rate of return on equity and the rate of return on assets, was presented as follows:

- ROE > ROA – effective use of equity,
- ROE = ROA – the same return on equity and assets,
- ROE < ROA – the costs of liabilities are higher than the income obtained from investing them.

Both the value of ROE and ROA do not have any unambiguous benchmark, but should be as high as possible and compared to the values obtained by banks of a similar nature, as indicated in the scientific study of Kałużny (2012). For this reason, in the conducted analyses, the values of indicators recorded in the analysed period in the European Union, Poland, Lithuania, Latvia, Estonia, and the Czech Republic were used as comparisons.

The values of individual ratios for the analysed banks in the adopted period of 2013-2018, along with the determined minimum, maximum and average values may be used not only to appropriately rank the obtained results, but also to predict the behaviour of banks in the near future.

Analysis of changes in selected indicators of financial efficiency of Ukrainian banks

The analysis conducted during the research covered seven different financial values significant from the point of view of the financial effectiveness of the bank's operations. In this article, due to volume restrictions, there is presented the analysis of ROA and ROE indicators.

The analysed group of items consisted of the 15 largest banks of Ukraine and is presented in Table 2.

Table 2: List of banks included in the analysis

No.	The name of the bank	No.	The name of the bank
1	PrivatBank	9	Ukrsibbank
2	Oshchadbank	10	Prominvestbank
3	Ukreksimbank	11	OTP Bank
4	Ukrhazbank	12	Ukrsotsbank
5	Raiffeisen Bank Aval	13	Credit Agricole
6	Alfa-Bank Ukraine	14	Citibank (Ukraine)
7	Sberbank	15	Procreditbank
8	First Ukrainian International Bank		

Source: own elaboration.

Total assets of a selected group of banks accounted for over 50% of the banking sector's assets in Ukraine in the period 2013-2015. In 2017-2018, the share of the surveyed banks in the sector's assets increased to over 85%. For this reason, it was decided that this group, as the key players on the banking market of Ukraine, will be the basis for research. The first of the analysed indicators was ROA.

Return on Assets (ROA)

ROA is a parameter included in the group of profitability ratios that do not generally have limit standards. Their amount is compared in time and in space, most often against other banks, preferably from a given sector. This value can also be compared with the adopted

forecasts (e.g. assumptions of the bank's economic and financial recovery plan). The higher the value of these indicators, the better. The threshold value for profitability indicators is zero, because a negative indicator indicates a loss being generated by the bank, which in turn is an adverse phenomenon indicating a lack of financial efficiency of the bank's operations. Zaleska (2007) point out that the negative value of this indicator indicates not only the balance sheet loss but also the incompetent management of the bank or criminal activities. Both situations can contribute to the bankruptcy of banks. Therefore, the analysis of ROA is extremely important in research on the financial efficiency of banking sectors.

In the case of the analysed group of Ukrainian banks, there could be observed ROA values below zero in the analysed period. The minimum value of this indicator in the analysed period ranged from - 61.5% (recorded in 2016 by PrivatBank) to - 6.48% (recorded in 2013 by Prominvestbank). The highest value of ROA was achieved for Citibank (Ukraine) in 2014 and it amounted to 13.08%. It should be noted that Citibank was characterised by one of the highest ROA values throughout the entire analysis period. In addition, the analysis of the value of this indicator showed that, taking into account the average ROA value for each bank in the entire analysed period 2013-2018, the best banks are, in the following order: Citibank (Ukraine), Credit Agricole, Raiffeisen Bank Aval, Procreditbank, First Ukrainian International Bank, Ukrsibbank. For these banks, the average of the six analysed years was above zero.

The average value of the indicator in the analysed timeframe ranged from - 6.53% in 2015 to 1.2% in 2013. The average values of this variable for the entire time series are presented in Tab. 3.

Table 3: Average, minimum and maximum ROA values

ROA	2013	2014	2015	2016	2017	2018
min	-6,48%	-13,32%	-4,867%	-61,50%	-14,97%	-11,33%
max	8,04%	13,08%	10,14%	7,39%	5,64%	6,08%
average	1,20%	-2,76%	-6,53%	-6,19%	0,04%	1,14%

Source: Own calculations based on data from the BankFocus database and from the financial statements of banks

Unfavourable ROAs that could be observed in the key Ukrainian banks in the analysed period were caused, on the one hand, by the outbreak of the armed conflict in Donbass and the associated adverse changes in the financial system, especially in the banking sector. On the other hand, the reasons for the decline in the efficiency of some banks were ownership transformations as well as economic and political changes taking place in Ukraine.

Comparing the results of the largest Ukrainian banks with the results achieved in the same period by the banking sector of this country (see Table 4), it can be seen that the majority of banks with ROA below the sector were in 2014. The years 2015 and 2018 also recorded poor results in this respect and while the 2018 result can be read as positive because the ROA value above the sector meant a result above zero for this indicator, in 2015, unfortunately, the result for the above sector cannot be read as positive. This situation concerned Raiffeisen Bank Aval, which had an above-sector ROA; however, it was still negative (-2.81%), which was interpreted as negative in the analysis of the bank's financial effectiveness, indicating the bank's financial problems.

Table 4: Value of ROA in the period 2014-2018 for the banking sector of Ukraine

ROA	2013	2014	2015	2016	2017	2018
Ukraine sector	0.48%	0.26%	-4.24%	-12.42%	-1.76%	1.60%
banks with ROA above the sector	10.00	4.00	7.00	12.00	12.00	9.00

Source: own study based on data from the International Monetary Fund.

When comparing the results of the banking sector of Ukraine in the years 2013-2018 in terms of the ROA ratio with the results achieved in the same period by the sectors of selected countries of Central and Eastern Europe (Table 4), it can be seen that in the years 2013, 2014 and 2018 ROA was more favourable for the Ukrainian sector than for the entire EU. It can be noted here that the poor results of 2015-2017 are the aftermath of the war which broke out in 2014.

Analysing the value of ROA in the Ukrainian sector and the value of this indicator in selected countries of Central and Eastern Europe, it can be noted that apart from 2018, the other years are the period in which the ROA of the Ukrainian banking sector was below the value of this indicator in countries such as Poland, Latvia, Lithuania, Estonia, and the Czech Republic, as shown in Table 5.

Table 5: Value of the ROA (%) in the period 2014-2018 in selected banking sectors

	2013	2014	2015	2016	2017	2018
UE	0.1	0.2	0.3	0.3	0.4	0.43
Poland	1.12	1.03	0.86	0.82	0.78	0.76
Estonia	1.77	1.58	1.08	1.55	1.36	1.42
The Czech Republic	1.08	1.18	1.17	1.15	1.09	1.1
Lithuania	1.02	0.88	0.92	0.98	0.88	1.24
Latvia	0.91	0.98	1.2	1.51	0.88	1.22

Source: Own calculations based on data from the BankFocus database and from bank financial statements, IMF data, ECB, World Bank.

The analysis shows that the bank which maintained the highest and most favourable ROA value throughout the entire period under review was Citibank (Ukraine). Credit Agricole had the second largest ROA in the period under review, with the only weakness being 2014, in which ROA was 0.43%, whereas ROA for the sectors of banks from Poland, Latvia, Lithuania, Estonia, and the Czech Republic was around 1%.

Return on Equity (ROE)

ROE is another indicator included in the group of profitability ratios. It allows for assessing the ability of the equity involved to generate profit. Similarly to ROA, it has no indicated boundary or development standards, although Zaleska (2017) mentioned that it is accepted on the market that the value of this indicator for the bank is 10% or more. In the analysis of the ROE indicator, it is important to remember that a properly shaped value of this indicator should be at least equal to the inflation rate, so that there is no recapitalisation in the bank. It is also worth mentioning that the following relationship is maintained in a properly functioning bank:

- ROE > ROA – effective use of equity,
- ROE = ROA – the same return on equity and assets,
- ROE < ROA – the costs of liabilities are higher than the income obtained from investing them.

Analysing the ROE for individual banks included in the analysis, it can be seen that only three of them, i.e. Credit Agricole, Citibank (Ukraine) and Procreditbank, maintained the ROE > ROA ratio throughout the entire analysed period. Ukrhazbank and First Ukrainian International Bank did not maintain a proper relationship between ROE and ROA in only one of the analysed years - respectively in 2014 and in 2015. The following regularities can be observed for the remaining ten analysed banks:

- five of them had ROE < ROA in two of the six analysed years,
- three banks did not maintain the ROE > ROA relationship for three years,
- two banks retained ROE > ROA in only one year.

Therefore, taking into account this aspect of the ROA and ROE ratios, it can be said that only three of the 15 analysed banks deserved to be called financially effective. These banks not only maintained the aforementioned desired relationship between the analysed indicators, but they were also the only ones to have favourable (positive) ROE and ROA values throughout the entire analysed period.

Table 6: Average, minimum, maximum ROE values for the analysed group of banks, and inflation in Ukraine in the period 2013-2018

ROE	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**
Ukraine sector	1,72%	-31,95%	-65,51%	-122,17%	-15,34%	14,61%
min	-47,83%	-178,36%	-279,07%	-123,64	-124,53%	-161,59%
max	51,60%	76,65%	451,93%	68,48%	55,65%	61,29%
average	7,96%	-34,42%	-5,84%	-83,71%	-2,53%	2,84%
inflation	-0,24%	12,07%	48,70%	13,91%	14,44%	10,95%

Source: Own calculations based on data from the BankFocus database and from bank financial statements, IMF data, ECB, World Bank.

Analysing the minimum values for the ROE in the examined group (see Table 6) of banks, it can be seen that this value ranged from -279.07% in 2015 to -47.83% in 2013. The maximum ROE in the examined group of banks was recorded in 2015. It amounted to 451.93%. Both the minimum and maximum ROE values in the examined group of banks indicate that the most difficult year for all banks was 2014, when as many as nine out of 15 banks had ROE below zero. Equally unfavourable were the years 2015 and 2016 when seven banks out of 15 reported ROE below zero. The analysis shows that the years 2017 and 2018 are characterised by an improvement in the economic and financial situation of banks in the studied group. Only three of the examined banks in the last two analysed years showed ROE below zero and they were: Sberbank, Prominvestbank, Ukrsotsbank in 2018, as well as Sberbank, Prominvestbank and Privat-Bank in 2017.

Regarding the relationship that indicates that ROE should be at least equal to the inflation rate, it should be indicated in the examined group of banks that:

- in 2013 the condition was not met only by Prominvestbank,
- in 2014, only two banks: Citibank (Ukraine) and Procreditbank met the condition,
- in 2015, three banks met the condition: Ukreksimbank, Prominvestbank, Citibank (Ukraine),
- in 2016, five banks met the condition: Raiffeisen Bank Aval, OTP Bank, Credit Agricole, Citibank (Ukraine), Procreditbank,
- in 2017, banks such as PrivatBank, Oshchadbank, Ukreksimbank, Ukrhazbank, Sberbank, Prominvestbank, Ukrsotsbank did not meet the condition,
- in 2018, banks such as Ukreksimbank, Oshchadbank, Prominvestbank, Ukrsotsbank, and Sberbank did not meet the inflation condition.

Analysing the relation of ROE to inflation based on Table 5, it can be seen that the entire banking sector had a problem with maintaining this relationship in the period from 2014 to 2017. Only in 2013 and 2018 it can be observed that the ROE of the Ukrainian banking sector is above the inflation recorded in this period.

This situation indicates the weakness of the banking sector of Ukraine in the analysed period. The comparison of the results of the banking sector about Ukraine with the results of the EU and selected countries of Central and Eastern Europe is presented in Table 7.

Table 7: List of ROE values (in %) in the period 2013-2014 for selected countries of Central and Eastern Europe and Ukraine

ROE	2013	2014	2015	2016	2017	2018
UE	2.1	3.8	4.6	4	5.9	6.16
Ukraine	1.72	-31.95	-65.51	-122.17	-15.34	14.61
Poland	9.97	9.35	7.74	7.49	6.88	6.90
Estonia	10.74	9.69	6.79	11.1	9.2	10.36
The Czech Republic	11.36	11.44	11.28	11.86	13.02	13.97
Lithuania	8.56	7.73	7.48	11.89	9.12	11.69
Latvia	8.75	10.24	10.75	14.34	7.61	14.33

Source: Own calculations based on data from the BankFocus database and from bank financial statements, IMF data, ECB, World Bank.

As presented in Table 6, ROE for the banking sector of Ukraine strongly differed from the ROE values recorded for the EU and other analysed countries in the same period. The most favourable situation was in 2018, which may be a signal that the bank of Ukraine is slowly overcoming the difficulties and problems arising during the armed conflict which began in 2014. In 2018, the banking sector of Ukraine recorded ROE at a level above the EU average and above the average ROE for countries such as Poland, Lithuania, Latvia, Estonia, and the Czech Republic.

Conclusion

Research conducted in the article proves that the financial effectiveness for both the 15 leading banks in Ukraine and the whole Ukrainian banking sector, measured by ROA and ROE, in the period 2013-18 was not satisfactory and is characterized by changeability. Considering the development of ROA and ROE indicators, two subperiods can be distinguished:

1) the years 2013-2016, in which the deterioration of the situation of banks was observed;
2) the years 2017-2018 characterized by a significant improvement in the condition of banks.

The analysis carried out in this paper clearly shows that the years 2017-2018 are characterized by an improvement in the economic and financial situation of banks. Taking into account two analyzed indicators, the situation of the 15 leading banks and the banking sector of Ukraine is in 2018 by far more favorable then in the previous years. 2018 is the year in which the banking sector of Ukraine recorded ROA and ROE above the EU average. That means that Ukrainian banks were more financially effective than most banks in the EU banking sector.

The analysis of the financial effectiveness of banks in Ukraine through the prism of selected indicators used to assess the condition of banks, i.e. ROA and ROE, provide support for the hypothesis presented in the introduction of this article: The difficult political and economic situation in Ukraine was not without an impact on the condition of the banking sector.

As indicated in this paper, in 2013-2018 Ukraine struggled with many internal problems and the political crisis which acted as a catalyst for economic depression. However, as in the case of assessing the financial efficiency of banks, when analysing the political and economic situation in Ukraine, it can be seen that since 2016 the situation has started to stabilise, creating grounds for improvement in future years.

One of the positive aspects of the changes recorded in the last two years of the examined period is the decrease in the number of financial resources frauds (Art. 222 of the CC of Ukraine). The analysis of the total number of financial resources frauds, according to reports of General Prosecutor's Office of Ukraine, indicates that the number of registered cases is constantly decreasing - from 345 in 2014 to 61 in 2017 and 58 in 2018.

As Pohoretskyi, Serhieieva and Toporetska (2019) emphasize, the main the main reasons that contributed to the largest losses of domestic banks, and as a consequence to the decrease in the number of banks in Ukraine were: the fraudulent receipts and non-repayment of loans involve. The number of banks in Ukraine in 2013-2018 was presented in Fig. 3.

Fig. 3: Number of banks in Ukraine during the examined period
Source: National Bank of Ukraine.

As shown by the analysis of the data presented in the figure, the number of banks in the period under analysis has been steadily decreasing, with the greatest year-on-year changes recorded in 2016 and 2017. The number of banks that disappeared from the market during the 6 examined years is nearly 100 entities (94 banks).

One of the significant changes that took place in the period under review was also the change of ownership in banks. One of the most important events was the nationalisation of Privatbank, the largest bank in the Ukrainian banking sector, in December 2016. It was the biggest nationalisation in the history of Ukraine. As indicated by Repko and Soltysiak (2018), investigations showed that 97% of loans given by this bank, formerly owned by the Ukrainian oligarch Ihor Kolomoisky, were issued to former shareholders and to related-parties. Fig. 4 presents the increase in the share of state-owned banks expressed as a percentage of total assets.

Fig. 4 : The share of state-owned banks as a percentage of total assets.
Source: own elaboration based on Kirchner, R. and Kravchuk, V. (2019).

Despite the improvement in the situation of the banking sector in Ukraine in 2017 and 2018, many issues still need to be strengthened in the context of measures to improve the stability of this sector, including crime. As Klochko, Kurylo, Kvasha, Zahynei and Logvinenko (2020) point out, effective interaction of all actors in combating crime in the banking business - from law enforcement agencies to bank clients - is important for ensuring stability of the Ukrainian banking system. According to the authors, the most importance law enforcement agencies include: National Police, Prosecutor General's Office of Ukraine, Security Service of Ukraine as well as National Anti-Corruption Bureau of Ukraine and State Bureau of Investigation. Other recommendations, important from the point of view of combating crime in the banking sector, indicated in this paper, are as follows:

- it is necessary to organize regional public councils and ensure cooperation between bank clients and local banking institutions (as part of the work of the National Bank of Ukraine's Public Council);
- it is assumed that the development of effective mechanisms for protecting rights and legitimate interests of depositors and creditors, as well as combating criminalization in the banking sector will be the main functions of these regional public councils;
- the relevant innovations require amendments to the Regulation on the NBU Public Council.

An important document, specifying actions to improve the situation of Ukraine, enabling the development of the financial sector in accordance with the expectations of the EU-Ukraine Association Agreement and Ukraine's other international commitments is Strategy of Ukrainian Financial Sector Development Until 2025 (2020), prepared by: The National Bank of Ukraine (NBU), the National Securities and Stock Market Commission (NSSMC), the National Commission for Regulation of Financial Services Markets (NCFS), the Deposit Guarantee Fund (DGF), and the Ministry of Finance of Ukraine. Actions strengthening the financial sector, specified in this document, refer to both the banking market and the nonbank financial institutions sector, as well as to capital markets. The five main development priorities of the financial sector indicated in the Strategy are:

- strengthening financial stability
- promoting macroeconomic development and economic growth
- developing financial markets
- expanding financial inclusion
- introducing innovations in the financial sector.

As the Ministry of Finance of Ukraine (2020) finds, the implementation of the Strategy will contribute to the creation of a transparent, competitive, stable and high-tech financial sector technologically, and thus will allow to the sustainable and inclusive development of the Ukrainian economy and to improve the well-being of households (through the efficient accumulation and redistribution of financial resources in the economy).

Abstract

This article focuses on the cost to income ratio as a critical measure describing the cost-effectiveness of banks. The article is a continuation of the research presented in the study "Financial situation of the banking sector in Ukraine in 2013-2018". The aim of this article is to present the results of analyzes on the cost efficiency of selected 15 leading banks in Ukraine in 2013-2018. This article focuses on the cost to income ratio (C/I). The research hypothesis is: cost effectiveness of leading banks in Ukraine, measured by the C/I ratio is negatively related to bank profitability in the period 2013-2018. The research presented in the article confirms the hypothesis. The cost to income ratio is negatively correlated with both ROE and ROA indicators. The only exception is 2015, when the C/I and ROE correlation was positive. The reason for this can be seen in the political and economic situation shortly after the outbreak of the conflict in Donbas.

Keywords: Financial Security of Banks, Benchmark Analysis of Banks, Financial Effectiveness, Cost-Effectiveness of Banks

Introduction

Political, economic and social changes taking place in the Ukrainian economy in 2013-2018 had an impact on the changes in the banking sector of Ukraine. At the end of 2014, it was noticeable that the economic crisis caused by political instability and the conflict with Russia had a significant impact on the situation of local banks. Data from the National Bank of Ukraine (NBU) from the end of 2014 indicate that 21 out of 184 commercial banks were subject to the liquidation procedure (NBU, 2013; NBU 2014; NBU 2015). In December 2014, another 16 banks were declared insolvent. The wave of bankruptcies observed in the banking sector of Ukraine in 2014-2016 was caused by the risky credit activity of banks, a significant number of unprofitable banks, as well as an inadequate policy of the National Bank of Ukraine. These unfavorable aspects of the operation of Ukrainian banks were reflected in the financial situation of some banks and, as a consequence, in a decrease of profitability and efficiency of Ukrainian banks against the background of European banks. In response to the bankruptcies of the NBU, to improve the financial condition of the sector and individual banks, it increased the minimum level of share capital from UAH 120 million to UAH 400 million in 2018. These changes can be considered as positive actions of the NBU to increase stability in the banking sector and bring the banking sector of Ukraine closer to European standards.

The massive wave of bankruptcies recorded in Ukraine in 2014-2016 made it necessary to conduct research on the financial efficiency of key Ukrainian banks. Our study focused on the analysis of changes in selected financial indicators in selected 15 largest banks of Ukraine. The period adopted in the study is 2013-2018.

The aim of this article is to present the cost-effectiveness of selected leading banks in Ukraine and the relationship between the cost income ratio (C/I) and ROE (return of equity) and ROA (return of assets) indicators. The article presents part of the results of research conducted by the authors as part of a project related to the issue of effectiveness of the banking sector in Ukraine. The analyzes conducted by the authors during the research covered 7 different financial values that are the most important from the point of view of this issue. This article focuses on one cost to income ratio describing the cost effectiveness of banks. It is a continuation of the research published in the article entitled "Financial situation of the banking sector in Ukraine in 2013-2018 from the point of view of changes in selected financial indicators of key Ukrainian banks" (Bywalec, Dudynets and Swacha-Lech, 2020). The article uses a critical analysis of the literature on the subject, analysis of financial indicator and Spearman rank correlation coefficient between C/I and ROE as well as C/I and ROA. There was also conducted a comparative analysis of changes in the size of C/I indicator over the years 2013-2018. The necessary empirical data were collected using BankFokus database, data from the International Monetary Fund (IMF), the World Bank (WB) and the European Central Bank (EBC) and the financial statements of banks.

The research hypothesis formulated in this article is: cost effectiveness of leading banks in Ukraine, measured by the C/I ratio, is negatively related to bank profitability in the period 2013-2018. This hypothesis is backed-up by the political and economic situation of Ukraine with the results of the effectiveness of banks.

Ukrainian Banking Sector

The banking system of Ukraine has a two level. The system is headed by the NBU and the second level consists of commercial banks, which number at the end of 2018 was 82 (according to NBU). Changes in the number of commercial banks in 2013-2018 in Ukraine are presented in Fig. 1.

Fig. 1: The number of commercial banks in Ukraine in 2013-2018

Source: own study based on NBU, Annual Reports 2013-2018.

We could observe a downward trend in the number of commercial banks in Ukraine in the analysed years. Particular attention should be paid to the period 2014-2016, when 67 banks were liquidated, as a result of which the Ukrainian banking system lost UAH 435 billion in assets. This corresponds to approximately 22% of Ukraine's GDP (*Bankruptcies of banks in Ukraine are ruining citizens, they are hitting the economy*, Obserwator finansowy.pl). As Kirchner and Kravchuk (2019) show the years 2013-2016 was characterized by the increase in the share of state-owned banks expressed as a percentage of total assets (from 18 in 2013 to 55 in 2018).

Negative consequences of bankruptcies in the banking system of Ukraine were felt very strongly by natural persons who lost their savings. As a consequence, a large part of UAH entered the market, winding a wave of devaluation of the national currency of Ukraine.

The bankruptcies of a large number of banks as well as the low level of deposit guarantees up to 200,000 UAH (about EUR 7,000) caused a decrease in public confidence in the Ukrainian banking sector.

As Barisitz and Lahnsteiner (2017) highlight the Ukrainian banking sector faced a deep crisis - shrinking lending a deposit-taking, sharply risking proportion of bad loans and recapitalisation needs. One of the most important aspects of banking sector analysis which show an impact of the crisis on banking sector is the size of total assets. The value of total assets, total loans as well as deposits in the Ukrainian banking sector in the years 2013-2018 is presented in Table 1.

Table 1: The value of total assets, total loans and deposits in the Ukrainian banking sector in the years 2013-2018

	2013	2014	2015	2016	2017	2018
Total assets (EUR m)	115700	68462	46537	43189	40240	42874
Total loans (EUR m)	72384	45423	26605	18953	16752	18559
Deposit from households (EUR m)	40021	21980	14973	15058	14316	16033
Total loans as % of total deposits	113.7	121.6	93.1	63.5	60.4	61.2

Source: Kirchner, R., Kravchuk, V. (2019). Banking Sector Monitoring Ukraine, Institute for Economic Research and Policy Consulting and German Advisory Group, Policy Briefing Series [PB/05/2019].

The impact of financial crisis in Ukraine is also noticeable in the analysis of sector efficiency expressed in ROA and ROE ratios. As shown in the table 2 the years 2013-2016 are characterized by the deterioration of the financial situation of banks. Negative ROE and ROA in 2014-2017 are due to bank losses during this period. Among the main reasons for this was the formation of huge reserves to cover possible losses on active operations, as it was stated above. As a result, banks did not have internal sources of bank equity management.

Table 2: Value of the ROA and ROE in the period 2014-2018 in Ukrainian banking sectors and EU (%)

		2013	2014	2015	2016	2017	2018
ROA	**Ukraine**	10.00	4.00	7.00	12.00	12.00	9.00
	EU	0.1	0.2	0.3	0.3	0.4	0.43
ROE	**Ukraine**	1.72	-31.95	-65.51	-122.17	-15.34	14.61
	EU	2.1	3.8	4.6	4	5.9	6.16

6	Alfa-Bank Ukraine	14	Citibank (Ukraine)
7	Sberbank	15	Procreditbank
8	First Ukrainian International Bank		

Sources: own study

In the period 2013-2015, the total assets of the analyzed banks constituted over 50% of the banking sector assets in Ukraine. In 2017-2018, the share of surveyed banks in the sector's assets increased to over 85%.

Due to the large share in total assets, the banks indicated in Table 2 have the greatest impact on the financial efficiency of the entire sector. These banks can be treated as patterns of behaviour on the Ukrainian market. Therefore, cost-effectiveness analyses and a correlation study between bank profitability and the C/I ratio were carried out for these banks.

Cost to income in assessing the effectiveness of banks

The effectiveness of banks is an extremely important issue in the context of assessing the activities of banking sector entities. The importance of this issue is reflected in the extensive literature on the problem of effectiveness. Articles that are part of the discussion on this subject concern both definition problems related to the term of effectiveness, as well as its types, measures or determinants of effectiveness (Casu and Molyneux (2003), Mester (1996), Huljak, Martin and Moccero (2019), Tripe (1998), Maudos, Pastor, Pérez and Quesada (1999), Bulajić, Jeremić, Knežević and Žarkić-Joksimović (2013), Chen (1998), Elahi and Poswal (2017)).

Both in the domestic and world literature the cost to income ratio is indicated as one of the significant indicators used to assess the bank's activity (e.g. in UK and Germany - Elahi and Poswal (2017), Australia - Tripe (1998), New Zealand - Hess, K. and Francis, G. (2004), Tripe (1996), Ghana - Antwi (2019), Naples - Pradhan and Parajuli (2017), Nigeria - Odunayo, Olarewaju, Oladejo and Migiro (2017), Kenya - Muriithi and Muigai (2017), Ukraine - Дудкин, Королев (2019).

As shown in the introduction, the problem of bank effectiveness is widely described in contemporary world literature. Jaworski (2006) indicates that effectiveness comes down to achieving the intended goals, ensuring the achievement of measurable economic benefits, greater than expenditure incurred. In terms of the literature generated for Poland, the problem of effectiveness is raised, among others, by: Capiga (2002; 2003; 2009), Siudek (2008), Kozak (2010), Kubiszewska (2015), Siudek and Drabarczyk (2015), Balina (2016), Kopiński and Porębski (2016), Kata (2017), Lepczyński and Gostomski (2018). This work concerns both issues related to theory (definitions, types of effectiveness) and practice (research for economic and financial effectiveness of selected banks). The following issues can be identified among the examined issues:

- measuring and assessing the effectiveness of commercial banks,
- measuring and assessing the effectiveness of cooperative banks
- economic growth and development versus financial effectiveness of banks,
- factors affecting the profitability and effectiveness of banks,
- dependence of the bank's performance on the gender of its president
- economic and financial effectiveness of banks in the conditions of low interest rates.

In the articles on the efficiency of the banking sector in Ukraine, the researchers refer to various aspects of the efficiency of the sector. They therefore examine intermediation-type efficiency of individual banks, bank lending efficiency as well as cost and profits efficiency. Zelenyuk and Zelenyuk (2014) estimate the intermediation-type efficiency of individual banks and analyze how bank specific factors explain the differences in the estimated levels of inefficiency across banks. They found strong support for the conclusions from the agency theory and proved that banks that were 100% foreign owned were significantly more efficient than locally owned and partially foreign owned banks, on average and ceteris paribus and, in particular, regardless whether they were headquartered in the capital city or in a region, in the East or in the West of the country.

Mohammad, Kots, Lyashenko (2016) analyzed in detail the forms of distribution by particular efficiency value levels of bank-lending in the real sector of Ukraine's economy. The crucial results of the study are as follows:

- there is the tendency to decline in average values of bank-lending efficiency in the real sector of Ukraine's economy, which is observed against the background of considerable values of inefficient component quota in error full dispersion of the observed model of the corresponding stochastic efficiency boundary;
- the efficiency of processes of transformation of attracted resources into lending resources with relation to banks functioning in Ukraine is determined in many respects by the adequacy of the real banks resources usage.

Mertens, A. and Urga, G. (2001) conducted the research related to cost effectiveness and profit efficiently of the banks in Ukraine in 1998. The authors proved that small banks operate more efficiently in cost terms, but they are less efficient in profit terms. They indicated that there is a significant difference in economies of scale between small and large banks. Large banks showed significant diseconomies of scale, while small ones - significant scale economies.

Capiga (2003) distinguished three types of banks effectiveness: organizational, financial and cost (Fig. 2).

Fig. 2: Types of banks effectiveness

Source: own elaboration based on Capiga (2003).

Organizational effectiveness is related to the organization's goals and resources. It refers to the conditions existing inside and outside the organization, and also includes the time at which this concept is evaluated. Financial effectiveness is in turn related to the financial position of the bank, the financial results obtained. In order to determine it, we use information from financial statements. Cost

effectiveness, in turn, refers to the assessment of whether a given production volume was achieved with an appropriate volume and structure of inputs.

As Miklaszewska (2010) indicates, many methods are used to measure the effectiveness of banks - from financial indicators to econometric models. Among the methods of estimating effectiveness, two groups can be distinguished - parametric and non-parametric. Parametric methods include Stochastic Frontier Approach and Thick Frontier Approach. An example of non-parametric methods may be Data Envelopment Analysis (DEA). DEA is a popular method used by many researchers (among others: Staub, e Souza and Tabak (2010), Xiaogang, Skully and Brown (2005), Wu, Yang and Liang (2006), Wang, Lu, and Liu (2014), Chen (1998)).

The cost to income ratio, which is the crucial focus of this article, is used in the index analysis to assess the bank's cost-effectiveness. Analysis of the value of this indicator allows determining whether the bank is or is not cost-effective. A decrease in the value of this indicator means an improvement in the bank's financial efficiency, which is explained by the fact that the same amount of profit is obtained when the bank incurs lower operating costs.

As Tripe (1998) points out, despite the fact that the C/I ratio refers to both costs and revenues, its interpretation and information value focuses mainly on costs. Lowering costs, with a fixed level of income, should lead to an increased profit, and thus to an increase in return on equity and share prices, which are a measure of investors' greatest interest in bank shares. When interpreting this indicator, it should be remembered, however, that its value affected not only by costs, but also by variations in incomes. They can be caused by internal and external factors - inefficient operations of banks, lowering margins or an economic slowdown.

In a situation of low interest rates causing a decrease in interest income streams, skilful cost management at the bank is becoming increasingly important. As emphasized by Lipski (2015), banks with a persistently high cost-to-income ratio in the long term will not be able to cope with the aggressive battle for the client.

Elahi and Poswal (2017) studied factors influencing cost effectiveness for the banks in UK and Germany. The explanatory variables include the following six values: profitability, credit risk, net interest margin, income diversification, financial leverage as well as bank size. To indicate profitability they use ROA ratio. Results of conducted research show that cost effectiveness is positively influenced by ROA for both economies, so higher the returns on total assets, higher will be the bank effectiveness. The authors emphasize that clients usually prefer those banks that have higher profitability. The best potential creditworthy borrowers will therefore be more willing to use the services of this group of banks. Similarly, people wanting to invest their funds will be more willing to choose banks with higher profitability, which will translate into significant share of deposits.

In the next parts of the article, the authors will first analyze the cost to income ratio for leading banks in Ukraine in 2013-2018, and then the relationship between the cost to income ratio and the profitability, measured by ROE and ROA.

Cost to income ratio analysis for leading banks in Ukraine in 2013-2018

In 2014, there was a significant increase in the C/I ratio for some banks. During this period, the costs of Ukrainian banks increased by 57.2%. Banks suffered significant losses from the temporary occupation of the Autonomous Republic of Crimea and the situation in eastern Ukraine. The second reason was the increase in the amount of deductions to reserves for possible losses from active operations. In general, in the banking system, deductions to the bank reserves increased 3.7 times compared to the ones in 2013, and the total expense share increased from 16.7% to 39.3%.

Those banks which pursued risky unbalanced policies or gave loans to finance large-scale projects appeared to be the most sensitive to shocks.

The banking sector of Ukraine was also negatively affected by the devaluation of the hryvnia exchange rate in 2014-2015. This led to the non-repayment of foreign currency loans to banks from a significant number of domestic debtors and the growth of problem assets. The share of problem loans of banks for the period 2013-2017 increased from 7.7% to 54.5%.

Considering the evolution of C/I indicator in the examined group of 15 Ukrainian banks, Citibank (Ukraine) should be mentioned as the undoubted leader. In all the analysed years, this bank recorded a C/I ratio below 50% (see Table 4). It should be noted that Citibank is a specific narrow-profile bank that does not work with individuals, so its indicators are much better than those of other universal banks operating in all market segments.

Table 4: C/I ratio value for the banking sector of Ukraine and for the best banks in the analysed group in the period 2013-2018 (%)

	2013	2014	2015	2016	2017	2018
Citibank (Ukraine)	23.82	17.04	26.41	9.52	18.55	14.00
Procreditbank	83.71	72.46	28.06	57.78	46.84	38.96
Raiffeisen Bank Aval	88.63	95.87	124.62	46.99	36.75	42.22
Credit Agricole	69.25	88.96	79.85	66.19	53.38	49.85
Ukrsibbank	98.08	122.96	99.23	119.95	63.59	50.50
OTP Bank	94.87	167.74	685.21	71.28	60.66	46.88
Ukraine sector	65.62	60.57	55.37	49.18	60.82	58

Source: Own calculations based on data from the BankFocus database and from bank financial statements.

Procreditbank was in second place in terms of the C/I ratio. In the case of this bank, in 2015, 2017 and 2018 a significant decrease in costs could be seen, which had a positive impact on the indicator. The level of the C/I ratio of OTP Bank in 2015 at 685.21% is mainly due to the growth of the bank's expenses to increase reserves to cover the risks of the foreign currency loan portfolio in the conditions of exchange rate instability. In the third quarter of 2015, the bank formed additional reserves for foreign currency mortgages, as well as for loans in Donetsk and Luhansk regions. Raiffeisen Bank Aval showed a C/I level below 505 in 2016-2018. The other three banks indicated in Table 2 recorded a C/I ratio below 50% only in the last year, 2018. The high level of the C/I ratio is observed for Raiffeisen Bank Aval and Ukrsibbank. These banks are characterized by the most conservative policy of formation of reserves, which they highlight in their financial statements.

The high levels of the C/I ratio for the other nine analysed banks reflected the behaviour of the Ukrainian market, which translated into a high level of C/I for the banking sector of Ukraine. As can be seen in Table 2, the banking sector of Ukraine only in 2016 recorded a value of cost-to-income below 50%.

When analysing the results achieved by the banking sector of Ukraine in relation to the C/I ratio in the EU (as presented in Table 5), it is easy to notice that the results of the Ukrainian sector were below the EU average. Such a level indicates that the banking sector of Ukraine, taking into account cost-effectiveness, did better than most countries included in the European Union.

Table 5: C/I ratio in selected countries of Central and Eastern Europe and Ukraine (%)

	2013	2014	2015	2016	2017	2018
EU	65.28	63.38	63.46	65.88	64.03	65.73
Poland	52.67	52.15	62.27	56.96	56.30	55.87
Estonia	50.16	48.26	46.86	47.99	52.01	55.32

The Czech Republic	28.49	35.64	30.55	46.09	46.60	38.45
Lithuania	54.27	45.06	43.05	37.32	51.08	38.81
Latvia	53.59	52.62	53.07	50.64	65.18	75.05
Ukraine	65.62	60.57	55.37	49.18	60.82	58

Source: Own study based on data from World Bank.

Analysing the level of the C/I ratio in the countries indicated in Table 3, it can be seen that in 2013 the situation of Ukraine from the point of view of this indicator was the worst among the countries concerned. It was similar in 2014. However, 2015 brought a slight improvement and, as can be seen in the table, only Poland (62.27%) had a worse situation than Ukraine in terms of C/I. In 2016, Poland and Latvia had C/I higher than Ukraine. In 2017 and 2018 only Latvia had a C/I ratio even worse than the Ukrainian sector, and it was 65.18% and 75.05% respectively. Therefore, as presented, the situation in terms of cost-effectiveness of selected banks of Ukraine and the entire sector in 2013-2018 varied. However, a favourable trend of changes could be observed, which resulted in the value of the C/I ratio in 2018 at 58%, close to the value indicated as preferred for the sector (50%).

Analysis of the relationship between the C/I ratio and ROE and ROA profitability

During the research the Pearson's linear correlation coefficient and Spearman's rank correlation coefficients between C/I and ROA and ROE were calculated, which indicates the strength and direction of the relationship between variables. Because of construction of these financial indices, we expected the negative value of the correlation coefficient, indicated that the increase in the C/I value was accompanied by a decrease in the tested value (ROE or ROA). When analyzing the correlation coefficients, it should be remembered that it takes values in the range from -1 to 1. A correlation value at level 1 is interpreted as an ideal positive correlation, while -1 as a perfectly negative correlation. A score of 0 means no linear correlation. Bojańczyk (2013) in his study proposes an interpretation of the value of the correlation coefficient (see Fig 3.). There is a strong relationship when the correlation coefficient exceeds 0.7 (or -0.7).

Fig. 3: The interpretation of the value of the correlation coefficient

Source: own elaboration based on Bojańczyk (2013).

Scatterplots showed us outliers in some years, so we decided to use rank correlation. In our research conducted for the 15 largest banks of Ukraine in the period 2013-2018, it was noted that the all values of the Spearman's coefficient, measuring the rank correlation between C/I and bank profitability ratios, are negative (see Table 6). Because usually the maximum of correlation between C/I and ROA or ROE was observed for indices from the same year, Table 4 shows rank correlation between variables from the same year.

Table 6: Spearman's correlation coefficient for C/I and ROE and ROA profitability ratios in the period 2013-2018

Year	2013	2014	2015	2016	2017	2018
Indices	C/I	C/I	C/I	C/I	C/I	C/I
ROE	-0.9143	-0.88214	-0.49643	-0.97143	-0.94643	-0.85357
ROA	-0.425	-0.93929	-0.82857	-0.97857	-0.95714	-0.91786

Sources: own calculations.

As you can see in Tab 4. in the examined period the group of examined banks showed usually a strong and very strong negative correlation between the C/I ratio and return on equity (ROE). The only exception was 2015, when the correlation was moderate negative. The reason for this can be seen in a consequence of economic disturbances resulting from the political conflict in Donbas, which translated into temporary disturbances in the banking sector of Ukraine.

Looking at the correlation between C/I and ROA, it can be seen that throughout the entire period considered it was negative. In 2013 it was very weak. The years 2014, 2016, 2017 and 2018 are a very strong negative correlation.

Analysis of correlation shows that cost-effectiveness assessment of banks based on the C/I index could be empirically seen as inverted problem of the bank profitability, measured by means of ROA and ROE.

Conclusion

The years 2013–2018 were a period in which Ukraine experienced many difficulties - both politically and economically. Armed conflict (the occupation of Crimea and some areas of Donetsk and Luhansk oblasts) and other political problem acted as a catalyst for economic crisis. Ukraine struggled with many internal problems, such as: high level of financial crimes, corruption or several waves of significant depreciation of the hryvnia at this time. Importance of the problems which Ukraine faced is perfectly defined by the sentence formulated in the study of the National Bank of Ukraine (NBU), the National Securities and Stock Market Commission (NSSMC), the National Commission for Regulation of Financial Services Markets (NCFS), the Deposit Guarantee Fund (DGF) and the Ministry of Finance of Ukraine (2020), which indicate that in 2014-2016 the state is “faced a triple crisis as the combined impact of a banking crisis and a currency crisis exacerbated a crisis in the real sector of the economy”.

Research conducted in the in the first part of the article proves that the cost effectiveness for the 15 leading banks in Ukraine in 2013-2018, shown on the whole Ukrainian banking sector, banking sectors of selected countries and the EU average, was characterized by volatility throughout the entire period examined. The best indicator value for both the 15 banks examined and for the entire Ukrainian sector was recorded in 2018.

The analyzes conducted in the second part of this article show a negative relationship between the cost to income ratio and ROE and ROA profitability ratios. This means that with the market trend to reduce the costs of banks’ activity, the profitability of banks will increase. This statement seems appropriate given the assumption of a normally functioning economy and the absence of political shocks. The research show that political conflicts translate into the relationship between C/I and ROE. It can be observed that in 2015, a year after the outbreak of the armed conflict in Donbass, the relationship between C/I and ROE changed to a positive one. Thus, with the increase in costs, an increase in the profitability of banks' capital could be observed.

An in-depth analysis of the cost to income ratio would require an extension of the research undertaken in this article to include a detailed study of the factors that affected the fluctuations of the

indicator over the period under analysis. It is therefore necessary to look in detail at the individual cost items each year and explain what factors influenced their fluctuations in value (e.g. costs related to salary). Analysis of these issues would allow full interpretation of the results obtained in this article.

It also seems interesting to propose to examine the relationship between the C/I ratio and ROE and ROA in other countries, which could lead to find out the reasons why the correlation between these indicators is positive. An interesting aspect of the research will also be the examination of the correlation between ratios cost to income and Tier 1.

The authors plan to expand research on the effectiveness of Ukrainian banks by further indicators (e.g. net interest margin) and further analysis. We also plan to undertake research on the efficiency of the banking sectors of selected European countries. This will allow interesting comparisons to be made between the countries studied and to identify certain patterns.

Gauging Social Media Users Satisfaction – Based on The Case of Facebook

Karol LOPACINSKI

Wroclaw University of Economics and Business, Wroclaw, Poland
karol.lopacinski@ue.wroc.pl
The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

Abstract

Customer satisfaction is a fundamental and key confirmation of quality of any product offered on the market. A satisfied customer is very often the guarantee of company strong market position and its competitive advantage. Therefore, it is understandable that more and more companies treat the customer satisfaction as the most important attribute describing the quality of the merchandises or services. It also concerns information systems such as social software / social networks that are offered on the market. Customer satisfaction studies concerning utilization of these products allows to know the factors that motivate people to use this type of websites. Equally important is obtaining information about which parts of this type of software operate unsatisfactorily for users. Thus this kind of knowledge is crucial in the processes of modifying and improving of community portals such as Facebook etc. The analysis of the Internet market clearly show that the average internet user increasingly willing to use different kinds of social networks. Therefore, it can be concluded that the satisfaction level of social media usage is shaped at a high level. However, there is a lack of studies on the topic of estimating the satisfaction of end-users of this type of software. The article presents the concept of estimating users satisfaction with social software, which is based on the achievements of marketing research and software quality studies. The basis of this concept is the model of user satisfaction in the context of social media that has been created by the author. The model is based on selected set of the most important end-user quality attributes describing the social networks. Such approach will not only determine the level of overall users satisfaction, but will also provide specific information for software improvement. The proposed model has been verified in the quantitative empirical research on the example of Facebook social network. The study have been carried out using survey method on the a group of active users i.e. university students.

Keywords: User Satisfaction, Social Media, Social Media Users' Satisfaction Model;

Introduction

Customer satisfaction is a fundamental and key measure of quality for products offered on the market. This also holds true in relation to such products as social media and software applications employed in the provision of such services. Studies of customer satisfaction of end users of social media platforms seem of particular importance in the context of future modifications and improvements, as they help recognize the most important factors that motivate users to invest their time and effort in this type of service. Another important benefit offered by that kind of analyses in this respect is the better understanding of reasons behind the enormous popularity of social media.

Professional ICT literature provides ample and frequent analyses of the social media phenomenon. Ever since the onset of such versatile platforms allowing for close integration and organization of activities of various virtual communities, the social media phenomenon has been studied at length and perceived as one of the most dominant trends in the development of modern communication systems. Researchers approach the subject from a multitude of perspectives, with the view of improving the reach and popularity of social media, providing added functionalities and areas of application, and facilitating their use for image-building and marketing purposes. Many studies are also devoted to the

task of analysing directions and perspectives of future development in this particular market segment. Analyses of internet and mobile markets clearly show that the average modern user of digital communication services is more inclined to reach for this type of service on a daily basis, which may be suggestive of the relatively high level of customer satisfaction from functionalities offered by social media applications. At the same time, literature studies suggest a clearly manifested disregard for a scientific approach to the evaluation of customer satisfaction among users of this particular type of applications. Even more baffling is the fact that social media falls behind other types of applications and software packages, which are typically subject to close examination in this respect – this observation holds true both with regard to standardized products and to dedicated systems employed in modern organizations.

In the light of the above, this paper represents an attempt at formulating a model of customer satisfaction to be used in the context of social media users. The model adopts some of the most useful properties of the available studies on customer satisfaction from software products, but it is construed and adjusted to fully correspond with the nature and specificity of social media. The conceptual structure of the model is built on a set of the most significant end attributes of quality expected by users from this type of application. For verification purposes, the model shall be employed as basis for quantitative empirical studies. This will have the added effect of improving the understanding of the growing appeal of social media and recognizing some of the most important factors motivating the users to reach for this type of service.

Customer Satisfaction as A Key Criterion in The Evaluation of Software Quality

Before we commence with our analysis of the notion of customer satisfaction from software-type products, it may be useful to approach it from a more general viewpoint, i.e. in terms of satisfaction displayed by consumers of any type of product offered on the market. It may be assumed that measurement and analysis of customer satisfaction is one of the key elements of the customer-oriented approach observed in modern companies.

A product of any type, even when presently perceived to be of utmost quality, may rapidly lose its appeal in the eyes of consumers, since the structure of needs and preferences of consumer base is nowadays quite volatile. In the light of such determinants as the rich offering of innovative products, frequent quality-of-life improvements, highly competitive markets and the new challenges of the information society, companies were forced to thoroughly restructure their traditional approach to customers and place them at the centre of any decision and activity.

Good evidence of the crucial role of customers in quality improvement processes can be found in many modern and fundamental theories of management, such as Total Quality Management, Kaizen, Lean Management and Business Process Reengineering (Pawłowska, Strychalska-Rudzewicz 2005). For example, customer orientation represents the core assumption and the principal objective of the TQM concept and is defined in terms of providing utmost customer satisfaction based on informed evaluation of customer needs, analysis of customer requirements, and measurement of customer satisfaction from products on offer (Kan 2002).

Strong customer orientation as basis for quality improvements of products offered on the market is also evidenced in the construct of the international ISO 9001 standard typically adopted by companies of every segment as a fundament of their quality management systems. The general principles section of the ISO 9001:2000 standard places the main emphasis on the postulate of strong customer orientation and the use of specific practices and techniques that target the customer base (Wawak 2007). This principle is mainly associated with the need for a rational evaluation of customer expectations at the level of product design, i.e. well ahead of the time when the finished product reaches the intended market. However, customer orientation is also expressed in the recommendations for continuous measurement of customer satisfaction from product use as basis for all decisions made with regard to the company offer of products.

According to Kotler (1994), satisfaction can be defined as "a person's feelings of pleasure or disappointment resulting from comparing a product's perceived performance (or outcome) in relation to his or her expectations" (Kotler 1994). A different approach to the definition of customer satisfaction can be found in Farris et al. (2010), where the notion is perceived as a measure of the degree to which the company offer of products or services fits or surpasses the expectations of the average consumer. Moreover, the authors perceive the category of customer satisfaction as "the number of customers, or percentage of total customers, whose reported experience with a firm, its products, or its services (ratings) exceeds specified satisfaction goals" (Farris et al. 2010). In contrast to the above, Kan addresses customer satisfaction from a purchased product as the conclusive verification of the assumption that the product on offer fulfils the expectations of the client base and is (as such) fit to use (Kan 2002). It seems that the most comprehensive definition is that by Marciniak, where satisfaction (or lack thereof) is described as an emotional state experienced by a customer in relation to the product purchase and subsequent use, resulting from confrontation between the customer's initial expectations towards the product and his/her practical experience from its use (Marciniak 2005).

It is worth noting that customer satisfaction (or user satisfaction) is one of the key attributes of quality for any product. Consequently, it may be useful to approach the studies and evaluations of customer satisfaction from the viewpoint of the constant quality improvement postulate. Implementation of quality management systems is nowadays a standard practice in many countries. However, this type of activities does not necessarily result in any tangible improvements that can be measured in terms of growing customer base, increased sales or improvement of the company competitive advantage on the market. Moreover, there is plenty of evidence for companies failing to maintain their position on the market despite their advanced implementations of quality management systems. As it turns out, both the sale and the profitability of business initiatives are – to a large extent – determined by unspecified and often sector- or product-specific psychological preferences. In view of the above, for a better understanding of the correlations between company results and their chosen approach to product quality improvement, it may be advisable to employ a comprehensive evaluation of customer satisfaction (Nieżurawski et al. 2010).

In analogy to the above, customer satisfaction from the use of software-type products, as the main objective of this paper, should be viewed in much the same context as satisfaction resulting from consumption of any other type of product. From the user's perspective, a piece of software represents a product utilized for the satisfaction of specific needs. Therefore, it may be assumed that the processes related to the purchase and subsequent use of a software application or IT system generate certain responses (be it positive or negative) on the part of their users.

According to SQuaRE document (Systems and software Quality Requirements and Evaluation) containing international standards for the development of software quality, the user satisfaction of any software product is defined as (Systems&software ... 2017):

- the extent to which user needs are met when a product or system is used in a specific context of use,
- the user's response regarding his/her interaction with the system including attitudes towards the use of the product or system.

Estimation of the level of satisfaction from the utility provided by a software product requires, most of all, specification of a detailed set of attributes describing the qualitative dimension of the studied product. Based on such a set, correct queries may be defined to study the perceived satisfaction from each of the defining elements as well as the level of significance attached to each such element. The sum of responses will serve as a knowledge base to support all future decisions designed to improve the utility, user interface, functions or any other constituent element of the product quality.

The conceptual basis for the study of customer satisfaction among the users of social media services on offer by Facebook

The postulated concept for the evaluation of user satisfaction from social media service functionality involves determination of the CSI (Customer Satisfaction Index) (Kozielski 2006), one of the key measures used in the evaluation of end user satisfaction in relation to various types of software. The CSI index allows for the estimation of levels of satisfaction from each of the identified attributes of quality (i.e. those confirmed by the users as the most significant) (Mazurek-Łopacińska 2005). As such, the index takes the form of the weighted average of levels of satisfaction reported for each of the constituent attributes.

The most important base for CSI estimation is the proper recognition of attributes deemed by users as the most significant. The initial phase involves construction of a list of attributes that best describe the utility of the software from the viewpoint of the end user. The list should then be verified at a later stage, for example in the course of in-depth direct interviews with users.

There are many approaches and classifications available for the task at hand, such as the IBM model CUPRIMDSO, the FURPS approach used by Hewlett-Packard (Nafees 2011), or the SUMI method (Mansor et al. 2012). Based on critical studies of professional literature related to software quality evaluation, the author decided to employ the McCall model and the current ISO/IEC 2510 standard as basis for the determination of initial candidates to the list of key attributes of the studied social media software.

The McCall model (McCall 1977, Deepshikha 2010) is a recognized model of quality describing attributes of software quality, both from the viewpoint of the provider and the end user. This model lists three types of product quality features that are important for:

- programmers who are responsible for maintaining and maintaining the system,
- programmers who are working on transforming the system,
- users who use the system operationally (Kobyliński 2007).

Due to the fact that the subject of the study is estimating user satisfaction, only the attributes from the third group of the McCall model were taken into account. They can be taken into account when determining the most important features of social software for users.

The set of attributes of quality defined in the ISO/IEC 25010 standard is derived from the standard's SQuaRE supplement (Systems and software Quality Requirements and Evaluation), containing detailed principles for the evaluation of IT systems' quality. Among other things, the document contains a postulate for a Quality in use model employing five fundamental characteristics describing the results of user interactions with a system under examination (Systems&software ... 2017). They were also taken into account when determining the most important features of social software for users. The selections of attributes employed in both the McCall model and the SQuaRE model contain detailed attributes which are then subject to user evaluations. It must also be noted that, despite the obvious differences in the approach to the task of quality evaluation, both models share a number of common properties. In the light of the above, it was possible to construe a model to describe satisfaction from the use of social media client software. Fig. 1 presents this author's postulate for such a model. The model is composed of eleven attributes, with four of them (namely: design/aesthetic, efficiency, productivity, and utility) further divided into detailed attributes. For this reason, the study involves evaluation of a total of 15 client software attributes that may impact the level of user satisfaction – this total was evidenced both in the design of surveys and in the context of analytical evaluations.

The preliminary set of thus defined key indicators of software quality may then be presented for user evaluation to produce a final set of properties perceived by users as the most significant. This task may be completed using various methods, such as online surveys and survey auditing. However, it seems that qualitative methods provide the best possible results, with the added benefit of identifying reasons behind users' evaluations and improved insight into specific behaviours displayed by users in

association with social media services. For this reason, it may be useful at this stage to introduce focus group interviews and brainstorm discussions in small groups.

Fig. 1 : Social media users' satisfaction model

Source: Own study

Based on the obtained results, it is possible to determine the set of the most important attributes of social software that were the basis for the construction of the questionnaire. The key part of the survey are questions allowing to estimate the level of user satisfaction with individual software features. The questions referred to subsequent attributes that should be assessed on a five-point satisfaction scale (Kan 2002), ie:

1	2	3	4	5
very dissatisfied	dissatisfied	neutral	satisfied	very satisfied

In addition, each of the features should be assessed in respect of its importance for the user using a five-level importance scale, i.e.

1	2	3	4	5
completely unimportant	not important	quite important	important	very important

Quantitative data collected during surveys will be the basis for calculating the customer satisfaction index for social media users. The calculation of the CSI indicator is based on the formula:

$$\boldsymbol{CSI} = \sum_{i=1}^{N} \boldsymbol{w_{iw}} \times \boldsymbol{s_i} \quad , \; where \quad w_{iw} = \frac{w_i}{\sum_{i=1}^{N} w_i}$$

CSI – customer satisfaction index for social media users
i - social software attribute
N - number of evaluated attributes
w_{iw} - relative weight of the i-th attribute
s_i - assessment of satisfaction with the i-th attribute of the software
w_i – weight of the i-th attribute

The resulting value of the CSI index represents the users' general level of satisfaction from the most significant attributes of the system. In our context, it may be advisable to contrast the resulting value against the partial weighted values for each attribute under examination. This will help identify the weak points of the examined system, i.e. functions and properties in need of improvement. In addition, analyses of the results should be performed in various cross-sections, i.e. individually for specific groups of customers or within specific sets of attributes.

Estimation of the level of satisfaction displayed by users of the Facebook social media service – results of empirical studies

This author's postulated concept for the evaluation of user satisfaction from social media client software on the basis of a model described in the previous section has been verified though empirical evidence i.e. quantitative surveys.

At the beginning, a detailed plan and schedule of surveys was defined, as well as the size of the research sample necessary to obtain reliable results. The survey study was performed as planned, between May and June 2019, among students of both full-time and part-time studies at Wroclaw University of Economics.

The size of the required (minimal) study sample to reach reliable results was calculate on the basis of the following formula:

$$N_{\min} = \frac{N_p(\alpha^2 * f(1-f))}{N_p * e^2 + \alpha^2 * f(1-f)}$$

where:

N_{min} – minimum study sample size
N_p – the size of the population from which the sample is taken
$\propto$ – confidence level for results
f – fraction size
e – established maximum measurement error

The general population from which the study sample came was all students of Polish universities in 2019. According to data from the Central Statistical Office, their number was 1230.3 thousand in 2018 people (Central Statistical Office, 2019). It was assumed that the confidence level $\propto$ was set at 95% ($\propto$ = 95% means the 95% probability that the measurement result is real), the fraction size (the fraction size was set at the standard level) was at a universal level i.e. 0.5 and the maximum measurement error could equal 5%. On this basis, it was calculated that the required number of respondents in the study was 384 respondents. This requirement was met because the final number of correctly completed questionnaires was 413.

The main research objective was to determine the level of satisfaction displayed by users in relation to functionalities offered by social media services, particularly Facebook. The author was intent on not only evaluating the level of satisfaction reported by students, but also to determine factors that may influence their satisfaction.

Therefore, the objectives of the survey were:

- obtaining Facebook users' opinions on its perception and main areas of application.
- learning the opinions and ratings of active Facebook users regarding specific features and functions of the portal,
- estimating the level of user satisfaction with certain attributes of social software.

Accurate estimation of the satisfaction level was ensured through informed evaluation of the students' reported opinions on specific attributes of the studied client software (based on the model of social media user satisfaction described earlier in this paper). The sets of responses allowed for effective segmentation of respondents by such demographic and behavioural traits as: gender, frequency of social media use, form of access, fluency, experience history, use intensity, and the number of contacts.

Thus identified, the responder segments served as basis for detailed analyses of satisfaction. This part of the study helped identify practical correlations between user satisfaction level and user characteristics. The results provided valuable insight for the final determination of factors that may impact the level of social media service satisfaction displayed by active Facebook users.

Before we commence with detailed analyses of the results obtained in the course of the survey, it may be useful to provide general information on the structure and population of the respondent sample. The study was conducted on a sample of 413 female and male representatives of the student community at Wroclaw University of Economics and Business, from various departments and on various stages of their education. The survey was attended by 254 female students (61.5% of the total number of respondents) and 159 male students (38.5%).

A decided majority of the respondents (as much as 83%) described themselves as frequent users (with at least several visits each day); 11% reported one visit per day, with further 4% reporting several visits per week. Only 2% of the respondents reported their visits to be even less frequent than that. As for the use history (experience), nearly 70% of the respondents had their profiles active for 5 years or more, and nearly 25% of them – for 3 years.

Knowledge of Facebook functionality was declared by respondents to be at more than a satisfactory level. When asked about their knowledge of Facebook functions and operating specifics, nearly half of the students assessed it at a 'high' level, with 23% subscribing to the 'extensive' or 'very high' category. More than ¼ of the students (27%) described their knowledge of Facebook as 'satisfactory'. Analysing the results from the angle of users' declared intensity of social media use over the last 12 months, it may be observed that the responding students generally increase the intensity (number and time) of visits over time or at least maintain a similar level of activity – these two opinions were jointly subscribed to by more than 83% of the respondents. At the same time, it must be noted that more than 15% of the students reported a decrease in use intensity.

Questions regarding the assessment of satisfaction with individual Facebook attributes (features) played a key role in achieving the research objectives. These features result from the analysis of the McCall model and the SQuaRE document and are included in the developed social media users' satisfaction model (see: Fig. 1).

Thus, construed, individual attributes of Facebook were presented for student evaluation both in the context of their relative significance and the level of satisfaction attached to them by the respondents. The wealth of responses allowed for the estimation of CSI indexes both for the entire respondent population and for specific segments thereof based on such user characteristics as gender, frequency of use, fluency, experience, use intensity dynamics, and the number of friends on Facebook.

Calculation of the CSI index was done using the procedure described in sec. 3 of this paper. Tab. 1 presents detailed results of the index describing levels of satisfaction expressed by all 413 respondents participating in the study.

Table 1 : Satisfaction index values for the entire research sample (N = 413)

	Satisfaction attribute	Weighted rating	CSI
1	Usefulness	3.82	76.32%
2	Pleasure	3.50	70.06%
3	Comfort	3.79	75.86%
4	Reliability	3.19	63.86%
5	Error tolerance	3.54	70.82%
6	Efficiency	3.77	75.35%
7	The speed of completing tasks	3.85	76.98%
8	Safety for health and behavior	2.80	56.06%
9	Data protection / web security	2.13	42.60%
10	Trust	2.84	56.83%
11	Flexibility	3.62	72.34%
12	Ease of use	3.98	79.52%
13	Ease of learning	3.38	67.55%
14	Consistency	3.02	60.36%
15	Clarity	3.15	63.08%
	Average	**3.36**	**67.17%**

Source: Own study based on surveys

In accordance with the adopted CSI formula, a product of the relevant satisfaction level and the weighted values for 15 attributes was calculated for each student. The resulting values were then aggregated separately for each attribute to yield the corresponding weighted values for each such attribute. Since every attribute was evaluated on a 5-point scale (with 1 representing the lowest, and 5 – the highest score), the resulting indexes of satisfaction from the use of Facebook service were calculated as percentage values for all respondents – these are presented in column 3 of Tab. 1. Calculation of the CSI index for all respondents was done based on the averaged values of partial SCI indexes for those Facebook attributes deemed of significance upon the level of user satisfaction. The examination revealed the index to be at the level of 3.36 in the 5-degree scale, thus amounting to 67.17%. This is not a spectacular result by any means, but it can be seen as attesting to the moderate level of satisfaction displayed by the respondents from the use of the service.

In view of the above, it may be useful to separate those Facebook attributes which are received with satisfaction from the ones that receive the lowest scores. The resulting ranking of weighted evaluations for each of the analysed attributes of the portal is presented in Fig. 2.

Fig. 2: CSI values for individual Facebook features in the opinion of all surveyed students
Source: Own study based on surveys

It may also be useful to confront the above ranking against information provided in response to a query of the most significant and the least important features of the studied service. The revealed significance of individual attributes is presented in Fig. 3. This approach allows for a reliable identification of Facebook's strengths and areas in need of improvement.

Results presented on both figures suggest that respondents attach great significance to such social media attributes as: speed in the realization of tasks, operational effectiveness, and ease of use. For Facebook, user satisfaction from these attributes was revealed to be fairly high. In particular, respondents were most satisfied from the ease of use, as attested by the corresponding CSI value of nearly 80%. High scores of 75%-77% were also registered in relation to such attributes as speed of operation, suitability for the tasks expected of the service, comfort of use, and operational effectiveness.

Fig. 3: The significance of individual features of Facebook in the opinion of all respondents
Source: Own study based on surveys

The fourth item in the respondents' ranking of attributes was related to protection of personal data – this clearly suggests that the participants placed great significance in securing their personal information from unauthorized use. The study revealed this aspect of Facebook to be one of the service's weakest points. As suggested by the results presented in Fig. 2, this particular attribute of the service received, on average, the lowest scores in terms of user satisfaction (with CSI at the level of 42.6%). This result signifies the urgent need for improvement. A decided majority of respondents (more than 70%) voiced their concern that the service could be seen as potentially detrimental to their online security and identity protection. At the same time, it must be noted that the opposite view was subscribed to by a marginal group (less than 7% of the respondents), as shown in Fig. 4.

Fig. 4 : Distribution of answers to the question: "Do you think that the use of Facebook may have an adverse effect on your online security / privacy?"

Source: Own study based on surveys

In addition, the respondents were asked to voice main reasons behind their security and identity concerns. The study revealed that the main concern for the users was the potential 'leak' of personal details and private information placed with Facebook to the outside. This response was subscribed to by nearly ¾th of all respondents. Negative perception was also registered with relation to the use of personal information details by Facebook and the sale of such information to third parties for purposes associated with marketing and product advertisement. More than 40% of the respondents expressed their negative view on Facebook's tracking of user behavioural patterns and responses collected over the course of their visits. Other concerns voiced by respondents included the following: sale of personal details to intelligence services, insecurity of private files shared via Messenger, publication of profile content without the expressed user approval, the threat of unauthorized access to private profiles, and stalking via Facebook.

As suggested by the above findings, a decided majority of Facebook users express their concern for the inadequate level of security offered at present. This observation finds further confirmation in the fact that positive evaluations in this regard were alarmingly scarce. The results show that nearly 30% of the respondent students reported to be fairly distrustful of the service, with 5% more expressing their complete distrust. Ca. 45% of the respondents were impartial in this respect, and positive scores were only expressed by a fifth of the respondent base. The above conclusions are corroborated by the fact that the attribute of trust towards the service was ranked 13th (third lowest position), despite the confirmed high placement of the trust attribute in terms of significance attached by the users to the service under study. As shown in Fig. 3, trust was ranked eighth on the list of the most significant attributes expected of a social media service.

Coming back to the results presented in Figs. 2 and 3, it should be noted that the list of concerns voiced by the students is not limited to trust and personal protection issues, as many users were genuinely concerned for the impact of social media services on their health and behaviour. While it is true that this particular aspect was ranked well below that of the service security (see: Fig. 3), this does not change the fact that the item received the second lowest ranking in terms of reported user satisfaction. Results show that the most important problem in this respect is the concern for the disrupting effect of Facebook upon other tasks and assignments. Nearly as many students also expressed their belief that the service offered by Facebook might have an addictive effect on users.

In relation to health issues, nearly a fourth of the respondents reported problems with concentration generated by the use of Facebook service, while 11% subscribed to having headaches related to Facebook visits. Other responses in this section included such negative effects as: deterioration of

personal relations with relatives, reduction of more active forms of diversion and interest, deterioration of social ties, anxiety, overstrain and exhaustion, time wastage, and vision problems.

Conclusions

The article emphasizes, that the condition for a correct estimation of the level of user satisfaction of social software is primarily the definition of a set of detailed attributes describing its quality. A set of such attributes was proposed by the author based on the analysis of software quality models, with particular emphasis on features relevant to end users. The presented research method is based on the use of the CSI customer satisfaction index, determination of which was possible due to the users' assessment of their satisfaction with the detailed features of the social networking site.

The proposed method of user satisfaction measurement has been tested on a university research group. The majority of respondents were long-term Facebook users. They can be defined as advanced or intermediate users when it comes to their knowledge of website functions. Taking into account the frequency of using the website, it was at a high level. Respondents declared that they visit the website regularly. However, in the case of about 15% of respondents, dissatisfaction with the website was visible and was reflected in the decrease in the number of their visits.

The answers given by the respondents were the basis for calculating the overall CSI satisfaction index from Facebook use, which was described by 15 previously distinguished features of the website. These features more or less affect the perceived satisfaction of users. The overall value of the index was 67.17%, which is quite a good result, however, it cannot be considered exceptionally high. It should be noted that 9 out of 15 satisfaction attributes that were rated by respondents, scored higher than the overall CSI index, while the remaining 6 scored lower. The final result was also influenced by the significance level of individual attributes for the surveyed users.

In particular, it refers to the data protection / web security attribute, which was considered the fourth most important attribute for the respondents, yet obtained the worst result within the CSI partial index. Users were particularly afraid of the "leakage" of their personal data to the Internet, the use of private data and photos by the portal, and their sale for marketing purposes. This shows that in this area Facebook in particular can look for a way to improve user satisfaction by providing a much higher level of personal data protection and online security.

The attribute related to the health/behavior problems was also given a very low rating. It obtained the second worst result among the CSI partial indicators. This means that respondents were aware of the fact that regular use of the site, not only affects their work efficiency and concentration negatively but can even causes an addiction. However, from the point of view of overall satisfaction from using the website, it was not of a key importance because the respondents considered that the significance of the listed problems is very small.

It should also be noted that Facebook's other weaknesses were its consistency in interface design and overall transparency. The low values of CSI indicators for these features indicate that the website's visual side did not satisfy the respondents.

On the other hand, it can be seen that the main advantages of Facebook are its functional features, such as ease of use, speed of task completion and the general suitability of the website for users' purposes and needs. These attributes achieved the best CSI partial results and were highly significant to respondents.

To sum up, the research based on the proposed social media users' satisfaction model allowed for a transparent illustration of Facebook's strengths and weaknesses, from the point of view of satisfaction felt by its users. This type of research should therefore be carried out by various social networking sites because they allow for the identification of existing problems and can be the basis for corrective actions. On the other hand, it is possible to determine future directions of website development based on

information about which areas and functionalities of the website meet the needs of users to the greatest extent and most strongly affect their satisfaction of use.

An important issue in conducting satisfaction surveys using the CSI indicator is also the need to carry them out in different periods of time, e.g. in the following months or before and after the work optimization within a given social networking site. Only then it is possible to determine the actual effects of the implemented modifications for end users and to plan further actions of this type.

Abstract

This paper aimed to analyse the evolution of the Romanian trade with agro-food products in the last decade. Romania was a net importing country for almost all this period, with few exceptions in 2013 and 2014 when the trade balance with agro-food products was positive. The Romanian trade with agro-food products had an upward trend between 2010 and 2019, but the deficit increased up to 1,394,099 thousand US $ in 2019. During the 2010-2019 period, Romania recorded surpluses only for 6 out of the 24 groups of marketed agricultural products: cereals; oil seeds and fruits; tobacco; live animals; animals or vegetable fats and oils; and vegetable plaiting materials. The deficit was significant mainly for the meat group, for which Romania made significant imports. The paper is based on specific trade indicators, and used data provided by International Trade Centre.

Keywords: Agro-Food Products, Romania, Trade

Introduction

Recent statistic on the evolution of EU 28 Agro-Food Trade (European Commission, 2019) underlined the EU's position as the largest global exporter and second largest importer of agro-food products, while the impact of UK Brexit seems not have a major impact on EU trade with the rest of the world, which continued to grow (European Commission, 2020). While the contribution of agriculture in Romania's GDP is significant (Popescu, 2013) and grew in the last decade (INSSE, 2020), Romania didn't succeed - with few years of exception, as Beciu (2017) and Arghiroiu (2015) mentioned- in its effort to became a net exporter of agro-food products.

In the last decade only few categories of Romanian agro-food products proved to be competitive in the international trade with these products that are imported mainly from the EU countries.

The largest distribution chains which control the market and which is based abroad, seems not to help Romanian producers in gaining a stronger position on the market. Even if the Romanian has significant agricultural surfaces, the Romanian agro-foods products can hardly gain sectors on market. A new marketing method misleads buyers who want to buy products made in their own country. Many agro-foods products are imported from abroad but they are packed in Romania, often in regions that are well known for their Romanian traditional products. The importing companies which are settled in one or other famous production areas for a particular product use their name clearly specified on the package, but make it difficult to read the origin of the product. The imports are encouraged by the lower prices of the most of agro-food imported products, but often the quality of similar products is not enough considered in their choice on their buying. While imported exotic fruits and some vegetables justify their selling on the market other agro-food products which are produced in enough quantities to cover the internal products can hardly explain their selling on the Romanian market, especially in conditions of abundance of similar Romanian products. One of the

vulnerable Romanian sectors is the livestock sector. Difficult adaptation of this sector to the EU legislation, its low production efficiency, the limited financial support by the state and the sanitary crises as African swine fever and bird flu led to the situation in which Romania became a net importer of meat products.

Results and Discussions

From the analyse of the 2010-2019 period (Fig.1.) we can notice that Romania had a positive balance in the trade with agro-food balance in 2013 and 2014 only. The Romanian trade with agro-food products had an upward trend between 2010 and 2019, but the deficit increased up to 1,394,099 thousand US $ in 2019. While the imports of agro-food products increased from 5,032,082 to 9,589,605 thousand US $ from 2010 to 2019, the exports increased from 4,051,120 to 8,195,506 thousand US $ in the same period of time.

Fig. 1: Trade evolution with agro-food products in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre

Fig. 2: Main sold of the agro-food groups cumulated in the period of 2010-2019 (US Dollar thousand) Source: Own calculations based on International Trade Centre data

From the analyse of the cumulated sold for each agro-food groups in the period of 2010-2019 the results indicated (Fig.2) that during the 2010-2019 period Romania recorded surpluses only for 6 out of the 24 groups of marketed agricultural products: cereals; oil seeds and fruits; tobacco; live animals; animals or vegetable fats and oils; and vegetable plaiting materials, the deficit being significant mainly for the meat group, for which Romania made significant imports.

In the figure 3 is showed the dynamics of the live animal group for the 2010-2019 period. Being one of the surplus groups, it can be noticed that for the entire period analysed, export values exceed those of imports, creating a surplus balance, with the maximum coverage of the imports by the exports in 2011 of 262 % and a minim of 168% in 2013. In 2019 Romania exported a value of 497,395 thousand $ for the category of live animals, while the imports reached a level of 209,397 thousand $.

Fig. 3: Trade evolution and coverage of imports by exports for live animals in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Fig. 4 : Trade evolution and coverage of imports by exports for meat and edible meat offal in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Romanian trade with agro-food products is in deficit mainly for the meat group of agro-food products. The figure 4 presents the evolution for the meat and edible meat offal group and indicate that in 2019 the coverage of the imports by the exports was only by 26 % in 2019, almost similar with

the beginning of the period, and the highest level was reached in 2011, by 55 %. The decrease of coverage level of imports by exports from 2018 and 2019 is associated with the impact of African Swine Fever which decimated the numbers of pigs in Romania.

Concerning the agro-food product group, fish, it can be seen that Romania is also deficient and the value of the balance followed the negative trend from year to year, reaching in 2018 a balance of -208,848 thousand $, corresponding with a coverage level of fish imports by exports of 12 %. (Figure 5).

Fig. 5 : Trade evolution and coverage of imports by exports for fish and crustaceans, molluscs and other aquatic invertebrates in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The evolution of the dairy trade is represented in figure 6, where it can be seen that the deficit increased compared to 2010, reaching maximum values in 2019, of 421,882 thousand $, corresponding to a coverage level of imports by exports of 36 %. The internal milk production doesn`t cover the internal milk consumption in Romania, due to very low yields recorded per cow, compared to the other EU state members. (Popescu and co., 2019)

Fig. 6 : Trade evolution and coverage of imports by exports dairy produce; birds' eggs; natural honey; edible products of animal origin in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The evolution of the other products of animal origin indicated a decrease of coverage of imports by exports from 80 % in 2013 to 47 % in 2019. In 2019 the trade balance recorded the highest deficit from the last decade, of 42,250 thousand $ for this category of products (Fig.7)

Fig. 7 : Trade evolution and coverage of imports by exports for products of animal origin, not elsewhere specified or included in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Few products from the category: live trees and other plants; bulbs, roots and the like; cut flowers and ornamental foliage are exported by Romania, so the coverage level of imports by exports fluctuated between 2 % in 2018 and 2019 and 5 % in 2012 and 2013 (Fig.8). In 2019 the trade balance for these products recorded a deficit of 169,370 thousand $.

Fig. 8: Trade evolution and coverage of imports by exports for live trees and other plants; bulbs, roots and the like; cut flowers and ornamental foliage in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of imports by exports for the edible vegetables and certain roots and tubers in the period of 2010 – 2019 decreased from 43 % in 2010 to 19 % in 2019 (Fig.9), when the trade balance for these products recorded the highest deficit, of 478,409 thousand $.

Fig. 9 : Trade evolution and coverage of imports by exports for edible vegetables and certain roots and tubers in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of imports by exports for the edible fruit and nuts; peel of citrus fruit or melons in the period of 2010 – 2019 decreased from 37 % in 2011 to 9 % in 2019 (Fig.10), when the trade balance for these products recorded a deficit of 674,620 thousand $, but in 2018 the deficit was higher, of 676,921 thousand $.

Fig. 10 : Trade evolution and coverage of imports by exports for edible fruit and nuts; peel of citrus fruit or melons in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The level of Romanian exports for the category: coffee, tea, mate and spices is low, so the coverage level of imports by exports fluctuated between 8 % in 2010 and 2011, and 11 % in 2017 and 2019 (Fig.11). In 2019 the trade balance for these products recorded a deficit of 256,112 thousand $.

Fig. 11 : Trade evolution and coverage of imports by exports for coffee, tea, mate and spices in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Cereals are the main group for which Romania has managed to achieve a surplus trade balance. (Fig.12). In the last decade the level of coverage of imports by exports increased from 326 % in 2011 up to 670 % in 2018. In 2019 Romania was the main exporter of cereals from EU (mainly maize and wheat), having as destination countries from EU as Spain and Italy but also countries from outside EU as Turkey, Egypt, Lybia or Morroco. In 2019 the trade balance recorded the highest surplus from the last decade, of 2,493,958 thousand $ for this category of products.

Fig. 12 : Trade evolution and coverage of imports by exports for cereals in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The level of Romanian exports for the category: milling industry; malt; starches; inulin; wheat gluten is low, so the coverage level of imports by exports fluctuated between 26 % in 2016 and 13 % in

2014 and 2018 (Fig.13). In 2019 the trade balance for these products recorded a deficit of 110,244 thousand $.

Fig. 13 : Trade evolution and coverage of imports by exports for products of the milling industry; malt; starches; inulin; wheat gluten in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The group of seeds and fruits of oilseeds is the second group for which Romania registered a trade surplus, as can be seen in the figure 14. The increase in demand for oilseeds is based on their processing into vegetable oils, stimulated by the world population growth, but also for feed purpose or for transformation into biofuels. In the last decade the level of coverage of imports by exports increased from 182 % in 2012 up to 362 % in 2016. In the 2019, the coverage level was about 273 %, corresponding with a surplus of 781,343 thousand $, but the highest surplus was recorded in 2018, of 922,597 thousand $.

Fig. 14 : Trade evolution and coverage of imports by exports for oil seeds and oleaginous fruits; miscellaneous grains, seeds and fruit in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

As regarding the lac; gums, resins and other vegetable saps and extracts group of products, it can be seen that Romania is also deficient and the value of the balance followed the negative trend from year

to year, reaching in 2019 a balance of -30,560 thousand $, corresponding with a coverage level of imports by exports of 5 %. (Figure 15).

Fig. 15 : Trade evolution and coverage of imports by exports for lac; gums, resins and other vegetable saps and extracts in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

For the group of vegetable plaiting materials; vegetable products not elsewhere specified or included in the analysed period (Fig 16.), Romania was either in the position of net exporter or net importer. In 2019 the coverage of the imports by the exports for this group of products was 74 %, but in 2014 the coverage level was around 158 %.

Fig. 16 : Trade evolution and coverage of imports by exports for vegetable plaiting materials; vegetable products not elsewhere specified or included in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

If at the beginning of analysed period, the coverage level of imports by exports for animal or vegetable fats and oils and their cleavage products and prepared edible fats was low (76 % in 2010 and 77 % in 2012), in 2018 this level increased up to 130 % and 129 % in 2019, the surplus recording in the last year of period around 57,603 thousand $.

Fig. 17 : Trade evolution and coverage of imports by exports for animal or vegetable fats and oils and their cleavage products; prepared edible fats in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The data of Romanian trade with preparations of meat, of fish or of crustaceans, molluscs or other aquatic invertebrates in the period of 2010 – 2019 (Fig. 18) indicated that only in 2013 the imports were covered by exports. In 2019 only 73 % of the imports were covered by exports and the deficit was about 76,047 thousand $.

Fig. 18 : Trade evolution and coverage of imports by exports for preparations of meat, of fish or of crustaceans, molluscs or other aquatic invertebrates in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of the exports by imports for the group: sugars and sugar confectionery in Romania between 2010 and 2019 was very low and it varied between 13 % in 2019 and 38 % in 2010 and 2014 (Fig.19). Only three enterprises are still producing sugar on the local market and only 22,4 thousand hectares were still cultivated with sugar beet in 2019.

Fig. 19: Trade evolution and coverage of imports by exports for sugars and sugar confectionery in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The export of Romania in terms of cocoa and cocoa preparation indicates (Fig.20) that Romania import raw material related with this group of products and resell on the international market.

Fig. 20: Trade evolution and coverage of imports by exports for cocoa and cocoa preparations in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

As regarding the preparations of cereals, flour, starch or milk; pastry cooks' group of products, it can be seen that Romania is also deficient and the coverage level of imports by exports oscillated between 30 % in 2010 and 40 % in 2019 (Figure 21). In 2019 Romania had a deficit of 376,468 thousand $ for this group of products.

Fig. 21: Trade evolution and coverage of imports by exports for preparations of cereals, flour, starch or milk; pastry cooks' products in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of the imports by exports for the group: preparations of vegetables, fruit, nuts or other parts of plants in Romania between 2010 and 2019 was also very low and it varied between 18 % in 2019 and 28 % in 2012. (Fig.22). In 2019 Romania had a deficit of 350,236 thousand $ for this group of products.

Fig. 22: Trade evolution and coverage of imports by exports for preparations of vegetables, fruit, nuts or other parts of plants in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of the imports by exports for the group: miscellaneous edible preparations in Romania between 2010 and 2019 varied between 29 % in 2010 and 41 % in 2016. (Fig.23). In 2019 Romania had a deficit of 412,155 thousand $ for this group of products.

Fig. 23: Trade evolution and coverage of imports by exports for miscellaneous edible preparations in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Even if Romania is an important producer for beverages, spirits and vinegar, in the period of 2010 – 2019 the coverage of imports by exports for these products decreased from 60 % in 2010 to 33% in 2019. (Fig. 24) In 2019 the balance deficit for these products was 374,819 thousand $.

Fig. 24: Trade evolution and coverage of imports by exports for beverages, spirits and vinegar in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The coverage level of the imports by exports for the group: residues and waste from the food industries; prepared animal fodder in Romania between 2010 and 2019 was also low and it varied between 27 % in 2010 and 45 % in 2019. (Fig.25). In 2019 Romania had a deficit of 336,014 thousand $ for this group of products.

Fig. 25: Trade evolution and coverage of imports by exports for residues and waste from the food industries; prepared animal fodder in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

The present of one of the top leaders, the British American Tobacco in Ploiesti - Romania is the explication of the positive Romanian trade balance for the tobacco products, which export tobacco in almost 50 world countries.

In 2019 the coverage of imports by exports for tobacco and manufactured tobacco went up to 260 %, based on an export of 1,080,477 thousand $.

Fig. 26: Trade evolution and coverage of imports by exports for tobacco and manufactured tobacco substitutes in the period of 2010 – 2019 (US Dollar thousand) Source: International Trade Centre and own calculations

Conclusions

Based on the analysis it was found that in terms of food products, Romania recorded trade deficit in the last decade with few exception (2013 and 2014). In 2019, besides the "Cereals" and "Oilseeds" group, the surplus existed only for the groups "Tobacco", "Live animals", "Animals or vegetable fats and oils" and "Vegetable plaiting materials". The meat and edible meat offal group is the mainly

deficient group of trade. In 2018 and 2019 Romania was affected by African Swine Fever which caused the increase of meat imports.

Building A Company's Relations with Its Employees – Components of The Personnel Policy of Polish Business Leaders

Katarzyna KUKOWSKA

Czestochowa University of Technology, Czestochowa, Poland
katarzyna.kukowska@wz.pcz.pl

Abstract

The study presents the results of research conducted among Polish business leaders. The market situation of relevant companies was characterised against the background of competition, allowing the identification of conditions that form the framework of activities undertaken in terms of the establishment and maintenance of relations in the internal community. The main research problem was an answer to the question, do companies undertake the indicated activities to reinforce the employees' bond with the company, and do they support the establishment of informal relations between employees. The self-assessment of the companies' position on the market, their financial and asset situations and their development and innovation level allows the conclusion that it seems substantiated that one should find themselves in the group of Polish business leaders. The analysed enterprises seem to be in stable positions, suggesting that in terms of the employee-organization relationship, such enterprises are more keen to financially and organisationally engage themselves in work aimed at the reinforcement of the internal work community. It was expected that the studied enterprises exercise engagement in activities related to employee integration. However, in half of the relevant enterprises, no such activities were conducted. Among the others, the activities most commonly undertaken was to support joint activities of employees and their families, organisation of employee sports teams and encouragement to do volunteer work jointly. In terms of the issue whether relations between employees at the work place should be exclusively professional, and only then informal – formal relations dominated in the majority of enterprises.

Keywords: Company's Relations with Employees, Internal Marketing, Social Exchange, Psychological Contract

Introduction

From the point of view of managing an organisation, the most demanding and at the same time the fundamental component of its operation is the social reality. People, acting within a specific cultural framework, within the scope of their social capital, shall by way of their behaviour generate results, the beneficiary of which will be the entity that employs them. The management of a social system is the more difficult that conditions influencing the participants in an organisation are frequently indirect, and standards of behaviour created by work colleagues function as an example to be followed, which can be both positive as well as negative. Human resources operating within a specific social environment tend do create a specific quality of work. Hence, all processes taking place within a company depend on the people. An example is the problem of implementation of the Lean Management concept, the efficiency of which is sensitive to social and cultural conditions, including education levels, life style, the awareness of rights and obligations, intensity of religious beliefs, social norms, the work ethic (Baskiewicz 2019, pp. 13731-13739). In terms of personnel policy, taken into account must be the fact that relations are an integral component of employees' daily lives at the workplace. The functionality of the practical application of knowledge about relations stems from their influence on the achieved results and the fulfilment of individual and collective needs. The complexity of the phenomenon and the research conditions of the societal reality that relations are may be explored among others through the human resources management theory (Golnau, Kalinowski, Litwin 2002), the perspective of an organisation's social capital (Kukowska 2013, pp. 145-149; Kukowska, Skolik 2013, pp. 140-144; Kukowska, Skolik 2013, pp. 20-34) and relational capital (Boyatzis, Rochford 2020; Żukowska, Kołodziejczyk, Mechło 2018 pp. 9-21).

From the point of view of management of a company and its labour resources, employee relations are of significance primarily within the context of their influence on employee efficiency and on the level of their identification with the company, which thanks to loyal, cooperating employees saves on costs stemming from personnel fluctuations. The issue remains open, whether the employee is, in practice, a resource or an engaged entity that may satisfy their basic needs of relations at the work place? The present study shows the results of analyses of the issue of activities in this regard by companies that became Polish business leaders. On the basis of a self-assessment of the enterprise's situation on the market as compared to the competition, the studied companies were described, permitting the identification of conditions, on the basis of which the relations between employees and organizations emerge. An attempt was made at identification of such activities undertaken within the scope of establishment of such relations.

Literature Review

It is complicated to comprehend what employee relations are, the topic covers in fact very diverse issues. They include legal aspects, meaning, acts of law governing employment (contracts concerning remuneration, practices and employment conditions), collective negotiations and disputes, equalisation of chances for the excluded, diversity management, work-life balance, practices ensuring employee satisfaction and security, employee participation in management-related decisions, communications, cooperation and control policies. Employee relations thus concern dynamic employee-organization relations within the context of satisfaction of the needs of the individual employees and managers. The objective of establishment of such relations is to improve employee morale and motivation, all of which should contribute to improvements in their performance, working in turn towards the company's success (Sequeira, Dhriti 2015, p. 2,17). The relationship between the enterprise and the employees constitutes the most sensitive area of organisational functioning, as the complexity of conditions always leaves a broad margin of spontaneity and unexpectedness. The issues of interpersonal relations from the point of view of their social and psychological effect on an organisation began to shift into focus between 1920 and 1930. Following World War II, organisational behaviour that was a response to outdated practices assumed by interpersonal relations began to gain traction (Kalwani, Mahesh 2020, p. 41). The fundamental theory concerning relations is the theory of social exchange as explained in the dynamic between employee and organisation, through anthropomorphisation of the organisation thanks to its representatives (agents), with the expectation of an answer concerning standards, values and rules that guide it (Shanock and Eisenberger, 2006, pp. 689-695). The employee adapts their engagement and behaviour in order to balance out the mutual exchange process. As the theory of social exchange assumes the effect of the ethic of reciprocity, the exchange of valuable resources maintains and strengthens relations (Tholén, Pousette, Törner 2013, pp. 62-69). However, if the effort made remains unnoticed by superiors, it becomes very probable for the ethic of reciprocity to be ignored (Blader and Tyler 2000, quoted in: Coyle-Shapiro, Shore 2007 pp. 166-179). Using the psychological conditions at the workplace as a basis, the concept of emotion management and the bond theory were developed, exposing the issues of dynamics of bonds as responsible for proactive behaviour, ethical decision making, effective negotiation behaviour and creative problem-solving (Kalwani, Mahesh 2020, p. 49; Zeidner et al. 2004, pp. 371-399). The causes of cognitive, emotional and physical engagement have a psychological basis, and one's psychological condition is a direct response to the condition of relations between employees and superiors. Collegial relations and the feeling of belonging, appreciation by co-workers and superiors are responsible for the feeling of security and the psychological meaning of work (Ariani 2015, pp. 34-35). All interactions and communications between managers and employees form the basis of cognition of mutual needs, allowing better adaptation and mutual functioning in line with expectations (Seth 2014, pp. 80-82). Hence, the management of such relations primarily entails the establishment of the best possible environment, in which employees would be able to develop their potential to the benefit of the company. In this sense, it is worthwhile for the organisation to establish an atmosphere of support and trust among employees, as they are the first line in the exchange of valuable information and resources, support, empathy or mentoring, creating social capital (Prusak, Cohen 2001, pp. 86-93). Before employees turn to their superiors, preceived as the formal side of the exchange, they will turn to their collegial

relations (Ariani 2015, p. 38). Employees and employers should be aware of their interdependency and note the advantages of cooperation for the purpose of achievement of common goals (Caldwell, Anderson 2018, pp. 2-3). The prevalence of this relationship on a subtle background refers back to the unwritten psychological contract between parties, perceived subjectively and reinforced in individual experiences of every individual (more broadly: Rousseau 1995; Caldwell, Hayes 2007, pp. 261-278.). Assumptions concerning the character of the relation between the employer and the employee within the psychological contract are a set of mutual agreements that give rise to a range of expectations that may have moral power (Sequeira, Dhriti 2015, p. 4). The conditions of this contract are susceptible to values represented by the organisational culture. The core of activities of an organisation is to model the values of the organisational culture in order to give credibility to the intention to support employees and perform duties with respect to them, for the purpose of establishment of relations based on trust. Uncertainty and the lack of satisfaction of the need of a bond may result in elevated stress levels, professional burn-out or employee fluctuation (Kalwani, Mahesh 2020 p. 49). In order to avoid unwanted effects, organisations undertake activities related to as internal marketing, which entails placing an employee in the position of an internal customer, and communicating with them through positive information about the organisation (Tsai, Tang 2008, pp. 1117-1118). The improvement of efficiency of influence on the levels of trust, ethic and cooperation between employee and organisation is served by the following rules: 1) high-trust relations, these depend on cooperation and engagement; 2) permanent communication, the character of which will provide certainty about the organisation's engagement in mutual understanding and provide information supporting efficiency and individual success; 3) always take into account the objective, mission and values of the organisation; 4) recognition of needs and fulfilment of the obligations (promises) made, including clear description of duties and control of their execution; 5) modelling of behaviour under guidance by the conviction that leaders and Human Resources Professionals are the models, whose behaviour communicates the values they preach and the devotion to the objectives and the mission of the organisation (Caldwell, Anderson 2018, pp. 15-17). Responsible management is the case when the company executes activities outside of its duties, paying attention to employee development, supporting cooperation and encouraging employees in civic terms (Bagieńska 2018, p. 24). The positive influence of Corporate Social Responsibility on employee behaviour shines through in engaging them in duties that project outside of their professional work (Shen, Benson 2016, pp. 1723–1746). When employees commence cooperation on the civic level, their individual results exhibit strong alignment with the results of the entire organisation (Kalwani, Mahesh 2020, pp. 51). In order to retain this positive relation, it is proper to assume the 4H model with respect to one's employees: help, hope, harmony and happiness in the creation of the working environment. The response that employees demand most from managers should be the 4C model: communication, commitment, contribution and competency (Saleh Dewydar 2015 p. 138). Among the numerous practices and activities that are characteristic for social responsibility, recalled are support for a healthy life style and healthy nutrition, offering cultural and sports activities and assurance of a work-life balance (Mandl 2009, p. 82). Hence, care for the social working environment also includes activities in the area of programming and organisation, which shall balance the professional area with the employees' personal lives. The significant factors embedded in the relations of the working environment that give rise to work-life balance include: treating employees as subjects, establishment of open relations, making it easier for them to communicate professional and personal needs, implementation of a managerial style that takes into account the establishment of bonds in the form of support in difficult life situations, identification of conditions of employee satisfaction, with particular attention to work-life balance needs (Słocińska A., Robak E. 2014, p. 176). Among the most up-to-date concepts of management concerning relations in the working environment, relational capital is most commonly indicated (semantically near to social capital). In the general sense, it is construed as the value of external and internal social bonds of an organisation that directly or indirectly contribute to the achievement of the enterprise's goals (Barão, Rodrigues da Silva 2012, pp. 220-243). Hence, it applies to all relations of the enterprise with its business environment, covering people, institutions, other businesses (Welbourne, Pardo-del-Val 2009, pp. 483-497). Relational capital is construed as a unique asset of an organisation, determined by internal relations. Hence, the capacity to establish it is a consequence of the condition of the relations within the working environment (Bombiak 2016, pp. 97-107). The High Performance Work Systems model seems to be a response to needs concerning solutions in terms of employee-organisation relations.

This concept entails the improvement of efficiency through transformation of the employee-organisation relationship into a partnerlike arrangement within the framework of joint achievement of the organisation's objectives. The basic practices of High Performance Work Systems entail the establishment of autonomous teams, assurance of the feeling of employment security and provision of specialised knowledge and training (Gojny-Zbierowska 2016, p.116).

On the other side of the approaches, theories, concepts, models and practices applied, describing the issues of relations in the social work environment, studies confirm that the most valued property of the working process is the possibility of cooperation with nice people (Nowicka 1999, pp 51-73). Practices in the area of support for relations between employees improve employee efficiency and hence the general performance of the organisation as a whole (Sequeira, Dhriti 2015, pp. 1-17). A higher level of employee engagement translates into higher financial results of the enterprise (Bagieńska 2014, p. 50). A study by S. Lachowski, M. Florek-Łuszczki, J. Zagórski and B. Lachowska showed that in Poland and west European countries, good interpersonal relations with co-workers and superiors influence one's general work satisfaction. Only good pay is valued higher (Lachowski et al. 2018, pp. 300–306). On the other hand, the main cause of resigning from work were bad relations with superiors (Szałach 2013, pp. 177-183). Interpersonal relations have a key influence not only on the general level of satisfaction with work, but also on health. As a result, flawed relations at the work place, symbolised by interpersonal conflict, impact the mental health of employees, shining through in more frequent cases of depressions (Lachowski et al. 2018, pp. 300-301).

Methodology

The objective of the study, a part of the results of which is presented in the present paper, was the identification of social and psychological factors supporting the development of personnel, the identification of intangible assets within an organisation and the processes of management of social capital and trust within organisations. The base for the study was the database of Poland's 500 largest companies according to a ranking by the website Rzeczpospolita, an influential daily with one of the biggest readerships in Poland. The study was conducted in the year 2019 among 179 of the largest companies operating in Poland, using the Computer Assisted Telephone Interview (CATI) and Computer Assisted Web Interview (CAWI). The fusion of these two quantitative methods increased the response rate. First, the study was conducted with entrepreneurs using the CATI. Respondents who refused to take part in the study, who would interrupt the survey or indicate a different time of provision of responses to the survey questions were provided with the option of filling in or completing the survey using a dedicated website. The gradual activity improved the comfort of respondents in terms of provision of responses, and improved the return rate of surveys and the quality of the receive research material. The sample was selected at random, with the draw repeated in case of a decline to participate. As a result of the draw, the study was conducted on a representative basis according to the following parameters: general population size – 500, estimation error – 6%, reliability: 95%. Enterprises taking part in the survey dealt mainly in production (42%) and services (27.4%). Other types of activities in the studied group were represented as follows: production and service business – 14.5%; retail – 8.4%, production and retail 0 7.8%. For the purpose of categorisation according to annual revenue, three scales were assumed (in million PLN): 5-50 – 17.2%; 51-200 – 68.2%; above 200 – 14%. In the majority of cases, the enterprises employed between 201 and 500 people (73%), with 27% of entities employing over 500 people, respectively.

Assuming that large enterprises undertake, as part of their personnel policy, diverse activities towards improving the relationship between the employee and the enterprise, the following research questions were assumed: 1) what kinds of activities do enterprises undertake in order to strengthen the bond between the employees and the company; 2) do they support the development of informal relations between the employees?

Research Results and Discussion

As assessed by the enterprises themselves, the situation was described by way of comparison with the competition, according to the following indicators: bigger profits, larger market share, faster development, greater innovation capacity, more successes and lower costs as compared to the competition (Table 1). In this area, for almost all indicators, the answer indicated most frequently was the one that could be described as evasive: "neither agree nor disagree". On average, this response was consequently selected by a quarter of respondents. The exception was to describe the enterprise as more innovative as compared to the competition, with the response pointed to most frequently was "I rather agree" - 24%. At the same time, the assessment of the own market situation against the backdrop of competition was selected the least frequently. An exception was the indicator of the company profits being higher than the competition, in which the response chosen least frequently was complete agreement with this statement – 14.5%.

Table 1: Market position of enterprises in comparison with the competitors

Indicators	Answers		
	I completely disagree/ I rather disagree	Neither agree nor disagree	I rather agree/ I completely disagree
bigger profits	34 / 35	48	36 / 26
larger market share	36 / 31	41	38 / 33
faster development	21 / 42	47	36 / 33
greater innovation capacity	27 / 42	38	43 / 29
more successes	33 / 38	45	41 / 22
lower costs	25 / 33	55	35 / 31

Source: Own study (N=179)

However, with the analysis data purged of enterprises responding "neither agree nor disagree" for the individual indicators, and assuming the entire scale of responses to be "I rather agree" and "I completely agree" or "I rather disagree" and "I completely disagree", the majority of respondents, though not over 54%, assessed their own enterprise better as compared to the competition for most indicators. This applied to the following indicators: higher market share – 51.5%, faster development – 52.3%, greater innovation capacity – 51.1% and lower costs as compared to the competition – 53.3%. The indicators of own profit (52.7%) and successes (53%) were assessed as minor compared to the competition.

The enterprises' own financial and asset situation as compared to the preceding year was also characterised, as follows: positive financial result, increase in company revenue, increase in own capital value, increase in company assets, increase in company market value or the indicator that in recent years the enterprise has been experiencing better net profit and productivity improvements (Table 2). Only in terms of assessment of own capital increases and enterprise asset value increases the highest number of responses was "neither yes nor no" (23.5% and 42.1%, respectively). It can be assumed that this response indicates that the enterprise situation did not change against the preceding year as compared on the basis of the assessed indicators. For the remaining indicators, taking into account the negative responses ("rather no" and "no") and the responses confirming growth ("rather yes" and "yes"), a positive image was obtained of the condition of the analysed enterprises.

Table 2: Property and capital condition of enterprises as compared to the previous year

Indicators	Answers		
	No/ Rather no	Neither yes nor no	Rather yes/ Yes
positive financial result	37 / 25	26	29 / 62
increase in revenue	32 / 33	27	38 / 49
increase in own capital value	32 / 34	42	34 / 37
increase in the value of assets	33 / 34	43	39 / 30
increase in company market value	32 / 34	37	37 / 39
(in recent years) better net profit	35 / 33	35	44 / 32
(in recent years) productivity improvements	25 / 34	39	45 / 36

Source: Own study (N=179)

Again, excluding from the pool of 179 those responses that would neither confirm nor deny the statement in line with the individual indicators, and on the basis of opposite responses on the scales, the following data was obtained: positive financial result in the preceding year was achieved by 59.5% of enterprises, revenue increased in 57.3% of cases, own capital value increase – 51.9%, asset growth – 50.7%, and enterprise market value growth – 53.5%. In recent years, however, increasing net profit is seen by 52.8% of enterprises, and productivity increases by 57.9% of enterprises.

In terms of characteristics of the development and innovation level, respondents would assess their position against the backdrop of the preceding indicators slightly less favourably (Table 3). Among the 179 enterprises, in the recent two years, new products were introduced by 44.7%, new investments were made by 45.8%, 51.4% implemented new technologies, product sales grew for 45.8%, resources increased in 39.7% of cases, and 39.7% was the rise in employee innovation capacity, 40.3% intensified market activity, enterprises competitiveness on the local market increased in 39% of cases, and new sales markets were acquired in 45.3% of cases. At the same time, in case of expansions of the customer portfolio and development of R&D activity, the response indicated most frequently was denial ("no" – 39.7% and 41.3%, respectively).

Table 3: Enterprises development and innovation level

Indicators	**Answers**		
	No/ Rather no	**Neither yes nor no**	**Rather yes/ Yes**
new products	28 / 40	31	35 / 45
new investments	40 / 31	26	38 / 44
new technologies	34 / 24	29	38 / 54
product sales increased	39 / 34	24	45 / 37
resources increased	34 / 36	38	35 / 36
customer portfolio growth	45 / 26	38	37 / 33
rise in employee innovation capacity	40 / 25	43	39 / 32
intensified market activity	33 / 28	46	44 / 28
increase of competitiveness on the local market	40 / 27	43	41 / 28
new sales markets	37 / 20	41	46 / 35
development of R&D activity	42 / 32	41	36 / 28

Source: Own study (N=179)

As assessed in the categories of market situation of the enterprise, financial and asset situation and research and development, the analysed enterprises have stable situations.

According to the assumed objective of the present publication, assessments were performed of the social sphere of selected components of the relation between the company and its employees (Table 4). The stable situation of the analysed enterprises suggests the assumption that in terms of relations with individuals, they do not limit their personal policy to employee development through qualification improvements and clearly determined career paths. As human resources management also covers activities aimed at the development of the social work environment and its surroundings, it was expected to see engagement by the analysed enterprises in activities integrating employees. However, in 50.3% of cases, the response was "we do not conduct such activities". In the group undertaking integration activities, the response indicated most frequently was support for common activities of employees and their families – 30.2%. A further form of activity was to organise employee sports teams – 25.7% and encouragement to joint volunteer work for the benefit of other employees, who are experiencing difficulties in life – 17.9%, as well as for the benefit of persons or institutions from outside of the company, who would need support – 17.3%. In 11.2% of cases, support was also provided for employee hobbyist groups. Beside the indicated examples of enterprise activity to build employee social capital, indicated were also such activities that could be caused by spontaneous activity of individual teams: "meetings in a relaxed atmosphere after work", "river canoeing", "supporting employees in terms of their life needs". Other responses concerned activities requiring the engagement of the management: "company events", "integration and training meetings and trips", "holiday meetings of the entire personnel", "joint outings (e. g. lunch, coffee with the boss)", "anniversaries (cake and financial award)". The quoted responses applied to 6.2% of the analysed enterprises. (Table 4).

Table 4: Enterprises' activities in terms of integrating employees

Activities aimed at the development of the social work environment and its surroundings	
Support for common activities of employees and their families	54 - 30.2%
Organising employee sports teams	46 - 25.7%
Supporting hobby groups among employees	20 - 11.2%
Encouragement to joint volunteer work for the benefit of other employees, who are experiencing difficulties in life	32 - 17.9%
Encouragement to joint volunteer work for the benefit of persons or institutions from outside of the company, who would need support	31 - 17.3%
Other types of activities	11 - 6.2%
we do not conduct such activities	90 - 50.3%

Source: Own study (N=179)

A further indicator was the enterprises' attitude towards inter-employee relations at the work place – describing the attitude towards the issue, whether they should be primarily professional, and only later collegial. The response given most frequently (53.6%) was: "Partly agree, partly disagree." However, 34.6% of respondents would agree with this statement, as opposed to 11.7%, who disagreed with it.

The lack of engagement of half of the analysed enterprises in activity that could strengthen relations in the social work environment suggests the conclusion that in the Polish reality, among leaders as well, many enterprises use traditional (imitative and repetitive) practices based on the development of competitive advantages through reduction of labour costs, and not through the utilisation of the unique potential that emerges through social relations. Searching for the causes of this state of affairs, one could indicate better readiness to invest in undertaking that are easier translated into financial capital. Furthermore, with the centrally-controlled economy in the portfolio, Polish entrepreneurs may have less experience in using policies of partnership and responsibility sharing.

Limitations and Future Research

The presented data constitutes a fraction of selected activities influencing the internal social environment that could be undertaken by enterprises. The acquired results only permitted a raw

sketch of the relationships between employees and organisations within the analysed enterprises in terms of satisfaction of selected social needs and preferred forms of organisation of cooperation in informal structures.

The acquired results must be amended and further studied in the future. It would be necessary to focus on a higher number of indicators that would comprehensively diagnose the quality of relations in the internal social environment. Subsequent research should entail an employee survey. A limitation of the presented results analysis is the lack of indication of the power of influence of the specific properties of the enterprises, e. g. the innovation capacity, on the employee-organisation relationship. In addition, one should also attempt to identify activities of enterprises that negatively influence the relationship between the employee and the organisation. It would also be interesting to research issues related to the quantitative assessment of enterprise value (economic capacity) of strong relations with employees.

Sustainability: Carpooling as a Component of Smart Mobility

Natalia BOICHUK

University of Opole, Opole, Poland

nataliia.boichuk@uni.opole.pl

Abstract

Purpose: The purpose of the article is to identify the perception of carpooling as a component of smart mobility in the opinion of city dwellers and the suburban area.
Methodology: The article is of an exploratory nature and is based on the results of in-depth interviews among residents of the suburban area and the city. The sample selection was intentional.
Findings: It was found that respondents are little familiar with the concept of smart mobility. They are distrustful of the concept of carpooling and sceptical about the safety of such a journey even if the identity of the driver or passenger is fully verified. Respondents also fear social mismatches, which can be a nuisance when traveling. The advantages of carpooling include savings, reduced congestion, the opportunity to meet interesting people, and a positive impact on the environment. The incentive to use carpooling may be ensuring travel safety, creating dedicated carpooling applications for employees of the organization, financial incentives and marketing activities.
Research limitations: The study was exploratory. Research should be conducted on a larger scale, including other smart mobility solutions.
Practical implications: If local authorities take measures to promote carpooling and at the same time ensure travel safety, then a reduction in the number of cars on the roads during peak hours and economic and environmental benefits can be expected.
Originality/value: The article presents qualitative research on carpooling in Poland, which enriches the literature. In addition, the results indicate the need for research in this direction, because the concept of sharing driving can bring measurable benefits.

Keyword: Carpooling, Sustainability, Smart Mobility.

Introduction

Sustainable development is defined as the development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs (United Nations General Assembly, 1987). Current solutions are based on combination of intelligent solutions supporting environmental protection, public education and developing the economy. On the other hand, sustainable transport and sustainable urban development are recognized as drivers of the country's economic growth. Forecasts show that the intensity of freight transport in urban areas will increase by 40% by 2030 and by over 80% by 2050 compared to 2005. At the same time, it is expected that passenger transport will also increase by about 34% by 2030 and by over 50% by 2050 compared to 2005 (Kiba-Janiak, 2016). This prognosis is also based on analyses of population movement, which indicate that the number of urban residents by 2050 may reach to over 80% of the world population. The increase in flows in urban areas affects congestion, air pollution and reduces the quality of life in cities (Rześny-Cieplińska, 2018). Therefore the issue of sustainable transport is becoming one of the key problems facing contemporary planners and researchers (Neoh et al., 2017).

Cities are the place where opportunities and dangers for stable development are concentrated. The city can be defined as "smart" when social capital, traditional and modern (ICT) communication infrastructure encourage sustainable economic development and high quality of life. Smart Mobility is often highlighted as a key system without which the Smart City could not be sustainable. Intelligent mobility solutions can have a positive impact on the functioning of the city and its inhabitants. The use

of public transport infrastructures is indeed certainly one of the best solutions to face the challenge of vehicular traffic congestion. However, conventional public transport denotes a service that follows fixed routes and schedules; it may not be available in certain areas, and usually, the distance to the stop locations may be huge in sparse areas. That is why public transport has lost its popularity in recent years, thus increasing the amount of passenger transport on the road. One of the tools to limit the negative effects that arise as a result of traffic is shared journeys. They are an opportunity to reduce road congestion, reduce exhaust emissions, save costs, and increase road safety. Joint journeys can be treated as an element of intelligent mobility, which has been widely popularized in recent years. In this context, carpooling has been a widely-accepted concept to implement Intelligent Transport Systems (ITS) in smart cities and to reduce the gas emissions caused by the use of the personal car (Mallus et al., 2017). Carpooling has been around for many years, but thanks to ICT it can gain a new level of popularity. The demand for public transport services is currently not high enough, which generates additional unjustified costs when providing these services. So carpooling can become an alternative in the absence of public transport. Furthermore, Çetin (2017) assumes that the development of sharing services will not have a negative impact on public transport.

The purpose of the article is to identify the perception of carpooling as a component of smart mobility in the opinion of city dwellers and the suburban area. The article is of an exploratory nature. Realization of the goal of the article will give the opportunity to create a tool to explore a larger population, and therefore an attempt will be made to create conditions for the development of these concepts under smart mobility. The research problem consists in examining the perception of shared journeys by residents and identifying the main factors encouraging them to travel together. Specifically, the study addresses the following research questions:

RQ1. How is smart mobility treated by society?
RQ2. How are carpooling perceived?
RQ3. What should be the incentives for carpooling?

The paper has the following structure: Part 2 defines the concept of smart mobility; Part 3 presents research on carpooling; Part 4 contains the research methodology; Part 5 includes results; Part 6 contains discussion; the article ends with conclusions.

Smart Mobility Concept

The concept of smart mobility is one of the components of smart city, which has been developed especially in the European Union since 2007. Smart city refers to city management aimed at improving the quality of life in urban areas. It is a comprehensive city strategy combining communication technology infrastructure and knowledge while using natural resources while respecting environmental considerations. Smart City includes different aspects of city management: building, energy, environment, government, living, education and mobility (Gil-Garcia et al., 2015). It seems that in the future smart concepts should be extended to the national level, i.e. smart country, where resource management will be based on a balanced approach to all ongoing processes. However, at present one cannot look so far, because intelligent solutions are not easy to implement and are not always accepted by the society.

The development and implementation of the concept “Smart Mobility” in all the major urban areas inside the European Union have to follow the European strategy Europe 2020. The strategy that was presented to all the member states of the E.U. and adopted in 2010 in the European Parliament, presents all the major activities that will be conducted developed in the union in the next 10 years. The main idea of this concept that the E.U. wants to implement is to integrate all the urban areas into the same pattern in all the things that are related to mobility / transport. Jeekel (2016) argues that the smart mobility could be considered the clever and active small brother of sustainable mobility. Benevolo et al. (2016) suggested that smart mobility could be seen as a set of coordinated actions addressed at improving the efficiency, the effectiveness and the environmental sustainability of cities.

Value in mobility is derived from traveller spend, whether this means spend on travel tickets, vehicle ownership, or services and apps (Wockatz and Schartau, 2015). Fundamentally, the commoditisation of individual journeys and the journey time of users is what makes smart mobility pay for itself, and represents a continuation of the long standing trend towards the neo-liberalisation of the transport system (Gössling and Cohen, 2014).

Pape and Lauwers (2015) note the other forms of mobility planning [Fig. 1]. It is conventional mobility, with essentially a focus on speed, convenience and affordability, and with a "predict and provide"-attitude. The next step it is a sustainable mobility, with a broad and multimodal system. And the last "city as a place"-approach where mobility should fit in the creation of attractive, liveable and efficient communities.

Fig. 1: Connection between different mobility approaches

Followers of the concept of smart mobility can meet their travel needs in a more ecological, socially desirable and more economical way. Ride can be done by public transport (e.g. buses, trams, subway, taxis), alternative means of transport (e.g. bicycle, scooter, rollers), shared types of transport (e.g. carpooling, ride sharing, car sharing). There is a transition in the role of the citizen in the transport system. This is both as a source and recipient of information through mobile communication and through bringing their resources to the shared mobility platforms (Dochert et al., 2018).

Šurdonja et al. (2020) in their empirical research found that responders in Croatia have more limitations in accepting new technological solutions for mobility in the future. Therefore, a wide campaign should be carried out among the public promoting intelligent solutions, outlining the benefits that can be achieved. In opinion of Balint (2017) by improving all of these kinds of smart transportation we can observe that the economy of the many large cities in the U.S.A. and in Japan has improve drastically, the quality of life also has improved and most importantly the environmental issues has been resolved up to a certain level by reducing the pollution level and the smog inside the largest cities in the world. With new technologies, it will become easier to share cars, to utilise their full capacity with ride sharing and on demand rides, meaning that cars can become part of the full spectrum of mobility options, with far less cars needed. In addition, researchers (Porru et al. 2020) suggest that intelligent mobility solutions can be implemented not only in cities but also in rural areas.

Carpooling

Sharing economy is a concept involving the sharing something yourself instead of buying goods or services. In terms of car transport, car-sharing and ride-sharing supported by advanced information and

communication technologies have begun to be accepted. It should be emphasized that carpooling should not resemble or consider itself synonymous with car sharing (Ciasullo et al., 2018). Carpooling implies the sharing of a car among private individuals, whereas car sharing is a membership-based service available to all qualified drivers in a community. A ride-sharing system is commonly seen as a system to bring together travellers with similar itineraries and time schedules. Car-sharing, ride-sharing and carpooling are effective to reduce total number of cars in our society comparing to owning cars for individual person (Aiko et al., 2017). In joint journeys, passenger safety is a very important aspect, which can be ensured by allowing public access to the ride, driver identification and passenger insurance (Chaudhry et al., 2018).

Participants would share rides to save time and money and, secondarily, to reduce environmental impacts. According to Kawaguchi et al. (2019) due to sharing concepts, CO_2 emissions will decrease significantly already in 2035.

Carpooling is a concept derived from ride-sharing and involves the use of shared cars by people with similar travel needs who decide to carry out common journeys between certain origins and destinations (Jamal et al. 2016). If we can take advantage of the free space in each car, this will lead us to its best use with an optimal equation for achieving: fewer cars in the streets with more number of passengers. For the first time carpooling can be used in practice during World War I, when the US government had to conserve resources, especially fuel. Joint journeys saved costs and provided mobility. Carpooling in 70's was very popular and then fell out of favour until the beginning of the new millennium. Travel comfort when using carpooling may be slightly lower than when using your own means of transport. Nevertheless, the benefits of using this solution in the form of reducing the number of cars on the road, reducing pollution and noise are a definite priority. Change in some socio-economic characteristics such as the increase in fuel price, in parking costs, or in the implementation of a new traffic policy, may prove to be an incentive to carpool. The latest technological advances, the widespread use of the Internet and the frequent use of mobile devices have given new impetus to carpooling, which has led to levels that in some countries exceed 10 percent of the total number of motor vehicle journeys (Chan and Shaheen, 2012). Carpooling can contribute to people abandoning the need to own a car and adopt carpooling to meet their mobility requirements, because almost the same benefits are offered in terms of freedom of movement and flexibility in both time and space. According to the research of Filck and Żak (2017), the main problem in carpooling is the coherence of the interests of passengers and drivers. To establish a shared ride, it is necessary that the driver and the passengers agree on a meeting point, travel conditions, travel costs. The carpooling service model implies significant trust concerns, especially derived from the fact that users must share their vehicle with strangers. According to research by Salamantis et al. (2019) a sense of security for traveling together can be provided by a reputation rating system. The reputation of each user should be depends on both the ratings of other users submitted to the system at the end of each ride, and their travel preferences.

Carpooling can be operated in two main ways: Daily Car Pooling Problem (DCPP, where users must agree on how to carpool on a daily basis) or Long-term Car Pooling Problem (LCPP, where users form groups and organize shared rides that persist during a certain period of time. (Bruck et al., 2017). In another classification there are three types of carpooling (Sghaier et al. 2010):

- Regular carpooling, which takes place regularly at known times and hours. These journeys mainly concern daily short drives, such as business trips,
- Occasional carpooling, which is the most common form of traveling together. Travels are unusual and usually relate to long distances (over 50 km) between cities,
- Factual carpooling, which applies to trips organized for special events such as concerts, celebrations. In this case, carpooling is proposed for logistics reasons, in order to counter parking problems, traffic congestion and difficulties concerning accessibility to the event covering places due to the important car's flow.

Nowadays, most of the carpooling services implement a "static" approach: when using such a service, the carpoolers have to post ridesharing requests and offers several hours before their desired departure time, and the shared ride has to be arranged before the trip starts (Mallus et al., 2017). A widely known example of carpooling in Europe is the BlaBlaCar system, enabling travellers to find a means of

transport at an affordable price. Also in many countries were created the similar platforms such as Amovens, ZimRide, RideSearch, eRideShare, Carpoolworld, pilot project in Germany Car2gether, Italian Jungo, Autostrade carpooling, Polish JedziemyRazem etc. Carpooling is also promoted at universities in Canada, the United States, Australia and even Greece (Liaskopoulou et al., 2017). Joint travels of students and university employees have a positive impact on travel costs and traffic flow at peak times. A mobile application enabling dynamic carpooling solutions was developed by scientists (Chorfi et al. 2015) in Saudi Arabia. This application is a real-time application, which connects people living in the same city and working at the same company or university and having the same travel needs. What is important - the application has the option to mark the travel option "only for women", which is useful for Arabic countries. Dynamic carpooling that instantly makes travel accessible through the use of ICT can gain popularity.

Methodology and Data Collect

The purpose of the article is to identify the perception of carpooling as a component of smart mobility in the opinion of city dwellers and the suburban area. The in-depth questionnaire interviews were conducted to achieve the research goal. The questionnaire consisted of open questions, which made it possible to find out in detail the opinions and feelings of respondents in relation to the issues examined. The selection of the sample was deliberate due to the nature of the study. The study involved 30 people compared for both sexes; aged 18 to 65; secondary and higher education; owning a car and not owning a car. They were inhabitants of the city and suburban area, commuting every day to work in the directions suburban area-city, city-suburban area, city-city. In qualitative research, the sample size of 30 respondents is justified. Guest et al. (2006) found that 12 interviews of a homogenous group is all that is needed to reach saturation. The explorations were conducted in March 2020. On average, the interview lasted about 30 minutes.

All interviews began with a question about understanding the concept of smart mobility. After answering this question, respondents were explained what about concept really is. Then, they were asked about their attitude towards shared journeys as a passenger and as a driver. Respondents were asked to indicate the advantages and disadvantages of carpooling after explaining exactly what this term means. The last question concerned the factors encouraging the use of carpooling. A flexible approach to interview resulted an additional information.

Rezults

The concept of smart mobility in public opinion

The concept of smart mobility is poorly known to respondents. This is the result of the lack of popularization of this term among the public. There is also a lack of promotion of smart mobility solutions on a large scale. The first associations of the population are associated with digital technologies and smartphones. In 2/3 of cases the answer appeared that smart mobility is intelligent route planning, choosing the optimal option and combining means of transport. However, such elements as joint travel, intelligent movement, low-combustion cars and those having the function of autopilot are not associated by society as smart mobility.

Perception of shared journeys

The respondents' opinions were divided. 2/3 of respondents said that shared journeys can be tedious, uncomfortable and dangerous. Other people perceive joint travel as an alternative to using public transport and their own means of transport. Men have a mainly negative attitude towards shared journeys, as this may change their plans.

Advantages of carpooling

Among the advantages of carpooling, the financial aspect has always appeared. Respondents believe that they could save money by traveling together. Drivers can use the saved money for current car repairs or insurance. Joint journeys also cover fuel costs. On the other hand, passengers in most cases have cheaper and more convenient access than public transport. Another effect of sharing is reducing the number of cars on the road at peak times. This results in shorter stoppages in traffic jams, and therefore faster travel and greater fuel savings. Thus, according to respondents, carpooling can have a positive impact on CO_2 emissions. Environmental benefits are becoming more and more desirable. Among the advantages of carpooling was the opportunity to meet interesting people, establish long-lasting interpersonal relationships and perform trip more enjoyable.

Disadvantages of carpooling

Travel safety plays a significant role when choosing a type of transport. Respondents say that carpooling is currently unsafe. When using carpooling in Poland, there are no internet platforms that accurately verify the identity of people offering a shared trip. This affects the sense of fear among users, especially women: "*Fear of who you meet and with whom you will stay for some time in one car often causes a tendency to choose another mode of transport"*. The solution is to create a travel network for commutes or studies, and authenticate users for random travels.

Social mismatches are the second factor that contributes to the reluctance to use and provide carpooling. The fear of a traveller who does not match the driver's lifestyle, behaviour and the oppressive atmosphere of travel discourages them from traveling together.

The disadvantage of carpooling is reduced travel comfort. The respondents' experience shows that: "*the driver offered a comfortable ride with two people in the back seats of an off-road car, where the driver does not smoke in the car - in fact the trip took place with three people in the back and two dogs, while constantly smoking cigarettes. This resulted in a very low comfort of travel"*. In carpooling, should be planning trip in advance, discuss the trip details with (time, pickup location, destination, baggage, breaks, etc.), which means less flexibility.

Limited access to information on journeys is also a barrier to widespread carpooling. The young generation commonly uses the Internet and has access to the network. The problem is the limited use of mobile applications by older people. Also in Poland currently there are no dynamic carpooling solutions, which necessitates planning a trip a few hours earlier. Therefore, dynamic carpooling models should be developed that will increase the number of trips using this alternative mode of transport in real time.

Factors encouraging to carpooling

Among the factors that may contribute to increasing interest in carpooling based on the respondents' answers, the following categories have been distinguished: safety, popularization, access to information on journeys.

Protection. There should be full verification of persons providing and using carpooling. All personal data should be properly secured and managed by carpooling platforms.

Popularization. Currently, joint rides are not promoted in Poland. There is no advertisement of carpooling platforms, enterprises do not create applications and portals dedicated to their employees. A chance to increase the interest in carpooling is to present the benefits of this solution and to direct advertising to specific groups of recipients. According to respondents' opinions: "*Mainly young people will use carpooling services, because older people are wary*". Such advertising should design and implement such security measures, to carpooling has become a common phenomenon. According to the answerer, figures should be provided to increase public awareness, because specific numbers are

more accepted than the advantages described in the form of text. Another factor aimed at encouraging drivers to travel together, aptly to the respondents' opinions, is establishing cooperation between carpooling platforms and e.g. petrol stations. An incentive for carpoolers as e.g. fuel rebates could have a positive effect in the form of increased joint travel offers. Also, a solution functioning in some countries has been identified, such as the ability to travel by bus lane when there are at least four people in the car. It is a matter of agreement with local authorities.

Access to trip information. In the opinion of respondents, the initiative of local authorities and enterprises to create carpooling platforms dedicated to employees of carpooling platforms will positively affect the image of these institutions. "Internal carpooling is desirable for greater safety, because you know at least the view of a particular traveller and there are no such fears as those of a stranger". In summary, a good solution would be to create a real-time carpooling application.

Discussion

The conducted research indicates that the respondents are not fully aware of the advantages and benefits of smart mobility and carpooling. The research results are largely consistent with the research carried out by Shaheen et al. (2016) which identified six main casual carpooling success factors: a time savings incentive for drivers; monetary savings for passengers; pickup locations near freeways, residences, parking, or public transit stops; a common drop off location; reliable public transit for the return trip; and a high-occupancy vehicle requirement of three or more occupants. By Witkowska et al. studies (2014) a positive attitude toward the use of carpooling emerged, whereby costs saving, protection of environment, and stress-free driving were revealed to be the key drivers of usage behaviour. The last element - stress-free driving - was not mentioned in this study, because respondents often feared social mismatches, which would have the opposite effect.

Similar results are also found in Ciasullo et al. (2018), where thanks to big data it was establish that the advantages of carpooling include economic efficiency, environmental efficiency, comfort, movement, socialization, reliability and curiosity. While, the disadvantages also included similar factors - lack of efficiency, lack of flexibility, lack of privacy, danger, lack of trust.

In the opinion of Olszewski et al. (2018) society can be stimulated to cooperate in carpooling through gamification. Nevertheless, according to the respondents' opinions, appropriate security measures should be introduced, dedicated carpooling platforms should be created, incentives for drivers in the form of e.g. fuel discounts, and a wide advertising campaign should be conducted.

Summary

Sustainable transport at the forefront with smart mobility is gaining an increasingly important role due to the increase in CO_2 pollution, nuisance traffic congestion in the city, noise and decreasing the quality of life of urban residents through the accumulation of these factors. Carpooling as a concept based on shared journeys, while sharing travel costs, can become one of the elements reducing the negative effects of urbanization and the automotive industry. Based on the research, it was established that respondents, both the older and younger generation, perceive smart mobility as using a smartphone to move and plan the optimal route. This means that measures should be taken to inform the public about the principles of this concept and the possibilities of its use. It was explained that carpooling is a known concept for all respondents, but opinions on this topic are divided. Some people consider carpooling as an alternative means of travel, which benefits both the driver and the passenger. On the other hand, the majority of respondents consider sharing travel as a burdensome phenomenon.

Among the main advantages of carpooling there are cost savings, reduced congestion, the opportunity to meet interesting people, caring for the environment. The disadvantages include the lack of trust in both the driver and passenger, the danger, the need to adapt to another person, the operation of the vehicle and the possibility of social mismatches. It has been identified that carpooling can gain popularity by presenting its advantages (savings, establishing interpersonal relations) to a wide

audience, creating safe travel conditions, internal organizational platforms for carpooling and the possibility of using bus lanes in the presence of four people in the vehicle. Nowadays, however, people are neither motivated nor encouraged by their local governments or employers to make use of such solutions as a carpooling. If local authorities take measures to promote carpooling and, at the same time, travel safety is assured, then a reduction in the number of cars on the road during peak hours and economic and environmental benefits can be expected.

Future research should be a quantitative research conducted on a larger scale, including other smart mobility solutions.

Abstract

Population ageing is a global social phenomenon that requires a better and faster implementation of advances in smart home technologies to create age-appropriated services and environments. Smart homes, which incorporate sensors, actuators and environmental and portable medical devices as well as modern communication technologies, can enable continuous and remote monitoring of the health and well-being of the elderly. Health monitoring is in line with current trends in the medical and social systems. The case study included in this paper presents a system for monitoring and assessing the health of the elderly in an intelligent environment. The major concern, in this sense, is to ensure optimal access to smart home technology for the elderly, aiming at the impact on quality of life, health and social involvement.

Keywords: Smart homes, Smart technology, Sensors, Elderly, Internet of Things.

Introduction

In most developing countries, the healthcare sector faces major economic challenges, particularly due to the growing number of people dependent on healthcare services, as well as the quality of care needed by the elderly. Older adults need more care and attention, as a minor illness or even small accidents can cause irreparable damage (Azimi et al, 2017).

Current studies also reveal that many older adults prefer to live in their own homes, but they need caregivers or medical experts to care for and monitor or help them. It is therefore essential to develop new tools and technologies to help older people age in their homes (Rashidi and Mihailidis, 2013).

Society is in a continuous transformation in terms of increasing the digitalization of the daily lives of the elderly. Numerous reports and analyzes conducted worldwide have shown that older people are willing to use a wide range of technologies to be safe at home, both for their personal health and well-being, and to maintain social ties (Syed et al, 2019).

As the number of elderly people increases, it is necessary to develop affordable, easy-to-use and discreet healthcare solutions for such people. It is necessary to monitor a person's daily life and work environment with the help of ICT, smart home technologies and stand-alone assistive devices (Blackman et al, 2016), (Muñoz et al, 2011). Smart homes can be adapted to remotely monitor the health of older adults by introducing smart and wearable sensors to track seniors' daily activities and help those in need of caregivers and experts.

Major advances in wireless technology, processing power and computing bring innovation in the healthcare sector, leading to the development of connected medical devices. These devices are capable of capturing, generating, analyzing and transmitting data. These devices, together with the data itself, create IoMT (Internet of Medical Things) - a connected infrastructure of software applications, medical devices, medical services and computing systems (Deloitte, 2018). IoMT-related devices can provide real-time monitoring to save lives in case of medical emergencies, such as asthma attacks, heart attacks, diabetes, falls etc. (Patel, 2019).

Overview of Smart Homes

Balta-Ozkan et al (2013) states that "*smart home is a residence equipped with a high-tech network, linking sensors and domestic devices, appliances, and features that can be remotely monitored, accessed or controlled, and provide services that respond to the needs of its inhabitants*".

To meet the growing need for health care services for the elderly, it is essential to develop affordable, discreet and easy-to-use healthcare solutions. Thus, smart technologies (for example: smart homes) are being used in the living environments of the elderly. These technical innovations have a varied potential for autonomy, communication, health and social contact.

Another function of smart homes is to improve the physical condition of the elderly. Smart homes have allowed the elderly who need medical care, but did not want to turn to the services of health care units for frequent health checks, and continue living independently.

One of the functions of the smart home is the real-time monitoring of the daily lives of the elderly, which has significant consequences for health problems. In addition to predicting the health conditions of the elderly and detecting abnormal events, this approach is useful for establishing medical emergencies that require the intervention of medical professionals. Therefore, continuous monitoring can improve safety and quality of life (Majumder et al, 2017).

Smart homes, which incorporate environmental medical sensors, wearable sensors and modern communication technologies, can enable continuous and remote monitoring of the health and well-being of the elderly at a low cost. These sensors and devices are designed to observe the environment, monitor the health of the inhabitant and provide proactive services in order to improve the experiences of the elderly.

The smart home system consists of three main technology sections:

- Sensors level - physical components (sensors, actuators).
- Communication level - wired / wireless network that connects the physical components and the control system.
- Applications and services level - control system.

Using the information collected from the physical components, the control system performs a simple automation of tasks, an analysis or prediction of the location of the resident and his behavior or recognition of the health of the person living in that house. Smart homes can provide greater comfort by automating care, instead of disrupting the normal lives of the elderly (see figure 1).

Smart Home Technologies

Smart housing technologies used for the elderly are "information-based technologies that passively collect and share information about residents with the residents, their family members and primary care providers." Smart home technology can also be defined as "using basic and assistive devices to build an environment in which many components in the home are automated and in which devices can communicate with each other." The smart devices in the house collect physiological data about location and movement, which can then be used to detect in time the problems that require the intervention of health care providers, residents and their families (Coardos and Marinescu, 2020), (Cocco, 2011).

Fig. 1: Smart homes integrated with automated systems for elderly healthcare (adapted from Majumder et al. (2017))

Smart home technologies (environmental sensors / portable sensors, healthcare management platforms, mobile devices, etc.) are used in many medical applications, such as remote health monitoring, health programs, chronic diseases associated with aging, and care for the elderly (Alexandru and Ianculescu, 2018).

Smart home technologies create the necessary framework for collaboration between the medical staff involved in the care of the elderly, as well as the patient and his family. Thus, it is possible to offer elderly-centered or even proactive care.

Elderly with complex needs have a reduced ability to perform daily activities due to physical, mental and psychosocial challenges that require continuous and complex care (Liu et al, 2016), (Hickam et al, 2013). Thus, new Smart technologies offer the possibility for older adults with chronic conditions and complex needs to stay at home and maintain an acceptable quality of life (Frisardi and Imbimbo, 2011), (Archer et al, 2014), providing a cost-effective approach to improving the quality of life and helping older adults to live safely in their own homes (Liu, 2012).

Smart home technologies have to provide (Liu et al, 2019):

(1) *Confidentiality*: reduced exposure of patients' privacy.
(2) *Security*: reduced errors and increased monitoring sensitivity.
(3) *Risk prediction*: due to the use of Big data to analyze and predict the risk of adverse events.
(4) *Personalized service*: addressing different types of chronic conditions so that older people can obtain monitoring indicators appropriate to their disease. This can provide a more personalized service for different seniors, promote their health and improve user satisfaction.

"Smart home" can allow older people to live independently at home for longer and reduce their dependence on formal or informal caregivers or allow caregivers to take better care of older adults. A

smart home can provide a variety of services ranging from simple task automation (e.g. room temperature control), analyzing or predicting a resident's location, recognizing the health of an occupant living in their own home, with the subsequent transmission of data for remote monitoring.
In fact, "Smart" is the allocation of software, hardware, cloud and detection technologies so that it can capture and communicate data with sensors in the physical world in real time, which can be used for advanced analysis and smart decision making (Papa et al, 2020), (Chang, 2017a, 2017b), (Nam and Pardo, 2011). The Internet of Things (IoT) creates a network of connected, uniquely addressable smart devices that communicate in real time via standard IP-based communication protocols. Connected “things” can range from something as small as smart LED lighting and smart locks, to something as innovative as smart healthcare monitoring and smart logistics management (Chang, 2017c). Data collected from smart devices can be sent to the cloud for permanent storage or real-time viewing, but also sent directly to a computer or smartphone.

Smart home technology, which can also be called 'home automation', means the use of home devices that connect through a network, most often a local LAN or internet (Wikipedia, 2020a). It uses devices such as sensors and other devices connected to the IoT that can be monitored, controlled or accessed remotely and provides services that meet the perceived needs of users (Hendricks, 2014).

Sensors and devices are integrated into objects and home infrastructure and are connected using network technologies. Each sensor is responsible for one or more tasks at the same time (Mshali et al, 2018).

There are three main classes of interconnected networks, which are often used in this field: environmental sensor networks, portable sensor networks, and multimedia devices:

- *Environmental sensors* are responsible for capturing and retrieving contextual data on the elderly and their environment. The sensors can be placed in a living environment or attached to various objects in the house to detect the activities of the elderly person. Such objects could be a sofa, table, bed, chair or floor that contain pressure sensors. The level of performance in the daily activities of the elderly can be measured by observing them in their living environment, as well as their personal interactions with household objects in a particular location.

  Environmental sensors can provide rich contextual information to detect daily activities and observe human behavior in the smart home. Environmental sensors are used for additional dimensions, such as light, temperature, humidity. They are located in different places to monitor environmental conditions and to identify daily activities. Power sensors are used to measure and manage power consumption and to detect the use of electrical devices using On/Off events. The use of electrical appliances such as microwaves, water kettles, toasters, room heaters and televisions can also be used to detect activity and to further refine behavioral information (Suryadevara et al, 2013).

- *Portable sensors* are used in the smart home to provide a continuous flow of information about real-time health conditions. They are often incorporated into accessories such as clothes, belts, watches or glasses. These sensors often use accelerometers to detect outpatient activities, or devices measuring vital signs, such as heart rate sensors to monitor the subject's health. Accelerometers and gyroscopes are the most common inertia sensors used to monitor body movements and positions, such as standing, sitting, and walking.

  Global Positioning Systems (GPS) can also be used as portable sensors to monitor location-based activities in an open or mobile environment. In the smart home, several biosensors are used to monitor the vital signs of the elderly, such as electrocardiography (ECG) sensors used to monitor cardiac activity, electroencephalography (EEG) sensors used to monitor brain activity, sensors of electromyography (EMG) used to monitor muscle activity and electrooculography sensors (EOG) used to monitor eye movements. Pulse oximeters are

used to measure blood oxygen levels (i.e. oxygen saturation), while photoplethysmography (EPG) sensors are used to monitor blood flow.

- *Multimedia devices*. The widespread use of household appliances, enriched by a set of sensors, helps to create an interactive healthcare environment. Integrated appliances can be electrical or electronic devices that perform several functions at home. Devices such as cameras, microphones, telephones, speakers and televisions create a platform for data exchange. These devices increase the subject's interactions with health applications and represent either new sources for collecting contextual information or means to provide guidance and counseling (Lemlouma and Chalouf, 2013).

Figure 2 shows an overview of the sensor networks in the smart home.

Fig. 2: An overview of the sensor networks used in the smart home (adapted from Mshali et al. (2018))

As the number of IoT devices increases, the communication networks that support them need to adapt. Communication infrastructures must be designed to allow the traffic they carry. Voice, video and data each have specific features and requirements for successful network transmission.

Depending on the distance range it covers, it is estimated to use several types of networks (figure 3). The most popular communication networks are: Nano Network, Internet of Bio-Nano-Things (IoBNT), BAN Network (Body Area Network), PAN Network (Personal Area Network), LAN Network (Local Area Network), CAN Network (Campus Area Network), MAN Network (Metropolitan Area Network), RAN Network (Radio Access Network), WAN Network (Wide Area Network).

Fig. 3: Types of IoT Networks (adapted from Wikipedia (2020b))

The most popular communication technologies are: WiFi, Bluetooth, ZigBee, Cellular, 6LowPan, Z-Wave, RFID, NFC, LoRaWan, SigFox. Depending on the application, data requirements, security requirements, power and battery life, IoT systems will dictate the choice of a technology or a combination of technologies. The most important communication technologies for IoT can be classified into (figure 4):

(1) LPWAN - large area but low power network,
(2) Short Range Network - short range network.

Fig. 4: IoT technologies

Providing a service is the most complex part of the smart home. The two main actors directly involved in smart home applications are the monitored subjects (e.g. patients, the elderly and people with disabilities) and the healthcare provider (e.g. doctors, nurses and volunteers in network coverage). End-user applications depend on the interaction between these two categories of actors.

The functionalities provided are influenced by the monitored subject and the services available. The processing system plays a major role in such context-aware applications, where the data collected must be relevant in order to be properly managed and interpreted. The necessary actions are taken to provide appropriate and personalized services depending on the situation. Context-aware features are personalization, provision of the necessary content and information; suggestion, in order to offer recommendations regarding the subject's behavior; configuration, automatical configuration of devices and user interface to optimize and adapt the interface based on the context of the subject.

In the processing system, several reasoning approaches and machine learning algorithms are used to understand the context of the subject and determine the services required.

The application implements a user interface, provides alerts and controls the sensors. The user interface is usually used to display information about the health of the subject, vital signs, changes in behavior, etc. Alert mechanisms are used in emergencies and are responsible for defining alert messages and selecting the network and service provider. Moreover, the context-aware application influences the sensor system based on the user's context. The aim is to provide an efficient monitoring system that optimizes system resources, controlling, for example, the durations, frequencies and quantities of data.

The impact of Smart Home Technologies in elderly lives

The progress of smart home technologies radically changes the society in which we live, the economy and the quality of life of the elderly, bringing benefits in the short and long term (Carnemolla, 2018).

Devices must share readings securely so that all warning signs can be retrieved and any daily information can be proactively sent to patients.

Regarding the impact of smart home technologies in the lives of the elderly, the medical branch has the highest utilization rate of smart home technologies among the elderly by monitoring health problems and age-specific dysfunctions using smart devices. Online health monitoring reduces periods of hospitalization and, subsequently, healthcare costs, facilitating an independent life with efficient management.

Another major impact of smart home technologies is the safety and comfort of the home – the two being central pillars in the lives of the elderly. The positive impact of these smart home technologies appears from the strong interest of older people in these technologies, as well as the willingness to know more and be trained to make better use of sensors and multimedia devices.

The smart home can have a major impact on the behavior and emotional state of the elderly, thus influencing the health, well-being and independence of the elderly. Smart home technologies work together to produce results that will give seniors independence, safety and well-being.

The main benefit of the impact of smart home technologies is that it can delay the institutionalization of the elderly.

Case Study

The project - " *Non-invasive Monitoring System and Health Assessment of the Elderly in a Smart Environment*" (RO-SmartAgeing) - aims to demonstrate the potential of smart technologies (such as IoT, cloud computing, Big Data) for the positive transformation of the way health care services are provided to the elderly and health care staff / provider.

This project aims to develop and validate a system for monitoring and assessing the health of the elderly that integrates physiological and non-invasive portable motion sensors for collecting medical parameters - an intelligent environment with discrete environmental sensors to monitor daily activities and the person's lifestyle and a cloud platform for data storage and aggregation, including the presentation of results generated by advanced data analysis.

This system creates a minimally invasive environment for the elderly, helps increase life expectancy, implements and integrates smart technologies to improve the quality of life of the elderly, monitors physiological and environmental parameters facilitating more efficient health management based on collected data helping to develop innovative personalized assistance services.

Among the most important features planned to be developed within the project are:

- non-invasive health monitoring in order to define a real profile of the elderly that presents the current state of some health parameters (physiological and cognitive);
- monitoring current activities and lifestyle;
- defining a model for tracking locomotor decline and preventing falls;
- personalized environmental adaptation allowing a controlled use of environmental devices or alarm triggers in the event of the occurrence of an abnormal health parameter or an unforeseen and dangerous event;
- supporting the doctor's remote assessment of the elderly current health status and early diagnoses;

- responsibility and involvement of the elderly in the optimal management of their own health;
- identifying the most representative ways of caring for the elderly.

The RO-SmartAgeing system will follow some essential aspects of monitoring an elderly person:

- *Medical records*: The system offers the possibility to store the records of the elderly in an electronic database providing access to them in a simple and fast way, with updated data in real time. Thus, doctors and caregivers can record information about daily activities, food, medicine, health, medical treatments, photos and other observations.

- *Remote monitoring*: With the help of IoT devices, the RO-SmartAgeing system ensures real-time remote monitoring of vital parameters of the elderly, which will be collected by sensors; they are selected based on user decisions and can be measured without intrusive sensors or human intervention. Data can be viewed in real time by doctors, caregivers, the elderly and the elderly's family.

- *Medical history*: From the moment the elderly person starts to be monitored in the intelligent environment and through the RO-SmartAgeing system, an initial clinical history will be created, with data such as surgical history, prescriptions, allergies, social data, etc.

- *Alert notifications*: When the IoT system detects a possible emergency related to the elderly person's health, it will generate an alert for the current doctor, caregiver or family member.

The main portable devices and the main actors that will be involved in the RO-SmartAgeing remote health monitoring system are shown in Figure 5.

Fig. 5: Proposed system with portable devices for the elderly for RO-SmartAgeing

The RO-SmartAgeing system fits in a category of systems that has the potential to facilitate not only the fact that an elderly can live independently for longer, but also to make health care services more

efficient by reducing the pressure on general health system, as a result of repeated and long-term institutionalizations.

Conclusions

"Smart home technology" is one of the emerging technologies that is developing at a competitive level in the technological world, improving security, comfort and health at home. It seems to show potential to help older people live longer, safely and independently in their homes. The interest of the elderly in these smart technologies is mainly related to: caring for devices to ensure the safety of the home, devices dedicated to health and communication.

The project "Non-invasive Monitoring System and Health Assessment of the Elderly in a Smart Environment (RO-SmartAgeing)" estimates that:

- it will be increased quality of life of the elderly and their family members by providing intelligent non-invasive services remotely such as: monitoring, diagnostics, support for daily activities, alerting accident;
- new scientific knowledge in the field of non-invasive intelligent services for the elderly, analysis and modeling of health and quality of life related to health, to assess acceptance and usefulness of smart home technology solutions in healthcare.

The RO-SmartAgeing system fits in a category of systems that has the potential to facilitate not only the fact that an elderly person can live independently for longer, but also to make health care services more efficient with smart home technology.

Acknowledgment

The authors gratefully acknowledge the contribution of Ministry of Research and Innovation for funding the project RO-SmartAgeing - "*Non-invasive Monitoring System and Health Assessment of the Elderly in a Smart Environment*" for the period 2019-2022.

Abstract

The retail industry is quite rotary, where there are many changes in a short period of time. In large international retailers there is a need to be able to differentiate the existing stores, in order to perceive their relevance to the business. For that purpose, data mining algorithms for clustering, such as k-Means, can be useful, combining two very important variables to observe the activity of retail stores: revenue and number of transactions. Using this method, it is possible to obtain a good differentiation between stores as to their activity so that managers can act accordingly. The study included the clustering of more than one thousand stores of a large food retail chain and revealed some at a very high level of activity and others at a much lower level. The clustering process using the k-Means algorithm was fully implemented in SAP HANA XS Advanced utilizing the Predictive Analysis Library (PAL). In a first phase, the clustering process involved the combination of the Elbow Method and Silhouette Coefficient to choose the optimal number of clusters. In a second phase, the capabilities of the Predictive Analysis Library for the k-Means algorithm were used to automatically choose the best number of clusters, based on the value of the Silhouette Coefficient. In the end, in both phases, two clusters were formed: one cluster housing the less active stores and the other encompassing the more active stores in terms of revenue and number of transactions. It was possible, then, to distinguish the stores under analysis, grouping them in a correct way, according to their relevance for the business.

Keywords: k-Means, Clustering, SAP HANA XSA PAL, Retail

Introduction

The retail industry is a business area where millions of transactions are processed by different operators, in several stores and under an immense variety of products. However, this sector is more complex than just selling goods to consumers. The retail industry can also encompass the design, manufacture and transportation of goods throughout the supply chain, as well as the use of different technologies to monitor and control the entire process (Beck and Peacock, 2009). Theoretically, the retailing concept would be simple: get the products at the right time, in the right conditions and with the best price for the consumer. Nevertheless, given the scale of this business, this process is much more complex and it is relevant to make certain types of analysis to the existing data.

Large retailers have different stores in several countries, so it is necessary to know which stores are more and less important to the business, those that contribute more and less to total revenue, and also those that perform a higher volume of transactions, annually. This is where Clustering algorithms can help differentiate each one by establishing different groups, based on some business variables.

The data of this study regarding transactions processed by the POS is hosted in SAP HANA, which can be accessed through the SAPA HANA XS Advanced Platform (integral part of the SAP HANA solution). SAP HANA has the Predictive Analysis Library (PAL), which enables, easily and without recourse to data extractions or connections to the database, via external applications, to execute some Data Mining algorithms directly over the data. Thus, and for this specific problem, it is possible to

recover the data and apply the k-Means Clustering algorithm, via SQL, directly in SAP HANA XS Advanced, obtaining, in the end, the expected result of clustering all the existing stores.

Related Concepts

Before starting to expose the methodology adopted and the results obtained, it is important to present a brief literature review of some concepts inherent to this study.

Clustering

Clustering is an Unsupervised Learning Data Mining technique capable of finding some structure in an unlabeled data collection and is usually applied in Machine Learning. This technique can be defined as the process of grouping a set of data objects into different subsets (clusters), so that the data objects present in the same cluster have a high similarity to each other, but are quite dissimilar to other data objects belonging to other clusters (Kononenko and Kukar, 2007; Hastie, Tibshirani and Friedman, 2009; Trivedi, Pardos and Heffernan, 2011; Han, Kamber and Pei, 2012; Singh and Bansal, 2015; Hossain, 2017; Kansal *et al.*, 2018; Syakur *et al.*, 2018). Albeit Clustering, as a Data Mining technique, can be used in a preprocessing task, it can also be used, in isolation, to find value in the data, observing the characteristics in each cluster and making deeper analysis in each one of them, as is the case of this study (Han, Kamber and Pei, 2012).

Clustering being a challenge in data mining research, it has some requirements that ideally should be satisfied: scalability; ability to handle different types of features; discovery of clusters with arbitrary shape; requirements for domain knowledge to determine input parameters; ability to deal with noisy data; capability of clustering high-dimensionality data; and interpretability and usability (Kononenko and Kukar, 2007; Han, Kamber and Pei, 2012). On the other hand, Clustering methods still have some problems. For example, dealing with large amounts of data can lead to problems with processing time; the efficiency of the algorithm can depend on the measure of similarity used; and sometimes the results can be interpreted in different ways (Kononenko and Kukar, 2007). Additionally, Clustering methods may differ at the partitioning level, the measures of similarity used, and also depend on whether Subspace Clustering is performed (Han, Kamber and Pei, 2012).

There are many clustering algorithms that can be used to solve various business problems. Generally, these algorithms can be classified into the following categories (Han, Kamber and Pei, 2012):

- Partitioning Methods: these algorithms divide a data set with n objects, partitioning it into k groups, where each group represents a cluster, each group having at least one object, being $k \leq n$. Partitioning Methods are based on distance and can use mean to represent the centers of clusters, being very efficient for small and medium data sets.
- Hierarchical Methods: given a set of data objects, a hierarchical method decomposes them hierarchically. In these methods, incorrect mergers or splits cannot be corrected.
- Density-based Methods: the general idea of these algorithms is to continue to increase a given cluster as much as the density in the neighborhood exceeds some threshold. Density-based Methods can handle arbitrary shapes and can filter outliers.
- Grid-based Methods: these methods quantify the object space in a finite number of cells, forming a grid structure. These methods have a fast processing time, since they typically depend on the grid size and not on the number of data objects.

This study focuses only on the use of a Partitioning Method (k-Means), more specifically centroid-based, and therefore more emphasis will be placed on this category.

Data Normalization

In most situations the data cannot be compared since it is not on the same scale. This is why it is necessary to ensure that a technique is used to make it suitable for comparison. To do this, Data Normalization should be a first step, as it guarantees that the data can actually be compared by

changing its scale of values to a specific range and minimizing biased values (Jayalakshmi and Santhakumaran, 2011; Han, Kamber and Pei, 2012; Patro and Sahu, 2015; Eesa and Arabo, 2017). Thus, the Data Normalization aims to give equal weight to all features, being very useful and used in Clustering (Jayalakshmi and Santhakumaran, 2011; Han, Kamber and Pei, 2012). There are several ways to perform Data Normalization, however, there are two that can be highlighted (the only ones that are supported by PAL in SAP HANA): **Quotient Transformation – Sum** (Object Normalization) and **Min-Max Normalization** (Column Normalization).

Quotient Transformation – Sum will normalize the sum of the modified values to 1 and the modified mean will be equal to $\frac{1}{n}$. Therefore, the mean will be constant across the attributes, but the variances will differ. Assuming that a data set has n features and $O\ (o_1, o_2, \dots, o_n)$ is an object in that data set, Quotient Transformation – Sum normalizes O into a new object $O'\left(\frac{o_1}{S}, \frac{o_2}{S}, \dots, \frac{o_n}{S}\right)$, where $S = |o_1| + |o_2| + \cdots + |o_n|$ (Milligan and Cooper, 1988; Walesiak, 2014):

$$o'_i = \frac{o_i}{\sum_{i=1}^{n} |o_i|} \tag{1}$$

Min-Max Normalization performs a linear transformation in the original data, modifying the value scaling between 0 and 1 and preserving the existing relations previously. However, Min-Max Normalization may be affected by the presence of outliers on the variable. Under the assumption that min_F and max_F are the minimum and maximum values for a feature F, respectively, Min-Max Normalization maps a value v_i of F to v'_i in a range between 0 and 1 (Milligan and Cooper, 1988; Jayalakshmi and Santhakumaran, 2011; Han, Kamber and Pei, 2012; Patro and Sahu, 2015; Eesa and Arabo, 2017):

$$v'_i = \frac{v_i - min_F}{max_F - min_F} \tag{2}$$

k-Means: A Centroid-Based Clustering Technique

The k-Means algorithm is very useful to make analysis to data coming from the POS, since its characteristics allow it (Yoseph and Heikkila, 2019), being currently the most used, popular and simplest Unsupervised Learning algorithm, when the objective is to find structures from the data (Chaturvedi *et al.*, 1997; Wedel and Kakamura, 2000 cited in Boone and Roehm, 2002; Singh and Bansal, 2015; Hossain, 2017; Kansal *et al.*, 2018; Syakur *et al.*, 2018; Yoseph and Heikkila, 2019), having an optimal behavior in terms of computing time (Baian, Firli and Tri cited in Syakur *et al.*, 2018) and helping in the Decision Making Process (Kansal *et al.*, 2018).

Assuming a data set (D), containing n objects in the Euclidean Space, this algorithm will partition the objects present in D into several k clusters ($C_1, \dots, C_k$). Mathematically, $C_i \subset D$ and $C_i \cap C_j = \emptyset$, for $i \geq 1, k \geq j$. In other words, each cluster must contain at least one object and each object can only be associated to one cluster. To evaluate the quality of the results, an objective function can be used, aiming at a high intra-cluster similarity and a low inter-cluster similarity. Each cluster C_i is represented by a centroid (the center point of the cluster), which can be defined by the mean of the objects present in the cluster. The centroids should be as distanced from each other as possible. This distance can be measured through the Euclidean Distance: the length of a line segment between two points x and y in a n-dimensional space. In this particular case, it can be considered an object $o \in C_i$ and c_i (centroid of the cluster C_i) (Prasad and Malik, 2011; Han, Kamber and Pei, 2012; Kodinariya and Makwana, 2013; Singh and Bansal, 2015; Hossain, 2017; Kansal *et al.*, 2018). Furthermore, the quality of a cluster C_i can be measured by the Sum of Squared Error between all objects present in C_i and the centroid c_i, being defined by (Han, Kamber and Pei, 2012):

$$SSE = \sum_{i=1}^{k} \sum_{o \in C_i} d(o, c_i)^2, \tag{3}$$

where SSE is the Sum of Squared Error for all objects in the data set; o is the spatial representation of the object; and c_i is the centroid of cluster C_i. In other words, for each object in each cluster, the distance from that object to the centroid of its cluster is squared and the distances are summed (Han, Kamber and Pei, 2012). The goal is always to minimize this objective function.

The k-Means algorithm is relatively easy to understand as it does not involve a very complex cluster formation process. As already mentioned, the algorithm basically defines the centroid of a cluster as the average value of the points in the cluster (Prasad and Malik, 2011; Han, Kamber and Pei, 2012; Kodinariya and Makwana, 2013; Amorim and Hennig, 2015; Singh and Bansal, 2015; Hossain, 2017; Kansal *et al.*, 2018):

1. Firstly, it randomly selects k objects from a data set D, each of which initially represents the center of the cluster.
2. Each of the remaining objects is associated to a cluster that is more similar to it, based on the Euclidean Distance between the object and the center of the cluster.
3. From iteration to iteration, the algorithm improves the SSE, being computed, for each cluster, a new center, using the objects associated to the cluster, in the previous iteration.
4. Afterwards, all objects are reassigned using the new center.
5. The iterations continue until the clusters obtained are the same as those obtained in the first iteration.

The need to specify the number of clusters (k) can be seen as a disadvantage if there is no prior knowledge of the business to know what the desired value for k is. Thus, the problem lies in finding the optimal value for k. It will be possible to perform different values for k and check the results obtained for each one of them (Han, Kamber and Pei, 2012). There are some measures that can be considered to choose the best for k, from the simplest, such as By the Rule of Thumb or Elbow Method, to the most efficient, such as Silhouette Coefficient or Cross Validation (Han, Kamber and Pei, 2012; Kodinariya and Makwana, 2013; Kansal *et al.*, 2018). The one that is natively supported by PAL in SAP HANA is the **Silhouette Coefficient**. Silhouette Coefficient measures the similarity of an object, relative to the cluster where it is inserted, comparing the cohesion (distance to all objects in the same cluster) and the separation (dissimilarity between clusters) (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015).

For a data set D with n objects, and assuming D is split into k clusters ($C_1, \dots, C_k$), for each object $o \in D, o \in C_i$ ($1 \leq i \leq k$), the mean distance between o and all other objects present in the same cluster is calculated as $a(o)$ (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015):

$$a(o) = \frac{1}{|C_i| - 1} \sum_{o' \in C_i, o \neq o'} d(o, o'), \tag{4}$$

where $d(o, o')$ is the distance between the objects o and o' in the cluster C_i. $a(o)$ can be interpreted as measure of how well o is associated to its cluster – compactness (the lower the value, the better) (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015). Similarly, the minimum mean distance between o and all clusters to which it does not belong can be defined by $b(o)$ (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015):

$$b(o) = \min_{C_j : 1 \leq j \leq k, j \neq i} \left\{ \frac{\sum_{o' \in C_j} d(o, o')}{|C_j|} \right\} \tag{5}$$

The cluster with the lowest value of $b(o)$ is the neighboring cluster of o. The larger $b(o)$ is, the more separated o is from other clusters. Thus, the Silhouette Coefficient can be defined as (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015):

$$s(o) = \frac{b(o) - a(o)}{\max\{a(o), b(o)\}} \quad (6)$$

The preferred case is when $s(o)$ approaches 1 (i.e., $a(o) < b(o)$), because the cluster containing the object o is compact and far from the other clusters. On the other hand, the worst situation is when $s(o)$ is negative (i.e., $b(o) < a(o)$), which means that o is closer to objects belonging to other clusters than those belonging to its cluster (Han, Kamber and Pei, 2012; Zhou and Gao, 2014; Amorim and Hennig, 2015).

To evaluate the quality of Clustering, the mean value of the Silhouette Coefficient of all objects in a cluster can be used. Additionally, the Elbow Method can also be used, together with Silhouette Coefficient, replacing SSE, to derive the best value for k (Han, Kamber and Pei, 2012). In Elbow Method there is a value for k where the cost falls sharply and after that it reaches a level where from then on the cost falls very slowly and this should be the optimum value for k. Nevertheless, this "elbow" cannot always be identified directly, since sometimes there is no "elbow" or there are several "elbows" (Han, Kamber and Pei, 2012; Kodinariya and Makwana, 2013; Kansal *et al.*, 2018).

Predictive Analysis Library (PAL)

SAP HANA provides a set of techniques capable of moving application logic to the database through the Application Function Library (AFL) where Predictive Analysis Library (PAL) is included. The Predictive Analysis Library (PAL) defines functions that can be called using SQLScript procedures to execute analytical algorithms. SQLScript is an extension of SQL in SAP HANA, which allows developers to define complex application logics through database procedures (SAP, 2015).

PAL includes predictive analysis algorithms in nine Data Mining categories (SAP, 2015):

- Clustering.
- Classification.
- Regression.
- Association.
- Time Series.
- Preprocessing.
- Statistics.
- Social Network Analysis.

Methodology

As already mentioned, the objective of this study is to cluster the stores of a large Food Retail Chain. The data is hosted in SAP HANA and the entire research process was done there, making it possible to increase performance through computing in the database itself, rather than at an application level.

The data refers to one year of transactions in all stores. In total, the data encompasses more than 1000 stores with different behaviors. In this case, a sales volume based approach was used, using the **revenue** and **total number of transactions**, over one year, to cluster the stores. The term "transaction" refers to each receipt line and not the receipt. The structure of the data used can be seen in the table below:

Table 1: Data Structure

Column Name	Data Type	Description
RETAILSTOREID	String	Unique Store Identifier
REVENUE	Double	Annual Revenue (€)
NUMTRANSACTIONS	Integer	Annual Number of Transactions Processed

This study was divided in two stages: the first stage was dedicated to combining the Elbow Method with Silhouette Coefficient to find the best value for k; the second stage was dedicated to using the capacity of SAP HANA to find the best value for k, automatically, without having to use the methods used in the first stage. In the end, it was possible to compare whether the two approaches produce the same results, although SAP HANA was used in both. Since there is no prior business knowledge of the ideal number of clusters, the objective is to discover it.

The figure below illustrates the workflow performed in the first stage in a simplified way:

Figure 1: First Stage Workflow

First, the data had to be retrieved by executing an SQL statement, since the data does not match this structure in any table of the original database in SAP HANA. After that, there are all the conditions to start the creation of the project:

1. In the development part of SAP HANA XS Advanced, a Multi-Target Application (MTA) was created in the Cloud Foundry environment.
2. Then, a SAP HANA Database Module was created, indicating the Module Name, the namespace, the Schema Name and the SAP HANA Database Version.
3. Afterwards, a HDB CDS Artifact (tables.hdbcds file) was created, to build the entity that will save the SQL statement result. The SAP HANA Core Data Services (CDS) transforms a SAP HANA CDS resource into a database object defined in the CDS file (e.g. tables, views, types).
4. After the file with the table structure was created, the result of the SQL statement was inserted into that table.
5. After that, another HDB CDS Artifact (PAL_AFL.hdbcds file) was created to build the types, entities and views that will send data to the algorithm and save the results received from that algorithm.
6. Then, the PAL k-Means.hdbaflprocedure file was added to build the procedure that will invoke the native k-Means method of SAP HANA, passing it the information of which tables are input and output. In other words, it turns an AFL language procedure resource into a corresponding database procedure object.
7. After that file was added, a .csv file containing the parameters to be sent to the k-Means algorithm was also added. In this file, one of the parameters is the k (number of clusters), taking the value 2 initially.
8. The PAL Params.hdbtabledata file was created which maps the parameters inserted into the .csv file to the k-Means algorithm.

9. Later, the k-means-clustering.hdbprocedure file was added to the project, to transform a procedure resource into a procedure database object.
10. Finally, the built procedure was called, repeating the process up to $k = 10$ to see the results for each value of k.

After the entire workflow was completed, Silhouette Coefficient values were recorded for each value of k. Input (to send data to the algorithm) and output (to save the data returned by the algorithm) tables were used to run the algorithm, which can be seen below:

Table 2: Input and Output Tables for k-Means algorithm

Table Name	Purpose	Type
Input Data	Sends the data to the algorithm	Input
Parameters	Sends the desired parameters to the algorithm	Input
Results	For each data object, saves the cluster to which it belongs, the distance to the centroid of that cluster and the Silhouette Coefficient	Output
Center Points	For each cluster, saves the information about its centroids (average values of each feature)	Output
Center Statistics	For each cluster, saves the information about its centroids (average value of Silhouette Coefficient)	Output
Statistics	Saves the Silhouette Coefficient for the optimum value of k. In addition, it stores information about the F-Test and Analysis of Variance (ANOVA) for each value of k.	Output
Cluster Model	Saves a JSON statement with the algorithm settings	Output

The Parameter Table is probably one of the most important tables, since it will be the one that will send the parameters to the algorithm, including the value for k. The following are the parameters used for the first stage:

Table 3: Parameters for the First Stage

Parameter Name	Used Value	Meaning
GROUP_NUMBER	2	2 clusters
DISTANCE_LEVEL	2	Euclidean Distance
MAX_ITERATION	100	Maximum of 100 iterations
NORMALIZATION	2	Min-Max Normalization
THREAD_NUMBER	2	2 threads
EXIT_THRESHOLD	0,000000001	Threshold for exiting the iterations

Although k was set to $k = 2$, it was modified from iteration to iteration until $k = 10$. In the end, all values of Silhouette Coefficient were compared for each value of k and the Elbow Method combined with each of these values was used to choose the value of k.

Regarding the second stage, the changes that were imposed were at the workflow level, since the value of k was no longer changed and a range for k was imposed, i.e., instead of changing the value of k in each iteration, only one iteration with k between 2 and 10 was performed and the algorithm automatically identified the best value for k. Consequently, the parameters sent to the algorithm were also modified to meet this need. The figure below illustrates the workflow performed in the second stage in a simplified way:

Figure 2: Second Stage Workflow

As can be confirmed in the image above, the workflow is quite similar to that of the first stage, but does not include iterations for the value of k, as the optimal value is automatically calculated. The following table shows the parameters used in the second stage:

Table 4: Parameters for the Second Stage

Parameter Name	Used Value	Meaning
GROUP_NUMBER_MIN	2	Minimum of 2 clusters
GROUP_NUMBER_MAX	10	Maximum of 10 clusters
DISTANCE_LEVEL	2	Euclidean Distance
MAX_ITERATION	100	Maximum of 100 iterations
NORMALIZATION	2	Min-Max Normalization
THREAD_NUMBER	2	2 threads
EXIT_THRESHOLD	0,000000001	Threshold for exiting the iterations

The results obtained will be presented and discussed in the following section.

Results and Discussion

First Stage: Using Silhouette Coefficient & Elbow Method

As already mentioned, in the first stage the value for k was varied between 2 and 10 and Silhouette Coefficient values were recorded for each one. In the image below, a graph is illustrated that permits to perceive the evolution of Silhouette Coefficient from $k = 10$ to $k = 2$:

Figure 3: Evolution of the Silhouette Coefficient

Silhouette Coefficient was used instead of SSE, but the Elbow Method can still be used to choose the best value for k. The closer the Silhouette Coefficient is to 1, the better, and by analyzing the graph of the figure above, it can be concluded that the optimal value for k is $\boldsymbol{k = 2}$, since there is a sharp increase from $k = 3$ to $k = 2$ (the "elbow") (Ženko, Dzeroski and Struyf, 2006; Keith, 2018; Syakur *et al.*, 2018). Between $k = 10$ and $k = 8$ the Silhouette Coefficient remains relatively constant. It is from $k = 8$ that the value starts to have a more noticeable increase, until it reaches $k = 2$ with the highest recorded value.

Additionally, in the table below, the values of Silhouette Coefficient can also be consulted, for each value of k:

Table 5: Silhouette Coefficient values for each value of *k*

k	Silhouette Coefficient
10	0,52958552
9	0,53065832
8	0,52846195
7	0,56028868
6	0,56406801
5	0,58857234
4	0,64194644
3	0,68137486
2	0,77137570

The remaining results are present in the following subsection, since the optimal value for k was automatically calculated in the second stage and it can also be verified if the optimal value for k was the same in both stages. The goal is to present the results when the value of k is optimal and not to present all the results for each value of k.

Second Stage: Detecting Automatically the Better Silhouette Coefficient

As mentioned, in the second stage, a value for k was given between 2 and 10 and, automatically, the algorithm in SAP HANA calculated the optimal value, without having to resort to more manual

analysis. As expected, the optimal value for k in the first and second stages were the same. Therefore, it is relevant to present and discuss the results obtained for $k = 2$.

Starting with all the output tables, below are the structures for each one:

Table 6: Results Output Table Structure

Column Name	Meaning
RETAILSTOREID	Unique Store Identifier
CLUSTERNUMBER	Cluster Identifier where each data object is inserted
DISTANCE	Euclidean Distance between the centroid of the cluster and the data object.
SILHOUETTE	Silhouette Coefficient of each data object

Table 7: Center Points Output Table Structure

Column Name	Meaning
CLUSTERNUMBER	Cluster Identifier where each data object is inserted
REVENUE	Revenue value for the centroid (mean value of all data objects in the cluster)
NUMTRANSACTIONS	Number of Transactions value for the centroid (mean value of all data objects in the cluster)

Table 8: Center Statistics Output Table Structure

Column Name	Meaning
CLUSTERNUMBER	Cluster Identifier where each data object is inserted
SILHOUETTE	Silhouette Coefficient value for the centroid (mean value of all data objects in the cluster)

Table 9: Statistics Output Table Structure

Column Name	Meaning
NAME	Name of the statistical measure
VALUE	Value for the statistical measure

Table 10: Model Output Table Structure

Column Name	Meaning
MODEL	Model Identifier
JSON	JSON statement for the output model

Additionally, two views were built: STORES_CLUSTERED and CLUSTERS. The first crosses the information from the original data with the Results Output Table, thus being possible to complement the information from the Results Output Table with the Revenue and the Number of Transactions; the second view uses the first view, crossing this information with the Center Points Output Table, saving the additional information of how many stores were associated to each of the clusters. The respective structures are indicated below:

Table 11: STORES_CLUSTERED View Structure

Column Name	Meaning
RETAILSTOREID	Unique Store Identifier
REVENUE	Annual Revenue (€)
NUMTRANSACTIONS	Annual Number of Transactions Processed
CLUSTERNUMBER	Cluster Identifier where each data object is inserted

Table 12: CLUSTERS View Structure

Column Name	Meaning
CLUSTERNUMBER	Cluster Identifier where each data object is inserted
REVENUE	Revenue value for the centroid (mean value of all data objects in the cluster)
NUMTRANSACTIONS	Number of Transactions value for the centroid (mean value of all data objects in the cluster)
STORES	Number of stores in each cluster

After the algorithm was run, $k = 2$ was obtained, meaning that the algorithm built two clusters from the original data: **Cluster 0** and **Cluster 1**. Cluster 0 contains 1227 stores and Cluster 1 contains 205. For each cluster it is important to analyze the values of its centroids. The table below summarizes the values of the centroids in each cluster:

Table 13: Centroids Values

CLUSTER	REVENUE	NUMTRANSACTIONS	SILHOUETTE
0	0,07023500345024111	0,13588420543697133	0,8057390972346350
1	0,34512470874756773	0,45125316220345957	0,5656981654737712

By examining the table above with the values for each centroid, it can be concluded that Cluster 0 contains the less active stores, i.e., those with the lowest revenue and number of transactions processed, since the centroid values for this cluster (average value of all objects in the cluster) are much lower than for Cluster 1. Therefore, it can be concluded that Cluster 0 contains the less active stores and Cluster 1 the more active stores. In fact, the cluster of the less active stores is considerably larger than the cluster of the more active stores.

On the other hand, the centroid value for the Silhouette Coefficient in Cluster 0 is relatively higher than in Cluster 1. In Cluster 0, the centroid value for Silhouette Coefficient is very close to 1, which means that the Cluster is quite compact and distant from Cluster 1. Nevertheless, Cluster 1 not only has a lower value than Cluster 0, but it is also quite distant from 1, and it can be concluded that objects in this Cluster can probably be closer to objects in Cluster 0 than to objects in the same Cluster.

By analyzing the results directly in SAP HANA XS Advanced it is possible to obtain the location of the centroids of each of the clusters:

Figure 4: Scatter Plot for the Centroids Position

For the execution of the algorithm, the data was normalized using Min-Max Normalization. Nonetheless, after the algorithm is called up, it is not possible to view the normalized data, and only the original data in each cluster is available for viewing. Although the data is not available after Normalization, it is still possible to check the disposition of each store in a scatter plot:

Figure 5: Scatter Plot for the Stores disposition

Analyzing the graph of the figure above, it is possible to verify a high point density for Cluster 0, confirming the theory that this Cluster is more compact and where the points are closer to each other (thus, the value of Silhouette Coefficient for its centroid is corroborated), unlike Cluster 1 that shows higher dispersion. This may mean that there are some outliers in the data, as k-Means is sensitive to outliers. As the goal was also to include outliers in the Clustering process, k-Means was used as the method for Clustering, being then possible to detect the most unusual stores. Thus, in the scatter plot it is possible to detect the stores that have a high activity and can be considered positive outliers.

Although there is a Silhouette Coefficient value for each centroid, the most important value is the value of this coefficient for the optimum value of k. As already mentioned, for $k = 2$, $\boldsymbol{s(o)} = \mathbf{0.7713756956906573}$.

Conclusions

All work was particularly focused on using the k-Means algorithm to cluster stores in the retail sector, conducting an in-depth technical analysis of existing SAP HANA methods to measure Clustering quality. SAP HANA is equipped with several algorithms that permit the execution of application logic in the database, considerably increasing computational efficiency. The k-Means algorithm was just one example of what PAL in SAP HANA has to offer to the developer community.

The k-Means algorithm proved to be quite efficient in running it on SAP HANA, taking less than 1 second to process the data and return the desired results. A very interesting advantage of SAP HANA, in relation to this algorithm, is its ability to automatically choose the best value for k, considering Silhouette Coefficient, thus reducing unnecessary human analysis. Although the Elbow Method, together with Silhouette Coefficient has been effective in this study, it may happen that in other situations there are different "elbows" and it is difficult to apply the same approach. Therefore, SAP HANA also comes to solve this problem, giving the possibility of obtaining the optimal result, without any interference from the user (except for the manipulation of the parameters to be sent to the algorithm). Another added value is the possibility to analyze the results obtained, directly in SAP HANA XS Advanced, through graphs that help to better understand the location of the centroids, for example.

On the other hand, this library provided in SAP HANA is not yet well known by the developer community and there is not much documentation on it, which makes it slightly difficult to use and develop in HANA. Still, it is a very powerful library, with a great deal of resources, which allows the developer to take advantage of the HANA environment, without having to use third-party applications and thus increasing computational efficiency.

With the results obtained in this study, it is now possible to identify the most and less relevant stores for the business, see which ones have more and less revenue and which ones have more and fewer transactions made annually. Actually, the group of less active stores is considerably larger than the group of more active stores. This is due to the amount of revenue generated and the number of transactions processed, given that not all stores have the same working capacity. Knowing how stores contribute to the business will drive manager's attention and allow for better decision making. For the less active stores, it will be necessary to consider whether they are really justified to remain in business, since they may only be reducing the final profit. The combination of the number of transactions and the revenue, during one year, is essential for the perception of business development in the retail market, since these two variables cannot be considered separately, as they could lead to misleading results.

In conclusion, PAL from SAP HANA has proven to be extremely useful and capable of solving real business problems, providing a different from the usual, yet efficient development paradigm.

The COVID19 Pandemic and Sustainability: Consequences for The Fashion Industry

Ewa Gluszek

Wroclaw University of Economics and Business, Wrocław, Poland
ewa.gluszek@ue.wroc.pl

Abstract

This article aims to understand how the epidemic crisis will affect the clothing industry's functioning and whether these changes will have a positive or negative impact on sustainable development. The analysis shows that most of the environmental consequences are related to the reduction of non-renewable resources and the reduction of environmental devastation. At the same time, social factors mainly concern job losses and the consequences in terms of poverty and hunger risk for many regions in developing countries. What seems interesting is that the changes in the functioning of the fashion industry have had an unambiguously positive impact on environmental factors, but definitely negative on social factors. The article uses research methods such as literature review, desk study (reports) and inference.

Keywords: sustainability, sustainable supply chain, fashion industry, COVID19 pandemic

Introduction

In recent years there has been a growing interest among governments, legislators, and managers in the idea of sustainable development. Businesses - especially those large companies with global brands and media visibility daily, with a strong economic, social, and environmental impact - have been in the center of public attention and under increasing social pressure. It applies, among others, to companies in the textile and apparel industry, which has been regarded as an anti-hero in sustainable development principles.

The industry is characterized by global, fragmented supply chains, steadily increasing outsourcing to developing countries, and the high environmental impact of production. The social pressure to increase corporate social responsibility forces many companies in this industry, to accelerate their search for ways to integrate sustainability into their supply chains. It seems all the more urgent as the further development of the fashion industry along its trajectory points to the possibility of catastrophic consequences in all dimensions.

The outbreak of the coronavirus pandemic severely hampered the industry's development and put into question the current business model. The economic effects of the crisis are becoming more and more visible and acute. A new report by Altagamma, BCG, and Bernstein predicts that the industry may lose up to 40 billion Euros this year through Covid-19, and its value will fall to 309 billion Euros, which is the lowest value in five years (Biondi, 2020). The main reason is not only delivery problems, but also hundreds of stores that are still closed or working short hours. Apart from these clearly adverse economic effects, however, the pandemic has many other social and environmental consequences. This article aims to understand how the epidemic crisis will affect the functioning of the clothing industry and whether these changes will have a positive or negative impact on sustainable development. In particular, the article tries to answer three research questions:

RQ 1. How has the pandemic affected the fashion industry?

RQ2: Do the identified changes in the industry supply chain impact the environmental or social aspects?

RQ3. Will these changes have a positive or negative impact on social and environmental aspects of sustainable development?

The article uses research methods such as literature review, desk study (reports, interviews) and inference.

Sustainable Development

The concept of sustainable development emerged in the 1980s and was disseminated with the Report of the UN World Commission on Environment and Development (OECD). It states that "sustainability means being able to satisfy current needs without compromising the possibility for future generations to satisfy their own needs." A decade later, the Elkinton concept of "Tripple Bottom Line" (TBL) has gained full recognition (Elkinton, 1998, 2004, in Caniato, 2012, p. 660). It proposes that enterprises' business performance should be assessed in parallel from three perspectives: economic, environmental, and social. It means that development can be both economic and social and environmental, and should also take into account the long-term perspective. It soon became apparent, however, that sustainability cannot be limited to the company alone, but must be extended to the entire supply chain and all key stakeholders. Sustainable Supply Chain Management (SSCM) can be understood as the strategic, transparent integration and achievement of an organization's social, environmental and economic objectives in systematic coordination of key inter-organizational business processes, in order to improve the long-term economic performance of individual companies and their supply chains (Carter & Rogers, 2008, p.368). Companies that strive to achieve at least a minimum level of sustainability must, therefore, extend all three elements of the TBL to each link in the supply chain (Koksal et al. 2017, p.1).

Sustainable Development in The Fashion Industry

The textile and clothing industry is a vital sector in the global economy. Globally, the $1.3 trillion worth clothing industry employs more than 300 million people throughout the value chain; cotton production alone accounts for nearly 7% of total employment in some low-income countries (Apparel & Footwear, 2016). Over the past 15 years, clothing production has roughly doubled, driven by the expansion of the middle class worldwide and an increase in sales per capita. It is mainly due to the 'fast fashion' phenomenon, which means the rapid introduction of new styles, increased number of collections offered annually, and often lower prices (A new textiles economy, 2017, p.18).

At the same time, it must be acknowledged that this is one of the most 'unsustainable' industries that exist, as the current system of production, distribution, and use of clothing operates in an almost linear fashion. It involves extracting large quantities of non-renewable resources to produce garments that are often only used for a short period, after which the materials are primarily lost in landfills or burned. It is estimated that more than half of the fast fashion clothing produced is disposed of in less than a year (A new textiles economy, 2017, p. 19). This linear system causes enormous consumption of resources, pollution and degradation of the natural environment, bringing about significant adverse social effects on the local, regional, and global scale. The textile industry relies mainly on non-renewable resources such as oil for the production of synthetic fibers, fertilizers for cotton growing, and chemicals for the production, dyeing, and finishing of fibers and textiles. Textile production (including cotton) also consumes about 93 billion cubic meters of water per year, contributing to problems in some water-poor regions (Ibid., p.20). The industry's massive carbon footprint goes beyond the use of raw materials - it also includes greenhouse gas (GHG) emissions from textile production, which amounted to 1.2 billion tonnes CO2 equivalent in 2015 (21 more than all international flights and shipping combined).

The textile and clothing industry not only sins against the environment but also causes many negative social consequences throughout the supply chain. Many workers in textile and clothing factories work under dangerous conditions in processes using hazardous substances and chemicals. The pressure to reduce labor costs results in the relocation of production to developing countries (Bangladesh, Vietnam), where decent wages, appropriate working conditions and working time and safety standards are rarely ensured (there is even talk of modern slavery). The effects of negative social impacts also affect local communities, which may suffer from bad environmental practices, such as pollution of local rivers by untreated production wastewater (Ibid., p.21).

Due to irresponsible practices throughout the supply chain, the fashion industry has, for many years, been subject to scrutiny and criticism by various types of sustainable development NGOs. The Pulse Score 2019 report shows that companies in this industry are still not implementing sustainable solutions quickly enough to offset the negative environmental and social impacts (Lehmann et al., 2019, p. 4).

The consequences of the COVID-19 pandemic for the fashion industry and their impact on sustainable development

The outbreak of the pandemic brought about dramatic economic effects for the fashion industry in particular. A report by Business of Fashion (BoF) and consultants McKinsey predicts that if stores are closed for two months, 80% of listed fashion companies in Europe and North America will be in a difficult financial situation (Amed et al., 2020a). The average market value of fashion and luxury companies fell by nearly 40% in the first three months of 2020 - a more sharp decline than the entire stock market. Global fashion sales are projected to fall by 30% in 2020 and the luxury goods market by up to 40%.

The following part of the article will analyze the most important consequences of the coronavirus pandemic crisis for the fashion industry and their impact on sustainable development practices, but only those concerning environmental and social aspects. This impact may be direct or indirect, positive, or negative.

Sourcing of Raw Materials and Materials

The COVID-19 pandemic has caused a sharp collapse in retailing and many disruptions in the fashion industry's supply chain. The first direct effect of the retail collapse due to the implementation of social distancing and border closure provisions was an almost immediate reduction in production and cancellation of orders. From an environmental point of view, this has the same benefits as a significant reduction in textile production means less environmental devastation. However, given the social consequences, this picture is no longer favorable. The latest statistics, collected by the ITMF - International Federation of Textile Manufacturers, show that in the first quarter of this year, brands and retail chains canceled 31% of orders from their textile suppliers worldwide, and a global turnover of the textile and clothing sector could fall by 28% in 2020 (Amed et al., 2020a). The International Labour Organisation (ILO) has described the pandemic as "the worst global crisis since World War II." It estimates that its impact could lead to 195 million workers being made redundant already in the second quarter of this year (in Bangladesh, India, and Cambodia).

Moreover, a direct consequence of the significant reduction in textile production is the very worrying phenomenon of withholding payments for ordered materials. It again leaves crowds of people without any material support, as this activity occurs in most countries where there are no social security systems based on insurance. However, many fashion companies are aware that such behavior dramatically undermines mutual trust and will be a severe barrier to restoring good relations in the future.

Likely, the increase in social and environmental vulnerability caused by the pandemic will result in higher pressure to use recycled materials for production. It creates an opportunity to drastically reduce the use of non-renewable resources and the negative environmental impact of the industry. At the same time, it provides an opportunity for innovative use of renewable raw materials for the production of plastic-based fibers, or the use of regenerative agriculture for the production of cotton and other cellulose-based fibers (A new textiles economy, 2017, p. 91). The use of recycling is also an excellent opportunity to reduce waste. Less than 1% of textiles produced for clothing are recycled, not to mention the high costs of storage and incineration (Ibid., p.112). Both phenomena, however, do not seem to have a significant social impact, except for the chance to develop knowledge and a certain number of jobs in companies working on such innovations.

Production

Just as in the case of the reduction in the production of materials and raw materials, the direct and immediate effect of the outbreak of the pandemic was a drastic reduction in the volume of production. From the perspective of sustainable development, we can again speak of the positive impact of this situation on the natural environment (reduction in the consumption of natural resources and raw materials and reduction of production waste) and the negative impact on social issues (loss of jobs and livelihoods of hundreds of thousands of employees).

Another critical effect of COVID-19 is the strengthening of partnerships with suppliers. The effects of the pandemic are expected to accelerate the building of close partnerships between retailers and their suppliers in all segments of the clothing market, from mass to luxury products. Companies need to invest in building closer relationships with their suppliers throughout the value chain to gain greater insight and impact and to become more agile and resilient to such crises (Roberts-Islam, 2020). Establishing close relationships with suppliers does not have any impact on environmental sustainability issues. However, it certainly has positive social consequences; above all, the improvement of supplier companies' position vis-à-vis their influential customers, more excellent stability, employment security for employees, or job guarantees.

Such strategic partnerships with suppliers (e.g., in the form of alliances) will also be necessary due to the gradual implementation of the digital transformation, consisting, among others, in wider use of digitization and modern 4.0 technologies. Tools such as virtual fashion shows, digital showrooms or live streaming trade, until recently used by only a few leaders in the industry, are now entering a wider circulation and become a must-have for companies wishing to stay on the market (Amed et al., 2020a, p. 32). The implementation of modern 4.0 technologies, such as the latest 3D design tools or the Internet of Things (IoT), is also observed at an accelerated pace. These technologies allow - even in the event of similar disruptions in the future - precise and up-to-date information on the various stages of production and distribution. They can, therefore, be used to track the entire supply chain and obtain immediate product information. A positive social consequence of this is that the transparency of the company's activities - both in terms of the quantity and method of manufacture of clothing and its carbon footprint - has increased significantly. Once the pandemic is over, transparency has a chance to become a strategy for rebuilding weakened trust in brands and retailers (Fashion Transparency Index p.47).

One of the most frequently mentioned consequences of the current pandemic is also nearshoring (or reshoring) (Amed et al., 2020a, p.33), i.e., the transfer of production to neighboring countries, due to lower transport costs, easy logistics and cultural/linguistic proximity. Closing the borders with all the focus revealed all the disadvantages and risks of outsourcing and increased the demand for "on-site" products. As a consequence, new jobs will have a positive social impact, due to the creation of production centers in, e.g., Central and Eastern Europe or Central America. A negative impact will be the reduction or loss of many jobs in developing countries.

Distribution

The coronavirus pandemic has also demolished the industry's current calendar with two main seasons (summer and winter) and a continuous race in the number of collections being launched. The critical event for the industry, which is decisive for the purchase of models for the next season, the so-called fashion week, held in several cities, has long been criticized for the incomprehensible and absurd waste of resources (expensive shows, trips, events for thousands of people in many cities, etc.) (Amed et al., 2020b). However, the shows and fairs themselves are already being successfully replaced by virtual events. On the environmental impact side, there is a "plus" due to reduced waste of resources associated with the organization of fashion weeks, fairs, and exhibitions (including reduced CO2 emissions associated with reduced business travel). In contrast, on the social impact side, there is a "minus" due to the loss of some existing jobs (bankruptcies of companies servicing this type of event, reduced demand for temporary workers). The sharp drop in sales resulting from the closure of shops and requirements of social distancing also resulted in a significant reduction in the transport of goods, which has some impact on the reduction of CO2 emissions.

An exciting direction of transforming the industry, which may gain momentum as a result of the pandemic, is the development of the 'clothing as a service' business model (A new textiles economy, 2017, p. 76). Such alternative business models are based on the resale or rental of clothing (rental subscription, short-term rental, sale of highly durable clothes, resale) and the provision of related cleaning, maintenance, repair services, etc. It is considered that the popularity of such business models may increase after the pandemic due to high levels of stock surpluses throughout the value chain. The increase in popularity of the "clothing as a service" business model would have a positive impact on the environment, reducing the need for new products and thus saving non-renewable resources. Secondly, it allows extending the life of clothes (time of their use) significantly, which is only 15 years worldwide has shortened on average by 36% (Ibid., p. 77), mainly due to the so-called fast fashion. Thus, the "clothing as a service" model becomes a kind of counterbalance to the cheap purchase of large quantities of clothes.

Retailing

The forced closure of stationery stores and the transfer of trade to the chain was the most visible and striking consequence of the coronavirus pandemic. The most affected were companies operating exclusively off-line, i.e., those where sales are conducted through stationery stores, but all players dramatically felt the effects. Experts from the industry claim that off-line trade will probably not return to the dynamics it had before the crisis for many years. It seems that the times of fast fashion (buy a lot and buy cheaply) are gone forever. From sustainable development, this is excellent news - the pandemic has become an impulse that rapidly changes the philosophy and functioning of the whole industry, making it more socially responsible. The closure of hundreds of thousands of stationery stores means, above all, saving resources: electricity, water, fuel, etc. In social terms, however, this means lost jobs and livelihoods for millions of people.

The consequence of closing the shops was the transfer of sales (like many other areas of life - communication, entertainment, etc.) to the Internet. The digitalization of sales is becoming a must-have for the entire fashion industry. It will perhaps consistently reverse the proportions between off-line and online sales, although until now, it was online sales that supported and added to fixed-line sales (Amed et al., 2020a).

Companies that have quickly improved their digital capabilities by introducing innovative ways of advising customers, presenting, and advertising goods (e.g. using social media, telephone applications, engaging influencers, etc.) are likely to do well and have a chance to maintain sales. The pandemic has accelerated well-established shopping habits; In Europe, 13 percent of consumers started visiting e-shops for the first time (April 2020), and in Italy, alone e-commerce transactions have increased by 81 percent since the end of February (Sneader and Singhal, 2020, p.3). Moving trade to the network will have positive environmental effects (related to saving resources) and, again,

several negative social consequences. These will be mainly bankruptcies of companies that do not have sufficient resources or competences to digitize their services, followed by the loss of many jobs and rising unemployment. The only positive social impact will be an increase in the digital skills of the part of the society that has so far been digitally excluded.

Consumer Practices

One of the most frequently mentioned effects of the pandemic is the observed increase in consumers' environmental awareness. Karl-Hendrik Magnus, one of McKinsey's partners and a clothing industry expert, believes that "consumers have seen how vulnerable the whole world is, and the whole crisis has raised awareness of social and environmental sustainability, even among those who have not been in the subject before" (Roberts-Islam, 2020). For this reason, he believes that a return to pre-crisis consumer behavior is unlikely. Before the crisis, there was a gradual change in preferences for goods marked as sustainable, and it can be assumed that the pandemic has significantly accelerated these changes. McKinsey's survey of 6,000 consumers in the UK, Germany, France, and Spain shows that an additional 16% will look for sustainable credentials once the stores are reopened. 20% of consumers intend to reduce their overall spending by the end of the year, and 45% will look positively on companies that communicate with care and purpose rather than prices and products. Younger consumers, in particular, are seriously concerned about social and environmental issues. These groups increasingly support their beliefs about shopping habits, favoring brands aligned with their values (Baum et al., 2020, p. 45).

Experts also claim that the pandemic crisis has drawn people's attention to other aspects of the clothing industry, such as social sustainability. These changes in awareness are followed by two crucial consumer practices, which are of great importance for the development of the fashion industry. The first is a higher demand for sustainable clothing, and the second is conscious self-restraint and more thoughtful shopping. The growing interest in eco-friendly clothing is probably the most critical impulse to revolutionize the fashion industry. It means many positive consequences on the environmental side: more significant use of recycled materials, organic farming (e.g., organic cotton), and less environmental devastation. It also has several positive consequences on the social side - the creation of new jobs associated with a higher demand for clothes lending and resale services, and the likely greater involvement of clothing companies in socially responsible activities, such as supporting local communities.

Self-limitation in clothing purchases seems to be the second essential consumer practice that can have a significant impact on the fashion industry. First, consumers are withdrawing from discretionary expenditure, which includes clothing. Secondly, many of them declare that they restrict future fashion purchases precisely because of social responsibility (anti-consumerism) (Amed et al., 2020a). After all, giving up the purchase of a product is the most sustainable thing any consumer can do, because buying a few additional products produced sustainably is still a waste of resources. The consequences of this practice on the part of the environment should be assessed unequivocally positively. One can mention the slowing down of the brutal fast fashion (which is associated with the reduction of resource consumption, environmental pollution, and waste reduction), as well as the reduction of resource consumption (including non-renewable ones) as a result of smaller production.

A summary of the impact of the pandemic on the fashion industry and its consequences (positive and negative) for sustainable development is presented in Table 1, but this is not an exhaustive list.

Table 1: Impact of the pandemic on the fashion industry and its consequences (P - positive and N - negative) for sustainable development

Supply chain	Industry implications of the COVID-19 pandemic	Impact on environmental aspects	Impact on social aspects
Sourcing of raw materials	**Restriction of textile production - cancellation of orders**	P – reducing environmental devastation	N – loss of jobs and livelihoods of millions of employees, increase in poverty
	Non-payment to producers for ordered and manufactured materials	no influence	N – job losses N – loss of confidence and difficulties in rebuilding future cooperation
	Increasing the use of recycled materials	P - reducing the use of non-renewable resources and reducing environmental devastation	P – new jobs in recycling companies P – innovations in fiber recovery and processing technology N – loss of some existing jobs
	Accelerating innovation in textile production	P – development of regenerative agriculture P – innovative use of waste for fiber production P – the use of renewable raw materials for the production of plastic-based fibers	P – development of new knowledge, innovations
	Reducing production volume	P – reducing the use of resources and raw-materials P – limiting the amount of production waste	N - loss of jobs and livelihoods of millions of employees, increase in poverty
	Strengthening partnerships with suppliers (e.g. strategic alliances)	No influence	P – greater stability, employment security, job guarantees
	Innovations increasing production efficiency -	P - reducing the use of resources and raw-materials	P – greater transparency (e.g., blockchain)

Production	**implementing technology 4.0 (4D, IoT)**	P – reducing resource waste P – reducing the amount of production waste (e.g., felling)	P – international virtual teams P – new jobs in technology companies that support fashion N – loss of some existing jobs
	Reshoring or nearshoring	P – smaller adverse effects of production on the environment	P – new jobs in Europe and America N – loss of some jobs in the Far East
Distribution	**Change of the fashion calendar - limitation of seasonality**	P – reducing resource waste P – reduction of business travel - lower CO2 emissions	N – loss of some jobs N – the bankruptcy of companies servicing fashion shows, fairs etc. P – new jobs in IT firms
	Restriction of transport of goods	P – lower CO2 emissions	N – loss of some jobs
	Accelerating the development of the "clothing as a service" model	P - reducing the use of non-renewable resources P - reducing environmental devastation	P – new jobs in companies based on new business models
	Virtual markets, fashion shows	P – lower CO2 emissions P – reducing the use of the resources P – less pollution	N – loss of some jobs P – new jobs in IT companies serving the industry
	Closure of stationery stores (decrease in sales)	P – reducing the use of non-renewable resources P – less pollution	N – loss of some jobs (sellers) N – lowering employees' salaries N – the bankruptcy of stationery retailers
	Transfer of sales to the network	P – reducing resource waste	N – the bankruptcy of stationery retailers

Retailing			N – exclusion of some customers (without internet access) P – acquisition of digital skills by new consumer groups
Consumer practices	**Increase in demand for sustainable clothing**	P – more extensive use of recycled materials for production P – wider use of organic and innovative materials P – reducing the use of non-renewable resources	P – new jobs (new business models) P – more socially responsible initiatives
	Consciously restricting purchases	P – slowing down "fast fashion" (reducing resource consumption, environmental pollution, reducing waste)	N – limiting production, which means job losses, increased poverty, etc.

Source: own work

The outbreak of the pandemic caused significant changes in the entire textile and clothing supply chain. All the consequences identified will have a greater or lesser impact on the sustainability of its businesses. These consequences concern both environmental and social aspects. They are positive, i.e., they are factors facilitating the implementation of sustainable development principles, or negative, i.e., they are barriers hindering adaptation to these principles. Attention is drawn to the relative balance of environmental and social factors and the fact that these factors are often repeated. It means that most of the environmental consequences can be reduced to a reduction in the use of non-renewable resources, less waste of resources, and environmental devastation. In contrast, most of the social factors are related to job losses, increasing the risk of poverty and hunger for many regions in developing countries. Characteristically, changes in the fashion industry's functioning have resulted in a positive impact on environmental factors, but definitely negative on social factors.

Summary

The outbreak of the coronavirus pandemic suddenly stopped the textile and clothing industry's development and questioned the business model. In the opinion of many experts, this is an excellent opportunity to rethink the industry's rules, which is considered to be exceptionally socially irresponsible and criticized for a massive waste of resources. The article analyses the issues of how the epidemic crisis affects the change in the functioning of the clothing industry and whether these changes will have a positive or negative impact on sustainable development. The last subchapter presents the consequences of the crisis, which concern both environmental and social aspects. Simultaneously, some of them are positive, i.e., they constitute factors facilitating the implementation of sustainable development principles, and some are negative, i.e., they constitute barriers impeding the adaptation to these principles of sustainable development. There is a relative balance of environmental and social factors.

Moreover, most of the environmental consequences are related to the reduction of the use of non-renewable resources and the devastation of the environment. At the same time, social factors mainly concern job losses and the consequences in terms of poverty and hunger risk for many regions in developing countries. What seems interesting is that the changes in the functioning of the fashion industry have had an unambiguously positive impact on environmental factors, but definitely negative on social factors. It leads to the conclusion that it is necessary to rethink very thoroughly how to rebuild the industry in order to counterbalance the negative social consequences and, at the same time, take advantage of the opportunities that arise to strengthen the positive environmental effects.

Abstract

Living to the age of 120 is not enough, people want a quality and satisfied life, not a vegetative state. Artificial Intelligence in medicine provides a potential for a healthy life. It brings about new approaches to monitoring a patient's state, robotic surgery, decreases difficulty of operations and improves considerably diagnostic possibilities. Artificial Intelligence is an important vehicle for solving ethical problems in treatment and the entire health system. This saves up time for a physician to talk to the patient and mutual trust is re-established, which is the essential of medical ethics. This article focuses on a search for attributes of technical aspects in medical science. Its objective is to identify elements of holistic medicine that can be employed for transfer of information in a human body. The research presents an important conclusion, which is linked with the fact that current technical aspects of medical sciences are narrowly specialized and the key in such segment specializations is not the ethical medical aspect of the problem, but the technical one. It can be presumed that Artificial Intelligence will enhance holistic and personalized medicine. Personalized medicine analyses a person as a unique individuality. Holistic medicine considers a person as one complete set, a holistic system of interlinked organs, links and relations, it does not separate the technical aspect from the ethical aspect. Artificial Intelligence can become an immensely important platform providing data to be implemented by holistic medicine that is seen as the key treatment of the future.

Keywords: Artificial Intelligence, robotic surgery, personalized medicine, holistic medicine, neuroplastic mapping

Introduction

Artificial Intelligence helps to cope with new technologies and new approaches to diagnostics on the technical level. It will not replace physicians since only humans are able of independent thinking, at least so far. It enhances new approaches to the ethical dimension of the physician – patient relationship and it can decrease direct as well as indirect costs. This approach is tied more with the multibranch view as it contains, beside the medical view, also ethical and economic aspects. It is not a partial view, but a comprehensive perspective is required.

Artificial Intelligence is something that people cannot imagine quite precisely what it is. While most people have heard of it, only few have actually encountered it. Artificial Intelligence is nothing but an algorithm, a set of procedures and tools, another version of smart software (Ranschaer, 2019) that can process great amount of data in an extremely short time. Artificial Intelligence in relation to medicine has several lines such as the technical level, ethical level and method of information transfer in a human body etc. All of these levels need to be first researched before any conclusions can be made in line with the aim of this article (Pernica, 2017).

Theoretical basis

Technical line of Artificial Intelligence in medicine

The technical part has three basic lines. First, it is a set of algorithms that map certain body functions such as heart rate monitoring, monitoring of neural systems, monitoring of biochemical function processes and others. It is further modelled, connected in various ways with possibilities of alternative scenarios and results in a form of body functioning. The second line concerns robotic surgery when Artificial Intelligence enables to reduce radically blood consumption, the size of intervention in the body, decrease post-operation complications, increase efficiency of surgeries and often even eliminate them and apply a less invasive procedure instead. A robot is mostly controlled by a human, but its memory enneagrams (Mitchell, 2019) contain all known interventions, procedures and detailed operations that have been implemented at medical facilities in the past 6-8 years. The third line of use of Artificial Intelligence is its employment in diagnostics. Artificial Intelligence, thanks to its speed of data processing, (Mařík, 2019) is able to consider thousands of pieces of input information about the state of the human body and find in them the most probable type of disease. From the perspective of diagnostics, this has occurred in the past 3 years.

Ethical-spiritual line of Artificial Intelligence

Information protection. Artificial Intelligence can protect GDPR and all other standards, data security and protection systems better than humans do. The ability to work with such information. It will create information background that will strengthen a physician's role. Artificial Intelligence should guarantee amazing speed or processing voluminous quantities of information. The human brain chooses the main article strategy and then proceeds accordingly, whereas Artificial Intelligence has a reservoir of solutions and we can choose from these outputs. (Fieschi, 2013) Artificial Intelligence is best at processing this amount of information, searches it to find key information and links relating to its processing (Wilks, 2019). It is an ethical dimension of a physician. But a physician remains the key.

Artificial Intelligence processes a patient's diagnostics, but it cannot tell what disease it is, what are the prospects of healing and consequences. Telling patients whether they are terminally ill or whether they will suffer lifelong consequences depends only on a physician's empathy and approach. The Hippocratic Oath includes an ethical dimension. What does this dimension actually mean? The crucial dimension of ethical in medicine is to do no harm to patients. There are still many diseases that do not need to be treated, the effort should only be to mitigate it. But it is often omitted that patients should be done no harm. How can this be achieved in the modern overmechanized times we are living in when everyone is extremely busy and do not have time for anything? By giving patients the time. The second crucial moment in medical ethics is the patient – physician relationship. What relationship can actually establish when a patient answers a physician 3-4 questions? This could be the solution to the problem: giving medical staff in the health care sector where everything is limited and physicians are rather clerks who spend 3 minutes out of the 4 they have typing on their computer.

To give physicians time for their patients, we first need to take off them the burden of having to do various analyses. (Strachotová, 2012) The situation with biochemical procedures, neural systems, internal procedures. All of this can be done by modern medicine, processing data with the help of Artificial Intelligence. Thanks to AI, we can have results in a very short time and they include all crucial functions: it is a great facilitation for physicians and give them more time to address the patient. At present, medical science is advanced to a degree comparable to engineers calculating fortified constructions using a slide rule. In fact, engineers do not even use calculators, they even skipped calculations on computers, but the

are now assisted by the computer in the design of constructions. By contrast, a physician still writes request forms for different types of examinations and then waits long for the results. Furthermore, they try to find any connections between input results and they typically go for the first or the second solution that comes to their mind as the most frequent one. Patients spend their days like messengers, doing errands with their request forms, they carry around printed outputs or data carriers, suffer mentally and fear what their diagnosis may eventually be. This results in a patient being more mentally disturbed than it would be necessary. Physicians have hard time to find another 15 minutes to fix a date with their patients. In a fortnight? In a month? And the process will be no different as results from one examination will be bad, the second ones will get lost as the patient carries them around and third examination will have to be redone. By contrast, Artificial Intelligence can process all of this in several seconds, find similar symptomatic solutions in its database and suggest the physician to take a look from the perspective of holistic medicine. Although it may sound as a cliché, it is essential even for banal illnesses these days.

Holistic Medicine

Holistic medicine could benefit from Artificial Intelligence. Nowadays, the ethical and technical aspect of medicine lies in the fact that medical science, similarly to other scientific and technical branches, is narrowly specialized. Medical specializations are very narrow. With such segment specialization, it is the technical aspect of the problem that has become crucial, while the ethical-medical aspect was sidelined. Holistic approach has completely vanished. As a result, processes of different interventions keep improving together with the technique and display of the processes, but the ethical dimension of the physician – patient relationship is neglected and the holistic perspective is completely omitted. It is complicated to operate and resuscitate a patient after a brain stroke. Even when a patient is technically "safe and sound", they lost the ability to speak, walk and they will always be restricted to help from others. However, this is usually unimportant from the medical point of view.

Speaking of holistic medicine, it is necessary to consider two lines: firstly, a human is considered as a set of complex problems that cannot be separated. In technical and ethical terms, we need to see a person as a unity, we cannot deal with technical and ethical aspects separately. Artificial intelligence will help, will give us a holistic picture, but the ethical part is up to physicians. Half of success of any treatment lies in the trust between the physician and the patient. Artificial intelligence can provide physicians with information and with technical preconditions of treatment. It may suggest alternative methods of dealing with a given condition (Agah, 2013). It can process further data from other specialists in the place of a specialized physician and advise of risks linked with the selected solution that might not have been foreseen and check for any contraindications of the chosen treatment. Artificial intelligence is aware of no ethics, it has no empathy, it cannot communicate any conclusions or opt for a treatment, this role remains up to physicians. The communication between the physician and patient is crucial and Artificial Intelligence cannot substitute it. Artificial Intelligence provides information and implementation background and enhances the need for the ethical relationship between the physician and the patient. At present, 90% of Artificial Intelligence deals only with technical aspects, i.e. it is employed in robotic surgery, new materials, new diagnostic techniques, now methods of screening, but it does not address the supportive care in relation to patients.

Thanks to concentration of the maximum amount of information, Artificial Intelligence can suggest several methods (Topol, 2019) of treating a condition. It can calculate all possible scenarios (Klečka, 2014), find symptoms and history of previously implemented approaches. It knows their consequences and results. It can usually analyse them better than people. But should the main criterion for the decision to be taken be the cost-effectiveness or possibilities of technical solution? Or should the ethical dimension be the key? Ethical dimension means minimizing a patient's suffering, reducing their stay in a hospital and the treatment time. When patients cannot be cured, it is impossible to do harm to them.

Artificial Intelligence is used for treatment of common conditions (gall bladder, appendix) as well as new ones. They can be classified in subgroups (oncological diseases, degenerative nerve diseases, rare diseases). An example of a new disease is progeria – rapid aging. It is linked with an ethical as well as economic problem. Medical science usually does not carry out specific research of such diseases as it is extremely expensive and inefficient with respect to the number of treated patients. Who would invest billions in the development of a treatment for a small number of patients? Artificial Intelligence can help deal with this in the future. Artificial Intelligence will make diagnostic aspects of such diseases faster, cheaper and more effective. Causes of two new types of diseases are starting to occur. Diseases that have been unknown before and are linked with the climate change on the planet. The second cause is chemization of food, the environment and everything around us. In the Czech Republic, there are approximately 8 diseases that have fewer than 100 patients. These patients are only kept in a state of vegetative survival, which absolutely abstracts away from the ethical way of life.

Transfer of Information in The Human Body, Neuroplastic Mapping

Despite immense progress, we still know very little about the human body. When physicians following principles of Chinese medicine insert correctly an acupuncture needle and the kidneys start working better as if by miracle, is it a result of their perfect knowledge? How a signal was transmitted when there is neither connection through nervous system nor biochemical? (Beneš, 2016). There seems to be a strange kind of energy which we know very little about that was transmitted from the puncture mark to the kidneys. The Chinese physician does not now anything more either as they learn about different marks on the body from their predecessors. And since this "treatment" has been used for several thousands of years, patients often confide more in this alternative, because it really relieves them from common diseases. However, nobody explains to such patients that the treatment just followed the principle "Because of your faith you will be healed" (Dolista, 2017) that is often the case in treatment with homeopathic preparations. Chinese physicians know the technical method of such treatments, but they do not know the reason why they work.

Information is the basic unit of a body. Information is transmitted within the body as well as beyond. There is an effort to map such information flows, read them and process them. Information is transmitted through the nervous system that has several dimensions: electric, neuronic, stimulating, vibrating, harmonizing. And then there is the last dimension: immaterial. But in fact, it is not immaterial. It is only a system that is not known yet. It cannot be tracked identified, measured, monitored or controlled. From the ethical perspective, this system tells us that we still know very little about the functioning of the human body. That means that from the technical perspective there is an urgent need for the development of sensorics, scanning, interconnectedness of functions. Complementing the holistic picture, which we can get thanks to Artificial Intelligence by processing big data and big analytics. A human picture is a combination of material and immaterial processes. Which ones are immaterial? Thoughts and consciousness. Nobody has ever seen them, although there is an effort to map them via electric signals. Still it cannot be said that there is nothing like consciousness in our brain because we all subconsciously feel that something like that exists. Neuroplastic mapping forms the hardware of our consciousness. But what is actually consciousness? What kind of energy is it, what kind of transfer? We need to search for the answers to the questions. Do we know the human body? We do not. Can Artificial Intelligence help us map interconnectedness in the human body? (Ryneš, 2019) Yes, it is, thanks to the ability to process huge volumes of information. Artificial Intelligence can change the structure of time that a physician spends on a patient (analogically to marketing, change from 4Ps to 4Cs) (Kisslingerová. 2011). Artificial Intelligence saves time that physicians can dedicate to patients and enhance the ethical dimension of the physician – patient relationship, establishing trust and increasing the probability of successful treatment and thus increasing the prestige of medical occupation.

Presuming that the human body is a unity of material and immaterial systems, Artificial Intelligence can help identify, map and connect everything and save time that physicians can dedicate to their patients. In return, patients will have more trust in them and will naturally tell them more input data needed for the diagnostics of a given condition. At the same time, this approach will improve one more thing: while diagnostic methods in relatively young patients can be often remedied in time, in patients older than 60 or 70, a mistake can have fatal lifelong consequences. This is also the ethical dimension.

Economic Dimension of Artificial Intelligence

Humanity is facing global problems, which are probably associated with negative human activity and which undoubtedly cause damage to health due to the polluted environment (Rozenský et al. 2019). Health care costs keep growing. While it is to the joy of pharmaceutical companies, physicians often work extremely long hours and their job requirements are huge: their mistakes can damage patients' health fatally. It should be avoided that physicians prescribe statistically defined medicine that has no effect on solving a patient's problems whatsoever. This is non-ethical on the part of the physician, it yields no results, it is only a waste of resources. The economy is concerned directly (i.e. physicians' salaries, costs of medicine, operating costs of medical facilities) as well as indirectly when patients, instead of generating GDP, use up resources, often unnecessarily and with no use. (Monte, 2019) If holistic medicine is applied with the help of Artificial Intelligence, the total treatment time will reduce by up to 40%, treatment costs will decrease and patients will recover soon in all respects. Artificial Intelligence can make operations more considerate shortening in consequence the time of hospitalization, in some cases it might no longer be needed at all. Artificial Intelligence can also help with a personalized medical procedure as it will check all medicine used by a patient together with their contraindications. Personalized medicine, tailor made to a given patient, can also be useful in future. Estimates of decreasing the medicine consumption are about 50 – 60% of current values. This economic dimension will subsequently have positive impact on the ethical dimension as these measures will substantially improve patients' quality of life.

Discussion and Conclusion

Artificial Intelligence in medicine can process patient's symptoms faster than it would take a physician to sit down at the computer. Artificial Intelligence can save time and physicians can spend this time on establishing trust with the patient. The time needed for dealing with patients' problems will be reduced. This will create time for a discussion with patients and it will subsequently re-establish trust, which is essential of medical ethics and a basic predisposition of successful treatment.

Artificial Intelligence is an immensely important auxiliary tool for dealing with ethical problems in treatment and the entire health system. AI will enhance holistic and personalized medicine. Personalized medicine analyses a person as a unique individuality with no such other in the world. It will not be replacement of the physician as such, since only humans (out of all the fauna and flora on the planet) can think independently. In the first place, Artificial Intelligence lacks empathy. Holistic medicine considers a person as one complete set, a holistic system of interlinked organs, links and relations, it does not separate technical aspect from the ethical. Artificial Intelligence can become an immensely important platform providing data to be implemented by holistic medicine seen as the key treatment of the future.

Artificial Intelligence helps to cope with new technologies and new approaches to diagnostics on the technical level, new approaches to the ethical physician – patient relationship and it can decrease direct as well as indirect costs. This approach is tied with the multi-subject view as it contains, beside the medical view, also technical, ethical and economic aspects. It is not a partial view, but a comprehensive perspective is necessary.

Abstract

Bread, just as other bakery products in general, has always been an important part of a modern human's food selection. However, the bread market has been through radical changes over the past centuries. Such changes are even more rapid and dynamic in our modern times. If companies want to succeed on the market, they need to understand the changes. Therefore, in order to understand the changes on this highly competitive market it is necessary to understand the trends in bakery operation economy, competitive environment, technological procedures, but most importantly: understand the consumer. This research was partially prompted by the fact that food production keeps growing, but the trends in bakery products do not correspond with such a growth. Its authors compare markets of two neighbouring countries, Germany and the Czech Republic. The objective was to describe changes and trends on both markets, identify similarities and/or differences in historic development, but primarily in the present. The authors focused, above all, on analysis of the causes of the changes. This paper presents a wide range of statistical data and a comparison of the two markets.

Keywords: Bakery, Czech Market, German Market, Trends

Introduction

Bread has always been important part on the menu of modern man. During centuries however, bread market has undergone dramatic changes. In our modern era, these changes are very fast and dynamic and bread market increased into billion business sectors in many countries. Despite these dynamic changes, we don't expect bread market to suddenly retreat, but if man wants to be successful on the market, he must understand these fast changes. To understand changes on this competitive market, man must understand trends in the economy, competitors, technological processes, but the most important thing without which he has no chance to survive is to understand consumer. First unconfirmed evidence of bread history we can find about 30000 years ago. According to Lohman (2012) other more proven dates to around 23000 years ago to the Upper Palaeolithic period. Form, type and quality was much more different as we know it nowadays. In nowadays Czech Republic territory, the oldest bread oven was found in village Bylany near Olomouc and its origin dates from around 4 800 to 4 600 BC (Hnutí, 2016).

In Germany evolved diversity of products, depending on region and different grain cultivation. The main two factors are pedological and climatic conditions and others could be different cultural development of each state (Deutsches Brotnstitut, 2011). In 13th century in Germany newly created cities established their independence and in accordance with customs and style a pronounced location-specific character (Brotexpert, 2017). Therefore, it could happen that bread forms changed from city to city and from landscape to landscape or had local idiosyncrasies. This boost of bakeries increased competition of an increasingly competitive

market which forced them more into inventions to stay efficient in order to secure sales. This initially led to local, later also to regional specialties (such as the Nuremberg gingerbread).

In nowadays Czech Republic regions, the growth of medieval towns and associated division of labour gradually pushed household productions. First bakeries were usually established in monasteries and under rich lords. In the 13th and 14th centuries, there were quite a lot of bakers. The bakers (same as in the rest of the world) were becoming wealthier and wealthier. Historical sources show, that in 1387 there were 159 bakers for Prague and of course most important from all baking products was bread (Hnutí, 2016). He played an irreplaceable role in the coronation of the Czech kings, when he was given priority over gold. In the first Czechoslovak republic - in 1930 – evidence show 13341 registered bakeries in which around 43000 people worked. In the 1950s, small businesses (in 1947 approx. 10000 bakeries with 45000 employees) were closed in the process of nationalization in connection with a change of the political regime after communist putsch in 1948 (Strachotová et al., 2018). After 1989, the privatization or restitution of all production capacities was gradually carried out, the renaissance of the craft bakeries and new technological trends. With the development of the market, the range of assortment is rising, manufacturers are grouped into production and sales groups to better withstand the pressures of concentrated business networks like supermarkets (Hnutí, 2016). German market was practically free if we count former Federal republic of Germany and these consequences in differences between these two markets we can see till nowadays.

Methodology

To describe the basic regularities we use descriptive statistics, it simply describes what is happening inside our sample or of what it consists of. It reduces big data into summaries, which serves us to simplify them and allows us to make observations and important comparisons inside unit. For forecasting of future trends are often used time series. Their main principle is to analyse data and predict how they will act in the future. As Litschmannova (2010) says, in prediction is sometimes very important elimination of random phenomenon on monitored indicator and to make time series smoother. For this are often used rolling means or medians.

Analysis of trend in time series is very important. As Hindls (2007) suggests, very popular method for trend estimation is least square method, which can be used if parameters are linear and we can estimate by this method linear and parabolic trend functions. For our estimation is this method sufficient. Now we will take a closer look on linear trend to indicate the procedure, which can be similarly applied with usage of literature on parabolic trend functions or common practise is usage of statistical software like SPSS or powerful Excel. At beginning of estimation, it is necessary to express trend, in our case now it is represented by general linear formula 1:

$$T_t{}' = \beta_0 + \beta_1 t \tag{1}$$

β_0 with β_1 symbolises unknown parameters and in accordance to linear regression we will come to system of two equations with two unknowns:

$$b_0 = \bar{y} - b_1 \bar{\bar{t}} \tag{2}$$

$$b_1 = \frac{\overline{yt} - \bar{y} * \bar{t}}{\overline{t^2} - \bar{t}^2} \tag{3}$$

Solving this we will acquire linear trend, but it is more appropriate to provide interval. For linear trend is interval prediction, where P>n defined as:

$$T_P - t_{1-\frac{\alpha}{2}}[n-2] * s * h_P < T_P < T_P + t_{1-\frac{\alpha}{2}}[n-2] * s * h_P \tag{4}$$

$t_{1-\frac{\alpha}{2}}$ is quantile of Student t distribution with n-2 degrees of freedom. Parameters s and h_P are defined as:

$$s = \sqrt{\frac{\sum_{t=1}^{n} y_t^2 - \sum_{t=1}^{n} T_t^2}{n-2}} \quad (5)$$

$$h_p = \sqrt{1 + \frac{1}{n} + \frac{(P-\bar{t})^2}{\sum t^2 - n * \bar{t}^2}} \quad (6)$$

Decision on which method to choose should be based on appropriate analysis of economic phenomenon, e.g. it is important to consider, if trend is growing, if function has inflex point, if method is designed for specific purposes (logistic trend was hugely used in estimations of biologic populations) or analysis of graph can be used, but this approach should be done very carefully, as is this method considered as subjective (Hindls, 2007). For realisation of this work were except of "harder" methods (e.g. statistical) used other relevant methods like descriptive, which is based on organised and description of processes, deductive method was used. We were trying to create conclusion from various information and general findings (for example from macroeconomic perspective in baking industry) or inductive method to form generalised answer.

Analysis of Czech Bread Market

Bakery market in Czech Republic is despite his communist history very competitive and most of the bakeries are funded through domestic capital (Dyntar, Strachotová, 2017). Foreign investments slowly decline or could be considered stable if we don't count companies returning from tax havens. Market is quite fragmented and doesn't have strong leader. According to Bisnode (2017) as leaders, we can mark company Penam and United bakeries. Strong leader in frozen semi-products is company La Lorraine. Other reason, why market doesn't have strong leader could be that profitability is lower as it is in other western countries. In recent years demand of customers for fresh products increased trend of semi-finished frozen products.

Transnational supermarket chains ruthlessly force bakers to concessions. Offer in bakery assortment is very rich and growth is noticed as well in regional specialties and bio products. Dřízal (2013) say, big problem on the market is very low prices on the market of EU. In 2015, according to (Hnutí, 2015) were margins of supermarkets 7x higher than margin of bakeries, see small margins of bakers (see fig. 1).

Fig. 1: Margin of bakeries on Czech market (Source: Self-plotted graph, data from Hnutí, 2015)

When we compare basic offer, which doesn't include regional specialities, we can say, that Czech market offers comparable offer of bread products to German for significantly lower price and price relations for baking products are therefore quite deformed. One of the reasons can be still very low purchasing power of Czech people. In the end of November 2017 was purchasing power of average German 2,65 times higher (22 239 euro to 8394 euro) than average Czech (Lichtner, 2017).

History indicates that volume of consumed baking products is slowly decreasing. According to the data of the Czech Statistical Office, in the year 1950 nearly 90 kilograms of bread per year were consumed per inhabitant in the year. By 2014 this volume fell by more than half (to 40 kg). On the other hand, previously, 27 kilograms of wheat bread products was consumed per capita, in 2014 it was more than 50 kilograms (Fryšarová, 2017) (see fig. 2). This group also includes pastries, such as baguettes, croissants, toast bread, but the croissant dominates it.

Fig. 2: Consumption development of baking products on Czech market (Self-plotted graph, data from Kozelský, Novák, 2018)

Current prices on the Czech market are relatively stabilised, strong turbulence in prices were around year 2008, bakeries then experienced shocks. As we see fig. 3, prices for baking products are approximately 1,9 times higher than price of bread. Exchange rate 1 EUR = 25,75 CZK. On one hand this can be advantage if bakeries use this price difference (Kutnohorská, Strachotová, 2019), but they must find the way how to persuade consumers to avoid supermarkets.

Fig. 3: Price development of baking products on Czech market (Self-plotted graph, data from Kozelský, Novák, 2018)

According to NMS market research from 2012, Czech consumers prefer preferences displayed in fig. 4 (HN, 2012). Research also mentioned that most of Czech consumers are buying in a bakery or shop with large assortment offer and significant amount of people don't mind buying semi-finished frozen products, even more, they appreciate freshness of baked frozen products in shops or bakeries.

Fig. 4: Czech preferences when choosing bread according to NMS 2012 (Self-plotted graph, data from Dřízal, 2017)

Another research from 2012 conducted by GFK brings very surprising findings. Only 27% percent of spending on baking products bought by Czech people is bread, the rest consists of bread rolls or sweet bakery products (see fig. 5).

Fig. 5: Spending on baking products by Czech consumers, GFK 2012 (Self-plotted graph, data from Šebková, Bodorová, 2012)

More than half of Czech buying baking products daily (see ig. 6) and most people spend their money in supermarkets (see fig. 7).

Fig. 6: Frequency of Czech buying baking products, GFK 2012. (Self-plotted graph, data from Šebková, Bodorová, 2012)

Fig. 7: Where Czech prefer to buy baking products, GFK 2012. (Self-plotted graph, data from Šebková and Bodorová, 2012)

Other interested finding was that almost two thirds of Czech population see bread as importance for menu. More than 85% of them buy fresh unpacked products. Around 14,3% of households declare that they bake bread at least once per month (Šebková and Bodorová, 2012). On the market, we can currently count around 700 hundred bakeries, recent years supermarket chains confirmed their position in baking their own produced baking goods or baking semi-finished frozen products. Bakeries are trying in this hard situation to change their competitive strategies, so they are trying to be closer to customer with quality fresh goods.

Approximately 24,5% of expenditures are on bread, rest is other pastries and sweet baking products. This verifies trend of continual decrease in consumption of bread products and newer study indicates as well increase of shopping inside small and specialised food stores, compared to 38% in 2012 it was around 44% in 2016 (Dřízal, 2017). Important finding unveiled KPMG market research. Conducted survey in 2016 proved that price is not the most important factor influencing consumer buying behaviours. Important factors we can see in fig. 8.

Fig. 8: KPMG Czech preferences when choosing bread in 2016 (Self-plotted graph, data from from Dřízal, 2017)

Revenues of baking companies on czech bread market are finally becoming stabilised and returns to pre-crisis period. Following fig. 9 shows us, how turbulent was market between years 2008-2016. Exchange rate for 1 EUR = 25,75 CZK.

Number of bakers has decreasing trend. For example, in 2008 sector employed approximately 34,5 thousand bakers, while in 2016 it was only around 30. One of the reasons could be highly demanded strenuousness from bakers, while average salaries are deeply under mean or modus of population. In 2016, the average salary of baker was around 637 EUR, while the average salary in the economy was at the level of 993 EUR, so salaries are approximately 64 % of average (Kozelský, Novák, 2018). This situation will probably exert pressure on growing salaries and subsequently on growing prices of bread products.

Fig. 9: Revenues of baking companies on Czech market in billion euros. (Self-plotted graph, data from Kozelský, Novák, 2018)

Analysis of German Bread Market

German bread market is one of the most developed markets in Europe. Slight difference from Czech market is, that baking products like bread rolls are as well very popular, a little bit different from standard czech roll, but slightly on decrease. German consumer spends approximately 10 % of his salary on food (for Czech consumer it was approximately 20%, but this problem could be caused by significantly higher salaries in Germany) (Brotexpert, 2017). Germans has higher purchasing power and prices for foods in supermarkets and mass stores are practically the same on both markets.

On German market there are 4 very strong retail groups: Edeka, Rewe, Schwarz (Lidl, Kaufland) and Aldi. These 4 players control approximately two thirds of food market. This pressure has impact as well for supply of frozen baking goods and one of the biggest player Aryzta reports bad results on this kind of market. Table 1 shows trend on the market of frozen semi-finished products. (Brotexpert, 2017). It is obvious, that as well as on the Czech market, there is a growing trend on German market.

Table 1: German market with semi-finished frozen baking products in thousand tonnes

Year	Production of baking products	Frozen baked goods	Import	Export	Pure export	Consume of bread products	Share of frozen products
2008	4,660.6	606.3	165.2	331.6	166.4	5,100.5	11.89%
2009	4,573.6	626.1	160.7	329.9	169.1	5,030.6	12.45%
2010	4,628.4	662.5	176.2	353.5	177.3	5,113.6	12.95%
2011	4,579.1	680.2	193.	370.2	177.2	5,082.2	13.38%
2012	4,947.9	685.2	200.7	389.7	189.	5,444.1	12.59%
2013	4,784.	715.4	224.2	420.4	196.2	5,303.2	13.49%
2014	4,827.5	749.1	217.3	423.6	206.4	5,370.3	13.95%
2015	4,922.7	791.8	258.1	461.8	203.7	5,510.8	14.37%
2016	4,943.4	828.5	262.7	497.2	234.5	5,537.5	14.96%

(Source: Data self-computed and self-customised from Statista, 2017)

To approximate share of frozen semi-finished baking products on the market, we have to find relevant data about all baking products on the market. We can see that on German baking market is pure export of baking products (which is not so significant and consists of) around 4%. Then we can approximate consume and from that equation we can calculate share of semi-finished frozen products on the market. Table 2 demonstrates how the calculation for finding trend works.

Table 2: Calculation of trend with frozen semi-finished products

Year	t	y_t	y_t*t	t^2	T_t	y_t^2	T_t^2
2008	1	0.11888	0.118878	1	0.119927	0.014132	0.014382
2009	2	0.12446	0.248916	4	0.123287	0.01549	0.0152
2010	3	0.12955	0.388649	9	0.126647	0.016783	0.016039
2011	4	0.13385	0.535385	16	0.130006	0.017915	0.016902
2012	5	0.12586	0.6293	25	0.133366	0.015841	0.017787

2013	6	0.13491	0.809449	36	0.136726	0.0182	0.018694
2014	7	0.1395	0.97647	49	0.140086	0.019459	0.019624
2015	8	0.14368	1.149412	64	0.143446	0.020643	0.020577
2016	9	0.14962	1.346615	81	0.146806	0.022387	0.021552
sum	45	1.2003	6.203075	285	1.200297	0.16085	0.160756
average	5	0.13337	0.689231	32	0.133366	0.017872	0.017862

(Source: Self-computed data using share of frozen products in Table 1)

According to (1) we will now demonstrate calculation of trend. From (2) and (3) we must calculate b_1 and b_0.

$$b_1 = \frac{0.689230607 - 0.133366303 * 5}{31.66666667 - 25} = 0.003359864$$

$$b_0 = 0.133366303 - 0.003359864 * 5 = 0.116566985$$

From these variables we can define trend function from (1) as:

$$T_t = 11{,}6567\% + 0{,}3360t\%$$

Data in 6th column are then estimated from our calculation and we can make prediction on next years. According to (5) and (6) we can calculate parameters s and h_P as following:

$$s = \sqrt{\frac{0.16085 - 0.160756}{9-2}} = 0.003657393$$

$$\mathrm{h}_{10} = \sqrt{1 + \frac{1}{9} + \frac{(10-5)^2}{285 - 9 * 25}} = 1.236033081$$

We decided to estimate trend for next 3 years, so similarly, we can calculate next parameter h_{11} = 1.3081 and h_{12} = 1.3884. According to (4) we can form interval and calculate standard error of estimation, we said that we will be trying to cover 95% of confidence interval, so from t-distribution $t_{0,975}[7]$ = 2,365; standard error will be:

$$\Delta_{10} = 2{,}365 * 0.003657393 * 1.236033081 = 1.0691\%$$

Interval with T_{10} = 15,0166 % will be then:

$$13.9474\% < 15{,}0166\ \% < 16.0857\%$$

And similar it will be with T_{10} and T_{11}:

$$14.2211\% < 15.3525\% < 16.4840\%$$
$$14.4876\% < 15.6885\% < 16.8895\%$$

For better vision, I plotted this trend into the Fig. 10. Dotted blue line represents computed trend, green line represents predicted values and red dashed lines represent 95% of confidence interval. As we can see, manual predictions can be time-consuming and more complex methods even more, so statistics programmes should solve this problem, but it is good for verification of theory.

Fig. 10: Estimation of trend with frozen semi-finished products (Source: Self-plotted graph, data from Table 1)

Current new trends on German market shows, that Spelt flour is becoming very favourite, it is kind of ancient wheat, but overall, ancient cereals to gluten free becomes very popular. With this trend is connected demand for natural products with less preservatives or additives (Stumpf, 2018). More trendy are usually younger people and there are some volatile trends on the market. People are also willing to pay if they get high quality and trendy is performance food – healthy food that increases performance of people (Wolf, 2017). Allgemeine Bäckerzeitung (2018) states that current problem that German bakers face is aversion of some customers to plastic packages. Lobbying on recyclable packages is also increased and production is trying to adjust to be ecologically friendly.

What is interesting on German market, that unlike Czech Republic where foreign investments are relatively stable, in Germany is increase of these investments in baking industry. For example, swiss company Valora took over Backwerk chains and fast food brands in Germany in 2017. As was mentioned before, retails such as Aldi, Edeka or Lidl has two thirds of food market share. In some weak areas this led to closing of single or weak bakeries. Fig. 11 represents decline of bakeries in Germany (Ebner, 2017). Prices per kg of bread and per kilogram of bread products are plotted in fig. 12.

Each year GFK making their panel research about bread consume in households. Favour for individual types you can see in fig. 13. Brown bread in the graph is originally called Mischbrot in German language and it is kind of mix between wheat and rye flour.

Fig. 11: Decline of bakeries in Germany (Source: Self-plotted graph, data from Statista, 2017)

Fig. 12: Prices per kilogram of bread and other baking products on German market (Source: Self-plotted graph, data from Statista, 2017)

Fig. 13: German most favourite breads in 2016 (Source: Self-plotted graph, data from Statista, 2017)

Despite the fact, that Germans are becoming more opened (accepting new products, vendors, etc.) consumers, significant number of Germans prefer to buy bread in specialised shops (bakeries). Even though this number is slowly decreasing, Germans are compared to Czechs more quality focused and less price sensitive, so bakeries maintain strong position, and this can be one of the reasons why foreign investments persist or are on increase. According GFK in 2017 (Statista, 2017), 58% of respondents prefer to buy bread from baker.

Fig. 14: German most favourite place to buy bread 2017 (Source: Self-plotted graph, data from Statista, 2017)

Conclusions and Discussion

As both countries had common history in several centuries, they had as well common habits. First bakeries were established in monasteries, in both territories worked regulations for bakers and bakers were respected people. German bread in some cities became very specific, especially favour for black bread was very rare, which was different than in Czech Republic or other European countries that time.

Current Czech bread market has growing trend in frozen semi-finished products, what proves good profit of the biggest company La Lorraine. Market is quite fragmented, what can be caused by low margins in the industry. One of the reasons is small purchasing power of Czechs. Consumption in baking products don't differ differently from past, but bread is on retreat, while other baking products are on the rise. Period after crisis in 2008 was very hard, but current numbers show stabilised number of bakeries. Slow trend is moving from price first to other important factors like quality.

German bread market has not significant growth in frozen semi-finished products, what is visible in losses of big company Aryzta specialised in this segment. Despite Czech market, slightly decrease noticing other baking products, while bread has much stronger position. Current new trend on the German market is return to ancient cereals (DINKEL), healthy diet, regionality and freshness. On German market is much higher number of foreign investments, the main reason is probably higher margins than it is in Czech Republic. Characteristics for both markets are better summarised and compared in following SWOT analyses in Table 3 and Table 4 from the perspective of new baker entering the market.

Table 3: SWOT analysis of Czech market

STRENGTHS	WEAKNESSESS
high demand for baking products	established bakeries on the market
lower costs (production and operating in relation to the economy)	weaker developed baking alliances
stable demand for particular products which comes from conservativism	still strong preference in price (slowly decreasing)
relatively high demand for products from soft dough	low margins from revenues
	weaker demand for bread

	prices strongly influenced by wheat markets
OPPORTUNITIES	**THREATS**
tolerance (demand) of baking products from frozen semi-finished products	increase of revenues in supermarkets
increasing demand for baking products instead of bread, can bring higher revenues	increasing consume of frozen semi-finished products
specialised shops can seduce increasing slowly increasing nr. of customers focusing on quality	increasing wealth and better lifestyle of citizens can lead to decrease in consume
increasing demand for smaller packages can increase margin	increasing trends for gluten-free products
increase for rye consisted products	decreasing number of bakers can increase production costs

(Source: Self-customised information)

Table 4: SWOT analysis of German market

STRENGTHS	WEAKNESSESS
strong baking alliances	established bakeries on the market
strong preference for bakeries	high costs (production and operating in relation to the economy)
preference in quality	higher bureaucracy - business environment is more controlled from governments
higher margins from revenues, comes from lower price sensitivity of Germans	prices strongly influenced by wheat markets
high, stabilised demand for bread	weak demand for products from soft dough
preferred smaller packages	relatively weak demand for baking products, large part is sold in supermarkets
OPPORTUNITIES	**THREATS**
willingness to try new tastes and specialities	strong group of supermarkets dominate food market
demand for performance food - connected with health lifestyle	increasing foreign investments
willingness of customer to pay if he is satisfied	large chains are extruding small bakeries from the market
accentuating regionality can seduce more customers	increasing trends for gluten-free products
quite strong demand for products made from controlled origin, especially bio or organic bread products	slow increase in frozen semi-finished products, because customers demand freshness
ecologically friendly packages can seduce people (there is significant part in population) caring about environment	

(Source: Self-customised information)

Secondary data in Czech market unveiled that bread products consumption on the market is higher that it is in German market. Differences in statistics are also caused by the fact that sourdough bread is popular in the Czech Republic. While in Germany they prefer whole grain products. Both markets are highly competitive, but problems in Czech market could cause lower purchasing power of people what leads to smaller margins of Czech bakers. Different are markets as well in the amount of foreign investments, German market attracts foreign investments more due to higher margins. Disadvantage of German market lies in high production and operating costs, so it requires higher initial costs.

Abstract

One of the conditions of manufacturing works survival in European competitive environment is to secure optimal performance and to reach maximum added value. Ability to satisfy customers and flexible response to their demands is a necessity. Company managers are presented with number of tasks by these demands in the framework of all company departments. One of them is machine and production facility maintenance. This part is intended to implementation of Six Sigma methodology. The aim of the paper is to define the procedure of individual steps so, that to lead to break through strategy to significantly improve customer satisfaction and shareholder value by reducing variability in every aspects of business. Thanks to this procedure can be expected enhancing the ability to delivery customer satisfaction and cost improvement results faster- within months from the start and sustains the rate of improvement on-going.

Keywords: Business process management, Six Sigma, customer satisfaction, phases of Six Sigma.

Introduction

This part is intended to use of Six Sigma methodology. A breakthrough strategy to significantly improve customer satisfaction and shareholder value (Klečka, 2014) by reducing variability in every aspects of business. It enhances the ability to delivery customer satisfaction and cost improvement results faster- according to Strachotová et al. (2018b) and Straka et al. (2016) within months from the start and sustains the rate of improvement on-going. The basic concepts of Six Sigma were developed at Motorola in the 1980's as they worked to improve the quality of their products and services (Tošenovský, 2003). They have been refined and improved over the years by many successful companies. By implementing a systematic, rigorous routine, they were able to improve their services or products and increase customer satisfaction, thus increasing profits. Six Sigma approaches business processes from a highly analytical point of view. It incorporates five levels of activity:

- Philosophy – the enterprise-wide embrace of defect reduction by making decisions based on hard data and customer focus. According to Straka et at. (2017), defect reduction applies to all enterprise processes. This aspect is important not only from the point of view of customers, but also has an impact on occupational safety and the environment (Botek, Strachotová, 2018; Strachotová et al., 2018b).
- This aspect is important not only from the point of view of customers, but also has an impact on occupational safety and the environment.
- Focus on the Customer - meet or exceed their requirements/expectations.
- Metrics – statistical focus to make process outcomes 99.9997% defect free, otherwise expressed as 3.4 defects per million opportunities (Barlow, 1999).
- Methodology – structured approach to solving problems that uses specific tools and process mapping to achieve the metric goal.

– Process based – the defects or errors introduced into products or services are based upon deficiencies in the processes (Abu-Taieh, Sheikh, 2007).

In short, George et al. (2002) state - Six Sigma allows an organization to reduce the variability in its products and services so that waste is reduced, efficiency is improved, and customer satisfaction is dramatically increased. Business problems are solved through rigorous application of data collection and analysis tools (Tošenovský, 2003). The training that Six Sigma users receive is quite intensive, progressing through several increasingly sophisticated levels based on experience and accomplishment. Professional Six Sigma consultants and practitioners usually work to become certified at the various levels (Gitlow, 2004), increasing their ability to help guide development and implementation of Six Sigma.

Theoretical Background

The methodology of Six Sigma is the key to its success. An organization follows a five-step progression (DMAIC) (Fig. 1) that uses information and statistical analysis to address the achievement of operational goals. There are some differences in the five steps depending on whether they are used to improve an existing process or design a new process. The end goal, though, is always to achieve the standard metric of 99.9997% defect free performance.

Fig. 1: The five phases of Six Sigma (Source: self-according to Gitlow, 2004)

1. Define. The Define phase is concerned with the definition of project goals and boundaries, and the identification of issues that need to be addressed to achieve the higher (better) sigma level.
2. Measure. The goal of the Measure phase of the Six Sigma strategy is to gather information about the current situation, to obtain baseline data on current process performance, and to identify problem areas.
3. Analyze. The goal of the Analyze phase of the Six Sigma quality effort is to identify the root cause(s) of quality problems, and to confirm those causes using the appropriate data analysis tools.
4. Improve. The goal of the Improve phase is to implement solutions that address the problems (root causes) identified during the previous (Analyze) phase.
5. Control. The goal of the Control phase is to evaluate and monitor the results of the previous phase (Improve).

Basically, identify an area where there is a process problem, measure it, work out why there is a problem and then fix it.

Project Selection

Proper project selection is one of the most critical factors influencing the outcome of consumer driven Six Sigma projects. Selecting a project that is too large will cause valuable time to be lost during the define phase as project teams struggle to scope their projects and develop “Problem statements” that can be addressed using Six Sigma. A fundamental formula used in Six Sigma is that “Y” is a function of “X”:

$$Y = f(X) \tag{1}$$

In mathematical terminology, “Y” is the dependent variable while “X” is the independent variable. Expressed in another way, “Y” is an output resulting from number of inputs or “X”. The typical diagram used to communicate this concept in consumer driven Six Sigma is as follows

$$Y = X_1 \; X_2 \; X_3 \; X_4 \tag{2}$$

Building on this concept, it canbe said that every "X" is correlated to "Y" at some deeper level in the process (Barlow, 1999). The diagram for this cascading relationship is as follows:

$$\begin{array}{l} Y = X_1\ X_2\ X_3\ X_4 \\ \Downarrow \\ Y = X_1\ X_2\ X_3\ X_4 \\ \qquad\qquad \Downarrow \\ \qquad\qquad Y = X_1\ X_2\ X_3\ X_4 \end{array} \tag{3}$$

This method of "drilling down" to the specific issues is the fundamental technique for both project selection and project scoping. Those trained in Six Sigma techniques are often heard describing issues in terms of the "X_s" and Y_s" (Tošenovský, 2003). On the Fig. 2 it has at one's disposal the example.

$Y = X_1\ X_2\ X_3\ X_4$ $\Leftarrow\Leftarrow$	The taste of a glass of lemonade (the "Y") is influenced by a number of factors including: º Type of lemon ingredient (an "X") º Amount of sugar added (an "X") º Type of water used (an "X") º Amount of ice added (an"X")
$\Downarrow$ $\Downarrow$ $\Downarrow$ $\Downarrow$	
$Y = X_1\ X_2\ X_3\ X_4$ $\Leftarrow\Leftarrow$	Extending the example, if the lemon ingredient factor was to be examined further, the "X" variables might include: º Fresh squeezed lemon (a potential "X") º Liquid concentrate (a potential "X") º Frozen concentrate (a potential "X") º Powdered lemon flavouring (a potential "X")
$\Downarrow$ $\Downarrow$ $\Downarrow$ $\Downarrow$	
$Y = X_1\ X_2\ X_3\ X_4$ $\Leftarrow$	Looking at "fresh squeezed lemons" might include examing: º Where the lemons were grown (an "X") º How the lemons were transported (an "X") º Age when squeezed (an "X") º How lemons were squeezed (an "X")

Fig. 2: Example for using Six Sigma methodology (Source: self-according to Tošenovský, 2003)

Y/X diagram on Fig. 3 illustrates how the project selection process is used to narrow high-level outcomes (big "Ys") down to specific actionable issues (project level "X_s"). Delivery conditions and delivery timing will be used throughout this part as example to explain Six Sigma tools and techniques.

Project selection is most often performed at the project champion level and is critical that black belts and project teams have specific issues to address (Barlow, 1999). Without clear direction, projects frequently stall in the define and measure phases as it becomes difficult to pinpoint what data to collect (George et al., 2002) and how to make use of it. To ensure that projects are appropriately selected, the champion can apply the project selection checklist appearing.

High level outcomes	$Y = X_1\ X_2\ X_3$	Y = the top line issue is what can be done to improve satisfaction, which can be broken down into sub grounds X_1 = consumers **X_2 = dealers** X_3 = internal customers
	$\downarrow$	
	$Y = X_1\ X_2$	Y = the decision is made to address dealer satisfaction, which is comprised of satisfaction with: **X_1 = processes** X_2 = product
	$\downarrow$	
	$Y = X_1\ X_2$	Y = focus is placed on satisfaction with processes, which include: **X_1 = inventory** X_2 = business management
	$\downarrow$	
	$Y = X_1\ X_2$	Y = inventory satisfaction includes satisfaction with: X_1 = ordering **X_2 = delivery**
	$\downarrow$	
	$Y = X_1\ X_2$	Y = attention is directed to inventory delivery, which includes: **X_1 = vehicle delivery** X_2 = parts delivery
	$\downarrow$	
Project level	$Y = X_1\ X_2$	Y = two issues influence satisfaction with vehicle delivery: **X_1 = condition** **X_2 = timing**

Fig. 3: Y/X diagram (Source: own)

Define phase

The purpose of the define phase is to further refine the Six Sigma project team's understanding of the problem to be addressed. In addition, the project team will use the define phase to get organized, determine roles and responsibilities, establish goals and milestones and review process steps. At the completion of the define phase, the project team will have:

- Defined the problem with a problem statement. Upon completion of this step, the team should have a problem statement that – describes the problem based on available data, does not include assumptions regarding possible cause or solutions, identifies key metrics.
- Specifically identified the process or product's customer
- Defined CTQs (Critical to Quality characteristics) from the customer's viewpoint

- Scoped the project
- Produced a refined problem statement

Identify customer – in this step, the project team will determine who is directly impacted by the problem and what costs can be associated whit that impact. During the identify customer step, the project team attempts to target a specific se of customers. Correcting the problem for this set of customers generates the largest benefit and improvement can usually be expanded to larger groups of customers.

Once a customer is identified, the project team will need to determine what is important to that customer from the customer's point of view. In Six Sigma terminology this process is referred characteristic (CTQs). Identification of CTQs ascertains how the characteristics appear when meeting customer expectations. After CTQs are identified, the project team must develop operational definitions foe each CTQ. Effective operational definitions:

- Accurately describe the critical –to-quality characteristic,
- Specifically annotate what is considered meeting the customer expectation,
- Are written to ensure consistent interpretation and measurement by multiple people.

Commonly used methods of identifying CTQs include, but are not limited, to focus group, surveys or interviews. Outputs of this step are CTQs, operational definitions and parameters for measuring too. When project team members the scope project do, must above all further specify project issues, develop a refined problem statement and brainstorm suspected sources of variation. Similar to the process used in project selection, team members must strive to reduce the scope of their project to a level that ensures the problem is within the team's area of control that ensures data can be collected to show both the current and improved states. A refined problem statement is a highly defined description of the problem. Beginning with the general problem statement and applying what has been learned through further scoping. Project team write and refined problem statement that describes the problem in narrow terms, indicates a level where the team will begin its work and identifies the extent of the problem and how it measured. Effective tools to scope projects include cause-and-effect diagram (fishbone), cause-and-effect matrix, FMEA and Y/X diagram.

Measure phase

The purpose of the measure phase is to establish techniques for collecting data about current performance that highlights project opportunities and provides a structure for monitoring subsequent improvements. Upon completing the measure phase, project team will have a:

- Plan for collecting data that specifies the data type and collection technique,
- Validated measurement system that ensures accuracy and consistency,
- Enough sample of data for analysis,
- Set of preliminary analysis results that provides project direction,
- Baseline measurement of current performance.

The key concepts of measure phase consist on sound data collection plan, identification of key process input variables (KPIV), variation displayed using pareto charts, histogram and run charts. The most important step of the measure phase is a well-prepared data collection plan. It is critical that the project team spends the appropriate amount of time developing the data collection plan. Investing time in developing the plan can help avoid collection errors that may result in data corruption or the collection of data that is not relevant to the project. Conversely, even the well-developed plan may require revisions as the project team becomes enlightened regarding. Process details. The project team should make certain that ample consideration has been given to the various factor (Xs) that might be causing variation in the process. It is very important that, where applicable, data be sub grouped to determine variation between the subgroups. For example, if the Xs were typos observed in a document, the project team might subgroup the data as follows: person-to-person, office-to-office, shift-to shift, week-to-week, etc.

In the next step must prepare perform measurement system analysis. It is important to ensure the information collected is a true representation of what is occurring in the process. At the conclusion of the measurement system analysis, the project team should know:

- Whether the measurement system is "capable" of gathering data that accurately reflect variation in the process,
- Whether there is measurement error, how big it is and method of accounting for it,
- What confidence level can be attached to the measurement collected,
- Whether or not measurement increments are small enough to show error,
- Whether the measurement system will be stable over time.

The project team member must conduct data collection, perform graphical analysis and conduct base analysis too.

Analyse and Improve Phase

As an outcome of the measure phase, the project team should be narrowing its focus on distinct groups of project issues and opportunities (Dyntar, Strachotová, 2015). The analyse phase allows the project team to further target improvement opportunities by taking a closer at the data. Upon completion of the analyse phase, project team members should be able to answer – what was the approach to analysing, what was the improvement opportunity, what are the causes contributing to the improvement opportunity, how was the data analysed to identify sources of variation or did analysis result in any changes to the problem statement or scope? (Strachotová, Pavlištík, 2017; Strachotová et al. 2017). The Fig. 4 shows mutual relations between single activities of analyse and improve phase and shows used tools too. To begin the analyze phase, the project team needs to confirm the type of data that has been collected, either attribute or variable. Based on the data type, the project team will use one of two sets of analysis tools:

1. Attribute data tools (attribute data reflecting one of two conditions such as Yes/No; Defect/No defect; Accurate/Inaccurate):

    - 1 proportion – test a data sample against a test proportion, target or defined standard; determines if there is statistically significant difference; Null hypothesis (Ho) = there is no significant difference between the sample data and the target; P-Value greater than 0,05 = accept null hypothesis; P-value less than 0,05 = reject null hypothesis
    - 2 proportions - test a data sample against one another; determines if there is statistically significant difference between the two data sample; Null hypothesis (Ho) = there is no significant difference between the two data samples (A=B); P-Value greater than 0,05 = accept null hypothesis; P-value less than 0,05 = reject null hypothesis
    - Chi-square – tests for independence between data samples (shows no relationship); Null hypothesis (Ho) = there is statistical independence between two data samples (no relationship exist); P-Value greater than 0,05 = accept the null hypothesis; P-Value less than 0,05 = reject null hypothesis.

2. Variable data tools (test for level of variation within a data sample):

    - F-Test - tests and compares two data sets for variance; assumes a random sample of normal data; Null hypothesis (Ho) = both data samples have the same degree of variance; P-Value greater than 0,05 = accept the null hypothesis; P-Value less than 0,05 = reject null hypothesis.
    - ANOVA (analysis of variation homogeneity of variance) - tests and compares there or more data samples for variance; Bartlett's requires normal data, levee's does not require normal data; Null hypothesis (Ho) = all data samples have the same degree of variance; P-Value greater than 0,05 = accept the null hypothesis; P-Value less than 0,05 = reject null hypothesis.

– 1-Sample T-Test – tests the data sample against a test proportion, target or defined standard; determines if there is statistically significant difference; Null hypothesis (Ho) = there is no significant difference between the sample data and the target; P-Value greater than 0,05 = accept the null hypothesis; P-Value less than 0,05 = reject null hypothesis.

Fig. 4: Analyse and improve phase (Source: self-according to Tošenovský, 2003)

As an outcome of the analyze phase, project team members should have a strong understanding of the factors impacting their project, including – key process input variables (KPIV) – also the vital few "Xs" that impact the "Y". Including sources of variation – where the greatest degree of variation exists. The purpose of the improve phase is to generate ideas, design, pilot and implement improvements and validate improvements. The team members can use next key concepts: brainstorming, "should be" process map, FMEA, etc. at the conclusion of the improve phase, the project team will have identified alternative improvement, implemented the best alternative for improving the process, validated the improvement and prepared for transition to the control phase. Design of experiments (DOE) is an effective tool that can be used in both the analyse and improve phase of the DMAIC process. However, DOE can be a difficult tool to use outsider of a manufacturing. environment where small adjustments can be made to input factors and output can be monitored in real time.

Control phase

The purpose of the control phase is to institutionalize process/product improvements and monitor ongoing performance. Following the improve phase, the project team needs to transition control of the process back to the process owner. To facilitate a smooth transition and ensure the project team's work sticks, a detailed control plan will be developed. The objective of the control plan is to document all pertinent information regarding – who is responsible for monitoring and controlling the process, what is being measured, performance parameters, corrective measures. Key components of the control plan include mistake proofing, long-term MSA plan, control chart – statistical process control (SPC),

reaction plan, update standard operating procedures. Upon completion of the control phase, the process owner will understand performance expectations, how to measure and monitor X_s to ensure performance of the Y, and what corrective actions should be executed if measurements drop below desired levels. Likewise, after completion of the control phase, the project team members disband while the black belt begins the next consumer driven Six Sigma project with a new team.

Conclusions and Discussion

One of the most powerful ways to improve business performance is combining business process management (BPM) strategies with Six Sigma strategies. BPM strategies emphasize process improvements and automation to drive performance, while Six Sigma uses statistical analysis to drive quality improvements. The two strategies are not mutually exclusive, however, and some savvy companies have discovered that combining BPM and Six Sigma can create dramatic results. Six Sigma methodology teaches and deploys hard skills and business practices emphasizing.

Variable data is sometimes more desirable than attribute data to use, because it requires smaller sample sizes. However, some projects appear to provide only attribute data (damaged units, number of incorrect invoices). The design of experiment (DOE) is an extremely valuable tool not only in identifying key input variables causing variation but also in setting the operating tolerances (precise levels) of the key input. DOE works well in manufacturing processes where equipment can be adjusted incrementally, and output can be analysed over time (see Fig. 5).

Fig. 5: Combining BPM and Six Sigma (Source: own)

With this basic understanding of BPM and Six Sigma in mind, it is easy to see how powerful it can be to combine the two practices. Their strengths complement each other and create a synergy that instils the entire operation with a focus on quality and performance. The strength of BPM lies in its ability to automate processes and workflow through modelling and examination of inputs, outputs and performance. It is not as strong, however, in its ability to analyse data associated with very difficult or multifaceted problems. Six Sigma fills this gap by providing the statistical analysis needed to deal with complex problems.

The strength of Six Sigma lies in its rigorous approach to data collection and analysis. Through this methodology it can identify even the smallest opportunities for process improvement, maximizing an organization's ability to institute necessary changes. It is not as strong, however, in its ability to monitor process improvements and ensure they are applied across the board. BPM fills this gap by providing tools to automate process improvements and connect those improvements across the entire organization. Both BPM and Six Sigma represent significant commitments on the part of a business or organization, and they take time to implement thoroughly. Tremendous organizational change is often required, leading most companies to start with a single department or pilot project and expand their use over a multi-year period. It is well worth the time and effort, though, to generate the substantial business improvements that are typical with BPM and Six Sigma.

Abstract

To be prepared for requirements of the future, it is necessary to question the actual state of maintenance and to generate new ideas for future development. Tools are important for the maintenance process, using which the sustainability of a maintenance department can be checked and potentials for improvement can be realized. In this paper, the key ingredients that ensure successful implementation of enduring plant maintenance programs and improved equipment reliability are analysed the modern concepts of Strategic Asset Management (SAM). The authors determine completely alignment of resources to achieve to business goals of the organization at the lowest cots through SAM. The authors found out the benefits of successfully implementing SAM include: Improved product quality, Lower costs for system and equipment maintenance, Increased availability of production systems and equipment, Enhanced morale among management and the workforce and Reduction in costs. This paper will be describing some of the fundamentals regarding the concepts, practices and processes of SAM.

Keywords: Maintenance System, Maintenance Efficiency, Data Evaluation

Introduction

Maintenance improvement programs are often started with grandiose goals and much ado. However, most of these programs either run out of steam at an early stage. They come to be viewed as resource burdens rather than a means to enhance overall productivity and increase profitability (Legát, 2016). However, it should be a target of every company management to accept rules for so called productive maintenance. Productive maintenance is a part of quality system. Walt (2006b) says, that basic requirement for any quality system, hence for maintenance quality system as well, is its continuous improvement based on analysis of the system behavioe, identification of weak points and making adequate corrections. Altough there are a number of indicators wich synthesize the effects od low-level metrics. According Crespo (2012) the analytical tools, if properly algorithmized, enable to prepare regular analyses of maintenance efficiency including detailed analysis and identification of weak points.

Maintenance is a significant zone of productivity increase and reduction of costs from the production operations effectiveness view. Unfortunately, present-day means of production care does not have a position, which it deserves in the companies. Maintenance is a neglected service department, representing only necessary costs for most of the managers (Yoshikawa, 1995). However, from several aspects it is important for the company management to effectively apply production facilities maintenance. These are as follows:

- Maintenance demands above all result from capital globalisation, production and supply chain. These demands generate pressure on material flow acceleration through production process. Each production facilities breakdown however is at the same time a cause of the flow breach,

leading to stock increase and thus to cost increase as well. It is understandable that these features have an unfavourable impact on company effectiveness, which may jeopardise order date.

- Maintenance can be a source of competitive benefit too. Regarding the fact, that input prices into production operations (raw materials, energy, and labour) are dictated by market, the producers have comparable conditions in this area. Different effectivity may be given by the fact, how the management takes care of the production facilities. There is a considerable share of machines in tangible assets in most of the companies.
- One of the most important maintenance features is machine and facility maintenance in operational and fit state, foreseeing rise of breakdowns and low-class production. There is a logical consequence to secure operational security, thus decreasing environmental impact. After all the operational security is determined by legislative demands and each company must keep them (Cambell, 1995).

In the last century, the industrial world developed maintenance and maintenance tools. They contributed to economic growth by doing right things every day. Time is changing: a lot of stakeholders and players are nowadays embedded in a growing global market. Further companies are creating a new entrepreneurial environment that brings out the best of everyone – worldwide. In the western world, competition between different management disciplines is keen, e.g. between Real Estate Management, Facility Management, Life Cycle Management. Maintenance Management and Physical Asset Management. Facility Management is defined as the integration of processes within an organisation to maintain and develop the agreed services which support and improve the effectiveness of these primary activities.

Theoretical Background

Maintenance costs versus maintenance value

Direct maintenance costs in Europe are estimated at about 1,5 mld. Eur/year. (Walt, G., 2006) Reducing maintenance costs to a minimum has become a challenge. But indirect maintenance costs including down time costs, quality, productivity, lawyers, loss of company image, training, investment in spare parts, etc. are 5 times higher than the direct maintenance costs (Walt, 2006 a). Life cycle considerations are included but they are not mentioned in newest definition of Facility Management. Where to save? That is the critical question. What about Facility Management, Asset Management and Maintenance management? In several countries nowadays, Facility Management is focussing on buildings, manufacturing plants, infrastructure and corresponding services. Maintenance is included in the Facility Management. The Facility Manager is a provider following the market rules.

A physical asset is an entity creating, sustaining or destroying value at any stage of its life cycle. (Amadi-Echendau, 2016) Asset Management covers production plants, buildings, power stations, communication, railways, roads and public service. Maintenance is of course an important part of Asset Management. General strategic guidelines signed by the top-management are the key to success for determining maintenance concepts together with all partners within and outside of companies. The amount of real maintenance efforts should be in function of customers need. This brings us to the question: What is the technical knowledge indispensable for Maintenance Managers and Specialists.

Asset Management

Asset Management is a term that has been getting a lot of press recently. The term implies many things to many people, and there is no industry standard for application. Implied in the term, however, are some basic concepts (Legát, 2016):

- Business goals drive decision regarding the use and care of equipment assets.
- Asset strategy is determined by operational considerations.
- Maintenance and reliability are means to a defined goal, not an end in themselves.
- The intent is to optimize the application of all resources, not just maintenance.

There have been attempts to define Asset Management as life cycle cost management; it has been used in the phrase "asset management reliability", which seems to be redundant or confusing; the term has been seen as a substitute for maintenance or reliability practices. As a "father" of the concept is considered Mr. Bradley Peterson, USA, and hid definition is: "Asset Management is a global management process through which one consistently make and execute the highest value decisions about the use and care of the assets." (Peterson, 2016)

Nowadays people have begun to understand the even broader vision for Asset Management than has been previously articulated. By Brad Peterson this has been named Strategic Asset Management (SAM). SAM is an integrated set of process that systematically derive the highest value from plant assets, through a consistent philosophy, plans and objectives and cooperative involvement by everyone in the plant. SAM represents a higher level of performance than is currently practiced or even recognized by the manufacturing community today. Any useful model to guide action will have several characteristics:

- Simplicity. All the greatest ideas are simple in concept. If not kept simple, they are not fully understood or remembered, and fail as guiding principles.
- Intuitive. Readers should be able to understand the underlying principles without guidance.
- Utility. The model should work consistently in application.
- Completeness. All necessary elements of success should be contained.

The SAM model indicates how these criteria are met. However, make your own judgments. The base principles of SAM model are present on Fig. 1.

Fig. 1: The SAM Model (Source: Self-plotted according to Shenoy, Bhadury, 2011)

Lead. There are hundreds of books written about leadership and each of them has some valuable point to make. Frequently, though, the description is of individual leadership and often charismatic leadership. Leadership in the plant setting is creating consistency of purpose and action. Manufacturing is a large set of complex and interrelated systems of marketing, technology, finance, human resource, execution function and equipment. Physical Asset Management then must take all of these into account. Putting things as simply as possible into SAM model, the LEAD element consists of the Managing System, Strategic Planning and Information Management.

Execute. Four functional areas exist in any manufacturing environment. These areas are the typical focus of leadership. If done well, they lead to functional excellence.

- Capacity Development. Is usually considered to be the Design Engineering and Project Management functions in an organization. This function consumes hundreds of millions of Euro in what are often risky bets made in market assumptions. A thoughtful and disciplined method to assure excellence in the assumptions, design, construction and preparation for production can be a valuable tool.
- Production Management. Everyone in the plant believes with good reason that production is the reason we are all here. And indeed, this is the vehicle for value creation.
- Logistics include materials management, purchasing and movements of people and materials. This function can make or break the Production and Asset Healthcare Management functions.
- Asset Healthcare Management. Is this just another term for maintenance and reliability? Perhaps at some levels it is. But it is concerned with optimizing and integrating with all parts of the business based on risk and value, and so goes beyond the traditional boundaries of maintenance reliability. (Walt, 2006 b) The Asset Healthcare model is the well-known SAM Diagram (Fig. 2).

Fig. 2: SAM Model functional pyramid (Source: Self-plotted according to Shenoy, Bhadury, 2011)

Enable. Many programs for change are viewed as a simple matter of documenting procedures and providing training. If these things are done, change should happen, right? Wrong. Human nature does not work that way. Prescriptive formulations may work for machinery, but the human machine is more complex! Let me refer to what Mr. Peterson says: "Most of our corporate clients have a large number of related but disintegrated goals, Safety, reliability improvements, Six Sigma, Lean Manufacturing, Supply chain rationalization, etc." (Peterson, 2016) These are often presented to the plant as a series of corporate staff visits, all requiring the plants time and attention. If the plant acted on the sum of these "required programs" with full enthusiasm, they would quit producing product. Their time and attention would be taken in team meetings, developing procedures and trying to rationalize the differing demands of each program. Fortunately, plant personnel know their jobs are tied to making budgeted quantities

of quality product. So, their view of change is to ignore these directives until they evaporate from lack of momentum and commitment.

The usage of the model. Each of the four areas can be handled in a step by step development towards Operational Excellence. In the SAM model the development for each of the areas has been illustrated by a triangle. The usage of the SAM model is a completely alignment of resources to achieve the business goals at the lowest costs. If you will be able to study the SAM model closer you will note that this about enabling change, not about the core maintenance or production process. Normally organizations seldom fail because they don't understand best practise but because they can't get them implemented. Therefore, the implementation of the SAM model focuses on change because it is the critical barrier for success.

The core group dealing with the betterment process must be the whole plant population. They have the power, collectively, to determine whether they will proceed, and how they will proceed. People are ready for SAM when the leadership agrees that:

- Asset integrity and condition are among the top three goals for the plant, now and forever.
- The way to improvement is not a project, but a fundamentally different way of operating.
- They are willing to invest their own time to make it happen and understand there will be investments before results.
- Function heads (production, maintenance, engineering, procurement) are willing to work together for change.
- They are willing to be measured and respond to identified gaps.
- They need help and are willing to accept it.

The leadership alignment around the strategic direction of the organization may be the single most important result of implementing the SAM model. This cohesiveness within an organization will certainly lead to financial results as well. The users of the SAM model have achieved benefits in excess of several million Euros within a short period of time taking a strategic approach to operations excellence. (Legát, Jurča, Hladík, 2014)) It has been detailing financial benefits from increased efficiency and increased plant capacity versus the costs of implementing the SAM model over a period of a number of years.

Discussion

The base for successful maintenance management is demonstrated in a control cycle model for maintenance, where the classical tasks of maintenance are described, the main tasks – as planning, controlling, execution and analysis – with detail tasks belonging to them (see Fig. 3). Accordingly, this check and evaluation tool is subdivided in following main section, which are described briefly (the whole questionnaire contains more than 250 queries. We will list individual areas and examples of questions from these areas:

Organisational structure & human resources:

- Ratio of employees for the functions c1arification - planning/preparation/ execution?
- Level of competence of the leading staff and qualification of workmen?
- How is wages policy organised? Are achievement-oriented elements included?
- Has the company any apprenticeship training, how is internal education and training organised?

Productions plants & operating staff:

- Condition of production and auxiliary plants?
- Process technology and standardising?
- Are plants and/or equipment's known which are strategic important for production?
- Are production data permanently recorded and analysed?
- How is the professional qualification of operating staff?

- Are they able to perform simple maintenance tasks by themselves?

Maintenance strategies & methods

- What are the reason for selection of a defined strategy?
- Are there working plans for preventive maintenance measures?
- Are diagnostic systems used for assessing and monitoring equipment conditions?
- Are the activities for weak point analysis of plants (equipment elimination) of failure causes?

EDP & work order system

- Is an EDP supported system (CMMS) installed?
- Is it used in network, is it regularly updated?
- How is work order management organised?
- Are clear rules available for periodization of work requests/work orders?
- Which work order type is predominant – single or permanent?

Work & capacity planning, scheduling

- Are maintenance works planned for a longer period (e.g. at least on week)?
- Can you find out any time?
- Whether all actual workload of the department?
- How will be that back log for the next days?

Work performance

- What is the share of planned work orders (concerning time and content)?
- Are estimations of expected workload made for each planned job?
- How is the (professional) structure of working groups?
- How is supervision and reporting organised for finished jobs?
- What is the ratio overtime?
- How many jobs are executed by every employee per day average?

Working place & equipment

- Location and level of utilisation of workshops?
- Equipment of workmen and workshops (standard and special tools)?
- Organisation of f10w of work in workshops?

Material management & subcontractors

- Number and location of storages for spare parts?
- How is demand-oriented provision of spare parts organised?
- Which persons can take material from the storage?
- Accessibility of storages out of normal working time?
- Procedure for purchasing spare parts?
- What is the strategy for using / buying external (maintenance) services?
- Is a system available for evaluation of suppliers and providers?

Technical documentation

- Structure of asset documentation?
- ls it permanently up dated?
- Can you find also maintenance relevant information in asset documentation (asset live cycle history, etc.)?

Maintenance budgeting & controlling

- ls it evident, which maintenance objects are very "maintenance intensive"?
- Can it be verified by plant related maintenance budgets?
- Do pre and post calculations exist for (bigger) maintenance jobs?
- Do you have hourly rates for single trades I professions I workshops?
- What is included in these hourly rates?
- Is an interpretation and / or analysis of maintenance costs done by kind of costs (internal, external, material) and by kind of services (inspection, preventive maintenance, repair, revisions, etc.)?
- Are maintenance related key figures used?

Quality & safety management

- Are only legal requirements fulfilled or do you have an applied management system?
- Can we see documented process flows for the performance of important maintenance measures?
- Are reclamations recorded and does somebody work on them?

- Does an employee suggestion system exist, with which improvements of plants / equipment are initiated?
- How do you estimate the safety consciousness of maintenance staff?
- Are analysis and debriefings of accidents and near-by-accidents done?
- Are "tool-box-meetings" held?

Communication

- How communication between production and maintenance is organised (e.g. during crashes, after completion, etc.)
- Does a structured reporting system in writing exist?
- Will maintenance staff be informed about contents of these?

Most of these criteria can be found out by direct questioning of different persons in the maintenance organisation, the other part will be answered by personal impressions during a tour of the plant and workshops. It should be a target of every company management to accept rules for so called productive maintenance. Afterwards the word productivity entered modern organisation philosophy of machines and facilities care indicated as TPM (Total Productive Maintenance). The describe order has been used for TPM efficiency assessment to. At literature is introducing many similar applications for efficiency assessment. This contribution produces results of maintenance productivity audit serving to the assessment of value reached in the framework of the TPM programme. The report was carried out in a rubber industry company before / during / after implementation first and second step of TPM methodology. I have chosen a spider diagram for interpretation to get a clear picture of determined actual situation, where you can easily see the strength and weakness of the checked maintenance organisation (see Fig. 3)

Fig. 3: Evaluation of Maintenance Organisation by OrgCheck (Source: own)

Conclusions

In the future, we will have to think in several dimensions: market – level of competence – design – operative and maintenance aspects – special branch knowledge, etc. It would be more natural and convenient to have all concerned discipline (Asset Management, Facility Management, Maintenance Management, etc.) under one roof. Strategic Asset Management is a systematic process that enables the dream of Operations Excellence. It emphasizes a logical approach to best practise through the development stages of the EXECUTE Triangles. Functional excellence will never be enough, however, to be the best. LEAD Functions are the glue that brings all the pieces together in an optimized set of systems, especially trough the mechanism of the Managing System and Strategic Plan. Finally, you can only be as successful as your workers endorsement and participation in this functional excellence practise. You must ENABLE your people to bring you the success you all desire.

Abstract

The world is no longer divided between male and female. The institute of a housewife disappeared. We have a unisex model, gender balance, asexual world. Polarization of society by possessions. It is only a partial list of facts that are linked with the You & I relationship. The authors analyzed available information on factors influencing the defined relationship with the objective to define a set of attributes affecting human society. They present a reflection to the reader in the discussion part. How is a view of current interpersonal relationships developing? They can be identified not only through the man and woman relationship, but also through the friendship, information exchange and the like. At present, the You & I relationship is becoming rather of a virtual nature. Information exchange takes place, but information no longer plays the role it once had. Rules in relationships are determined by ethics that can be seen as an algorithm, a program that defines more than just the emotional aspect of relationships. The dynamic balance in the You & I relationship takes on a spatial form. There is something that cannot be seen, something that represents a spiritual value that plays a certain role and counterbalances the material world.

Keywords: Marriage, Natality, Motherhood, Hormonal Anticonception

Introduction

An overpopulated planet and long-term shortage of workers in Europe and in the USA. What is the reason why the number of people in productive age in the Western World diminishes? (Zimmermannová, J., Hájek, M. and Rozenský, 2017) Not enough babies are born, the average natality in Western Europe is 1.4 baby per mother. Traditional values once fulfilling marriage and the You & I relationship are vanishing. The world is no longer divided between male and female. The institute of a housewife disappeared. We have a unisex model, gender balance, asexual world. Polarization of society by possessions. It is only a partial list of facts that are linked with the You & I relationship.

Businesspeople from industry, agriculture and service sphere in modern Western world have constantly reported – with some exceptions – a shortage of suitable labor force, which prevents them from expanding, while our planet is overpopulated. People are the predominant animal species whose requirements for resources keep growing. In Europe (and other developed countries such as the USA, South Korea, Japan, Singapore etc.) we have seen depopulation for at least past 30 years. Fewer babies are born than before. The average in Europe has been around 1.4 baby per mother in the past 30 years, the exception being rich countries such as Norway and Switzerland with average near 3. In the USA, the natality growth is mainly due to the Hispanic minority that has historically always had more children. The fundamental difference is quite obvious. Africa and a large part of Asia prefers quantity to quality, while Europe, the USA, Russia, South Korea, Japan, Singapore are heading the quality street. The policy of one child with the preference of a son was applied for decades in mainland China. Is it normal that we

decided, on our own accord, to decrease the population in the northern hemisphere? No member country from the G20, the most developed economies in the world, does not achieve – with the exceptions of aforementioned exceptions (Norway, Switzerland) – the reproduction value of 2.1.

The traditional marriage in traditional localities is decreasing. There is a growing number of unmarried couples and children who do not leave the household. Male fertility is descending. Women working in men's job positions postpone their motherhood and focus on their careers instead. The consumerist lifestyle and accumulation of assets is on the rise. There are more and more single parents and the traditional (i.e. Christian) model of family, with a husband and a wife raising their children together, is falling apart. The You & I relationship typically first has a sparkle alongside with passion, relationship, talking, but what is left in the end is just the talking. All that remains over time is only the relationship itself, although it is very important. The relationship in digital era is getting a new form. Emphasis is laid on lifestyle that differs from the one that our parents and grandparents had. There is no time for anything, the genuine family spirit is disappearing. Asia sees a formation of a principle of spiritual renaissance (Lípa 2018): searching for a soul mate that we find in the You & I relationship, i.e. in our closest circle. What are the consequences for the future? What changes does Industry 4.0 implement and what things will Society 4.0 substitute?

Theoretical background

Changes in the relationship between a man and a woman in the past 100 years

120 years ago, the modern role of a man and a woman was quite unambiguous in most of the G20 member states. The First World War, the Russian Revolution, post-war Spanish flu pandemic period, first urbanization pressure (work was hard to find in the country, it was hard to earn a living), migration waves to the USA, hyperinflation in Germany, all of these phenomena were the causes of the lack of labor force. Industrialists exerted big pressure requesting that women filled in the vacancies. After the First World War there were first women physicians, scientific workers (Bajtoš, 2003) and others. Women in many countries gained the right to vote with the principle: if we can work like men, we want the same rights like men. The Wall Street Crash of 1929 and the following economic crisis slowed down the situation. Meanwhile, Hitler's Third Reich returned back to the roots and the personality cult meant also preference of the cult woman seen as a mother and natality slightly rose. Nevertheless, after the outbreak of the WWII the problem with the shortage of labor force renewed. It was partially solved with forced workers from abroad (the UK and France used workers from their colonies, Germany from invaded countries). After the end of the WWII, Germany was short of 50 million people, other millions were captured in Russia. The population growth rose immediately after the war as many couples waited for the war to end before they decided to conceive. However, this population wave weakened in the course of the following years (the Iron Curtain in Europe, long-term lack of consumption goods, ratio system, changes in political regimes). All countries dealt with the shortage of labor force in a similar way. The UK and France searched for workers again in their (this time former) colonies. West Germany made use workers from today's Turkey. This caused another wave of anti-Semitism, racism and animosity in many countries. It did not break out fully in the 1950s but waited for the following generations. In the 1960s, hormonal contraception for women first occurred and women took over the right to decide when to have children and regulate their number. The 1970s saw another population wave. While it was artificially supported in some countries, it was mostly spontaneous for a single reason: it was perfect time for baby boomers to have children. At the same time oil shock caused first global changes (Strachotova, 2012) in terms of approach to the planet and natality. First globalization moments after 1980 caused several fundamental changes:

- Multinational corporations were established, their economic influence being larger than that of smaller countries.

- Transformation in society occurred, traditional pyramid structure changed, narrowed, it mostly kept only added value and all non-essential production or with low added value became outsourced from sub-supplier chains, often dispersed all over the world.
- Arrival of new technologies, the Internet, lifestyle started changing. Women took intensively once male roles, the institute of a housewife was abandoned, unisex menswear for women.
- First agglomerations with dozens of millions of inhabitants were formed. This led to economic pros such as high density of people, so advertising was not needed for most services: there were enough customers nearby and demand for anything that was once the domain of women (outsourcing of housework, equalization of man's and woman's roles).
- Emancipation in terms of sex, homosexuality stopped being a crime in many countries, but rather an expression of the opinion of the You & I relationship.

These historic changes in the relationship between a man and a woman correspond with economic changes shown in Kondratiev's cycles (Alexander, 2002) of economic-technologic development (see Fig. 1 and 2). The difference between identical charts is given by the use of different axis measures.

Fig. 1: Kondratiev /World Economy Act" (Source: Alexander M., The Kondratiev Cycle: A Generational Interpretation, Indiana, iUniverse, 2002, 41 page)

The contraception pill changed the world. It broke the rule that it is the man who decided about conception during an intercourse or is the one responsible for the use of contraception (prophylactic). The woman took over the right to decide when to have children, who with and regulate the number. From the perspective of the You & I relationship it was one of positive options for women, especially those from totalitarian countries and countries from the former Eastern Bloc. The dismal solution in the case of

unwanted conception was abortion. That was illegal in many countries (Dolista, 2017) and was considered a crime committed by the mother-to-be and the physician who performed it. This is one of the historic reasons in transfer between generations (typically mother-daughter). The frequency of use of hormonal contraception differs by countries (see Table 1).

Fig. 2: Kondratiev /World Economy Act" (Source: Alexander M., The Kondratiev Cycle: A Generational Interpretation, Indiana, iUniverse, 2002, 76 page)

Hormonal Contraception

Table 1: Percentage of women using hormonal contraception

Czech Republic	52%
France	50%
Netherlands	41%
Germany	40%
Slovakia	32%
EU average	24%
USA	17%
China	1.2%

Source: Trends in Contraceptive Use Worldwide 2015, United Nations, New York, 2015

The proportion of women using hormonal contraception often shows the lobbing power of pharmaceutical companies in a given state. Much lower percentage in the USA is due to the fact that ethinylestradiol (synthetic estrogen) is considered a proved carcinogen in the USA (Maizes, 2010). Another difference between the USA and Europe is that there are more sterilized women and men in the USA (Harrison, 2012) than numbers of those using hormonal contraception!

What changed significantly was the attitude of once families and now women to their bodies. 100 year ago, a young lady first had her menstruation at around 17 years of age. Such a young lady went to a couple of balls under the supervision of a chaperone and she got married. Optionally, families made an arrangement about a marriage (Dolista, 2019). It was king of automatically expected that children would be born soon (Payne, 2019) and natality in Europe was multiple compared with today, in the Czech Republic it was 6 children per mother. Nowadays, young ladies have their first menstruation at around 12-13, while having firs menstruation at 9-10 years of age is no exception. Their body than has a long reproduction period in regular cycles. The legal age for sexual activities differs, typically it is 14-15 years of age. If a young lady starts to be active around this age and uses hormonal contraception (Roztočil, 2011), she can easily live through 20 years of sexually active life with a state of artificially induced infertility. This is one of the causes of complications when trying to get pregnant. (Vrba, 2017)

Another, and even more significant, adverse phenomena of using hormonal contraception is that the egg gets actually fertilized. The body assesses this wrongly (Hehlmann, 2010) and expels the fertilized egg (Adam,2003) from the reproduction process. This can happen several times over the 10-20 years of use and a woman may only notice it as stronger menstruation. Subsequently, when such a woman plans to conceive, her own body believes that conception is undesirable again (as it has been the case several times before), which leads to miscarriage. Last but not least, hormonal contraception alters chemistry in the couple. Although it is unscientific, this fact has been confirmed many times: while there was mutual attraction in the couple, after starting taking the pill (or vice-versa after stopping taking it with the view of conceiving) attraction between the man and woman vanished.

Situation in the Czech Republic after the 1989 change of regime

In the past 30 years since the change of regime, the Czech Republic has seen a wide range of changes. From the economic perspective, the purchasing power parity increased tenfold. The economy is extremely dependent on the automotive. Arms industry either totally ceased to exist or it reoriented. The Czech Republic is a leader in the field of nanotechnologies. The change of regime did not favor natality. New possibilities linked with open state borders meant that "Husák's" baby boomers born in 1970-1975 often postponed starting a family and women had their first baby at 30 years of age instead of once common 22. Economy set for the usual 180-190 thousand newborns a year switched to 140 thousand newborns. However, the Czech Republic needs approximately 180 thousand children a year to achieve the rate of natural increase. The Czech Republic has the highest rate of hormonal contraception users (52%). Natality has varied between 1.1-1.5 in the past 25 years. A positive trend could be seen in 2014-2019 when natality grew to 1.7. There are 23 thousand interruptions per year in the Czech Republic, which is partly given by abortion tourism (the Czech Republic has liberal attitude to abortions, unlike some neighboring countries). The number of IVFs is around 30 thousand cases paid from the public health insurance budget and another 15-20 thousand cases per year paid by private payers. The Czech Republic has – at least in Europe – the densest network of assisted reproduction and boasts high-quality medical care. Sadly, this is redeemed by impersonality, sometimes on the very border with cruelness, in provision of gynecological care. Most women undergo a gynecological intervention as outpatients (approximately 1 million interventions) while there are approximately 100 thousand surgeries (data from 2016).

The You & I relationship is affected by several factors. The worldwide trend of migration to anonymity of big cities. It the Czech Republic it is a common refusal of maternal model and extramarital children. While the number of unmarried couples living together was close to zero, nowadays therre are more extramarital children than children born in a marriage. The divorce rate is higher than the wedding rate. Until the 1960s, divorce was considered a taboo. This is also due to economic reasons, entitlement to a higher social contribution and/or allowances paid to single-parents that unmarried mothers are often considered. Furthermore, there is the effect of mummy's boys, meaning children who share one household with their parents until they are 25-30. This issue was given media coverage several years ago, Hollywood even shoots comedies about how parents can get rid of their overgrown kids by arranging a fake wedding. According to

available data, the percentage of 25-29 year-old men sharing a household with their parents is as follows 56% in Slovakia, 53 % in Bulgaria, 52% in Greece, 50% in the Czech Republic, 47% in Italy and 17% in Germany, 14% in Austria, 12% in France, 4% in Norway and 1.8% in Denmark (see fig. 3).

Fig. 3: Percentage of population under 30 living with parents in one household (Source: https://www.czso.cz/csu/czso/aktualni-populacni-vyvoj-v-kostce, picture author)

This problem is the case also in the Czech Republic. The data was obtained from the last census. 32.2% of mummy's boys in 1995 has grown to 50% of 25-29-year-old who share a household with their parents. The trend is slightly better with ladies: while in 1995 15.1% of 25-29-year-old women lived with their parents in one household, the number grew to 31.1% in 2014. According to the sociologists from the Institute of Sociology of the Czech Academy of Sciences this is merely evidence of the fact that it takes longer to mature and be ready to fly the nest and start a family. 25 years ago (in 1995), most 25-year-old women already had a baby. This has shifted and now the average age of primiparas is 30. The less independent a person is in a private life, the less independent they are at work and the more they are likely to avoid risks. The rule of thumb says that the weaker the will to take risks, the lower economic productivity. The US economy is still an environment where people are willing to take risks. By contrast, European economy prefers to be on the safe side.

Conclusions and Discussion

How are current human relationships evolving? Not only between a man and woman, but also in friendship, information exchange etc. Originally, the You & I relationship was based on friendship, communication, nonverbal meeting, practical aid etc. At present, the You & I relationship is shifting to the virtual world (sending text messages, giving likes, etc.). People are not in physical contact, which is in contradiction with the structure of nonverbal systems. Millions of years of evolution were based on physical contact and face to face information exchange. Looking from the neurologic perspective of the You & I relationship, it is an information flow. And the current form of the You & I relationship jeopardizes the information flow as it moves to a different level in terms of quality. In the future, digitization of the relationship will deepen even more, meaning it will take on some form of information exchange by the means of media, virtual reality or something similar. The biggest problem of digitization lies in the fact that it threatens security protocols that Mother Nature endowed us with. They concern the ability to process information, create an abstract image of reality built upon such information. If that is replaced with this immaterial, nonverbal, virtual milieu, a person receives far too much information that

they cannot cope with. A human body cannot function in the system of virtual reality. Information exchange does still take place, but fails to fulfil the task it should. Then the actual "self" works in a mode it has not been set for, not verbally nor sensorially. It does not utilize the thing that once formed a network of friendly relationships between people, friends and partners. And if this "self" is not formed, the basis is unstable.

In this sense, ethics ensures criteria significance of all information. That "self" transforms, because the criterion of significance of information in the human brain and its structures is the emotional code. An emotional code generates the structure classified as "important – unimportant", "vital – nonvital". Ethics is part of the emotional code. Should we put ethics aside, all we are left with is information about which we do not know if it is important or unimportant, good or bad. Ethics determines the rules, it is something like an algorithm, a program that defines, besides the emotional aspect, how to proceed within a program. If ethics and morality is absent, it is only an information flow with no structure whatsoever. Ethics arranges information hierarchically. It is the key paradox: with no ethics there is just an information chaos. If there are no rules, a relationship is not bound by anything. And when it is not bound, there is no fixed point – Euclid's "place to stand" (if it is found, the world can be moved).

Dynamic balance in the You & I relationship takes on a spatial form. It is a philosophy of "black and white" things. And then there is something that cannot be seen – a spiritual value that plays a certain role and counterbalances the material world. It influences the immaterial world as much as the material one. Chinese strategy of harmony and continuity proclaiming that continuity lies in a marriage persisting and harmony in that once "I am big, once you are big". Marriage was originally an economic relationship helping people survive, associate and form a group that had descendants and could survive more easily out in nature. Subsequently, there was a second stage of gradual asset accumulation and it was always more convenient to have own children so that they could inherit property. Obviously, then there was the problem with splitting the property. Today's family has transformed back into a smaller group and it contributes to the importance of the You & I relationship. The present problems are posed by economic stress, economic slavery, lack of time and lack of communication. The inability and unwillingness to accept information exchange within a family. It is substituted by the Internet, different communication channels and the like. A family is today primarily focused on what symbolizes its position within a society, i.e. social status degree of consumption etc. Such a family is not concerned about what could be referred to as the "genuine family spirit", i.e. connecting people in the closest circle. The main problem is that people claim to have no time. But do people actually care to communicate inside families? Or do they only bother to communicate about necessary things, but not about topics that really matter such as the meaning of life, what to endow children with, how to prepare them for life and similar. If this trend continues and digitization penetrates all problems it may easily happen that a family will no longer be the basic unit of society. Instead, the basic unit will be an individual with his or her ideas, desires, options and possibilities. And such an individual will be exposed to squalls in historic development as they will have no footholds. An individual's view of life is different. It alters consumption. What will individuals consider basic needs? Material assets, experiences or some type of sharing or communication via technical media? An individual may formally have 2,000 friends, but in fact none. Or will the principle of spiritual renaissance return? Looking for a kindred spirit, finding it first inside the family, i.e. in the closest circle and then in a broader circle in the water-circle-like way? Asians have discovered the need for spiritual renaissance. It is likely that something similar may happen in the "developed world". The question is how to create conditions and – most importantly – how to indicate people that face to face communication is irreplaceable, meaning how to show them what the basic principle of nonverbal systems from the perspective of human communication is.

Abstract

Considering certain issues, it should be emphasized that poverty is a global problem that cannot be solved by the efforts of individual countries alone. This study provides a factual assessment of human well-being, with a particular emphasis on poverty, inequality and vulnerability based on the most relevant and accessible data. Particular attention is paid to the causes and its scope. The problem of poverty is an obstacle that impedes the development of each individual, each country and the world as a whole. The implementation of the proposed Individual Poverty Plan can be a financial solution for poverty prevention and elimination in the long term. According to the New Paradigm of Poverty, the perception of poverty needs reconsideration as a stage of life. The New Paradigm suggests a comprehensive analysis of what causes poverty.

Keywords: poverty, poverty measurement, Gini index, inequality.

Introduction

The community and economic development face many different issues. One of the most significant is poverty. It often refers to individual failure, and all programs address poverty once it has already occurred. It is one of the most critical issues for all types of communities regardless of economic system development nature. Nevertheless, profile, scope, depth of poverty has undeniable interregional differences.

Evolution of poverty consists of the following key stages:

1) XVII – mid-XIX century - formation of ideas about nature and causes of poverty as part of social Darwinism, egalitarianism and the statistical sociological approach;

2) The end of XIX – the beginning of XX century – formation of the concept of minimum subsistence level, an absolute approach which was based, on the minimum set of goods and services necessary for maintaining physical subsistence and its productivity;

3) The period of 1960-1980 – developing the concept of deprivation (relative approach), social exclusion, and culture of poverty.

Based on the above stages, we can consider the following theories of poverty (fig. 1).

Fig. 1: Stages and main theories of poverty

There is no unified worldwide understanding of poverty despite the approaches to diversity in sociology. Interregional differences explained with the methodology of poverty measurement. Although the World Bank established an absolute poverty line of $1.90 per day, more developed countries apply a relative approach in its monetary and non-monetary expression.

Results

The UN General Assembly, in resolution 70/1 of September 25, 2015, identified the main goals in the field of sustainable development. The first goal is the complete and widespread eradication of poverty in the world in all its forms by 2030.

The problem of poverty and misery is one of the most urgent issues in the modern world, and it is most acute in developing countries, where the share of the poor often makes up 60–70% of the population. The World Bank's Poverty and Social Justice Database contains estimates for 168 countries, and over the past ten years, new estimates have been published for approximately 80 countries. At present, they are available from 1,500 annual data sets of observations in various countries — this is more than three times higher than in the early 2000s.

The statistics show that more than 19% of people live below the poverty line in New York City, 33,9% - in Ukraine, 19,7% - in Germany, 12,9% - in Russia, and the number of people living on the edge is only growing. Every member of all communities is likely to face poverty at least once per lifetime.

Based on the data of the Economist analytical magazine, a forecast of the level of poverty in stable and unstable countries was determined, which should have decreased to 9.9% by 2020, and by 5.4% by 2030, which makes 386 million people living in poverty. but it’s more a myth than reality because per capita consumption and consumption distribution in each country can change, and most likely the current level of 15.2% of poverty will remain the same in 2030 (figure 2).

Fig. 1: The number of poor people in stable and unstable countries, million people

There is no single approach to the definition of poverty in the countries of the world. Hence, each government determines the poverty of its population by its standards, and it is simply incorrect to compare poverty indicators calculated by different methods. The same citizen, depending on the selected evaluation criteria, may turn out to be under the poverty line for one, and not for others.

Currently, poverty measures do not include any precautions methods for poverty awareness. The perception of poverty needs reconsideration as a stage of life, according to the New Paradigm of Poverty. The implementation of an Individual Poverty Plan can be a financial solution for poverty prevention and elimination in the long term.

The traditional description of community is people united on the same territory, or same religious or economic principles not prevalent in the bigger society (Sanders, 1970). The modern description does

not have a place limit and relates to the social relations that bond people (Bradshaw, 2008). Community development includes economic, social, and environmental pillars. The economic part is the most significant, but economic growth will not always have a positive outcome. Subsequently, developers conclude that increasing wealth and jobs may lead to inequality and destabilize the community (Leigh & Blakeley, 2013). In the process of global development, the population-level grew, but the economic gain did not match the trend in the long run (Firebaugh, 2003). The increase in the number of people did not boost the living standards in a long perspective and resulted in global income inequality and increasing poverty around the world. Inequality includes a different aspect of life, from money to power. It is common to define three forms of inequality – economic, political, and social (Rothman, 2005). Economic inequality reflects a difference in wealth and material resources, social – status and level of well-being, and political is power and authority. Therefore, the people from the lowest social class became the poor, and the poverty levels grew over time.

The Gini coefficient is a statistical indicator of the degree of stratification of society relative to any economic feature (annual income, property, real estate) used in countries with developed economies. The level of annual income is taken as a calculated indicator.

The distribution of population between countries allows for accurate and uneven distribution of income in society.

The value of the Gini coefficient ranges from 0 to 1. The more its value deviates from zero and approaches unity, the more income is concentrated in the hands of individual population groups, and the higher the level of social inequality in the state, and vice versa. The Gini Index is a percentage coefficient. The dynamics of the Gini index by country presented in Table 1.

Table 1: Ginit Index Dynamics by World Countries, %

Country	Years					
	1990	2000	2010	2014	2015	2016
Brazil	60,50	-	-	51,50	51,30	-
USA	-	40,40	40,40	-	-	41,50
Russia	-	37,10	39,50	39,90	37,70	-
Belarus	-	31,20	28,60	27,20	26,70	27,00
Canada	-	33,30	33,60	-	-	-
Germany	-	28,80	30,20	-	31,70	-
Turkey	-	-	38,80	41,20	42,90	41,90
Kazakhstan	-	-	28,00	27,00	26,90	-
UK	-	-	34,40	34,00	33,20	-
Spain	-	-	35,20	36,10	36,20	-
France	-	-	33,70	32,30	32,70	-
Austria	-	-	30,30	30,50	30,50	-
Ukraine	-	-	24,80	24,00	25,50	25,00
Slovenia	-	-	24,90	25,70	25,40	-
Denmark	-	-	27,20	28,40	28,20	-
Czech Republic	-	-	26,60	25,90	25,90	-
Uruguay	-	-	44,50	40,10	40,20	39,70
Vietnam	-	-	39,30	34,80	-	35,30

In the 2016 Human Development Report, the highest Gini indexes were found in countries such as South Africa - 63.4%, Haiti - 60.80% and Botswana - 60.3%. Minimum rates - in Sweden - 23.00% in 2005.

Data on the Gini index in the countries of the world are presented taking into account the available statistical information and survey data, which were conducted in several countries.

Among the countries represented in the table, countries with the highest Gini index on average for the period from 2000 to 2016 can be distinguished. The maximum indicator is noted in Brazil, but in dynamics, it shows a decrease of 9.2 percentage points, although Brazil remains among the countries with the highest level of income inequality. In 2000, the countries with the highest Gini index among the countries surveyed were the United States and the Russian Federation — 40.40 and 37.10%, respectively. In dynamics over 15 years, these indicators have changed slightly.

In 2010, Uruguay, 44.50%, Vietnam, 39.30%, and Turkey, 38.80%, can also be classified as countries with a high level of income inequality. The Gini index in Turkey is increasing and by 2016 is 41.90%.
Among the countries surveyed, the minimum Gini index was observed in Slovenia - 25.4%, Ukraine - 25.50%, and the Czech Republic - 25.9%.

The old or new paradigm describes poverty perception. The old paradigm concludes that individual failure is the cause of poverty (Rank, 2004). This view is tight to one-dimension only and does not consider the influence of other factors. The ideology behind it describes the economic system as the main generator of well-being and prosperity of opportunities. Besides, social welfare can encourage people to take benefit of government help and drop the school. The economic development resulted in the need for specially skilled workers, and those without special education becomes less valuable on the labor market (Rank, 2004). This concept is widely used in modern politics and government measures of poverty. The New York City issues a yearly report about poverty levels. In 2017, statistics showed that people under 18 and over 65, and females tend to be the poorest. From the ethnicity and race side, the highest level of poverty belongs to Asians and Hispanics, following by Black. The report shows the relation to the Old Paradigm because poverty analysis describes different individual characteristics.

As for Ukraine, there has been a decline in the poverty rate as measured by the state statistics Service, from 51,1 percent in 2016 to 34,9 percent in 2017. At the same time, the share of poor people covered by social support programs increased from 70,3 percent in 2016 to 73,6 percent in 2017. However, such aggregate statistics do not reflect the gendered profile of poverty in Ukraine. Single female-headed households and elderly women constitute the highest risk for poverty among families with many children. Moreover, some ethnic groups, e.g. Roma, experience severe discrimination and barriers in accessing services. Ukraine continues to face mounting problems due to its pension system. The deficit of the Pension Fund is currently at 6,4 percent of GDP. At the same time, the amount of payment distributed per person is extremely low. Around 12 million Ukrainian pensioners receive an average of less than USD 70 a month nationwide. The situation is further compounded for Ukrainians living in the non-government-controlled area (NGCA) due to the linkage between IDP registration and pension eligibility. As of August 2014, the number of registered pensioners in NGCA was 1,278,200 people. However, as of July 2018, it was reported by the Pension Fund that only 477,000 pensioners with NGCA residence registration received pensions. The Ministry of Education and Science (MoES) started implementing the 'New Ukrainian School' action plan, which aims to equip students with the knowledge needed to think critically, set and achieve goals, work with teams, and in multicultural settings. This new way of learning will be applied to all first-graders in the 2018/2019 academic year. There is currently a discrepancy between skills acquired through education vis-à-vis those sought after in the labor market. A survey conducted by the World Bank shows that 40 percent of firms in the key sectors of agriculture, food processing, information technology, and renewable energy report a significant gap between the skillset of their employees and those needed to achieve business objectives. In 2018, the health care system underwent major reforms. In March 2018, the National Health Service of Ukraine (NHSU) was established.

Measures intended to decrease the scope of poverty have a specific methodological base developed and adopted throughout the long-term studying of the problem.

Thereby the current situation in the world requires the involvement of government with specific social policies intended to alleviate poverty.

Considering this problem, it is worth saying that the modern world gives significant attention to its study. For instance, experts of the World Economic Forum, which takes place in Davos annually, calculated social mobility index which shows how citizens are attached to their socio-economic status – if those who were born in low-educated families or poor families can secure a better life for themselves.

Nine key socio-economic indicators were used for calculations: healthcare quality; accessibility of education; quality and equality of education; the possibility of continuous learning; availability of technology; employment opportunities; fair pay; working conditions; social safety; efficiency and transparency of public institutions. Moreover, each indicator assigns a score from 0 to 100. The more the country gets, the higher it stands in the rating.

The top ten were European countries: Denmark - 85.2; Norway - 83.6; Finland - 83.6; Sweden - 83.5; Iceland - 82.7; Netherlands - 82.4; Switzerland - 82.1; Austria - 80.1; Belgium - 80.1 and Luxembourg - 79.8. The United States were ranked #27.

Ukraine was ranked #46 with 61.2 points that brought her to the second part of the chart. The country is behind Romania (#42), Russia (#39), and Poland (#30). However, Ukraine is higher than in Greece (#48), Georgia (#53), and Turkey (#64).

Thus, the New Paradigm suggests a comprehensive analysis of what causes poverty. Multiple factors affect poverty, from structural failure to quality of life. The new paradigm begins with the consciousness of an insufficient number of jobs availability. The shortage of jobs leads to inequality because the system is granting jobs in priority to those who have more skills or better education. The lack of labor market increases the poverty risk for vulnerable groups. The quality of life plays a significant role in the ability of people to make a conscious decision. The poverty measures need to consider the condition and quality of life. Poverty impacts physical and mental health and can extend the time for an individual to find the job. The increase in crime exposure is growing in correlation to poverty. Families on the edge of poverty become victims of crime more often than those from higher social class (Rothman, 2005). The final factor considered under the New Paradigm is poverty as a stage of life. The risk that anyone can encounter is a poverty characteristic (Rank, 2004). Global economic development tends to change the need for certain professions, and implementing technology increases the vulnerability of individuals. That increases inequality and stratification. As a result, there is a need to create awareness through different programs, like poverty risk assessment and preparing financially and mentally.

The importance of estimating poverty as a risk can help prevent poverty. If an individual is prepared to take the risk, it needs less effort to overcome this stage of life. No poverty measures reflect community culture, which is necessary to understand because every community has a unique culture that is formed historically and may react uniquely to government programs (Lyon & Driskell, 2012). Considering all factors, there is a need for implementing an instrument that will prepare individuals to face poverty at any stage without taking into account their skills or knowledge. The financial part can be the most challenging for anyone. So, from banking experience, every fifth person does not have savings. The Individual Poverty Plan can help to support poverty when it is approaching. The implementation of the Individual Poverty Plan (IPP) can help to prepare people to face the risk of poverty and eliminate it in the long term.

The IPP is a financial product that requires the participation of private businesses, government, and individuals. Banks will initiate IPP in numerous communities throughout the retail channels. The presence of banks and insurance companies has a large footprint across the nation. The financial corporations are significant because they have access to those who have an account or insurance already and can encourage and educate about poverty. The role of government is in providing tax benefits for individuals willing to take advantage of IPP. Numerous investment products offer tax-

deferred options or pre-tax. Similar to Individual Retirement Plan (IRA), the Individual poverty plan needs to have a limit for the year equal to the threshold in the state of residence and determination the risk of poverty. The targeted segment is households that are close to the poverty line. For example, the 2017 New York City Poverty report declared more than 40% in this category. It creates an urgent need for an effective solution. In the case of a poverty event, the individual allowed to use funds to cover living expenses while looking for a job or starting the business. If poverty did not occur, the funds would transfer to the Retirement fund or be distributed towards a down payment for a house purchase. Government support has also to address the issue through poverty awareness programs, creating a sense of urgency for everyone. The awareness around poverty will motivate individuals to obtain the Individual Poverty Plan. The benefits for households include but not limited: emergency savings funds, pre-tax contribution, lower poverty risk, poverty awareness, and a potential increase in retirement funds.

Conclusions

Community development faces many different issues, and some of them are easier to overcome than others. While the modern approach does not limit to the place, we propose community as people united by the same needs and most likely share the same location. The primary goal of development is the satisfaction of current needs, and most importantly - address future needs. In our opinion, one of the most significant issues to face is poverty. Some areas are more vulnerable because of historical inequality. For sustainable development, it is critical to be prepared and aware of poverty. It requires the change of poverty perception and incorporating new effective programs. The idea of implementing an Individual Poverty Plan is a financial solution that can help minimize the impact of poverty once it is approaching or in the early stages. It will encourage individuals to create an emergency fund. The IPP is based on the Rank`s New Paradigm of Poverty. Poverty addressed as a stage of life and supports basic life needs, allowing find a new job or start a business. The investment side of the plan meant for funds to grow. The accessibility of the program will promote equality, and the role of every actor is critical. The successful implementation of the program will result in preparing individuals to face this stage of life, minimize the risk of becoming poor, and in the long term - eliminate it.

Abstract

The article is devoted to the results of the research of small business development in Russia and Poland for 10 years. The data comes from the reports published by Polish Agency for Enterprise Development and the Russian SME Resource Centre (RCSME). The author analyzed the following indicators: the number of active SMEs, the amount of employees in SMEs and their contribution to Gross Domestic Product (GDP) both in Russian Federation and Republic of Poland. The concept of the ecosystem in terms of studying the changing processes considered in the article. SMEs have a key role in these processes. Recommendations for small and medium entrepreneurship development are given at the end of the article.

Keywords: Ecosystem, Small and Medium-Sized Enterprises, Gross Domestic Product, Innovation Models.

Introduction

The development of economic systems is now inextricably linked with international cooperation advantages, including the implementation of joint investments in the implementation of various interaction projects. The key strategic direction in these conditions should be the interaction of SMEs through the creation of new business models and processes based on ecosystem approach and through cross-border cooperation. The term "ecosystem" is quite complex and does not have a single definition. The fundamental idea of this concept is that enterprises build their strategies and create competitive advantages based on resource sharing, network externalities and spillover effects. Firms in this context of collaboration, recognize the holistic value in products and services for future customers, and create and capture value by actors. This collaboration involves producers, suppliers, distributors, financial institutions, research institutions, clusters, value networks, etc. The existence of an innovation ecosystem would provide platform to the organization to exchange products and services to the users of those

products and services. This requires the development of new theories and approaches that reflect real trends, one of which is ecosystem theory. Before moving on to the question of the company's development on ecosystem principles, let's consider the history of the establishment of small and medium-sized enterprises (SMEs) both in Russia and Poland.

The development of SMEs started only in the nineties of the XX century. The fall of communism released the entrepreneurship of the society, which was the trigger of the long process of economic transition. However, the process was not smoothly as the circumstances were changing, also for SMEs. One of the most important turbulence was the world economic crisis[1]. These facts encouraged the authors to make research about the development of small and medium-sized enterprises in Russian Federation and Republic of Poland in the years 1994-2016. They decided to analyze the following indicators: the number of active SMEs, the amount of employees in SMEs and their contribution to Gross Domestic Product (GDP).

The structure of the article is as follows. First, the literature review was done. Then the development of SMEs in Russian Federation and Republic of Poland was analyzed. The conclusion was presented at the end of the paper.

Definition of SMEs

According to Law 209-FZ, legal entities, individual entrepreneurs are deemed to be small or medium businesses if they meet three criteria regarding ownership structure, workforce and volume of revenue. Key components of SME classification in Russia are similar to those used in EU (figure 1):

1. Ownership structure: SME's stake held by one or several legal entities, which are not small or medium businesses, should not exceed 25%
2. Workforce: Number of employees should not exceed 250 people
3. Volume of revenue: Annual turnover should not exceed 25 euro mln.

These limits (regarding revenue only) are set by the Government of the Russian Federation once every five years.

Żmija (eds), *Expectations and challenges of modern economy and enterprises*: *problems – concepts – activities,* Cracow University of Economics, Department of Economics and Organization of Enterprises, Foundation of Cracow University of Economics. — Cracow 2016, pp. 117–124.

Figure 1:SME Segmentation

Source: European Commission, Small and medium-sized enterprises (SMEs): SME Definition; Federal law № 209-FZ "On small and medium business development in Russian Federation".

Many authors find the role of SMEs as significant in the economy. These enterprises are responsible for stimulation of economic growth, innovation and modernization of the economy, creation of new jobs, using of production factors or reduction of GDP fluctuations. Moreover, while economic transition, they also contribute to the creation of private ownership, employ human resources from the state sector, create economic infrastructure through the development of cooperation and subcontracting and the base for the development of large companies[2].

Nowadays, most of active entities in Poland are SMEs (over 99%). Furthermore, most of employees work in these companies (about 70%). SMEs have also significant contribution to GDP (a little more than 50%). The total number or registered operating SMEs in Russia as of January 2017 is 4.5 million, including micro-, small, medium-sized enterprises and individual entrepreneurs. They provide jobs for over 18 mln. people, which is 25% of total employment in Russia's economy. The core of the SME sector in Russia (94.3%) is composed of segment of individual entrepreneurs – 2.4 mln. or 53.3% of all SMEs - and micro enterprises – 1.9 mln. or 41% of all SMEs. Small enterprises account for 5.2% of all SMEs, while medium-sized enterprises make up 0.3% of all SMEs. Micro enterprises and individual entrepreneurs account for 55% of all jobs at the SME sector.

The development of SMEs is, however, connected with many factors for example the interest rates3 or policy of commercial banks4.

The research questions are as follows:

1. How the number of active SMEs was changing in the years 1994-2016?
2. How the number of employees in SMEs was changing in the years 1994-2016?
3. How the contribution of SMEs to GDP was changing in the years 1995-2016?

The data comes from the reports published by Polish Agency for Enterprise Development and the Russian SME Resource Centre (RCSME).

Development of SMEs in Poland

The growth of small and medium-sized enterprises was very fast in the nineties of the XX century – see figure 2. The number of active entities reached almost 1.8 million in 1999. However, this amount was decreasing at the beginning of the XXI century, probably because of the slowdown of the Polish GDP growth. The number remained flat in the following years. In 2005 the amount of active SMEs started to rise again and reached almost 1.9 million. Unfortunately, the world economic crisis hit these enterprises in 2009. Nevertheless, their number started to increase again in 2010 and did not stop until 2016.

Figure 2: The number of active SMEs in Poland in the years 1994-2016 (in thousands)

Figure 3 presents the number of employees in SMEs. There was stable growth from the beginning of analyzed time span untill 2002. After the fall in 2003, the amount of employees in theses companies started to increase again. It peaked in 2008 – over 6.5 million of employees. However, there was a slight decrease in 2009 during the world economic crisis. Ever since, the number of employees in SMEs was quite stable in the following years.

[4] Duda J., Woźniak M., *Bank policies towards SME sector in Poland and selected countries worldwide, „Managerial Economics"* , vol. 19 no. 1, 2018, pp. 25–47.

Figure 3: The number of employees in SMEs in Poland in the years 1994-2016 (in thousands)

Figure 4 presents the contribution of small and medium-sized companies to GDP. There was a significant increase (about 19%) between 1995 and 1998. The contribution of SMEs to GDP stabilized in the following years and amount 49%. Then, this number started to fall but not sharply. The low point was in 2008 – about 48%. After that, it started to rise slightly untill 2013. Ever since, it remaind flat – just over 50% of GDP.

Figure 4: The contribution of SMEs in Polish GDP in the years 1994-2016 (in %)

Development of SMEs in Russia

In 2010-2014 the number of microenterprises steadily grew, although the growth rates in recent two years have decreased (figure 5). In fact, the number of micro- and small businesses has noticeably increased by 28% within 4 years, from 1644.3 thousand in 2010 to 2103.8 thousand in 2014. In 2014, the total number of microenterprises increased almost by 1/3, as compared to 2010, and attained 1868.2 thousand.

However, the number of new microenterprises in 2014 was only 40 thousand, as compared to 2013, or 2.2%.

The growth in number of micro- and small enterprises in recent 5 years has been accompanied by a lowering in number of medium-sized businesses.

Figure 5. The number of active SMEs and employees in Russia in 2010-2017 (in thousands)

The five years, 2010-2014, demonstrated a noticeable 34% increase in employment at microenterprises, from 3.3 mln. people in 2010 to 4.4 mln. people in 2014. The total employment at micro- and small enterprises grew within four years by 10.2% - from 9.7 mln people in 2010 to 10.8 mln people in 2014. In the segment of medium businesses the total employment reduced from 2.4 mln people in 2010 down to 1.6 mln people in 2014, or by 35%.

The number of SMEs in Russia has grown on 1.3% in 2017, with all of that growth coming from microenterprises. The study found that the number of small enterprises actually shrank by 1.6%, while the number of medium-sized businesses fell by 3.4%.

The total sales revenues of micro- and small enterprises steadily grew within 5 years and attained 26392.2 bln RUR in 2017, which is 40% higher than that in 2010 or 18933.8 bln RUR. The total sales revenues of medium-sized enterprises decreased within 7 years from 7416.2 bln.RUR. in 2010 till 5027.8 bln RUR in 2017, or by 32%.

Rosstat published information about the share of the small and medium-sized businesses (SMEs) in Russia, RBC reports. According to data for 2017, the share of SMEs in the economy is 21.9%[5]. In monetary terms, the share of small and medium businesses amounted to more than 20 trillion rubles.

[5] Russia in figures, 2017. Federal State Statistics Service. http://www.gks.ru/free_doc/doc_2017/rusfig/rus17e.pdf

Figure 6: The contribution of SMEs in Russian GDP in the years 2010-2017 (in %)

Russia's Economic Development Ministry expects the share of small and medium-sized enterprises (SMEs) in the country's GDP structure to double by 2030 despite the economic downturn. Since 2005 the Ministry of Economic Development has run the federal program of SME financial support. The main priorities of this program are: innovative companies, mid-sized companies, assistance in the development of leasing for small entities, support for enterpreneurs by grants, creation of business incubators, individual parks and enterpreneurship.

Innovation Ecosystems for SMEs

Moving towards a collaborative innovation requires an internal change. Innovation models could be understood from the collaborative perspective. These models are directly related to the level of openness. Starting with the collaborative models by Barrett[6], innovation models are divided in the following categories:

- In the first model, called Ad hoc, there is usually an absence of policies to engage partners. In other words, there is no platform supporting the collaboration. The control is just on the focal form, and there is no interaction among 3rd parties
- The second model, hub-and-spoke is a closed platform, where there is an central platform for collaboration, but there is no interaction among third parties.
- The third model is a network model. The principles are the same as in the second model. The difference with the previous model is that the enables interactions between actors in the network.
- The forth model is an open platform model. In this model, all the involved interact with each other within an ecosystem. The control is distributed, the platform is shared among participants in the network, and interactions among thirds parties are common. The open platform model is the one with the biggest level of openness.

[6] Barrett et al., 2011. M. Barrett, C. Velu, R. Kohli, T. Salge and D. Simoes-Brown. Making the Transition to Collaborative Innovation: Issues of Readiness, Trust and Governance. Nesta, (May), 1–12, 2011.

An important trend in the evolution of innovation processes is the transition An important trend in the evolution of innovation processes is the transition to a model of open innovation, based on the use of internal and external sources of innovation, the transition to non-linear models of the organization of the innovation process. All these issues are important for the formation of an innovation ecosystem in the metallurgical industry of Russia. According to open innovation mode and business ecosystem structure, open innovation process is embedded into business ecosystem framework. Then, a theory model of open innovation based on business ecosystem is built which is shown below (figure 7).

Figure 7: The open innovation based on business ecosystem

Source: ***Leveraging the Innovation Ecosystem for Business Advantage: A Cross-Border Study***

This model contains multiple main innovators such as producers, users, suppliers, partners and external environment, etc. It reflects the open innovation process of business ecosystem formed by many subjects. Open innovation breaks organization boundary, pays attention to the use of internal and external resources, and stresses labor division and cooperation. Because open innovation is implemented in relatively open environment and is a loose, flexible innovative mode. Although more new ideas and innovative thinking can be brought in, the difficulty and cost of management are also increased at the same time. In open innovation mode, enterprise can obtain necessary technology through outside world to reduce costs and improve product quality so that competitiveness can be improved. However, if it excessively relies on suppliers and partners, the technical health state itself may be affected.

In this regard, the triple helix is considered a universal model of the collaboration, since it forms the mechanism of self-development of complex non-linear systems of any level, based on the resonant interaction of three key subsystems.

Displacing the traditional management mechanism involving a hierarchical center, this model determines the institutional structure of both innovation clusters and the entire innovation economy, contributing to its clustering. Due to the continuous interaction of the state, science and business, the system generates so-called mutual information (new knowledge), which is distributed in the course of communication between all economic agents, which gives the system integrity and dynamic stability. An innovation ecosystem is said to be thriving and healthy when the resources invested in the research economy (either through private, government, or direct business investment) are subsequently replenished by innovation induced profit increases in the commercial economy. At that point, the two economies (research and commercial) exist in balanced equilibrium and the innovation ecosystem is deemed to be healthy.

Conclusion

The development of small and medium-sized enterprises both in Poland and Russia was significantly in the nineties of the XX century, taking into account all three analyzed indicators: the number of active companies, the number of employees in these enterprises and their contribution to GDP. However, this process stabilized from the beginning of the XXI century. The world economic crisis caused the fall in the amount of active entities and the number of employees in SMEs 2009. For the purposes of small and medium entrepreneurship development, increase of SME share in GDP, rise in employment and development of domestic competition, the State should provides support for SMEs. This support can take different forms: financial support, special tax regimes, renting or acquisition of property under favorable conditioning, provision of services or delivery of goods for state needs ect.
Recommendations for creating successful ecosystems SMEs:

• Increase cross-border collaboration;
• Build innovation centres that facilitate the innovations of others;
• Create places where young people feel they have ‘cultural self-confidence’ and where they can meet face to face, as experts say that is when successful innovations emerge;
• Ensure a friendly regulatory environment;
• Lower barriers to innovation by encouraging ‘balanced risk-taking’ and providing financial incentives to entrepreneurialism;
• Recognize which start-ups are more likely to succeed and channel the resources to them instead of trying to support as many start-ups as possible.
• Combine financing with commercial mentorship;
• Support the government in creating a modern workforce for the future.

Abstract

The rotation of goods in a warehouse facility is one of the basic elements for assessing the functioning of warehouse management. This aspect is most verified in the process of goods release from the warehouse. However, high goods turnover is conducive to the occurrence of distortions, therefore risk management is necessary. The purpose of the paper is to present a model for implementing risk management at the stage of stock release from the warehouse using process decomposition and maintaining an appropriate level of product rotation.
The method of decomposing the process of goods release from the warehouse allows to transform the stage of stock release from the warehouse, by separating it into individual subprocesses. The elements supporting the model development are the disposable time scheme and determination of the average enterprise work intensity. Entrepreneurs' awareness of the expected volume of releases from a warehouse will enable comprehensive risk management, without reducing the number of pallets issued from the warehouse.

Keywords: Decomposition, Release Process, Risk Management

Introduction

Comprehensive risk management is necessary for every logistics company, however, the fear of reducing the number of activities performed by employees discourages the implementation of risk management methods. The purpose of the article is to present a model for implementing risk management at the stage of stock release from the warehouse using decomposition of the process and maintaining an appropriate level of goods rotation.

The characteristics of the process decomposition method allows to transform the stage of stock release from the warehouse, by separating it into individual subprocesses to implement risk factor management. The elements supporting the model development are the disposable time scheme and determination of the average enterprise work intensity. The correct implementation of the risk management procedure makes it possible to maintain an appropriate level of product rotation in the warehouse, while maintaining the quality of work performed and executing shipments on schedule.

Risk management in the process of releasing goods from the warehouse

The entrepreneur's willingness to succeed is inherent in the need to contact risk, which is why proper and effective interference management is needed [1]. Risk management includes planned and purposeful analysis and control of risk occurring in the enterprise. An important link is the combination of all elements for comprehensive risk management in warehouse administration [7] [8]. Warehouses are divided into four zones related to the implementation of the storage process: receipts, storage,

picking and deliveries [9]. The most important task of warehouse management is the constant flow of movable goods to final recipients [3]. The stage of goods release from the warehouse is the last phase of the warehouse process. After this stage, the goods are transported from the storage or picking zone to the goods release zone, as ordered by the next link in the supply chain. An important element is the control of the released stock. It involves checking the goods issued with documentation. If the result of the check is positive, the goods can be loaded on an external means of transport [5] [11]. There are two types of goods release [6]:

- internal release – delivery of the goods within the same entity,
- external release – transport of inventory to the next link in the supply chain.

One of the methods to implement risk management is process decomposition. In logistics, this method allows for change of the composition of components and processes [4]. At the storage stage, decomposition consists in identifying elements that can be extracted by transforming material streams and using existing resources [2]. It makes it possible to add new elements to organization's activities, keeping in mind the disposable time and the intensity of work involved.

Research Entities

The research was carried out in 16 enterprises providing warehouse services in Poland. Among these enterprises, 10 entities provide warehouse outsourcing services (marked with the letters A-J), and 6 entities have an ownership warehouse (marked with the numbers 1-6). They stock goods belonging Fast Moving Consumer Goods industry which is a fast-moving industry. In terms of finished products, analyzed warehouses mainly store food, cosmetics, detergents, cigarettes and alcohol [10]. All research entities meet the following elements:

- mechanized warehouses,
- number of storage places 10,000 - 25,000 pallets,
- distribution and / or industrial warehouses,
- inventory storage method - shelf method.

At research facilities a logistic audit was carried related to the operation of warehouse management, on the basis of which the research was conducted.

Intensity of Labor Consumption

The intensity of labor consumption at the stage of goods release from the warehouse is very important to determine the time needed to complete the order and ship the goods on schedule. In order to determine the average labor intensity of research entities, the number of pallets issued within one shift (8h) was determined, based on the following formula:

$$p = \frac{s}{e * 8}$$

Equation 1 : Formula for average labor consumption

Source: Own study

where:

p - quantity of pallets in one work shifts
s - average spended goods in one week of one work shifts
e – employee

A table below presents the average number of pallets issued per shift in a given entity.

Table 1 : The average number of pallets issued per shift

Enterprise	A	B	C	D	E	F	G	H
Number of pallets issued	387	782	983	650	1052	972	481	658
Enterprise	I	J	1	2	3	4	5	6
Number of pallets issued	624	1173	363	825	1028	544	671	937
The average number of pallets issued per shift								**758,13**

Source: Own study based on data from enterprises

The average intensity of labor consumption in the process of goods release from the warehouse in the entities surveyed is approximately 758 pallets. It does not mean that forklift operators should dispatch 95 pallets from the warehouse within 1 hour, as they are required to perform additional tasks, including warehouse facility inspections, preparation of shipping documentation, or take a break during work performance. The diagram below shows the element that facilitates the optimal use of the time of warehouse operators at a given work intensity.

Figure 1: The disposable time diagram

Source: Own study

The labor intensity of 100% means that the potential of employees during the release of goods from the warehouse is at the maximum level, i.e. it can exceed the rate of 95 pallets/hour. On the other hand, the 50% labor intensity indicator indicates a reduced number of pallets issued from the warehouse, due to additional manipulation activities carried out by warehouse operators.

Risk management is an inseparable element of modern warehouse management. More and more companies are aware of the risk but are afraid of reducing product turnover by implementing a risk management procedure. There are numerous risk factors in the goods release proces. A table below (Table 2) presents the distortions.

Table 2: Risk factors in the process of goods release from the warehouse

Risk factors for the goods release process
1. Release of wrong goods from the warehouse,
2. Release of an incorrect quantity of items from the warehouse,
3. Picking the goods from the wrong place from the warehouse,
4. Damage to products when loading goods onto an external means of transport,
5. Issuing improperly prepared shipping documentation,
6. Goods release with a time delay.

Source: Own study based on data from enterprises

In the case of the entities surveyed, there is a probability of occurrence of all risk factors, which is why implementing risk management is so important. The decomposition of the process of goods release from the warehouse consists in dividing the goods release stage into subprocesses to implement the

risk management procedure while maintaining an appropriate level of product rotation. A model below presents the method of organizing the process of goods release from the warehouse.

Figure 2 : Model of the organization of the goods release process from the risk managing warehouse

Source: Own study

The model of work organization in a warehouse facility consists of 6 stages. The most important element is the decomposition of the release stage into relevant subprocesses, taking into account the number of employees and technical resources. Based on this data, research entities can determine the average workload on a given day and put the relevant data on the disposable time scheme. The above elements will enable the implementation of risk management in the process of goods release from the warehouse, followed by constant measurement and assessment of performed activities.

Summary

The article presents a model for implementing risk management at the stage of stock release from the warehouse using process decomposition and maintaining an appropriate level of goods rotation. The model includes the involvement of existing technical and human resources in the researched entities. The decomposition of the process of releasing goods from the warehouse allows for transformation of the composition of the process, by dividing this stage into individual subprocesses for the purpose of comprehensive management of risk factors and maintaining an appropriate level of the release of goods from the warehouse. Awareness of disposable time, intensity of labor consumption and the need to manage risk factors enables correct and scheduled release of goods from the warehouse.

Abstract

Nigeria, based on well-regulated financial standards, has a relatively highly developed financial system due to the sophistication level of its financial intermediaries and markets. However, there is need for improvement as well as some level of uncertainty about whether finance for growth interacts with credit to the private sector to significantly influence channelling funds for investible purposes, given Nigeria's unique characteristics. This article examines the role of credit towards private sector on finance for in Nigeria, with specific insight and implications for Nigeria over the period 1980-2018. For this purpose, the study utilises data from secondary sources from the central bank of Nigeria annual reports. The Autoregressive distributed lag (ARDL) and cointegration method of estimation are used to analyse the time-series data. The results show that among the finance for growth variables, stock market capitalisation and remittance inflows significantly and positively affect credit to the private sector in Nigeria. This study recommends policies that will further increase credit stock market capitalisation and remittance inflow be trailed vigorously by the government to encourage financial intermediation, which will assist in channelling funds for investible purposes and thus cause financial development in Nigeria.

Keywords*:* Financial Development; Credit; Economic Growth; Nigeria.

Introduction

Nigeria, based on well-regulated financial standards and best global practices, has one of the profoundly evolved monetary frameworks in Africa. This can be attested by the very high turn of events and modernity of its money related mediators and markets, just as by the size, profundity, and access to its monetary administrations (Ejemeyovwi and Osabuohien, 2018). Like some other financial framework, Nigeria's financial framework comprises of two exceptionally created portions – both the banking section and the market fragment. The bank-based share centre stage, however, with banks providing loans to private sectors for intended investment purposes, is therefore referred to as the "bank-based financial system" in Nigeria. The uniqueness of Nigeria's financial related framework can likewise be clarified by the nature and lop-sidedness of its budgetary foundations' administrative structure, just as by the legitimate system that oversees payment activities. Moreover, dissimilar to most African nations where just a couple of banks command the market; Nigeria presently has twenty-two dynamic commercial banks in the country (Central Bank of Nigeria-CBN, 2019).

The CBN has embarked on a financial sector deregulation exercise in the financial markets and banking institutions with series of financial reforms in order to keep up with the increasing demand for innovation in the world. These reforms comprised efforts to reduce financial repression, rehabilitate the financial infrastructure, reinforce the regulatory and supervisory environments also the legal framework, rejuvenation of the financial structure, that is, the banks and stock markets clearing and settlement transactions and general restoration of soundness in the banks. The recent emergence of a well-regulated financial system in Nigeria can be attributed to these reforms. The increased availability of Automated Teller Machine (ATM) in the banks shows portrays the transformation of the Nigerian banking sector. Nigerian Inter-bank Settle System (NIBSS), revealed in 2019 quarter I, that the total number of Automated Teller Machines (ATMs) in Nigeria is 18,321. While the total number of transactions performed is 650.06 million, the transaction value is N4.76 trillion. The record shows that 711,299,990 volume of transactions valued at N40.48 trillion took place in the first quarter of 2019. Credit extension towards the private sector has also been growing tremendously over the fiscal years. In the second quarter of 2019, the Nigerian banking sector has N15.3 trillion as the total value of credit towards the private sector (NBS, 2019). Similarly, the reform procedures correspondingly gave room for the increment in stock market performances; with Market Capitalisation (MC), growing by 15.37 per cent to N13.62 trillion as at quarter three (Q3) 2019, from N11.72 trillion at end-December 2018. Though, all-share index (ASI) declined by 11.62 per cent to 27,779.00 index points, as at quarter three (Q3) 2019 2019, from 31,430.50 index points as at quarter four (Q4) 2018 (CBN, 2019).

This study made use of the evolving demand method to finance – growth link grilling through the examination of the role of private sector credit in financing for growth. More specifically, how private sector financing interacts with growth finance to have a significant impact on the channelling of funds for investment purposes. We battle that unwinding the job of credit to the private part in the money related development connection is a researchable subject on account of the capacity of the banking sector to move financial capital accurately to net investors from net savers in an economy. The financial system in Nigeria is also highly developed and ranked among Africa's top financial sectors with its banking regulations. (IMF, 2018), given these financial successes, it is interesting to know whether there is any interaction between finance for growth and credit availability by the financial framework in Nigeria potentially has any noteworthy development outcomes.

In entirety, this examination endeavours to address first, regardless of whether there is a critical nexus between credit to private division and finance for growth. Second, research if the associations advance or weaken banks' capacity to move financial assets from net savers in an economy to net investors. Third, examine if credits requested by private segments from the banking segment moderate the finance-growth nexus. These three fundamental issues are examined with measurable notices from the national bank of Nigeria's yearly information traversing 1980-2018. Rather than a multi-nation investigation, we explain our choice to concentrate on a solitary nation concentrate on Al-Yousif's (2002) proposal that fund development nexus cannot be summed up across countries because financial arrangements are nation explicit. Their presentation relies upon the effectiveness of the organisations that execute them. The rest of the area of the paper is organised as follows; Section 2 tends to the assessment of literature while Section 3 presents the methodology and data utilised in the investigation, Section 4 contains the analytical conclusions and discussions, while the last segment finishes up with some policy options.

Review of Related Literature

Aljebrin (2018) examined the effect of private-segment bank advances on Saudi Arabia's economic development by applying the FMOLS strategy for the period 1990-2016. The investigation presumed that the drawn-out effect of household bank credit on financial development was both positive and critical. Ben et al. (2014) utilised the Autoregressive Distributed Lag (ADRL) model to investigate the connection between domestic credits and Tunisian economic development. The investigation reported that the effect of bank credit on economic development was positive and significant. Their discoveries showed that an expansion in private credit of 1% added to an ascent in genuine GDP per capita of 3.36%. Odhiambo (2008) analysed the causal course between monetary turn of events and financial development in Kenya by inspecting the effect of swelling on the money related

development nexus. The experimental outcomes uncovered that the monetary development of Granger is causing money related advancement in Kenya regardless of whether the causality is evaluated in a bivariate structure or a triradiate setting. The examiner reasoned that the development of the money related area in Kenya is, to a great extent dependent on, as opposed to gracefully, interest for budgetary administrations. Different discoveries show that Granger's monetary development is causing expansion, while Granger's swelling is causing money related improvement in Kenya. The discoveries apply independently of how the causality is estimated in the short run or over the long haul.

Adeleye, Osabuohien, Bowale, Matthew and Odutan (2018) utilised yearly information from 1980 to 2016 to analyse the impact of the money related changes using a credit card advancement in Nigeria. The examination work is centred around the hypothetical premise of the McKinnon-Shaw theory concerning the significance of money related changes in a slacking economy. Breaking down the information with the portrayal of mistake revision with autoregressive dispersed slack (ARDL) and jumping testing methods, the examination that there is expanded money related intermediation at a higher genuine loan cost as prove by credit advancement. Different outcomes detailed by the investigation are that reserve funds in the money related division, swelling rate, and per capita GDP are away from indicators of credit development and genuine loan fee (the Financial Reform Indicator), while short-run connections are constrained markers. What's more, the investigation shows that there is a drawn-out co-incorporation connection between local credit and different covariates, just as between the genuine loan fee and its regressors. This is similar to the submission made by Karakara and Osabuohien (2019) in the case of Burkina Faso and Ghana based on survey data.

Bongini et al. (2017) analysed the effect of bank advances on the monetary improvement of the nations of Central, Eastern, and South-Eastern Europe utilising bank advances as a pointer of money related achievement. The examination utilised the GMM approach for the investigation of the time arrangement 1995–2014. Gauge results demonstrated that bank credit is boosting financial development. Sufian, Kamarudin, and Nassir (2016) took a gander at the determinants of productivity in the Malaysian financial part, considering the effect that bank start would have on viability. Sufian et al (2016) considered six bank-explicit factors in the relapse model as a productivity measure, including the proportion of advance misfortunes over all-out stores, non-premium salary over all-out resources, non-premium expenses over all-out resources, net renting over complete resources, all-out resource log and investor value book valuation as a level of complete resources. The specialists utilised the advance misfortune proviso as an intermediary measure for credit hazard, non-premium benefit as an intermediary measure to broaden into non-conventional activities. In contrast, the non-premium cost was utilised to give subtleties on how the banks' operational expenses shift.

Osman (2014) investigates the impact of Private Sector Credit on Saudi Arabia Economic Growth (GDP) using Auto-Regressive Distributed Lag (ARDL) and cointegration techniques. The author contends that monetary establishments assume a crucial job in sifting data through screening loan specialists and topsy-turvy data. In this manner, their improved productivity is of fundamental significance in guaranteeing that Saudi Arabia's private segment acknowledges altered for unbalanced information. Comparative discoveries have been recorded from inquiring about directed by Al-Malkawi and Abdullah (2011) on the connection between monetary soundness and financial development in the UAE. To break down this organisation, this exploration utilised the ARDL strategy for cointegration and two measures. The examination distinguished a significant negative connection between credit-drove monetary creation by the private part and financial development. Fapetu and Obalade (2015) investigated the impact of the sectoral designation of store cash support credits and advances on financial improvement utilising a norm, least-square procedure. Results demonstrated that even the advantage doled out to approach, labourers, and masters had considerable positive supporters of the financial turn of events. In any case, it has been revealed that bank credits don not ordinarily make a noteworthy commitment to the monetary turn of events.

Summarily, the above review of related literature presumes that the finance-nexus issues are still contentious. Apart from being widely debated, the empirical literature appeared to be weakened by non-country-specific studies and an examination of how accurately banks can give out credits for various investible purposes (Ejemeyovwi, Osabuohien, & Osabohien, 2018; Ejemeyovwi, Adiat, &

Ekong, 2019). This study is an attempt to satiate such openings in the finance-growth nexus literature.

Method

Model Specification

Following the finance literature, the study adopts the model of Law and Habibullah (2009):

$$CPS = \beta_0 + \beta_1 DGS_t + \beta_2 SMC_t + \beta_3 RINF_t + \epsilon_{it} \quad (1)$$

Equation (1) depicts the long-run relationship between CPS and FFG measures. However, before estimating the Long-run model, the existence of Long-run relationship must be established. Following Pesaran *et al.* (1997, 2007) and Ang & Mckibbin (2007), an ARDL specification of equation (1) is as specified below;

$$CPS_t = \sigma_0 + \sigma_1 CPS_{t-i} + \sigma_2 DGS_{t-i} + \sigma_3 SMC_{t-i} + \sigma_4 RINF_{t-1} + \sum_{i=0}^{P} \varphi_i \Delta CPS_{t-i} + \sum_{i=0}^{q_i} \gamma_i \, \Delta GDS_{t-i} + \sum_{i=0}^{q_2} \delta_i \, \Delta SMC_{t-i} + \sum_{i=0}^{q_3} \theta_i \Delta RINF_{t-i} + \varepsilon_{it} \quad (2)$$

Where:

ε_t represents white error noise term, Δ is the first difference operator, CPS_t is a credit to the private sector (% of GDP), GDS_t is gross domestic savings (% of GDP), SMC_t is stock market capitalisation (% of GDP), $RINF_t$ is of remittance inflow (% of GDP). This model will be determined to utilise the ordinary least squares (OLS) method, (p+1)(q1 + 1)(q2 + 1)(q3 + 1) whole of relapses to be processed to acquire the lag-lengths of the condition. The utilisation will decide between various lag-lengths of information standards like Akaike (AIC) or Schwarz (SC). The Schwarz Information Criterion (SC) is increasingly perfect to AIC because it grades to plot progressively closefisted conditions (Pesaran and Shin, 1995; Acaravci and Ozturk, 2012). ARDL limits F test statistics which is determined through burden balance to zero imperative on every single unsurprising coefficient of the lagged level factors. Consequently, the hypothesis (null) of no cointegration to the alternative hypothesis of long-run cointegration presence becomes:

$$H \quad 0: \beta_0 = \beta_1 = \beta_2 = \beta_3 = 0$$

$$H_1: \beta_0 \neq 0, \beta_1 \neq 0, \beta_2 \neq 0, \beta_3 \neq 0$$

The model (long-run) shows the balancing relationship between long-run and short-run error correction model used in measuring short-run dynamic effect(s) identified when cointegration is found using the ARDL restricted error correction model (RECM) towards determining the long-run and short-run elasticity coefficients. A typical model showing a long-run relationship is:

$$CPS_t = \beta_0 + \beta_1 DGS_t + \beta_2 LSMC_t + \beta_3 RINF_t + \varepsilon_{it} \quad (3)$$

Short-run relationship model (RECM, Restricted error correction model) stated as;

$$\Delta CPS_t = \alpha_0 + \sum_{i=0}^{P} \varphi_i \Delta CPS_{t-i} + \sum_{i=0}^{q_i} \gamma_i \, \Delta GDS_{t-i} + \sum_{i=0}^{q_2} \delta_i \, \Delta SMC_{t-i} + \sum_{i=0}^{q_3} \theta_i \Delta RINF_{t-i} + \omega ECT_{t-1} \quad (4)$$

Where:

ω displays a coefficient of the error/equilibrium correction term '*ECT*'. This demonstrates the velocity of the variable to collide to equilibrium and predicted a large value which is found to be negative. The ECTt-1 variable error/equilibrium correction term found in equation (4) is one lagged value estimating the ordinary least squares (OLS) residuals in the long-run model as situated in equation (4). Coefficients of the Long-run with approximate αi coefficients can also be determined using the (UECM) spelt in full as 'Unregulated Error Correction Model'. The approximate long-run

connection for any regressor is gotten by; (β1⁄β0) performing diagnostic tests would check the functional type misspecification and residual assumptions in the minimal error correction model, for example, no serial correlation, normality, and homoscedasticity.

Data

This analysis made use of annual time series data, which covered the duration of 38 years (1980 - 2018). The data are obtained mainly from Nigeria's Central Bank annual reports and annual statistical bulletins (Economic Surveys and Statistical Bulletins) for the same period. Table 1 lists the variables used in the analysis.

Table 1: Description of Variables

Variable	Descriptions	Sources
The stock market capitalisation to GDP ratio (SMC)	This alludes to the number of offers recorded separated by GDP. Market capitalisation (additionally alluded to as market esteem) is the price tag in addition to the measure of gave protections. Recorded household firms are the locally consolidated firms recorded toward the year's end on the stock trades of the nation.	CBN (2019)
Gross domestic savings as a share of GDP (DGS)	Gross domestic savings was measured as GDP less total consumption spending (total consumption).	CBN (2019)
Remittance inflows to GDP (RINF)	This includes workers' remittances and employee compensation, current migrant workers transfers, and salaries and wages earned by non-resident workers.	CBN (2019)
Liquid Liabilities (LL)	This alludes to the money related framework's fluid liabilities (cash in addition to request and enthusiasm bearing liabilities of banks and non-bank monetary delegates) partitioned by GDP likens. It is a standard pointer of the money related extension and hence of the monetary delegate segment's full scale (King and Levine, 1993a).	CBN (2019)
Private Credit (CPS)	Equals the amount of loans to the GDP split private sector by financial intermediaries. The financial intermediation indicator is more than just a calculation of the scale of the financial sector.	CBN (2019)

Results and Discussion

The results of unit root test are based on three (3) different approaches, namely: The Augmented Dickey-Fuller (ADF), Phillips-Perron (PP), and Dickey-Fuller GLS (DF-GLS), the results are presented in Table 2. The findings demonstrate that Commercial Central Bank Asset (CC), Private Sector Credit (CPS) and Domestic Savings (DGS) have unit roots [stationary] as the sequence is rejected at the point of 1 % and 5% conventional rates. These imply the series are integrated of order zero I (0).

On the other hand, the outcome clearly shows that the null hypotheses that the LL, RINF, and SMC have unit roots [are stationary] cannot be rejected at a level 1percent, and 10percent conventional under at least three test approaches. All together words, the outcomes clearly show that the null hypotheses that the LL, RINF, and SMC have unit roots [is stationary] can be rejected at the first contrast under the two alternatives. These infer that the arrangement is incorporated of request one that is, I (1). In this manner, to make every one of the arrangements fixed, they must be differenced once. It is, in this manner, worth reasoning that the arrangement has various requests of a mix that is,

both I(0) and I(1) and study continues to limits testing of ARDL way to deal with look at the short and since a long time ago run connections among the arrangement.

Table 2: Stationarity Test Results

Variables	@LEVEL		@1ST Diff.		Order of Integration

Following the unit root result in Table 2, the study employed ARDL cointegration approach, which is the bounds test to investigate the presence of long-run relationships among the variables. The test is conducted on the variables considered in this model, and the result is presented in Table 3. The computed F-statistic value is 16.008, which is greater than the upper critical bound values of 5.61. This suggests that the null hypothesis of no cointegration can be safely rejected at 5% significance level and concludes that there is cointegration. Alternatively, this implies that there is a long-run relationship among the variables.

Table 3: ARDL Bounds Co-Integration Test for Credit to Private Sector and Finance for Growth Indicators

Test Statistic	Value	k		
F-statistic	16.00888	3		

Critical Value Bounds				
Significance	I0 Bound	I1 Bound		
10%	2.72	3.77		
5%	3.23	4.35		
2.5%	3.69	4.89		
1%	4.29	5.61

To examine the association amid credit towards the Private Sector and the finance for growth indicators, the study employed the Autoregressive distributed lag (ARDL) approach. The choice of this model is informed by the fact that involved variables are not integrated of the same order. In this model, the dependent variable is the financial intermediation indicator (Credit to Private Sector-CPS). In contrast, the independent variables are Gross Domestic Savings Ratio (GDS), Remittance Inflows Ratio (RINF) and Stock Market Capitalisation Ratio (SMC) and lag of Liquid Liabilities (LL). The selected ARDL representation for the model presented is ARDL (1, 1, 1, 1).

From the result in Table 3, the F-statistics (2175.48; p = 0.000) is decidedly(highly) significant at level 1%. This confirms the usefulness of the model. Also, the R^2 (coefficient of determination) is 0.99.81, implying that about 99.81% of the variations in current LL is clarified by the finance for growth indicators. Another diagnostic that endorses the usefulness of the model is Durbin Watson statistics. The Durbin Watson statistics of 1.429 indicates the absence of serial correlation. Alternatively, it specifies no correlation amid successive error term of each of the models.

Note*: *** and * denote significant at 1% and 10*, respectively. Others are as defined in Table 2*
Source*: Authors' Computation using EViews 10 Software*

The result in Table 5 displays the long-run dynamics of the relationship between credit toward the private sector and finance for growth indicators. As seen in the result, a negative and insignificant relationship exists amid Gross Domestic Savings Ratio (GDS) and credit to the private sector (CPS) at 5% significance level. This implies that a unit increase in DGS will not significantly affect private sector credit in Nigeria. Stock Market Capitalization Ratio (SMC) exhibits a strong and positive relationship with credit to the private sector (CPS) at 5% significance level, and the positive relationship is very significant. The coefficient of Remittance Inflows Ratio (RINF) is positive and also significant (coeff. = 0.11; p-value = 0.05) at 5% level of significance.

Conclusion

Commercial banks are business organisations established to carry out the banking operation and maximise return to their shareholders. Banks not only grant loans and advances to customers just to fulfil their operational function but to make profit. This profit can only be earned through the interest charged on loans and advances to customers. The interest charged by banks on loans are normally arrived at by taking into account the prevailing market rate as well as the rate of monetary policy from the Central Bank of Nigeria (CBN). The interest rate of banks is usually higher than the monetary policy rate of the apex bank and incorporated with other charges such as administrative fee, and handling/processing fee. as determined by the banks from time to time. Loaning is one of the primary exercises of business banks and other budgetary establishments in Nigeria as clear by the size of advances that structure banks' benefits and the considerable yearly increment in the measure of credit allowed to borrowers in the nation (Akujuobi and Nwezeaku, 2015).

The investigations on fund development nexus are very much reported in the account writing. In any case, this current examination looked credit to the private part inside the setting of account for development. This goal was accomplished by utilising the autoregressive circulated slack (ARDL)-Bounds testing strategy in breaking down time arrangement information crossing time of 39 years (1980-2018). The experimental investigation depends on the supposition that when account for development is first-rate, banks will be a better situation in directing assets for investible purposes. The examination discovered proof of noteworthy short-run cointegration between credit to private and money for development factors, yet irrelevant since quite a while ago run relationship. Given these outcomes, the examination suggests that strategies that will additionally expand credit securities exchange capitalisation and settlement inflow be sought after overwhelmingly by the administration to support monetary intermediation, which will help with diverting assets for investible purposes and along these lines cause money related improvement in Nigeria.

Abstract

The dynamics of the demographic processes of the Mari El Republic is determined by the socio-economic development of the republic, cultural features and political factors. Creating favorable conditions for a long and healthy life of people is the ultimate goal of the development of any progressive society. The analysis of trends in changes in the standard of living of the population shows how effectively the society copes with this task.

Keywords: Dynamics, Demographic Processes, Population, Basic Socio-Demographic Indicators

Introduction

The dynamics of changes in demographic indicators requires regular analysis and forecasting of demographic processes. The problems of depopulation in the republic negatively affect its socio-economic development. Studying the causes of changes in the population allows us to assess the situation in the republic correctly and identify objective trends in the further development of the population.

Materials and Methods

The purpose of the work is to study the characteristics of demographic processes in the Republic of Mari El, their interaction with the socio-economic development of the region.

The object of the study is the population of the Mari El republic.

The subject of the study is the demographic situation in the Republic of Mari El, its dynamics.

The theoretical basis of the study was the scientific works of famous demographers, sociologists and economists Antonov A.I., Borisov V.A., Vishnevsky A.G., Kvashi A.Ya., Korotaeva A.V., Chudinovskikh OS, Khoreva B.S. and etc.

The methodological basis of the work is the research in the field of analysis and forecasting of demographic processes.

In the course of writing the work, the analysis of special literature, statistical data, legislative and regulatory documents in the field of demographic policy was used.

Research Results and Discussion

The problem of demographic processes has acquired great importance in the modern period and its neglect can ultimately lead to significant economic problems.

Analysis of the demographic processes in the republic for 1990-2018 shows that the main trends of this period are:

- decrease in the economically active population;
- decline in living standards;
- depopulation of the population.

The Republic of Mari El is one of the Russian regions with a simultaneous natural population decline and migration flow. Migration is associated with the parameters of socio-economic development, the distribution of productive forces, urbanization intensity. Mostly young, partially middle-aged, the most mobile and healthy people with the best professional qualifications are involved in migration flows.

Table 1: Population Change *

year	At the end of the year, thousand people			In % of the total population	
	All population	urban	rural	urban	rural
1990	755,3	468,8	286,5	62,1	37,9
2000	739,1	464,8	274,3	62,9	37,1
2005	711,5	449,1	262,4	63,1	36,9
2010	695,5	439,5	256,1	63,1	36,9
2015	685,9	449,5	236,4	65,2	34,8
2016	684,7	450,7	234,0	65,6	34,5
2017	682,3	451,4	230,9	65,8	34,2
2018	680,4	453,4	226,9	66,2	33,8

** All tables are based on The Republic of Mari El in numbers: A Brief Statistical Digest (2019)*

As of January 1, 2019, the resident population of the republic amounted to 680.4 thousand people, and compared to the corresponding date of 1990 (over 28 years) it decreased by 74.9 thousand people. (table 1). Throughout the entire period under review (1990-2018), there has been an increase in the share of the urban population and a decrease in the rural population in the total population. The share of the rural population in the total population for 28 years in the republic decreased by 4.1%. The reason for the decrease in the rural population is the decrease in living standards and the migration of the rural population to the city.

In a research study by Drepa, E.N. (2009) an important role in demographic processes is played by the age-sex structure of the population. It accumulates and stores the stock of demographic inertia, the population growth potential, by virtue of which the population movement continues for a certain time after the driving forces of this movement have dried up or changed their direction to the opposite. Therefore, the influence of the age structure is always taken into account when analyzing the dynamics of demographic processes.

Table 2 shows the distribution of the specific gravity of the population in the Republic of Mari El by age groups.

Table 2: Distribution of the specific weight of the population of the republic by age groups

All population	Including old age,% (as of January 1, 2018)														
	0-4	5-9	10-14	15-19	20-24	25-29	30-34	35-39	40-44	45-49	50-54	55-59	60-64	65-69	70 and older
100	6,9	6,5	5,4	4,6	4,9	7,2	8,8	7,3	6,5	5,9	6,8	8,4	7,5	5,3	8,0

According to table 2, the number of children aged 1 to 15 years is 18.8%, and the population of 60 years and older is 20.8%, that is, the population of the republic is demographically aging.

The age composition of the population of the Mari El Republic is shown in table 3.

Table 3: Age structure of the population of the Republic of Mari El (in % of the total number)

Year	Population younger than working age	Population of working age	Population older than working age
1990	27,1	55,2	17,8
2002	19,5	61,9	18,6
2005	17,1	64,6	18,3
2010	16,7	62,7	20,6
2015	18,5	58,1	23,4
2016	19,1	56,8	24,1
2017	19,5	55,7	24,8
2018	19,8	54,7	25,5

The working-age population is 0.5% less in 2018 than in 1990, and the population older than working-age is 7.7% more. Thus, over the past 28 years (from 1990 to 2018) in the Republic of Mari El, the population has been increasing over the working age.

The most important characteristic of the current demographic situation is the age and sex structure of the population. Both in the last century and at present, a significant excess of the number of women over the number of men remains.

The ratio of the number of men and women for the period under consideration is shown in Figure 1. At the beginning of 1990, for every thousand men in the republic, there were 1,142 women, by the beginning of 2019, 1,145 women (Fig. 1).

Fig. 1: The ratio of the number of men and women, people.

Table 4 summarizes the main socio-demographic indicators in the Republic of Mari El.

Table 4: Demographic indicators of the Republic of Mari El

Year	1980	1990	2000	2005	2010	2015	2016	2017	2018
Number of births per 1000 population	18,6	15,8	9	10,5	12,7	14,4	13,9	11,9	10,8
The number of deaths per 1000 population	11,4	10,3	14,6	17,2	15,2	13,8	13,2	12,4	12,7
Life expectancy at birth, years	…	68,8	64,6	63,4	67,3	69,8	70,8	72,2	71,7
The coefficient of natural increase (decrease) in the population (per 1000 people)	+ 7,2	+ 5,5	- 5,6	- 6,7	- 2,5	+ 0,6	+ 0,7	- 0,5	- 1,9

The nature of the birth rate, at present, is determined by social decisions on marriage, divorce, economic factors, the level of education of women and their employment.

Over the past twenty years, the death rate in the republic has exceeded the birth rate, with the exception of 2015-2016. Over the period under review, the natural decline in the population of the republic peaked in 2005, after 2010, a slight improvement began, the maximum of which was reached by 2016, mainly due to an increase in the birth rate. In 2017-2018 the number of deaths per 1000 population again exceeds the number of births, that is, there is a process of depopulation.

Depopulation is such a state of the society when each subsequent generation of the society does not make up for the previous one. The aggravation of this trend leads to the development of a demographic crisis, which is characterized by the fact that, along with depopulation, there is an absolute population decline, a sharp increase in mortality and other negative phenomena and processes leading to a demographic catastrophe.

Such demographic trends can lead to devastating consequences for the economy: a reduction in the share of the able-bodied population leads to a reduction in human capital and, therefore, can lead to a decrease in productivity; the pension system and social insurance system may become too burdensome; the growth of the elderly population requires a significant increase in health care costs.

One of the main family problems in the republic is a low level of cash income. Therefore, the problems of the demographic situation are largely related to the low level and quality of life of the population.

Table 5 shows the dynamics of cash incomes of the population in the Republic of Mari El

Table 5: Dynamics of cash incomes of the population of the Mari El Republic

Year	Indicators				
	Nominal cash incomes of the population, million rubles	Real cash income, in % of the previous year	Living wage per capita per month, rub.	The ratio of per capita income and living wage, times	Fund ratio (coefficient of income differentiation), times
2000	9500,9	104,1	868,6	1,2	10,5
2005	28563,9	116,5	2296	1,4	10,4
2010	86502,1	103,6	4847	2,1	13,0
2015	152546,9	97,6	8717	2,1	11,7
2016	153548,7	94,2	8852	2,1	11,6
2017	155127,7	97,5	9114	2,1	11,4
2018	157198,1	96,1	8968	2,1	11,1

Here is the dynamics of the average monthly nominal accrued wages in the republic for 2000-2018. (fig. 2)

Fig. 2 : Average monthly wages for employees of organizations in the Mari El Republic for 2000-2018

As can be seen from the graph, there was an increase in wages in nominal values. But, nominal wages give little insight into changes in the welfare of the population. It is much more important to study the real indicators of the population's income from labor activity. To do this, we use the statistics of the inflation.

To analyze the real change in the values of the average monthly wage indicator in dynamics, we take the value of 2000 for the base year and recalculate the wage in accordance with the inflation rate. Recalculation is carried out according to the following formula (1):

$$k = \frac{100 - \text{Уровень инфляции}}{100}\% \quad (1)$$

уровень инфляции - inflation rate

The resulting coefficients are multiplied by the corresponding level of wages (table. 6).

Table 6: The dynamic characteristics of nominal and real wages in the Republic of Mari El in 2000-2018

Year	Average monthly accrued wages (nominal)	Growth rate,% of the previous year	Inflation rate,%	Recalculation	Average monthly wages in comparable prices (real)	Growth rate,% of the previous year
2000	1164,8	100	20,20	1	1164,8	100
2010	12650,6	10,86 p.	8,78	0,9122	11539,88	9,91 p.
2015	21946,8	173,5	12,91	0,8709	19113,47	165,6
2016	23305,3	106,2	5,38	0,9468	22065,46	115,4
2017	25439,5	109,2	2,48	0,9752	24808,60	112,4
2018	27701,1	108,9	5,53	0,9465	26219,09	105,7

We will display the dynamics of real wages in Fig. 3.

Fig. 3: Average monthly wages in comparable prices for employees of organizations in the Mari El Republic for 2000-2018

Real average monthly wages in general for 2000-2018 increased, but remained 7% less than the nominal average.

Conclusion

Thus, a decrease in the mortality rate and an increase in life expectancy in the Mari El Republic are possible with the implementation of large-scale regional programs to overcome the demographic crisis, including the growth of real incomes of citizens.

Only properly organized work on managing the demographic situation can overcome the demographic problems of the Mari El Republic and ensure the transition from degradation to demographic growth and development.

Abstract

The article considers the importance of investment processes in ensuring the sustainable development of the region, defines the concept of "economic security" and the principles of building economic security at the meso- level, identifies risks and threats that affect investment activity of the region.
Theoretical and methodological approaches to the management of regional investment processes based on the principles of economic security are developed. A system of indicators is proposed to systematically characterize and monitor regional development in order to ensure economic growth and regional security.

Keywords: economic security, investment, investment process, socio-economic development of the region; economic stability, investment, investment process, socio-economic development of the region.

Introduction

In accordance with the National Security Strategy of the Russian Federation approved by Decree of the President of the Russian Federation dated December 31, 2015 No. 683, the main strategic threats to national security in economy include its low competitiveness, lag in the development and implementation of advanced technologies, imbalance in the national budget system, and uneven development of regions. At the same time, the global vector of development in the context of transition to a new technological structure is largely determined by the accelerated development of innovative sectors of economy and the implementation of innovative development strategies, including regional ones. Innovative development requires an awareness of the need to restore the structural balance of economy, increase the level of scientific and technological development and, consequently, activate investment processes.

Investments, acting as a system-wide growth factor and a key condition for the formation of quantitative (economic growth) and qualitative (economic development) vectors of evolution of the economic system determine the main parameters of modernization and expanded reproduction.

According to I.R. Prigozhin, transition to a new quality takes place at bifurcation points — critical states of the system in which the system becomes unstable with respect to fluctuations and uncertainty arises whether the system will become chaotic or it will transfer to a new, higher level of arrangment. Transitions at bifurcation points can lead to both progressive changes and regressive. In this regard, it is significant to strengthen the regulatory role of the state in the investment process on the basis of the concept of a cost-effective state that ensures national security in the context of internationalization of economy and the most important task of managing investment processes is to identify bifurcation points (threats, risks) in the socio-economic system at all levels, including the meso- level, to prepare adequate measures to prevent regression.

Thus, the importance of the research is determined by the increasing practical importance of solving the problem of vector formation, the role and tasks of the state in the investment process and substantiating the paradigm of managing investment processes based on the principles of economic security.

Materials and Methods

The main object of the study is investment processes in the region, management mechanisms for solving the problems of economic growth and ensuring economic security of the region.

The subject of the study is the risks and threats of regional development, a set of theoretical and methodological approaches to the management of regional investment processes.

The degree of development of the problem is characterized by a variety of studies in various areas of investment management.

In the study of the regional investment processes the basis is the theoretical provisions set forth in the works by I.V. Borzakov, E.V. Bykovskaya, A.G. Granberg, V.P. Zhdanov, A.S. Melnikov, M.I. Samogorodskaya and others; in the study of investment environment, investment climate and investment attractiveness – by L.L. Igonina, N.V. Nikitina, Yu.A. Pogodin, T.V. Teplov and other researchers. The results of studies by E. Bem-Baverk, I.A. Blanc, I.L. Vilensky, D.A. Endovitsky, V.V. Kovalev, V.N. Livshits, K.R. McConell, G.A. Makhovikov, A. Smith, F.U. Sharp were also analyzed.

To form the author's position on the importance of building an investment policy on the principles of economic security in order to ensure sustainable development the works by Abalkin L.I., Azarskaya M.A., Bendikov M.A., GlazyevS.Yu., Gradov A.P., Endovitsky D.A., Ilyin I.V., Ilyashenko E.A., Kleiner G.B., Larionov I.K., Oleinikov E.A., Ortynsky V.L., Pozdeev V.L., Senchagov V.K., Tambovtsev V.L., Tsukanov V.Kh. and other scientists were studied.

However, the current conditions of development of the regional economy, the need to introduce principles of economic security at the meso-scale and activate the role of the state in managing investment processes determine the urgency of the problem and the need for its further development.

The methodological base of the research is constituted by the provisions of the conceptual approach on a dialectical basis. Formal-logical and general scientific methods are used to ensure the required depth of the study of the problem: abstract-logical, historical, monographic methods, deduction, induction, synthesis, balance method, etc.

The study is based on the principles of objectivity in considering regional investment processes, historicism and investment coherence. The principle of objectivity in considering the investment processes involves the study of socio-economic phenomena based on a causal relationship, taking into account the peculiarities of the region development. The principle of historicism means consideration of issues of managing regional investments in development - the study of genesis and phased transformations. The principle of investment coherence means that all economic phenomena, processes, elements of regional investment management are considered in interconnection.

Investment coherence - the coordinated flow of time, space and resource support of investment processes, their management for transition of quantitative changes to new qualities - is reflected ultimately in synergistic and multiplicative effects. An increase in the efficiency of regional economy and a decrease in the entropy of regional investment processes (risk reduction, increase in investment security) are possible on the basis on achievement of internal coherence of investment processes, their streamlining (synchronization), adaptability (an adequate reaction of the regional investment process entities to environmental changes) in the economic system.

Research Results and Discussion

The economic security of the Russian Federation is largely ensured by the balanced, integrated and systemic development of its constituent entities and the effective activity of the regions. The increasing role of the regions is dominant in the economic and political life of the Russian Federation and the analysis and forecast of their development become especially relevant in the context of creating prerequisites for accelerated technological development. It is important to justify the priorities and tasks of regional development in accordance with the Strategy for Spatial Development of the Russian Federation for the period up to 2025, taking into account the risks, threats and restraining factors of regional development, the formation of an investment policy based on the principles of economic security as part of the general socio-economic policy of the region.

Obviously, the management of investment processes in the Russian Federation on the basis of the state-territorial structure of the country is a level system, the subjects and objects of which have a certain autonomy and diverse interests and goals. The top hierarchical level in the investment management system is management at the level of national economy, which ensures its sustainability. The next level is management at the regional economy level, then - management at the level of an economic entity.

The regional investment processes have specific features:

- variability of individual parameters of the system and its stochasticity, which allows to form regional development options;
- openness of the regional investment system, its ability to interact with the environment;
- stability as an ability not only to resist entropy (destroying the system) changes, but also to adapt to changing conditions and maintain equilibrium.

Peculiarities of regional investment processes, the uneven socio-economic development of the regions of the Russian Federation, differences in the production structure, transport accessibility and availability of resources, an impact on the country's administrative and distribution system processes in the region make it necessary to take into account the formation of the mechanism for managing the regional investment process along with macroeconomic factors (strategic goals and objectives of the national economy, national programs, projects) the factors acting at the meso- scale (goals and objectives of the socio-economic development of the region).

The study allowed us to determine conceptual approaches to the management of regional investment processes based on the principles of economic security.

The security of regional economy reflects the state of its economic potential, internal structure and management system, which ensures efficient use of natural, labor, material and financial resources, guarantees protection of the region from negative changes in external conditions, maintaining competitiveness and adapting to changing conditions and the boundaries of its economy . Despite the differences in approaches found in scientific literature characterizing the concept of “economic security”, the following is common: the economic security of a region means protection of its economy from external and internal threats, in which, based on the efficient use of resources, sustainable economic growth, socially oriented development of the region are ensured, which helps meet the needs of society.

Over the past century and a half three main approaches (paradigms) of theoretical economists have been formed to what should be considered the main threat to the national economy and how to deal with it:

1) the cameralistic concept - the concept of protecting foreign economic security (since the mid-19th century; revived by left-wing radical economists since the last third of the 20th century) (F. List, R. Prebish, A. Emmanuel and others): the main threat is external: competition of foreign states, among neoclassicists - inflation and low competitiveness of national business on a global scale; methods of struggle - protectionism, the integrated development of national economy;

2) Keynesian concept - the concept of protection against internal macroeconomic threats (since the second third of the 20th century) (J.M. Keynes): the main threat is the internal one: market "failures" - instability of economic growth, economic depression, unemployment, inflation; control methods - state regulation of production, employment and money circulation;

3) institutional concept - the concept of protection against administrative barriers (since the end of the 20th century) (E. de Soto): the main threat is internal: the "failures" of the state - administrative barriers - "bad" laws and / or poor implementation of "good" laws, rent seeking; methods of struggle - reduction of registration procedures and payments, the fight against bureaucracy and corruption.

The study showed that development of regions that are part of the country's economy is influenced by systematic risks affecting the country's economy as a whole (they cause external threats to the stability of the region) and risks specific to the region (they cause internal threats to the stability of the region). External risks may include instability in the global economy and the country's economy, imbalance in the national budget system, insufficient investment in the real sector of economy, poor innovation activity, natural disasters, changes in the structure of government, etc. Internal risks include geographical location, demographic indicators, climate conditions, low economic growth due to internal reasons, including limited access to long-term financial resources, insufficient development of transport and energy infrastructure, deterioration of fixed assets of the region's enterprises, etc. Among the threats that persist in Russian economy and have a restraining effect on it at all levels include weak control of export earnings, freedom to export capital abroad, offshoring, currency and financial speculation in financial market and absence of restrictions on the activity of foreign capital (national operation mode for non-residents), which determine the outflow of capital from the country and the lack of interest in investing in Russian economy, on the one hand; on the other hand, increased interest rates, an increase in the tax burden, which hinders the formation of internal and external sources of investment financing in conditions when access to foreign credit resources is limited as a result of sanctions.

Modern economic development more and more proves the need to change approaches, characteristic of the neoclassical and neo-Keynesian directions, to establish the functions of the state in a market economy, when the state regulates only what the market cannot regulate. The dynamism and unpredictability of economic processes, the changing role of international institutions in their regulation, globalization, the presence of external and internal threats to the development of economy necessitate the construction of state management of socio-economic development, including investment processes, based on the principles of economic security.

The principles of ensuring economic security are fundamental ideas, guiding principles that are determined by political, economic, spiritual, moral and other factors, guiding principles that reflect the nature, features and purpose of activities of specially authorized bodies and officials to ensure economic security. The key principles for building economic security at the meso -scale can be specified as follows:

- maintaining a steady rate of economic growth in the economic system of the region, budgetary security and sufficiency;
- ability to implement large-scale economic projects in current social and explosive situations in the troubled territories or economic miscalculations at the federal level;
- maintaining stability of labor resources and the level of employment in accordance with the reproductive needs of the region; maintaining a decent standard of living in the region;

- ability to pursue their own economic policies within the framework of the system of economic federalism and to adequately respond to force majeure situations at the federal level.

In the Russian Federation Institutions, mechanisms and tools for ensuring economic, including investment, security have been formed: Decree of the President of the Russian Federation dated May 7, 2018 No. 204 “On National Goals and Strategic Tasks of the Development of the Russian Federation for the Period until 2024” established national goals ; the Unified Plan for the achievement of the national development goals of the Russian Federation for the period up to 2024 defined the trajectory of indicators reaching target levels; The Ministry of Economic Development prepared an Action Plan to accelerate the growth rate of investment in fixed assets and an increase up to 25% of their share in gross domestic product, aimed at improving investment climate, financing investment activity. These documents provide for improvement of control and supervision system, licensing activities (completion of the reform of control and supervision activities, updating industry legislation), the establishment of stable "rules of the game" in taxation and non-tax payments (systematization and consolidation of uniform rules for introducing, amending and levying non-tax payments) and improvement of bankruptcy proceedings. But formation of mechanisms and tools is based on the extrapolation of the prevailing trends in the pre-sanction period and covers mainly the fiscal policy.

In the context of changes in the technological structure in order to stimulate innovative activity and investment activity, along with the fiscal policy being implemented, it is necessary to develop mechanisms of monetary, industrial and foreign economic policy in terms of stabilizing the ruble exchange rate, forming sources of investments, increasing the availability of credit resources and expansion of lending to industry through mechanisms for project financing and public-private partnerships, reducing the key rate to a level not higher than the profitability of an industry, reduction of tariffs of infrastructure monopolies, state support of certain sectors of economy, tariff regulation of foreign trade and export support, control over the targeted use of budget allocations and the movement of capital abroad, currency regulation. It is necessary to consider the issue of setting target parameters not only for inflation, but also for the ruble exchange rate, growth in monetary aggregates and changes in key rates. The development of mechanisms and tools for ensuring economic security, the system of its indicators at the meso -scale, the creation of a unified system for collecting, recording, analyzing and disseminating information to establish priorities and tasks for regional development also require elaboration.

Analysis of theoretical studies showed that when forming the modern paradigm of managing the region’s investment processes, one should take into account its socio-economic realities, which determine the need to build a system of monitoring the region’s socio-economic indicators and tools for regulating investors' activities to ensure economic security at the meso-scale.

A qualitative characteristic of regional development can be expressed through comparing one indicator selected as the main (for example, the value of the gross regional product), several priority indicators and aggregated indicators. Building a system of indicators for a systematic characteristic and monitoring of regions is important for the development of state regional policy, mechanisms and instruments of which should be formed taking into account economic, social, natural and other conditions that have a decisive effect on the formation of comparative advantages of the region in the framework of social division of labor.

Corresponding member of the Russian Academy of Sciences Hamidullin F.G. attributes to the main indicators characterizing interests of the region in security and ensuring acceptable living conditions and personality development for the majority of the population, the stability of the socio-economic situation, the integrity of society and economy the following : the ability of economy to function under expanded reproduction, the boundaries of critical dependence of economy on imports of the most important types of products, whose production at a required level can be organized in the region; financial system sustainability; a satisfactory standard of living of the bulk of the population, which allows to avoid the danger of uncontrolled social, labor, interethnic and other conflicts.

Taking into account the official statistical data, an assessment of security and sustainability of the region development can be carried out according to such key parameters as:

- the level of general economic development of the region and business activity,
- the level of development of investment infrastructure of the region,
- innovative development,
- demographic characteristics of the region.

When assessing the level of general economic development of the region we study the potential need for investment volumes, the possibility of forming investment resources with our own sources, the capacity of the regional market and the return on capital established in the region in various areas of investment activity. The composition of the analytical indicators used for such an assessment may include:

- the region share in GDP;
- index of physical volume of GRP; index of physical volume of GDP and GRP;
- dynamics of investments;
- the share of investments in fixed assets in GRP; the share of investments in fixed assets in GDP and GRP; correlation of investment and GRP;
- capacity growth index, capacity utilization;
- index of production volumes (industrial production index, industrial production volume, agricultural production volume);
- comparison of production and investment dynamics;
- the degree of asset deterioration, including machinery and equipment, return on assets, the coefficient of renewal of the asset, the coefficient of wear;
- labor productivity index;
- sources of financing investment activity, state financing, external sources (bank lending), foreign investment: structure, dynamics; share of credit in sources of financing investment activity; loan interest;
- liquid resources of the region;
- profitability level of enterprises, the proportion of unprofitable enterprises in the total number of functioning enterprises;
- rate of return on investment (amount of investment); index of return on investment (base - the average value in the country).

Additionally, the following indicators can be calculated:

- investments in fixed assets per 1 rub. of industrial products;
- the volume and dynamics of capital investment per inhabitant;
- the volume of industrial production per capita;
- the volume of production of certain types of agricultural products per capita.

When assessing the level of development of the investment infrastructure of the region, the possibilities of quick implementation of investment projects are investigated. In this case, the following indicators are considered:

- the number of contracting construction enterprises of all forms of ownership;
- volumes of local production of the main types of building materials;
- production of energy resources per capita;
- the proportion of transport in GRP;
- density of railways;
- density of paved roads, etc.

Innovative development is characterized by the following indicators:

- research and development costs as a percentage of GRP;
- the proportion of organizations engaged in technological innovation.

The demographic characteristics of the region are based on the study of otential volume of the population's demand for consumer goods and services and the possibility of attracting skilled workforce in invested production. The analyzed indicators include:

- the proportion of the population of the region in the total population of the country;
- coefficient of tension in the labor market (person / place);
- the proportion of the working-age population in the total population of the region;
- the availability of qualified specialists (share of employees with higher and secondary vocational education);
- the proportion of the population with incomes below cost of living.

Additionally, the following indicators can be calculated:

- the average level of wages of employees;
- the ratio of urban and rural residents;
- the proportion of the population employed in social production at enterprises of all forms of ownership.

A study of the region development on the basis of the above mentioned indicators provides an information base for monitoring compliance with the basic principles of economic, including investment, security of the region.

Conclusion

In the context of creating prerequisites for accelerated technological development based on vigorous investment activity, to ensure sustainable economic development of the region, it is necessary to form a regional investment policy based on the principles of economic security, taking into account risks, threats and restraining factors.

Generalization and systematization of various aspects of theoretical, methodological and applied research carried out within the framework of investment issues in order to highlight the general patterns in investment management, which are invariant in various regions, as well as studies on the issue of ensuring economic security, allowed convergence of approaches to ensure effective management of regional investment processes based on the principles of economic security.

Based on the use of unified statistics, a system of indicators is proposed for systematic characterization and monitoring of regional development in order to ensure economic growth and regional security.

Abstract

In modern conditions of globalization and internationalization of the society, the importance of knowledge of a foreign language(primarily English) by university graduates at a level that would allow them to fully realize the potential of international professional communication is growing. Various methods are effective in solving this problem, allowing integrating the study of a foreign language and non-linguistic subjects: Content and Language Integrated Learning (CLIL), English as a Medium of Instruction (EMI), English for Specific Purposes (ESP), Content-Based Instruction (CBI), language immersion, etc. The conducted study revealed the similarities and differences of these methods to determine the possibilities of their practical use.

Keywords: Content and Language Integrated Learning (CLIL), English as a Medium of Instruction (EMI), English for Specific Purposes (ESP), Content-Based Instruction (CBI), language immersion.

Introduction

With the globalization and internationalization of the society, the importance of knowledge of a foreign (primarily English) language by graduates of higher educational institutions at a level that would allow them to become full members of the international scientific, business, cultural community is growing. Moreover, even good knowledge of a foreign language for everyday communication is often not enough for a free orientation of specialists in industry market information, specialized literature, and effective communication with business partners from foreign countries. Only the study of a foreign language for professional purposes gives the university graduate the opportunity to participate in professional intercultural communication, is a key factor in the formation of professional and communicative competencies and, in general, a socially successful, competitive, professional person.

In international practice, Content and Language Integrated Learning - CLIL, English as a Medium of Instruction (EMI), English for Specific Purposes (ESP), Content-Based Instruction (CBI) have become known as effective methods for ensuring the formation of professional and foreign language competencies, language immersion, etc. The purpose of this study is to study the similarities and differences of these methods, to determine the possibilities of their practical use in the practice of Russian universities.

Materials and Methods

As research materials, we use the publications of foreign and Russian specialists who used the above methods in pedagogical practice and studied them as a subject of authors'scientific interests.

When conducting the study we applied:

theoretical methods: study, analysis and generalization of scientific literature in the subject area of research, synthesis, comparison, specification, interpretation, comparison,

general empirical methods: the study and generalization of pedagogical experience.

private empirical methods: the study of documents.

Research Results and Discussion

Content and Language Integrated Learning (CLIL), the use of which is recommended by the European Commission for education at various levels, including higher education, was considered as the main methodology, in relation to which a comparative analysis of approaches to the integration of foreign language learning and non-linguistic disciplines was conducted. This technique is gradually gaining popularity in the educational system of Russia.

The term CLIL was coined in the 1990s. by a group of EuroCLIC Network researchers from European countries who were involved in language education in Europe (Cenoz et al, 2014). Its leading representative is David Marsh, a specialist in multilingual education, the author of such works as Profiling European CLIL Classrooms: Languages Open Doors (2001), Content and Language Integrated Learning (2010), etc.

The book by Coyle et al (2010) gives a comprehensive definition of CLIL, which emphasizes its characteristic features: CLIL is a two-focus educational approach in which a foreign language is used to study and teach both academic discipline and a foreign language. Thus, CLIL is an "umbrella term" encompassing a variety of techniques (Marsh, 2008, Mehisto et al, 2008) but CLIL is distinguished by the guiding role of the content of a non-linguistic discipline. It is important that CLIL is not a way to learn a foreign language using the extended subject context as an example. It is not a way of studying the content of non-linguistic discipline, simply translated into a foreign language (Silva and Albuquerque, 2016). The key to CLIL is its bifocal focus on both teaching content through foreign language and teaching foreign language through content.

Currently, the concept of CLIL is interpreted quite widely, and in the scientific and methodological literature there are many different definitions of it. Despite the widespread use of the term CLIL, discussions about the essence of this approach, the search for its specificity in comparison with other methods of teaching subjects and a foreign language continue.

Some authors adhere to a categorical position, believing that the variety of CLIL definitions makes it impossible to identify the key characteristics of this technique, which would distinguish it as truly original and independent (Cenoz et al, 2014).

The authors of the work agree with those researchers who do not consider CLIL as a radically new approach, since foreign and second languages have long been used to teach various disciplines in secondary and higher education (Popova et al, 2018). We also support the view that CLIL cannot be understood as a kind of English for Specific Purposes (ESP) or to equate the concepts of CLIL and English as a Medium of Instruction (EMI) (Sidorenko and Rybushkina, 2017).

Here are a few arguments that support our point of view.

Firstly, although in practice the predominant part of educational programs using CLIL is implemented on the basis of English, which turns CLIL into CEIL (Content and English Integrated Learning), however, in general, CLIL is wider than ESP or EMI, since it can be implemented on the basis of other languages.

Secondly, CLIL is a convergence of subject content and language categories, which allows us to consider this approach on a par with the above methods, but CLIL is distinguished by numerous special didactic methods for providing integrated learning (fusion), which carry the novelty of the approach. Thus, problem-based learning, collaboration training, presentation skills, role-playing games, exercises on compiling intelligence cards, etc. are considered elements of novelty.

Thirdly, the ESP methodology is mainly aimed at teaching a foreign language directly, while the substantive aspects are of secondary importance (Popova et al, 2018). ESP programs are aimed at developing students' linguistic competence, therefore, the central link is the improvement of foreign-language communication skills, and knowledge of terminology, grammar and discourse features that are characteristic of the professional sphere are assessed (Khalyapina, 2017).

CLIL has an ambivalent focus on both special content and a foreign language, while EMI is not a methodology for teaching a foreign language at all: it is the use of a foreign language as a means of studying academic disciplines (Popova et al, 2018).

Since the ESP technique is designed to study the language, the teachers are not tasked with creating a logically structured and consistently revealing the topic of educational material (it is understood that the student already has knowledge in the subject and only needs to clothe them in a new form in a foreign language). EMI, on the contrary, assumes a sufficient level of students' knowledge of a foreign language and concentrates on the content of the subject, with almost no attention to the linguistic component. It is CLIL that allows us to maximize eliminate the shortcomings of each of these approaches, integrate language teaching and the content of a special discipline (Silina and Surinova, 2017).

CLIL also has an intersection with the basic ideas of language immersion and content-based learning - Content-Based Instruction (CBI). Immersion in the language environment significantly accelerates the process of learning a foreign language, and learning new things about a specific subject, rather than new ones about a language, increases students' motivation. As with CBI, language and discipline teachers often work together when using CLIL, directing their efforts toward solving common problems (Vyushkina, 2015).

Therefore, some researchers believe that the terms CLIL and CBI have the same content, while others indicate an important difference between them - CLIL is used in classrooms where a non-language subject is studied, and CBI is a method of teaching a foreign language on material related to subjects (Cenoz et al, 2014, Vyushkina, 2015, Dalton-Puffer et al, 2014).

Thus, Content and Language Integrated Learning covers situations of teaching a non-language subject “through the medium” of a foreign language. CLIL is a method of teaching subjects through a foreign language (teaching content through foreign language) and teaching a foreign language through the subject itself (teaching foreign language through content). CLIL assumes a dual unity of subject content and language learning. Thus, the language is used as a means of studying the content, and the content, in turn, is used as a resource for learning the language (Zaripova et al 2015).

A distinctive feature of CLIL is that it is not just an approach to teaching a foreign language or subject, but an integrated form of learning for both. Not only is the discipline taught through a foreign language, but a foreign language environment is created in which students are immersed. In the

classroom, they work with authentic materials, using a foreign language to study the real world. Teachers use not only language teaching methods, but also didactic methods of teaching non-linguistic disciplines.

Using CLIL, students can study one or more subjects in a foreign language. It is not assumed that students are able to speak a professional foreign language before starting to study a specialized subject. They learn the language at the same time as the special subject (Baturina et al, 2017). In the context of CLIL, a language that acts as a learning tool can be either a foreign language, a second state language, or a language of a national minority (Grigorieva and Yakhina, 2017). As a rule, the language of instruction is a foreign language that is rarely or never used in a social context outside the classroom. Classes form the main, and often the only, environment in which students can use the language they are studying (Filipovich, 2015).

Conclusion

Thus, techniques that use a foreign language in the process of obtaining subject knowledge have both similarities and differences. It should be noted that the diversity of approaches to distinguishing between methods of integrating language and academic disciplines is largely due to the peculiarities of using terminology in different regions. CBI represents American experience and is comparable to ESP; The appearance of the term CLIL is associated with European countries, but recently this approach has been widely used outside Europe and is used in a wide international context. In our opinion, the task of a clear separation of methods and their definitions does not have significant practical value. More important is the possibility of using a combination of methodological and didactic elements of various approaches in the interdisciplinary integration of a foreign language and professional disciplines of higher education in order to achieve the planned learning outcomes and form the required competencies of students depending on the characteristics of specific educational situations.

Abstract

One of the most important indicators reflecting the level of development of innovative activity in the state is the volume of innovative goods produced in the country. At the same time it is important to take into account regional aspects, especially in connection with the recently growing role of regions as sources of innovative changes. Therefore the focus of this study is the regional differentiation of the proportion of innovative goods, works, services in the total volume of goods shipped, works and services performed, considered for the period of 2016-2018. As measures of the level of differentiation of the analyzed indicator the absolute and relative range, variance, standard deviation and coefficient of variation are calculated. It was revealed that the uneven production of innovative goods, works, services in the Russian Federation is high and it increased during the analyzed period.

Keywords: innovation, innovative products, regions, Russian Federation.

Introduction

Currently, innovation is the main driver of economic growth. It can be argued that science and innovation have become the main driving force of social progress, a measure of economic development (Golova and Sukhovey, 2017, Kokkinou, 2010, Maradana et al, 2019, Mayer et al, 2012, etc.).

When developing and implementing innovative policies it is necessary to take into account regional aspects, since the role of regions and cities as sources of innovative changes is currently being strengthened. The unevenness of innovative development of regions in a state is noted in many countries even small ones (Fil'a and Kučera, 2015, Hudec and Procházková, 2015, etc.).

The differentiation of Russian regions in terms of innovative indicators is very significant which is associated with uneven population composition, production structure and socio-economic development of various constituent entities of the Russian Federation with different historical, geographical and national characteristics (Golova and Sukhovey, 2017, Gubanova and Kleshch,

2019, Gusakov, 2014, NRU HSE, 2020, Nureev and Simakovsky, 2017, Piskun and Khokhlov, 2019, etc.).

The ongoing research of regional features of innovation in Russia analyzes mainly the indicators of resources of innovative development (research and development costs, characteristics of the educational system, the number and quality of organizations and personnel involved in research and development, etc.). However a fundamental condition for the effectiveness of innovation processes ensuring economic growth, increasing national competitiveness and other positive changes in the development of the country is the practical implementation of innovations in the economic activities of specific enterprises, therefore, in this study we focus on the rate of production of innovative goods, works, services. This work is a continuation of the research presented in earlier publications (Rodionova, 2019).

Materials and Methods

The basis of the study was the information presented in the statistical collection “Regions of Russia. Socio-economic indicators” (Rosstat, 2019).

According to the methodology of the Federal State Statistics Service (Rosstat) innovation activity refers to the type of activity associated with the transformation of ideas (usually the results of scientific research and development or other scientific and technological achievements) into technologically new or improved products or services introduced on the market, into new or improved technological processes or methods of production of services used in practice. Innovation involves a range of scientific, technological, organizational, financial and commercial activities and it is in their entirety that they lead to innovation.

As innovative goods, works, services, Rosstat considers goods, works, services, new or subject to technological changes of varying degrees over the past three years (Rosstat, 2019).

As indicators of the level of regional differentiation the authors calculate the absolute and relative range of variation, variance, standard deviation and coefficient of variation.

Research Results and Discussion

Content Table 1 presents the rating of the constituent entities of the Russian Federation with an indication of the federal district (FD) in terms of the volume of innovative goods, works, services as a percentage of the total volume of goods shipped, works and services performed for 2016-2018. Due to the limited volume of publications the first and last 20 positions in the ranking are given. The indicators of the Arkhangelsk and Tyumen Regions were taken into account with the inclusion of their constituent autonomous districts and the latter did not participate in the rating.

Table 1: the proportion of innovative goods, works, services in the total volume of goods shipped, works and services performed

Name	2016, %	Name	2017, %	Name	2018, %

Analytical indicators					
Average across Russia	8.5	Average across Russia	7.2	Average across Russia	6.5
Range	27.2	Range	27.4	Range	24.3
Relative range	3.20	Relative range	3.81	Relative range	3.73
Dispersion	40,86	Dispersion	35,98	Dispersion	31,91
Standard deviation	6,39	Standard deviation	6,00	Standard deviation	5,65
Coefficient of variation	0,75	Coefficient of variation	0,83	Coefficient of variation	0,87

The data in Table 1 indicate a decrease in the share of innovative goods, works, services in the total volume of shipment in the Russian Federation over the past three years from 8.5% to 6.5%. The share of innovative goods, works, services for the analyzed period decreased in 43 regions, growth is recorded in 34 regions and in 5 regions the share of innovative production remained unchanged.

It should be noted that the Strategy for Innovative Development of the Russian Federation for the period until 2020 (Strategy, 2011) involves an increase in the share of innovative goods, works, services in the total volume of goods shipped, works performed, services of industrial production organizations to 15.4% by 2016 and up to 25% by 2020 year. Obviously, the possibility of reaching the final level of the indicator planned by the Strategy is doubtful. Although the indicator analyzed by us in Table 1 was calculated by Rosstat for a wider range of production activities, its value of 6.5% in 2018 leaves little hope that in 2020 Russian industrial production will reach the level planned by the Strategy at 25%.

The change in the calculated differentiation indicators is not the same: the absolute and relative range of variation increased in 2017 and decreased in 2018, the variance and standard deviation tended to decrease. The coefficient of variation, which can be considered as the main measure of differentiation of regions by the level of production of innovative goods, works, services is very high and during three years increased from 0.75 to 0.87.

The largest number of leading regions by the analyzed indicator is concentrated in the Volga Federal District. The three regions that hold leading positions in the ranking - the Republic of Mordovia, the Republic of Tatarstan (Volga Federal District) and the Khabarovsk Territory (Far Eastern Federal District) - show a fairly significant gap in the relative volume of production of innovative goods from the rest of the Russian Federation. Throughout the entire analyzed period the republics of Mordovia and Tatarstan, Samara, Nizhny Novgorod, Moscow Region and Perm Territory retain their place in the top ten. It should also be noted that the Tyumen Region, excluding the Khanty-Mansiysk and

Yamalo-Nenets Autonomous Regions, is characterized by one of the highest rates of the share of innovative goods (15.8%, 17.8% and 19.5% in 2016, 2017 and 2018 respectively).

In the year 2018 24 subjects of the Russian Federation have the share of production of innovative goods, works, and services at the level above the average for Russia. An extremely low level of production of innovative goods is observed in a number of regions of the North Caucasian, Far Eastern and Siberian federal districts.

Significant changes in the level of production of innovative goods are observed in the Belgorod Region (an increase from 7.3% in 2016 to 14.9% in 2018), the Bryansk Region (decrease from 18.8% in 2016 to 3.3% in 2018), Moscow (decrease from 13.6 % in 2016 to 3.0% in 2018), Arkhangelsk Region (excluding the Nenets Autonomous Region - fluctuation from 0.9% in 2016 to 28.4% in 2017 and 12.4% in 2018, including the Nenets Autonomous Region - fluctuation from 0.5 % in 2016 to 15.3% in 2017 and 5.6% in 2018), Rostov Region (decrease from 14.5% in 2016 to 5.8% in 2018), Sevastopol (a decrease from 12.8% in 2016 to 4.5% in 2018), the Republic of Mari El (fluctuations from 8.2% in 2016 to 14.2% in 2017 and 2.8% in 2018), Trans-Baikal Territory (decrease from 7.2% in 2016 up to 0.5% in 2018), Khabarovsk Territory (fluctuation from 14.1% in 2016 to 23.8% in 2017 and 21.3% in 2018).

Conclusion

Thus uneven share of production of innovative goods, works, services in the context of the constituent entities of the Russian Federation is very high (coefficient of variation > 0.33) and over the three analyzed years it has increased even more. This state of affairs cannot be evaluated positively.

It is necessary to continue the study of indicators of innovative development of regions, including other indicators related to both creation and implementation of innovations. The urgent tasks are to search for the interconnection between the volumes of the regional resources for innovative development and production of innovative goods, determine the reasons for the low share of the output of innovative goods, works, services in most constituent entities of the Russian Federation, identify the factors of low innovative activity in outsider regions and establish the need to increase it.

The final goal of research of regional innovation in Russia should be to build a typology of regions identified by production, technological and socio-economic characteristics in order to formulate strategies for the innovative development of territories of different types, ensuring an efficient transfer of innovations, a rational level of production of innovative products and alignment of levels of development of innovative activities in the regions.

Abstract

The work is devoted to the study of the structure of the universal set of abstract risks of the development of discrete economic systems under conditions of probabilistic uncertainty from a set-theoretic point of view, as well as the formulation of a number of related problems. In particular, the article shows a trivial characterization of a universal set of abstract risks in the form of an isomorphism of the corresponding factor monoid with the operation of calculating the joint risk of a monoid of integers by multiplication. Using the methods of information theory, the components of dividing the risk space, which form a subtler, in relation to the named isomorphism, characterization of the universal set of risks, are investigated. The relevance of entropy approaches to risk analysis is shown. The problem of risk factorization, interesting from the point of view of system analysis, is formulated. Formal statements of factorization problems are given.

Keywords: Algebraic Theory of Risk, Probable Uncertainty, Discrete System, Entropy, Complexity, Quotient Algebra.

Introduction

In the monograph by Urazayeva (2013), the most general formalism was proposed, which allows, on the one hand, to trace the pathways of risk genesis as a phenomenon of consciousness, and, on the other hand, to form new, more effective approaches to solving computational problems of the theory of risk of discrete systems under conditions of probabilistic uncertainty. This formalism is called the "algebraic theory of risk" (ATR).

Practice has confirmed the fruitful use of the ideas of the ATR, both in the socio-economic sphere (financial applications, papers by Urazaeva (2011, 2012, 2013, 2014), personnel management tasks, papers by Borodin (2014)) and in the study of technical systems, papers by Borodin (2014, 2015) and papers by Urazaeva (2010, 2015).

The most important abstractions of the ATR are the concepts of risk, multiple risks, and the algebraic operation of multiplying risks, interpreted in terms of the subject area as the operation of calculating the joint risk.

Risks in the ATR are represented by multisets whose carrier is the subset of the direct product $C \times \mathbf{I}$, where the set of all mappings of the state of the system onto itself C together with the composition operation of these mappings form a commutative monoid, and $\mathbf{I} = [0,1] \subset \mathbf{R}$ is the unit segment, where $\mathbf{R}$ is the set of real numbers. Accordingly, many risks are many multisets of the form

$$\mathsf{R} = \left\{ \boldsymbol{R} : \ \boldsymbol{R} \in \mathsf{A}, \Sigma_{x \in \operatorname{Supp} \boldsymbol{R}} \ k_{\boldsymbol{R}}(x) \operatorname{pr}_{\mathbf{I}} x = 1 \right\},$$

where $\mathsf{A} = \{ \boldsymbol{A} : \ \operatorname{Supp} \boldsymbol{A} \subset C \times \mathbf{I} \}$,

$\operatorname{Supp} \boldsymbol{A}$ – multiset carrier $\boldsymbol{A}$,

$k_{\boldsymbol{R}}(x)$ – the multiplicity of the element x in the multiset $\boldsymbol{R}$,

$\operatorname{pr}_{\mathbf{I}} x$ – the projection of the element x onto the set $\mathbf{I}$.

Thus, it is obvious that R is the set of all possible discrete probability distributions over C, otherwise, the set of all possible distributions of the development options of the discrete system.

Above R you can define the operation of multiplication (calculation of joint risk):

$$\boldsymbol{A} \square \boldsymbol{B} \underset{Def}{=} \left\{ k_{\boldsymbol{A} \square \boldsymbol{B}}(u) * u : \ k_{\boldsymbol{A} \square \boldsymbol{B}}(u) = \sum_{\substack{x \in \operatorname{Supp} \boldsymbol{A}, \\ y \in \operatorname{Supp} \boldsymbol{B}, \\ x y = u}} k_{\boldsymbol{A}}(x) k_{\boldsymbol{B}}(y), \right.$$

$$\left. u \in \bigcup_{\substack{x \in \operatorname{Supp} \boldsymbol{A}, \\ y \in \operatorname{Supp} \boldsymbol{B}}} \{ x y \} \right\}.$$

Here, the product of the elements is defined as follows:

$$z = x \mathrm{g} y \underset{Def}{\hat{\mathrm{U}}} \operatorname{pr}_C z = \operatorname{pr}_C y \circ \operatorname{pr}_C x, \ \operatorname{pr}_{\mathbf{I}} z = \operatorname{pr}_{\mathbf{I}} x \times \operatorname{pr}_{\mathbf{I}} y .$$

In the monograph by Urazayeva (2013), it was proved that algebra $\langle \mathsf{R}, \square \rangle$ is a commutative monoid. The use of this fact, as well as the development of the corresponding theory, allowed us to develop a number of new, more effective, risk analysis algorithms.

At the same time, the question of the structure of the set R remained outside the scope of the study, Urazayeva (2013). The study of the structure of the set R is not only fundamental, but, as will be shown below, has immediate practical significance, since it is associated with such risk characteristics as complexity and entropy.

The purpose of the study (Materials and methods)

We introduce the set of risks with the same (fixed) number of possible outcomes:

$$\mathsf{R}^{\#k} \underset{Def}{=} \left\{ \boldsymbol{R} : \boldsymbol{R} \in \mathsf{R}, \left| \boldsymbol{R} \right| = k \right\}, \; k \in \mathbf{Z}_0^+,$$

where $\mathbf{Z}_0^+$ – is the set of non-negative integers.

Using this definition, one can introduce on many risks the ratio of coincidence of the number of outcomes:

$$\boldsymbol{R}_1 \,\#\#\, \boldsymbol{R}_2 \underset{Def}{\Leftrightarrow} \exists k \left(\boldsymbol{R}_1 \in \mathsf{R}^{\#k}, \boldsymbol{R}_2 \in \mathsf{R}^{\#k} \right).$$

Obviously, the factor monoid $\langle \mathsf{R}, \square \rangle / \#\#$ is isomorphic to the monoid $\left\langle \mathbf{Z}_0^+, \times \right\rangle$. This is a trivial characterization of the structure of many risks.

Are less trivial characterizations of the structure of multiple risks possible? If possible, then what are the features of the identified components. The answers to these questions are the goal of this paper.

Not entirely trivial characterization of multiple risks

Note that this paper generalizes and substantially refines the results published in the papers Borodin (2016). Let us introduce another kind of subset of the set of risks - a set of risks, which includes all joint risks from two sets with a fixed number of outcomes:

$$\mathsf{R}^{\#m\#n} \underset{Def}{=} \mathsf{R}^{\#m} \square \mathsf{R}^{\#n} \underset{Def}{=} \left\{ \boldsymbol{R}_1 \square \boldsymbol{R}_2 : \boldsymbol{R}_1 \in \mathsf{R}^{\#m}, \boldsymbol{R}_2 \in \mathsf{R}^{\#n} \right\}.$$

Let us prove that $\mathsf{R}^{\#m\#n} \subset \mathsf{R}^{\#mn}$, or, otherwise, that $\mathsf{R}^{*mn} \underset{Def}{=} \mathsf{R}^{\#mn} \setminus \mathsf{R}^{\#m\#n} \neq \varnothing$. To do this, consider two multisets from R:

$$\boldsymbol{R}_1 = \left\{ k_{11} * (c_{11}, p_{11}), k_{12} * (c_{12}, p_{12}), \ldots, k_{1i} * (c_{1i}, p_{1i}) \right\},$$

$$\boldsymbol{R}_2 = \left\{ k_{21} * (c_{21}, p_{21}), k_{22} * (c_{22}, p_{22}), \ldots, k_{2j} * (c_{2j}, p_{2j}) \right\},$$

as well as their product:

$$\boldsymbol{R}_1 \square \boldsymbol{R}_2 = \left\{ k_1 * (c_1, p_1), k_2 * (c_2, p_2), \ldots, k_n * (c_n, p_n) \right\}.$$

Without loss of generality, we assume that these multisets do not contain elements insignificant from the probability theory, in other words, elements with a zero second component. Further, assuming that the elements of these three multisets are ordered by increasing their second component, we can talk about the compatibility of the following system of equations:

$$\begin{cases} p_{11}\ p_{21} = p_1, \\ p_{1i}\ p_{2j} = p_n, \\ p_{11}\ p_{2j} = p_r, \\ p_{1i}\ p_{21} = p_s, \end{cases}$$

where $r, s \in \{2, 3, \dots, n-1\}$.

Multiplying the left and right parts of the first and second, as well as the third and fourth equations in the system and comparing the obtained equations with each other, we obtain the compatibility condition of the system:

$$p_1\ p_n = p_r\ p_s, \quad r, s \in \{2, 3, \dots, n-1\}.$$

This condition is far from being satisfied for all fixed nonzero p_i, $i = 1, 2, \dots, n$ which proves the above statement.

It is known that the set of non-negative integers can be decomposed as follows, Vinogradov (1952):

$$\mathbf{Z}_0^+ = \{0, 1\} \cup \mathbf{P} \cup \left\{ p^e : p \in \mathbf{P}, e \in \mathbf{N}_{>1} \right\} \cup$$

$$\cup \left\{ \Pi_{i=1}^n\ p_i^{e_i} : p_i \in \mathbf{P}, e_i \in \mathbf{N}, i = 1, 2, \dots, n,\ n \in \mathbf{N}_{>1} \right\},$$

where $\mathbf{P} = \{ 2, 3, 5, 7, 11, 13, \dots \}$ – many prime numbers,

$\mathbf{N} = \mathbf{Z}^+$ – many natural (positive integer) numbers,

$\mathbf{N}_{>1} = \mathbf{N} \setminus \{1\}$ – - many natural numbers, large units.

Using this partition and the previously proved statement, many risks can be represented as follows:

$$\mathsf{R} = \{\varnothing\} \cup \mathsf{R}^{\#1} \cup \bigcup_{p \in \mathbf{P}} \mathsf{R}^{\#p} \cup \bigcup_{\substack{p \in \mathbf{P}, \\ e \in \mathbf{N}_{>1}}} \left[\left(\mathsf{R}^{\#p} \right)^e \cup \mathsf{R}^{*p^e} \right] \cup$$

$$\cup \bigcup_{n \in \mathbf{N}_{>1}} \bigcup_{\substack{p_i \in \mathbf{P}, \\ e_i \in \mathbf{N}, \\ i = 1, 2, \dots, n}} \left[\prod_{i=1}^n \left(\mathsf{R}^{\#p_i} \right)^{e_i} \cup \mathsf{R}^{*(\Pi_{i=1}^n\ p_i^{e_i})} \right].$$

This characterization of the structure of set of risks is no longer trivial; it contains members that, being in the same equivalence class of factor monoid $\langle \mathsf{R}, \square \rangle / \#\#$, differ significantly from each other in terms of complexity.

Information-Theoretical Analysis of the Components of the Set of Risks

We introduce two special constants. Let H_0 be the informational entropy of the procedure of equiprobable choice of one of the natural numbers, H_1 - the informational entropy of the procedure of equiprobable choice of some real number. Using the constants introduced, one can calculate the

entropy characteristics of the elements of the components of the set of risks R obtained in the framework of a nontrivial partition. These characteristics are shown in table 1.

Table 1: Entropy Characteristics of the Components of Set of Risks

Component number	Partition component	Power of multisets belonging to the component	Informational entropy of the multiset
1	$\{\varnothing\}$	0	0
2	$\mathsf{R}^{\#1}$	1	H_1
3	$\mathsf{R}^{\#p}$	p	$p\,H_1+(p-1)H_1=$ $=(2p-1)H_1$
4	$\prod_{i=1}^{n}\left(\mathsf{R}^{\#p_i}\right)^{e_i}$	$\Pi_{i=1}^{n}\ p_i^{e_i}$	$\Sigma_{i=1}^{n}\left[p_i\,H_1+(p_i-1)H_1+H_0\right]=$ $=n\,H_0+H_1\left(2\Sigma_{i=1}^{n}p_i-n\right)$
5	$\mathsf{R}^{*(\Pi_{i=1}^{n}\ p_i^{e_i})}$	$\Pi_{i=1}^{n}\ p_i^{e_i}$	$H_1\,\Pi_{i=1}^{n}\ p_i^{e_i}+\left(\Pi_{i=1}^{n}\ p_i^{e_i}-1\right)H_1=$ $=\left(2\Pi_{i=1}^{n}\ p_i^{e_i}-1\right)H_1$

It is easy to see that the informational entropy of the elements of the fifth component is greater than the entropy of the elements of the fourth component with equal powers of multisets. The fundamental significance of this difference lies in the ability to explain why sometimes risks of the seemingly same complexity are managed differently: for some risks, it is sometimes easy to find a compensation scheme, for others, it happens that we fail to do that at all. For example, one thing is a retail loan portfolio, papers by Urazaeva (2012, 2013), consisting of 1000 homogeneous agreements (2^{2000} outcomes, complexity $7H_1$), and quite another is an investment project lasting 1 year, when one or several random events occur during each business day, each of which affects the future development of the project (outcomes - at least 240, complexity, as a rule, at least $479H_1$). Another example in this area is the competitive advantages arising from the implementation of the concept of a managed contract, Variash (2005) and Urazaeva (2007) .

Tasks Associated with Building Multiple Risks

At the same time, a large number of works has been devoted to improving the accuracy of measuring risk and reducing the calculating resources. In this case, the following problem is often solved. Knowing the risks of developing individual subsystems, we assess the risk of developing the system as a whole. That is, in fact, we are talking about solving a direct problem. Significant progress in this process has been achieved within the framework of the development of the ATR; the corresponding algorithms are often more accurate and more stable than algorithms that implement, for example, the Monte Carlo method, Borodin (2014).

At the same time, another task is often of interest. We observe the implementation of risk events for the development of the system, accumulate statistics and want to understand: 1) is it possible to explain the behavior of the system as a “black box” by the presence of (independent) subsystems, is it possible to assess the risk of development of each such subsystem (identify the subsystems). In other words, we can talk about the relevance of solving the inverse problem.

Consider the options for setting inverse problems in the ATR, induced by the study of the structure of the risk set.

It was shown above that the factor monoid $\langle \mathsf{R}, \bullet \rangle / \#\#$ is isomorphic to the monoid $\langle \mathbf{Z}_0^+, \times \rangle$, however, this isomorphism does not fully reflect the structure of the universal set of risks R, the nature of the set of risks is more diverse than the nature of countable sets. In particular, already at $k \geq 4$ the family $\mathsf{R}^{\#k}$ already contains elements characterized by different informational entropies, depending on the possibility of representing these elements in the form of products of other elements from R.

The last remark leads to the idea that the possibility of representing the risk of a system as a product of simpler risks means simplifying the study of this system, its decomposition into simpler subsystems. Traditionally, the problem of dividing an element of an algebraic system into a product of other elements of this system is called the *factorization* problem. In the context of the topic under discussion, we can say that risk factorization is the identification of subsystems.

Successively consider a number of options for the formulation of the factorization problem.

1. The simplest statement of the problem of risk factorization: for some risk or its part $\boldsymbol{R} \in \mathsf{R}$, it is necessary to find out the possibility of representing it in the form of a product $\boldsymbol{R} = \prod_{i=1}^{n} \boldsymbol{R}_i^{k_i}$, where $n \geq 2$, $\boldsymbol{R}_i \in \mathsf{R}$, $k_i \in \mathbf{Z}^+$, $i = 1, 2, \ldots, n$, and, if the answer it is so, find this representation. Here $\mathbf{Z}^+$ is a set of natural numbers. In the presence of such a representation, the following (trivial) relation holds for the powers of multisets: $|\boldsymbol{R}| = \prod_{i=1}^{n} |\boldsymbol{R}_i|^{k_i}$.

Using the simplest example, we show that the factorization problem in this formulation is incorrect in the sense of ambiguity of the solution.

Let the mapping $c: \mathbf{R} \to \mathbf{R}$ be given by the correspondence $c: s \mapsto s + x_c$, $x_c \in \mathbf{R}$. Consider for this case the product of two risks with two outcomes in each:

$$\{1*(x_1, p_1), 1*(x_2, p_2)\} \circ \{1*(y_1, q_1), 1*(y_2, q_2)\} =$$

$$= \{1*(x_1 + y_1, p_1 q_1), 1*(x_1 + y_2, p_1 q_2), \{1*(x_2 + y_1, p_2 q_1), 1*(x_2 + y_2, p_2 q_2)\}$$

and another product:

$$\{1*(x_1 + z, r p_1), 1*(x_2 + z, r p_2)\} \circ \left\{1*\left(y_1 - z, \frac{q_1}{r}\right), 1*\left(y_2 - z, \frac{q_2}{r}\right)\right\} =$$

$$= \left\{1*\left(x_1 + z + y_1 - z, \frac{r p_1 q_1}{r}\right), 1*\left(x_1 + z + y_2 - z, \frac{r p_1 q_2}{r}\right)\right.$$

$$\left. 1*\left(x_2 + z + y_1 - z, \frac{r p_2 q_1}{r}\right), 1*\left(x_2 + z + y_2 - z, \frac{r p_2 q_2}{r}\right)\right\} =$$

$$= \{1*(x_1 + y_1, p_1 q_1), 1*(x_1 + y_2, p_1 q_2), \{1*(x_2 + y_1, p_2 q_1), 1*(x_2 + y_2, p_2 q_2)\},$$

where $z \neq 0$ and $r \neq 1$. Note that the right-hand sides of these relations coincide. In other words, factorization of the result is possible only up to two constants z and r.

2. From a probability-theoretic point of view, structurally different risks can be indistinguishable. To describe this situation, following the monograph by Urazayeva (2013), we introduce the concept of a congruence of indistinguishability. We introduce a map $\mathcal{K}: \mathcal{P} \to \mathcal{P}^1$ where

$$\mathcal{P}^1 = \left\{ \boldsymbol{R} : \boldsymbol{R} \in \mathcal{P},\ \forall x \left(x \in \operatorname{Supp} \boldsymbol{R} \right) \left(k_{\boldsymbol{R}}(x) = 1 \right) \right\}.$$

We define the mapping $\mathcal{K}$ as follows:

$$\mathcal{K}(\boldsymbol{R}) \underset{Def}{=} \left\{ 1 * \left(\mathcal{C} \sum_{\substack{x \in \operatorname{Supp} \boldsymbol{R}, \\ \operatorname{pr}_C x = \mathcal{C}}} k_{\boldsymbol{R}}(x) \operatorname{pr}_{\mathbf{I}} x \right) : \mathcal{C} \in \bigcup_{x \in \operatorname{Supp} \boldsymbol{R}} \left\{ \operatorname{pr}_C x \right\} \right\}.$$

Using the map $\mathcal{K}$, we introduce a congruence of indistinguishability k as follows:

$$\boldsymbol{R}_1 \, k \, \boldsymbol{R}_2 \underset{Def}{\Leftrightarrow} \mathcal{K}(\boldsymbol{R}_1) = \mathcal{K}(\boldsymbol{R}_2),\ \boldsymbol{R}_1, \boldsymbol{R}_2 \in \mathcal{P}.$$

In practice, there are also situations when some outcomes are realized with zero probability, otherwise, these outcomes are not observable. To formalize this situation, we introduce a congruence of significance, Urazaeva (2017). We introduce the mapping $\mathcal{S}: \mathcal{P} \to \mathcal{P}_{>0}$ where

$$\mathcal{P}_{>0} = \left\{ \boldsymbol{R} \in \mathcal{P} : \forall x \left(x \in \operatorname{Supp} \boldsymbol{R} \right) \left(\operatorname{pr}_{\mathbf{I}} x > 0 \right) \right\}.$$

We define the mapping $\mathcal{S}$ as follows:

$$\mathcal{S}(\boldsymbol{R}) \underset{Def}{=} \left\{ k_{\boldsymbol{R}}(x) * x : \operatorname{pr}_{\mathbf{I}} x > 0,\ x \in \operatorname{Supp} \boldsymbol{R} \right\}.$$

We determine the congruence s of significance using the mapping $\mathcal{S}$:

$$\boldsymbol{R}_1 \, s \, \boldsymbol{R}_2 \underset{Def}{\Leftrightarrow} \mathcal{S}(\boldsymbol{R}_1) = \mathcal{S}(\boldsymbol{R}_2).$$

Now we can formulate the factorization problem in an extended statement: for some risk or its part $\boldsymbol{R} \in \mathcal{P}$, we can find out the possibility of the inclusion $\prod_{i=1}^{n} \boldsymbol{R}_i^{k_i} \in \boldsymbol{R}a$, where $n \geq 2$, $\boldsymbol{R}_i \in \mathcal{P}$, $k_i \in \mathbf{Z}^+$, $i = 1, 2, \ldots, n$, $a \in \{k, s, k \times s\}$, and, with a positive answer to this question, find options for the left side of this inclusion.

3. The solution of the factorization problem in the second statement in the general case is ambiguous not only parametrically, but also structurally. To reduce structural ambiguity, we introduce a functional of information risk entropy $H: \mathcal{P} \to \mathcal{H}$, where $\mathcal{H}$ is a linearly ordered set of possible values of entropy in the model, a set endowed with the structure of an addition semigroup. Now we can reformulate the previous statement of the problem as follows:

$$< n^*,\ \boldsymbol{R}_i^*, k_i^*, i = 1, 2, \ldots, n^* > \ = \underset{\prod_{i=1}^{n} \boldsymbol{R}_i^{k_i} \in \boldsymbol{R}a}{\arg\min} \sum_{i=1}^{n} H\left(\boldsymbol{R}_i\right).$$

Asterisks mark the elements of the corresponding sets that deliver the minimum complexity (entropy) of the factorization result.

Research Results and Discussion

Summing up, we note that in this paper we studied the structure of the universal set of abstract risks of the development of discrete systems in the context of the analogy with the factorization of integers. Differences in the risk factorization potential and integers were found within the risk equivalence class and the non-negative integer isomorphic to it. The revealed difference is characterized by the partition of the corresponding equivalence class into two subsets whose elements differ significantly in the value of information entropy. Considering that the use of the entropy risk measure along with the traditional one allows more precise risk management, including in the conditions of incomplete or poor-quality information, Urazaeva (2007), we can talk about the fundamental role of this study for the development of ATR.

As for factorization, it is obvious that in the general case it is a difficult task. So the complexity of solving the problem of factorization of large natural numbers has generated a whole layer of cryptographic primitives, including such a well-known cryptosystem as RSA. The RSA cryptosystem today, more than four decades after its invention, is considered to be a practically stable cryptosystem, and all this is due to the complexity of the corresponding factorization problem, the progress in solving which for the mentioned period was not too significant. At the same time, as was shown in this paper, the risk monoid is isomorphic to the monoid of non-negative integers by multiplication. On the other hand, it is also shown here that, when examined in more detail, the risk monoid has a more complex structure with respect to the monoid of integers. This fact will be complicated or facilitated by the solution of risk factorization problems so far. The answer to this question is also an urgent problem. So far, there are no ideas for solving the risk factorization problem in the general case for the second and third statements. The development of the factorization algorithm in the first formulation is currently carried out by the authors of this article. Good prospects are visible in solving this problem.

In general, there is a certain interest in factorization problems in statements similar to those given not only in the field of computational risk theory. These are, for example, applications of mathematical physics, Maslov and Chebotarev (1999), and Chebotarev (1999), as well as problems of the theory of queuing systems, Borovkov (1972).

Conclusion

All the results presented in this article are new. Novelty is determined by the absence of studies in the open world literature similar to the development of the ATR in the monograph by Urazayeva (2013), which, in turn, served as the basis for this work.

Abstract

The aim of this work is to identify opportunities for digital transformation in the agro-industrial complex on the basis of state support. The research was based on the works of both domestic and foreign scientists on the theoretical and practical aspects of state support for digitalization of the agro-industrial complex, as well as official statistics and documents characterizing state and targeted programs for agricultural development. The methodology of the work was the dialectical method of cognition and a systematic approach. In the process of research, such general scientific methods and techniques as scientific abstraction, analysis and synthesis, grouping methods, and comparisons were used. This paper presents the main directions of financial support for agricultural organizations in Russia and foreign countries, and also analyzes the allocated support in foreign countries. The authors also reveal some issues of the application of digital economy technologies in the agricultural sectors of Russia. The digital backwardness of the country is emphasized, which creates significant barriers to the digitalization of individual sectors of the economy. The work also focuses on the informatization of agriculture in the context of the digital transformation of the economy. Analysis of statistical data over recent years allows us to conclude that the most positive results in this matter have been achieved in the Central, Ural and North Caucasus Federal Districts. To strengthen the positive results in the development of the agro-industrial complex, constant state support for the innovative development of agricultural producers in the Volga, Siberian, and North-West federal districts is necessary. To date, the necessity of providing state aid to agricultural producers is still very acute. In modern economic conditions, the key to sustainable development of an agricultural

enterprise is its optimal financial support. State support is an integral part of the system of state regulation of all sectors of the agricultural sector.
The factors hindering the development of digitalization in agriculture are highlighted. The directions of increasing the competitiveness of agriculture on the basis of its digitalization are formulated. The main parameters that determine the fate of digital innovation in agriculture are determined.

Keywords*:* Government Support, Agriculture, Digital Agriculture, Digitalization.

Introduction

A significant part of the costs of supporting agricultural producers is consolidated by the activities of the State Program for the Development of Agriculture and the regulation of agricultural products, raw materials and food markets for 2013-2020.

The implementation of the program involves the achievement of the following goals: ensuring the security of the Russian Federation, taking into account the territorial and economic affordability of agricultural products; a significant increase in the produced value added in the agro-industrial complex; growth in agricultural exports; increase in physical volume of investments in fixed assets of agriculture. The main target indicators in achieving these goals are the following (table 1).

Materials and Methods

As noted above, targeted programs have been implemented to manage budget expenditures in the agricultural sector for a long period of time. In the Russian Federation, a mechanism has been developed for direct state support of agricultural producers through subsidies and aimed at reducing the cost of agricultural products.

Table 1: Target indicators for the development of agriculture and markets for agricultural products, raw materials and food for 2018-2020

Name	2018	2019	2020
Agricultural production index (compared to 2015),%	99,4	107-109	109-111
Produced value added in agriculture, billion rubles	3600-3750	3750-3890	3890-4050
Growth rate of exports of agricultural products (compared to 2015),%	117-123	125-128	132-133
Index of physical volume of investments in fixed assets of agriculture (compared to 2015), %	111	111-112	111-113
The amount of household cash (on average per 1 household member per month), rubles.	17 100-17 450	17 460-17 800	17 900-18 300

Source: compiled by the author according to Rosstat.

Thus, the development of agriculture and agricultural markets is characterized by 5 target indicators, the value of which should increase by 2020.

The instruments of state financial support may include price regulation of the agricultural market and targeted subsidies, as well as soft loans and various kinds of compensation payments.

Agriculture is a branch of the economy aimed at providing the population with food and obtaining raw materials for a number of industries. The agricultural sector is one of the most important,

represented in almost all countries. In order for this industry to occupy a worthy position in our country, comprehensive state support is needed.

In the Russian Federation, state support is aimed at: the allocation of subsidies to agricultural producers, the formation and development of the structure of the agro-industrial complex and rural development.

Here is an analysis of the statistics provided by the Federal State Statistics Service. I would like to note that the volume of agricultural production of all agricultural producers in current prices during the period from January-September 2019 is 4098.7 billion rubles.

According to the Ministry of Agriculture of Russia, 118.8 million tons of all categories of grain were threshed in farms (in the initial weight), which is 7.1% more than in 2018. The number of cattle in farms of all agricultural producers amounted to 18.8 million heads, which is 0.5% less than the previous year, including cows - 8.0 million, pigs - 25.7 million, sheep and goats - 24.2 million, poultry - 560.8 million heads. Household farms accounted for 41.5% of the livestock, 11.0% of pigs, 46.1% of sheep and goats (at the end of September 2018 - respectively 41.7%, 12.2%, 46.9%). These indicators show us a large increase in indicators of agricultural production sectors in the Russian Federation thanks to the help from the state. Indices of agricultural production for 2017 and 2018 are shown in Figure 1.

Figure 1: Index of agricultural production in the Russian Federation for 2017 and 2018.

Source: compiled by the author according to Rosstat.

We should not forget the volume of Russia's GDP, which for the II quarter of 2019 amounted to 26,188.0 billion rubles in current prices. The index of its physical volume relative to the II quarter of 2018 was 100.9%. The dynamics of GDP production over 5 years is shown in Figure 2.

Figure 2: Dynamics of GDP production in % of the value of the conditional average quarter (1/4 of the nominal value of GDP for 2016)

Research Results and Discussion

Agriculture and its business entities occupy a special position in the conditions of market relations and cannot equally participate in intersectoral competition. According to various estimates of specialists, only due to price disparity, more than 250 billion rubles of financial resources are withdrawn annually from agriculture. This once again suggests that without special attention from the state many problems of modern agriculture cannot be resolved, and first of all, ensuring the food sovereignty of the state.

According to table 2, it is clear that the funds transferred to agricultural from the federal budget for the period under review in the Russian Federation increased by 11.2% or by 17 224.8 million rubles. and in the reporting period amounted to more than 170 million rubles. A significant increase in the structure of the constituent entities of the Russian Federation by means of state support to agricultural producers falls on the Central Federal District and amounts to 12.3% or 6657.6 million rubles. The least state support allocated to agricultural organizations falls on the Siberian Federal District and amounts to 1.3% of increase or 190.3 thousand rubles.

Table 2 : Amount transferred to agricultural producers from the federal budget, million rubles

Entities	2016	2017	2018	Deviations (+,-)	Growth rate
Central F.O.	54 028,2	52 642,9	60 685,80	6 657,6	112,3

Let us analyze the state support in the Russian Federation and foreign countries. In foreign countries, an indirect form of state support predominates, in which it is possible to solve a whole range of problems of the industry and even society as a whole.

Table 2: Directions of state support for agriculture of foreign countries

The country	Direction of state support
Germany	Concessional lending for the implementation of specialized technologies in production. Cooperation is common among small farmers. The state provides for the provision of financial assistance and tax benefits. Indirect measures are taken to expand cooperation in the agricultural sector.
Austria	Agricultural investment loan and special agricultural loan. Tax incentives for calculating income tax.
France	Concessional lending is used for technical modernization, as well as for the purpose of increasing soil fertility
Great Britain	Benefits and subsidies are received through commercial banks.
Sweden	Income tax benefits Established incentives for investment growth.
USA	Direct financing of the production of the most necessary and significant agricultural products. Preferential targeted lending to the activities of industry entities. The system of lending to farmers. Stimulating the production of high-quality agricultural products. Protecting the interests of agricultural producers in the foreign market. Modernization and increase of technical equipment of production.
China	Targeted subsidies. Tax exemptions. Financing infrastructure projects and scientific activities in this industry. Concessional lending. Price regulation.
Italy	Credit cooperation system.
Spain	Agricultural insurance system.

	Subsidies and other mechanisms of state intervention in the framework of the pan-European agrarian policy are crucial for buffering the variability of prices for agricultural products.
Denmark	The state provides guarantees to farmers for their loans and soft loans to young farmers who have acquired their own farm.
Greece	Tax incentives, according to which agricultural producers are generally exempt from taxation.
Australia	Support is provided to compensate for losses caused by natural or man-made factors.

Source: compiled by the author based on an analysis of information from electronic sources.

Discussion

A significant difference between the foreign experience and the domestic one is the practice of interaction between state bodies and commercial structures, such as banks, insurance organizations, which allows expanding the possibilities of obtaining financial assistance by manufacturers, and also helps to attract private capital and public funds for the development of the industry.

Today the world does not stand still, and with it the economy is trying to move forward. In order to reduce the lag in labor productivity, crop yield and other indicators behind the countries with traditionally developed agriculture, Russian Federation pays more and more attention to the development of government support measures in terms of stimulating the development of digital technologies in the agricultural sector. The introduction of modern technologies in the agro-industrial complex was approved at the government level. The Ministry of Agriculture of the Russian Federation not only developed the concept, but also approved the departmental project "Digital Agriculture" as part of the segment development program until 2024.

The introduction of digital technologies in agriculture implies not only pilot technologies and other technologies of industrial modernization, but also integration and multi-layered forms of cooperation.

In Russia, the digitalization of the agro-industrial complex has already been made a priority at the national level.

As noted in the Digital Agriculture project itself, this platform will build work and provide a system of access to information about the counterparty, and this, in turn, will allow for prompt verification of enterprises to address serious issues such as financing of this organization, lending and insurance [6].

We agree with this goal of the project, because the development of agricultural organizations in both regions and organizations of the country as a whole, first of all, should be based on state financial support, which will strengthen their work, increase efficiency and solve the most important financial problems. We believe that, in turn, the effect of the introduction of digital technologies will create a data stream for creating end-to-end chains from agricultural production to consumption with integration into related sectors of the digital economy.

One of the main objectives of this project is to increase the effectiveness of government support measures in stimulating the digitalization of the agro-industrial economy by identifying and analyzing problems and conditions that hamper the development of digital technologies in the agro-industrial complex of the studied subject of the Russian Federation, as well as determining the main and most promising digital technologies from the perspective of agricultural producers [6].

When considering the term "digital economy", in the narrow sense, an economy based on digital technologies and including the sphere of electronic goods and services is considered. An expanded understanding of the digital economy, according to the Doctor of Technical Sciences of the Russian Academy of Sciences R. Meshcheryakov, is "economic production and the use of information and communication technologies", thus, covering all areas of activity.

Just recently, vehicle control panels, high-performance monitors, speed controllers, and automatically-controlled transport platforms were the focus of attention. Today, customer attention is shifting to artificial intelligence and machine learning solutions. The use of digital algorithms in mobile software for processing aerial photographs, scanned images is in demand.
Modern technologies allow agricultural producers to optimize resources, get larger crops and reduce costs. Thus, accurate fertilizer application along with sowing gives an economic effect of up to 30%, and the differential systems of plant protection application save millions of rubles.

V. Maslova, N. Zaruk, K. Fuchs and M. Avdeev note in their work that inorder to increase the level of production and the competitiveness of grain and its processed products in the EAEU countries, it is necessary to develop and introduce high-quality seed production, to introduce more intensively new low-cost technologies, improve price relations in the grain market, provide state support to the grain subcomplex, harmonize internal requirements for grain quality with the requirements of foreign producers, expand the export of flour and products of deep processing of grain, to develop internal and external infrastructure, and to improve the transport and logistics system of the grain market in the long term. We agree with the authors, because these factors are the key to successful production and achieving results with high profits and high-quality products. [7].

Usenko L.N. and Kholodov O.A. distinguish world leaders in this field, such as the USA, China, South Korea, Singapore, Germany, Sweden. At the same time, they note BGG's analytics on the global digital economy in the world, which will reach $ 16 trillion by 2035. Note that today the share of the digital economy of US GDP exceeds 10.9%, in Europe it amounts to 5.0% [8]. The share of the digital economy in the GDP of individual countries is shown in Table 3. Further digitalization, according to McKinsey analysts, can provide from 19.0 to 34.0% of Russia's GDP growth, and the share of the digital economy can be 8.0-10.0% GDP of the country.

Table 3 : The share of the digital economy in the GDP of individual countries as to 2017

	Digital Economy Indicators					
Countries	**Private consumption in the digital environment**	**Business investment in the digital economy**	**Government spending on the digital economy**	**Export control**	**Import control**	**The size of the digital economy**
USA	5,3	5,0	1,3	1,4	-2,1	10,9
China	4,8	1,8	0,4	5,8	-2,7	10,0
Great Britain, Germany, Italy, Sweden (average)	3,7	3,9	1,0	2,5	-2,9	8,2
India	3,2	2,7	0,6	5,9	-6,1	6,3
Brazil	2,7	3,6	0,8	0,1	-1,0	6,2
Czech	2,2	2,0	0,5	2,9	-2,1	5,5
Russia	2,6	2,2	0,5	0,5	-1,8	3,9

Source: developed on the basis of research materials.

We would like to understand what technologies are being applied today in Russian and foreign agriculture.

In South Korea, the experience of “smart animal husbandry” is developing with the help of biocompatible sensors that are mounted on animals and collect accurate data on their physiological condition. Spain can be a good example of robotic automatic harvesting technology. Dropcopter technologies have already been launched in the United States to disperse pollen into various crops (almonds, apple trees, cherries, pears). About 70% of rice in Japan is also “protected” by drones, and the amount of plant protection products is declining. Some manufacturers claim that the use of

agrodrons in combination with spot spray technology can reduce the volume of chemicals by 95% [2].
Harvest CROO Robotics (USA) is very close to launching its automated strawberry picker Berry 5 (B5). Neither a driver nor a garden tractor is required for the pick-up robot to move the machine along the landings.

We should also mention LindsayCorp in the United States, which has teamed up with TheClimateCorp (Bayer's digital farming ecosystem) to create an interface and exchange data. Information about accurate monitoring of irrigation, as well as data visualization will be available to general users. In Norway, the YaraWaterSolution network for irrigation planning is particularly interesting. The company's platform is based on water sensors that measure the smallest changes in the turgor pressure of a plant leaf, which is described as the plant's "blood pressure". Data is processed and visualized on the MyYara "contact portal". Then, the platform develops sound and specific recommendations for irrigation, which are offered to customers in an easily accessible form through web software [3].

In Canada, Semios has set up their automated, remotely controlled sensor networks for monitoring and treating plant diseases, identifying pathogenic insects on garden and nursery crops using laser technology. And FFRobotics in Israel is known as the developer of the already patented robotic fruit picker, which is due to appear on the US market in 2020. The robot provides a 10-times increase in fruit picking. This season, the system is being tested in the apple orchards in Washington [3].

To increase profitable agricultural business, Indian companies create their own special applications and programs. One of them is IFFCO Kisan-AgricultureApp, which is considered the most popular application for the farming community, a kind of assistant to the Indian farmer to make informed decisions by referring to individual agricultural information (latest prices on the local market, weather forecasts, agricultural advice, tips for the best practices related to agriculture, livestock, horticulture, as well as all government news related to agriculture) [2].

In China, a new technology has been developed, or rather, a device that is smaller than a conventional mobile phone, when you hover over the leaves, it shows how much nitrogen, phosphorus, potassium, chlorophyll, water and other elements are present in the plant, which allows you to accurately determine its condition. Then, these data are stored for subsequent analysis, comparison and forecasting [2].

We want to note that the European Commission unveiled a plan for transforming pan-European science and innovation policy for 2021–2027, presenting a new format for the seven-year framework program (FP) of the EU, called "HorizonEurope"*, and a number of related programs. One of the most important areas of the "HorizonEurope" is the formation of a European innovation "ecosystem" by expanding support for innovation [1].

In his speech at DATAGRI 2018, the forum on promoting digital transformation in the agri-food sector, held in Cordoba, EU Commissioner for Agriculture Phil Hogan said that we need to enhance the use of digital technologies in the agricultural sector, because the problems that crop producers face today are huge: they are asked to produce more and better products using fewer resources, and they should reduce the environmental footprint of production. In addition to changing consumer requirements, farmers will have to face climate change and price fluctuations in world markets [1].

Consider the Russian experience of agriculture digitalization. Today, Russia is part of a group of active followers, but continues to lag behind the leaders. The share of the digital economy in Russia today, according to various estimates, ranges from 2.0 to 4.0% of the country's GDP. In Bashkortostan, entrepreneurs decided to increase the productivity of the agricultural complex through automated control systems. They equipped part of the plantings with modern fog devices that create the best conditions for plant growth. The automated system independently regulates the humidity in greenhouse plantings according to sensors that respond to the rate of evaporation from the leaves. A sensor also controls field irrigation system, which starts working approximately once every six hours.

It should be noted that the technological level of agricultural enterprises of the Tomsk Region and the production culture achieved in the dairy complexes of the Tomsk Region were highly appreciated. "Smart greenhouse", built by the Zhigalevs farm in the Tomsk region, where strawberries grow all year round, all production processes are automated, energy-saving lighting and heating systems are used.

The introduction of digital solutions is a growth point for the agro-industrial complex, which helps to increase efficiency at different stages of the agricultural sector and reduce the impact of the human factor. The Krasnokamsk mechanical repair plant, which is part of the Rosspetsmash Association, is a good example. It has combined its innovative developments of forage harvesting machines assigning KRMZ Innovation brand to them. Using the GPRS or LoRaWan wireless protocol, online monitoring of the operation of the machines, the quality of the future fodder and the work of the operators can be carried out, as well as indicators affecting the quality of the prepared fodder and the efficiency of the operator can be evaluated. The data on the fodder are shown in your personal account in the form of tables, diagrams and graphs.

“Altaiskie Zakroma” Agroholding is also moving into the digital future. At the Novoelovskaya poultry farm, which is part of its structure, all stages of production, starting from fodder supply to climate control in the poultry houses, are monitored online (Smart Farm system).

In the Nizhny Novgorod open-field vegetable growing, the development of digital technologies began later, but is becoming increasingly important. Agrofirma Vesna,OOO (growing sugar beets and legumes, producing sugar) says that they first equipped all the equipment with geolocation sensors, formed a monitoring service, purchased servers, software for working with geodata, compiled electronic field maps and conducted agrochemical soil analysis. This year, they plan to introduce production software in order to make all operational and technological processes digital, form plans for the placement of crops and technological operations using electronic field maps, see the status of production stages online, record deviations and promptly make adjustments [15].

Food storage and processing has its own high-tech features. Thus, the MTS group has developed a project to increase the efficiency of vegetable stores - such a case of digital transformation is presented on the site of the Digital Economy ANO and was used in the Kirov region [15].

The implementation of the digitalization program of the economy can be an impetus for the implementation of future technologies, such as virtual and additional reality, robots, drones and artificial intelligence. Suppose an audit of the land fund using unmanned aerial vehicles. Using drones, enterprises can save on tax and rent payments. There will be an opportunity to use differentiated fertilizer application, which implies monitoring the territory: while the enterprise receives an index of vegetation and soil heterogeneity zones and forms a fertilizer application rate based on the current nitrogen content in the foliage. Another area is the differential application of plant protection products. Here we are talking about processing only areas with infected plants and weeds.

We have identified factors that impede the formation of a digital economy in agriculture, which are divided into external and internal (Table 4).

Table 4 : Factors Constraining the Development of Digitalization in Agriculture

External factors	Intrinsic factors		
	Production	**Economic**	**Factors due to the economic activities of the enterprise**
- natural and biological basis of agriculture; - deficiencies in legal regulation; - underdeveloped infrastructure providing the promotion and implementation of digital technologies; - underdevelopment of the digital technology market; - lack of financial support from the state (for example, difficulties in obtaining state subsidies for the introduction of digital precision farming technologies).	- difficulties in predicting the final results due to high production risks in agricultural production; - uncertainty of the timing of the implementation of digital technologies; - the dependence of the production process on natural and biological factors.	- uneven formation of stocks of own financial assets; - high cost; - duration of the payback period of digital technologies; - lack of information on sales markets; - presence of economic risks; - low consumer demand for digital technologies in agriculture.	- lack of qualified personnel; - lack of opportunities to attract investors, scientific organizations.

Source: compiled by the author based on studies

The main external factor is the low level of allocated state support for the implementation of digitalization. We believe that these factors should not be the case, agricultural organizations need to organize their work properly, and, above all, to work on the development of the concept of digital agriculture. As a solution to this problem, it can be proposed to establish interaction between the state and organizations, which will allow to obtain relevant information about the organization. The information collected will help to solve a number of issues, including those that allow optimal selection of a combination of state support measures.

Based on the analysis of the opinions of representatives of the agricultural business, the authors formulated a number of typical industry problems that can be solved by system digital solutions, including platform ones.

These problems are:

- duplication of industry reporting collected by state bodies;
- lack of systematization of economic indicators and the provision of open data needed by agribusiness;
- lack of a systematic base of digital solutions for agribusiness of domestic and foreign developers;
- underdeveloped infrastructure for the transmission of data collected by agricultural machines and units with telemetry equipment, etc.

Modern agribusiness feels the need to consolidate efforts with the state to determine the overall industry digitalization strategy and priorities, while giving preference to domestic solutions, therefore, an important part of agricultural digitalization at the state level is the creation of state-wide platforms for integrating industry information.

The development of the concept of a digital platform for agriculture, including the formation of target processes and mechanisms implemented by the platform, as well as the conceptual requirements for the platform for agricultural activities, should, in our opinion, include the following processes:

- development of regulations for the transfer of monitoring results and analytical information on agricultural resource facilities and products from the digital platform to the regional governing

bodies of the agro-industrial complex of the constituent entities of the Russian Federation for accounting, monitoring and analysis at the regional level;

- development of regulations for interagency cooperation (including the Ministry of Agriculture of Russia, Ministry of Economic Development of Russia, Rosreestr, Roscosmos, Roshydromet, etc.) for data transmission to a digital platform for the purpose of subsequent accounting, monitoring, analysis;

- development of options for integrated digital products for agricultural producers, including the best combination of government support measures for commercial agricultural services (financial, insurance, leasing, service, educational, consulting), and procedures for their transfer to agribusiness.

In order to stimulate the filling of the platform with data, it is necessary to develop measures of state support for agricultural producers in terms of subsidizing the transfer of data on resource objects (agricultural land, livestock, agricultural machinery), raw materials and finished products that can be sent to the platform through digital products and technologies.

The implementation of the presented functionality of the agricultural digital platform will contribute to the solution of the following tasks:

- Integration of the agricultural digital platform at the federal level with regional and municipal;
- Providing state support to agricultural producers through a single digital platform;
- Digitization and placement in the agricultural digital platform of all data on resource objects, agricultural raw materials and finished products.

The digitalization of agriculture will contribute to its development in such key areas as technical and technological improvement, economic growth, increasing environmental friendliness and human resources and, as a result, increasing the competitiveness of agriculture (Figure 3).

Figure 3: Directions for improving the competitiveness of agriculture based on its digitalization
Source: compiled by the author based on studies

The open question remains how to make new digital developments reach the agricultural producers. In this regard, it is proposed to intensify government support for the introduction and use of digital technologies in agricultural production.

To do this, it makes sense to concentrate more on stimulating agricultural producers, to apply digital innovations without stopping the work on the invention and the creation of these technologies.

State support should be divided into two areas. The first should relate to the production of those types of products for which the threshold level of self-sufficiency in the country has already been achieved

(grain, sunflower, poultry, etc.). Here the emphasis needs to be placed on the reorientation of the manufacturer from the modernization of existing technical and technological means of production to the use of digitalization elements based on the expansion of foreign trade and export activities.

The second direction should concern the production of agricultural products for which there is no minimum sufficient value to ensure food independence. In this case, you need to focus on the domestic market and carry out parallel development of modernization of existing production facilities and digitalization.
More and more new digital solutions are being created for the agricultural business. Some of them are widespread, others "stop working" at the stage of pilot trials. Many people want to know what information innovations take root in agricultural organizations? We conducted a study in which five key parameters were determined that determine the fate of digital innovation in agriculture. These parameters are presented in Figure 4.

Figure 4: Key Features of Digital Innovations Affecting Their Distribution

Source: compiled by the author based on studies

The first factor determining the fate of any innovation is economic. If the new solution does not bring economic profit, it will eventually stop working. Any digital solution in agriculture should provide optimal productivity and maximum profitability for the producer. A digital solution will be successful if it is able to work effectively for many thousands of users who have simultaneously approached it with a wide range of requests in a wide geographical applicationt, so scalability is the second factor affecting the fate of innovations.

Flexibility is a term often used only in software development, in agriculture it needs a detailed definition, which should be built into the solution technology. This allows you to quickly find solutions based on already completed work: seeded crops, field characteristics and growing conditions. The fourth characteristic of an effective digital solution is accessibility. Agriculture, like no other market, needs solutions that will take into account the remoteness of the farm, the limited communication methods. Therefore, digital platforms for agriculture should be able to work in the cloud, as well as in limited local work conditions.

The ultimate feature of a viable solution is usability. Each digital solution for agriculture is a "digital double" of all real processes of growing plants and animals, as well as farm management processes. The user interface should be as simple and complete as possible.

As noted in their works, O. Frolova, V. Makarychev, N. Yashkova, l. Kornilova, A. Akimov: "The digital economy plays an important role in assessing the food security of the region. We believe that digital technology will contribute to:

- optimization of the logistics of supplies of raw materials;
- optimizing the composition of the raw material zone of the region according to predefined criteria;
- calculation of the necessary internal volume of food production, taking into account the population of the region and its gender composition;

- getting ahead of the required volume of production of raw materials in the region, as well as the need for resources for its production (sown area, livestock, livestock, agricultural machinery and labor), based on planned labor productivity.

We agree with the opinion of these authors and believe that to implement all plans for the future, starting with the digital transformation of Russian agriculture, it is necessary to create a sustainable business model that would facilitate the widespread use of digital technologies at all levels of the agricultural sector [12, p. 8].
We will answer the main question: how do we introduce digital technologies in the economy? Is there a support program at the moment? And here is the answer. Literally at the beginning of the new year 2020, the Innovation Support Fund began selecting applications for the Development program as part of the federal projects Infrastructure Information and Digital Technologies of the national program Digital Economy, the Fund's website reported.

The Development Program is aimed at supporting developed enterprises that have a positive business reputation and experience in selling high-tech products on the market, but feel the need for additional R&D to improve work efficiency by diversifying the developed types of products, creating and developing new sales markets.

The goal of this program is to accelerate the technological development of the Russian Federation, increase the number of companies implementing technological innovations, create and implement end-to-end digital technologies based on domestic developments.

This competition "Development - Digital Technologies" was launched on 13.01.2020 and is aimed at supporting small businesses that implement innovative projects to develop new types of high technology products in order to ensure the accelerated implementation of digital technologies.

The projects are selected in the areas of end-to-end digital technologies:
1. artificial intelligence;
2. virtual and augmented reality technologies;
3. new production technologies;
4. Internet of things;
5. robotics and sensorics;
6. 5G communication technology;
7. satellite communications;
8. distributed registry systems;
9. quantum computing;
10. quantum communications;
11. quantum sensorics and metrology.

It should be noted that the main parameters of support provided by the Foundation for the Promotion of Innovation under the Development Program are grants of up to 20 million rubles; extrabudgetary co-financing (at the expense of own or borrowed funds) - at least 30% of the grant amount, and one should not forget about the term of R&D - no more than 23 months.

Small enterprises that do not have unfinished grant agreements with the Innovation Assistance Fund can take part in the competition. Priority is given to projects with a large amount of extrabudgetary funds and a large planned revenue. Based on the results of the fulfillment of the contract, the grant recipient must file an application for registration of the results of intellectual activity abroad in accordance with the agreement on patent cooperation.

Conclusion

In the medium term, the strategic goal of the development of agricultural production should be the digital transformation of the industrial and economic relations of business entities through the use of a wide ICT sector.

The introduction of digital solutions is a growth point for the agro-industrial complex. They help to increase efficiency at different stages of the work of agricultural enterprises and reduce the influence of the human factor. Small farms and large agricultural holdings, both in Russia and in other countries, are interested in them.

Digitalization is beginning to come to the agricultural sector and is one of the main vectors of its development. The challenge facing the industry, and the challanges for developers, and most importantly, specialists who are involved in putting the developments into practice, is how they will be integrated. Such integration is impossible without the involvement of artificial intelligence, the systematization of large databases, since their volumes are growing exponentially. At the same time, we hope that in the near future many farmers in our country will be able to use the potential of digitalization to achieve conditions for sustainable economic growth in agricultural production.

For the introduction of digital technologies, there is state support for individuals and leading companies, which provides a digital transformation of priority sectors of the economy and social sphere by stimulating the development of end-to-end technologies, technological solutions and products based on them. Among these technologies are artificial intelligence, robotics and sensor components, quantum technologies, distributed registry systems, wireless technologies, new manufacturing technologies, virtual and augmented reality technologies.

Still, one of the main tasks of the state today is to make agriculture “smart” and technologically advanced. Advanced technologies and market developments and everything related to remote sensing of the earth, the use of drones, both air and ground, is a digitalization of the management and improvement of agriculture.

Abstract

The article discusses theoretical and methodological approaches to the formation and development of an innovative agricultural system. Based on the analysis of theories of innovations, the authors clarify the essence of innovations and innovative systems, prove the need for a transition to innovative systems, taking into account current global trends and internal contradictions in the economic environment. The features of the process of formation of an innovative agricultural system as a result of transformation of the agro-industrial complex in the context of transition to an export-oriented economy are disclosed. A methodology based on an assessment of the institutional component of an innovative agricultural system is proposed. Based on the analysis of innovative development indicators, the influence of the level of the institutional component on the innovative activity of agricultural organizations in Russia is proved. The authors reveal the reasons for the low innovation activity in the agricultural sector and, on this basis, propose a system of measures and tools aimed at supporting and stimulating innovation in the agricultural sector.

Keywords: innovation, innovative agricultural system, food security.

Introduction

In the context of globalization and the ever-increasing influence of geopolitical processes, national economies need to reach a new level of development, which allows them to advantageously position themselves in the global economic space.

It is known that the competitiveness of the country as a whole will depend on the competitiveness of industries. Increasing competitiveness of the agricultural sector will not only meet the needs for food products, but also ensure the growth of efficiency of the entire agricultural sector.

The Doctrine of Food Security of the Russian Federation, approved by Decree of the President of the Russian Federation No. 20 of 01/21/2020 speaks about national interests of the state, including "... the creation of a highly productive sector in agriculture, developing on the basis of modern technologies and provided by scientists and highly qualified specialists."

The agro-industrial complex is closely connected with many sectors of economy and food security depends on its state. The formation of a highly competitive agricultural sector directly depends on the development of innovation in the agricultural sector. However, most of the scientific developments are unclaimed due to various reasons. The development of scientific results is proceeding at a slow pace in view of the lack of demand from farmers, there are gaps in legal support of innovations and their promotion in production, issues of legal regulation of intellectual property require improvement.

One of the problems of growing competitiveness of Russian agro-industrial complex is the export-raw model of economy of our country. This model has now outlived itself and slows down the progressive development of the country's economic system. At the present stage of development of economic relations, new approaches to ensuring economic growth are necessary, based on scientific, technological and innovative components.

Innovative food security systems are most promising. Most foreign countries made transition from extensive development paths to intensive innovative models back in the 90s of the XXth century. Through innovation not only food security is ensured, but also up to 90% of economic growth in agricultural production. Domestic experience indicates that a significant part of innovation, as before, enters the country from abroad. Economic sanctions call into question further interaction with foreign partners.

In this regard, the formation of the conceptual foundations of the study of innovative agricultural systems in order to increase the competitiveness of the country's agriculture is of particular importance. The analysis of the world experience in the development of innovative systems and the possibilities of using highly efficient models of innovative systems in Russian conditions is essential. Based on the foregoing, there is an essential need to generalize approaches and clarify the theoretical and methodological aspects of formation and development of the domestic agricultural innovation system.

Materials and Methods

The study was jointly attended by teachers and staff of Cheboksary Cooperative Institute and Chuvash State Agricultural Academy. The scientific problem was studied by use of available information resources, including electronic library networks, information and reference systems, official websites of state authorities of the Russian Federation, Rosstat (Russian Statistical Agency), HSE (Russian Higher School of Economics) research results, expert assessments and author developments. The objects of research are the elements and arising within the agrarian innovation system relations, the methodology for assessing its formation and development for the purpose of ensuring food security. In the process of research, the methodology of dialectical development, system analysis, methods of statistical, comparative analysis, analogies, rating estimates, methods of economic and mathematical modeling were used.

Research Results and Discussion

In modern conditions, it is impossible to carry out innovative activities based on a fragmented formal approach. The effectiveness of investment sphere will depend on the development of the innovation environment and investment climate.

The balanced development of innovative agricultural systems dictates the need for theoretical and methodological substantiation of formation of the national agricultural innovation system, which would contribute to sustainable economic growth and food security.

In the process of development of the innovation theory various approaches to the management of the innovation process in the foreign works of such authors as K. Aures (2004), K. Watanabe (2000) Itskovich (2000), L. Leydesdorf (2000), B. Lundvall (1992), Metcalf (1995), R. Nelson (1993), C. Freeman, (1995), K. Fakuda) (2000), I. Schumpeter (1948) were proposed.

The concept "innovation system" was first proposed by K. Freeman in 1987 when describing the economic growth of Japanese economy in the post-war period "... a national innovation system should be understood as a network of public and private sector institutions, whose activity, as well as joint work is aimed at creation, import, modification and diffusion of new technologies." In the works of K. Freeman the emphasis is on the institutional aspect of innovation.

What is important in our opinion is the conclusion that the institutions that make up the innovation system include not only the organizations where research is conducted, but also the way in which resources are managed at the level of both organizations and at the national level. The author formulated theories on technological revolutions, in which innovation leads to a change in the technological base of society and also empirically proved the influence of the main exogenous and endogenous factors on the development of national innovation systems.

R. Nelson concludes that market regulators in the mechanism of state innovation policy have the greatest effect. At the same time, the national aspect requires an individual targeted approach to the mechanism of state regulation, which in turn leads to the idea of only general laws that can be universally applied to achieve economic goals.

The focus of B. Lundwall` theory is on the relationship between producers and consumers of new knowledge and technologies. B. Lundwall is the developer of the systemic aspect of the concept of innovative systems. Elements of the system are formed together, consciously and spontaneously in order to achieve the effect.

In the XXI century. innovation is viewed from the perspective of the ecosystem approach.

Russian scientist Golichenko O.G. believes that a national innovation system is a combination of state private and public organizations and the mechanisms of their interaction within which activities are carried out to create, store and disseminate new knowledge and technologies.

Ivanova N.A. in her writings gives the following definition: "A national innovation system is a set of interconnected organizations engaged in the production and commercialization of scientific knowledge and technologies within national borders. At the same time, it is a complex of institutions of a legal, financial and social nature, ensuring innovative processes and having strong national roots, traditions, political and cultural features "[17].

Thus, an innovation system is a set of interconnected institutional structures working independently and in collaboration in order to ensure innovative processes taking into account national characteristics.

The need for development of the agricultural sector based on innovation is explained by the following reasons:

- globalization of economy;
- market stimulation of agricultural development;
- involvement of private sector in the processes of generation, diffusion and application of knowledge, information and technology;
- significant impact of biotechnology on agricultural production and processing systems;
- changes in the environment, climate change, degradation of ecosystems;
- transformation of the agro-industrial complex and creation of export-oriented agricultural economy.

The World Bank defines an innovative agricultural system as "a network of organizations, enterprises, individuals whose activities and interactions are focused on the implementation of new products, new processes and new forms of organization in economic practice in conjunction with institutions and policies that affect their behavior and performance efficiency. "

Derunova E.A. believes that the innovative regional agrosystem at the same time possesses the features of an innovation system and the specific characteristics of agricultural production. Consequently, the innovative agricultural system is an element of the national innovation system and a logical stage in the transformation of the Russian agricultural sector.

In our opinion, the elements of the agrarian innovation system, taking into account the conditions of a market economy, should include:

- a subsystem of knowledge generation, education and training (universities, research organizations, institutes, colleges, research funds);
- a subsystem of entrepreneurship and production of products, services (manufacturers of products, supply sectors, processing and transport organizations);
- a subsystem of technological infrastructure, the transfer of scientific knowledge and best practices (innovation entrepreneurship support centers, business incubators, consulting engineering firms, information centers, implementation services);
- a subsystem of innovative infrastructure (banks, financial, credit institutions, marketing and transport communications, etc.);
- demand subsystem (markets, consumers of products and raw materials);
- a management subsystem (regulatory unit, management and regulation unit that possesses a mechanism for integrating all subsystems and elements of an agricultural innovation system).

The principles of formation of agricultural innovation systems are:
- priority of the innovative scenario for the development of the agricultural sector;
- partnership between stakeholders, integration of science, education, production;
- taking into account regional features in agricultural innovations;
- improving management quality;
- elements of an innovation system are not only scientific research, but also social, human, financial and other resources available to society;
- organizations are called upon to show flexibility, interact in partnership, provide assistance, resolve conflicts, etc.

The methodology for formation of an agrarian innovation system includes such factors as:
- institutions involved in the transformation of the agricultural sector into an agricultural innovation system;
- causes, effects, and patterns of innovation processes in the formation of an agrarian innovation system based on their analysis and evaluation;
- evaluation of innovative models.

We will evaluate the innovative development of the domestic agro-industrial complex by analyzing the dynamics of indicators of innovative activity as well as investment, innovative and production potential of the agro-industrial complex.

To understand the general trend, we will conduct a comparative analysis of innovation activity in Russia and Western Europe.

Table 1: Indicators of the dynamics of the share of innovative goods, works, services in the total volume of goods shipped, work performed, services of Russia and European countries for 2007-2018,%

Country	2007	2013	2018	2018 (+,-) to	
				2007	2013
Russia	4,6	9,2	6,5	1,9	-2,7
Great Britain	8,5	14,1	15,5	7,0	1,4
Germany	19,2	13,0	14,0	-5,2	1,0
France	13,0	1,5	9,9	-3,1	8,4

The proportion of innovative products in Russia is noticeably inferior to that of Western Europe. Compared to 2007, in 2018 an increase of 1.9% is observed in the Russian Federation, however, compared with 2013 a decrease of 2.7% is observed.

In the UK in 2018 compared with 2007, there was an increase of 7.0%, in Germany and France a decrease of 5.2 and 3.1%, respectively. In 2018 compared with 2013, in all foreign countries the share of innovative goods, works, services increased by 1.4; 1.0 and 8.4% respectively.

Table 2: Dynamics of indicators of innovation in industrial production and in agriculture of the Russian Federation for 2016-2018

Indicators	2016	2017	2018	2018 (+,-) to	
				2016	2017
The proportion of organizations implementing technological innovations, in the total number of organizations, %					
- industrial production	9,2	9,6	9,4	0,2	-0,2
- agriculture	3,4	3,1	3,2	-0,2	0,1
The volume of innovative goods, works, services, million rubles at current prices:					
- industrial production	3723693,4	3403055,2	3693061,6	-30631,5	290006,4
- agriculture	22222,9	28446,0	33829,1	11606,2	5383,1
The proportion of innovative goods, works, services in the total volume of goods shipped, work performed, services,%					
- industrial production	8,4	6,7	6,0	-2,4	-0,7
- agriculture	1,4	1,8	1,9	0,5	0,1
Costs of technological innovation, million rubles					

- industrial production	777518,6	848045,9	886785,8	109267,2	38739,9
-agriculture	14963,3	15806,0	21960,5	6997,2	6154,5

Agriculture is characterized by a fairly low innovation activity, the share of organizations implementing technical innovations is only 3.2%, which is 0.2% lower than in 2016 and a slight increase of 0.1% is observed compared to 2017. Innovative products in agriculture is only 1.9%, the growth compared to 2016 is only 0.5% and compared to 2017 an increase of 0.1%. The costs of technological innovations in 2017 increased, but insignificantly and remained almost at the level of 2016, in 2018 the increase amounted to 6154.5 million rubles.

At the next stage, it is advisable to evaluate indicators of the innovative potential of the agrarian innovation system.

Table 3 : The dynamics of indicators of the investment potential of the agricultural sector of the Russian Federation for 2016-2018. [14.24]

Indicators	2016	2017	2018	2018, % to	
				2016	2017
State support for agriculture under the State Program for the Development of Agriculture, million rubles	295928	257529	249504	84,3	96,88
Investments in fixed assets aimed at development of agriculture, billion rubles	511	434	474,8	92,92	109,4
Costs of technological innovation, million rubles	14963,3	15806,0	21960,5	146,76	138,94

The amount of state support for the agro-industrial complex reduced throughout the analyzed period. So, in 2018 compared with 2016 the decrease was 15.7%, compared with 2017 by 3.22%.

Investments in fixed assets aimed at development of agriculture in 2018 compared to 2016 decreased by 7.18% and amounted to 474.8 billion rubles compared with 2017, an increase of 9.4% is noted. The costs of technological innovation increase throughout the analyzed period, namely by 46.76 and 38.94%

Table 4: Indicators of dynamics of innovative potential of the Russian Federation for 2016-2018

Indicator	2016	2017	2018	2018 , % to	
				2016	2017
The number of personnel engaged in innovative work, people	722291	707887	682541	94,5	96,4
Costs of technological innovation, billion rubles	1284,6	1405,0	1472,8	114,7	104,83
Number of organizations performing research, pcs.	4032	3944	3950	97,97	100,2

Despite the increase in technological innovation costs in 2018 compared with 2016 by 14.7%, compared with 2017 by 4.83%, the number of personnel engaged in innovative development has a steady downward trend. So in 2018 compared with 2016 the reduction in the number of employees amounted to 5.5%, compared to 2017- 3.6%.

The number of research organizations decreased in 2018 compared with 2016 by 2.03%, compared with 2017 a slight increase was noted at the level of 0.2%.

Table 5 : The dynamics of indicators of production potential and demand for innovation in agriculture of the Russian Federation [14,24]

Indicators	2016	2017	2018	2018 (+,-) to	
				2016	2017
The share of innovative products in agriculture in the total volume of goods shipped, work performed, services,%	1,4	1,8	1,9	0,4	0,1
Created varieties and hybrids of agricultural crops	356	369	---	13	---
New technology developed	258	256	---	-2	---
New food items developed	192	188		-4	---
Number of patents received	738	729	---	-9	---

Despite a slight increase in the share of innovative products in 2018 by 0.4% compared to 2016 and 0.1% compared to 2017, in general, there is a decrease in the production potential and demand for innovation in agriculture. Innovation potential remains low, despite rising costs of technological innovation. Further development of the agro-industrial complex is possible only on condition of effective mechanisms to stimulate innovative activity in the agricultural sector.

Conclusion

At present, the development of an agrarian innovation system is carried out under conditions of a sufficiently high level of scientific potential of the agro-industrial complex and low productivity of scientific activity against the background of a declining innovation activity of the bulk of agricultural producers. The reasons for low innovation activity are the lack of a systematic approach to the development of innovations, insufficient state financing of an innovation process, violation of proportions of inter-institutional interaction and high risks in the development and implementation of innovations.

Table 6 presents the directions of support and stimulation of innovation in the agricultural sector.

Table 6 : Directions for the development of innovation in the agricultural sector

Direction	Instruments	Result
1. State support for innovation in the agricultural sector	- program-targeted stimulation; - competitive basis for the implementation of projects; - preferential lending; - government insurance subsidies	- increase in profitability of investments; - minimizing the risks of project activities; - improving financial stability, solvency and innovative returns
2. Stimulating the process of knowledge generation, education and the commercialization of innovations in the agricultural sector	- organization of integrated scientific, educational and production structures, technological platforms; - motivational tools to support agricultural producers; - involvement of agricultural producers in the formation of programs of information and	- formation of a research base; - revenue growth from the sale of innovative products; - development of integration; - competent staff

	consultation centers; - high-quality training and retraining of personnel capable of working in conditions of intensified innovation	
3. Stimulating consumer demand	- conducting mass presentations, demonstrations, exhibitions, fairs of innovative products; - improving product quality due to new technologies, reducing costs and increasing labor productivity	- increase in the share of innovative products; - increasing the competitiveness of agricultural products% - formation of relations with innovative consulting and technical centers
4.Stimulating sales and expanding markets for innovative agricultural products.	- new product channels; - distribution networks; - formation of clusters	- growth in sales; - increase in market share; - increased demand for innovative products

The priorities for the development of an agricultural innovation system will be:

1) development of the agro-industrial complex, taking into account the directions of the state's innovative policy and the needs of the region;
2) development of agricultural science and education;
3) optimization of resources for the development of agribusiness;

Institutional factors should stimulate innovative activity, innovative activity of enterprises, it is necessary to improve the mechanism of state support, focused on the systematic implementation of domestic innovative solutions.

Abstract

The article considers the problem of the correlation interaction of value orientations of the social ideal with the imperatives of the economic sphere of social reproduction. Awareness of the social ideal by society is nothing more than an awareness of the path of one's own civilizational development in general and of the methods of economic production as well. Potential opportunities and models of social ideals are projected onto a complex of methods of economic interaction. The economic ideal is a spiritual-worldview category and is recognized by society as an image of truth, goodness, culture. The economic system is a special sociocultural phenomenon, which on the one hand is organizationally included in the spiritual and moral potential of society, and on the other hand, it is initially influenced by its cultural priorities.

Keywords: socio-economic ideal; economic person; economic paradigm.

Introduction

Understanding the problems of organizing the economic system of social life cannot claim to be complete without addressing the problem of man. It is quite obvious that in scientific, strictly economic doctrines, a person is considered as a consumer of goods and services and the creator of goods and services, as well as the whole variety of material and spiritual elements of national and global wealth. However, the analysis of a person in anonymous form, only from the standpoint of the mechanical functioning of the economic system, has led to insurmountable obstacles in understanding the organization of people's activities in the economic sphere. Understanding the functioning of the economic system must be enriched by its study in the axiological and spiritual-anthropological aspect.

In this regard, it seems urgently necessary to consider the spiritual and value aspect of economic activity. A person as a subject of economic activity should be analyzed at the following levels:

- firstly, reproductive, revealing the importance of economic phenomena in the reproduction of man as a person and an equal member of society, which in turn allows us to determine the value of economic relations in the organization of the social system as a whole;
- secondly, on the ethnocultural one, which allows one to determine the ethnic specificity of the content of its economic motives, the hierarchy of cultural values (and economic values as well). A person is a special system that defines production activity as the initial basis for the construction of harmonious social relations, the achievement of which is directly related to the level of development of a complex of spiritual qualities, mental foundations, the degree of humanization of the system of scientific, industrial, state and political organization.

Methodological Framework

The methodological basis of the study was made by the principles of universal communication, systemicity, historicism, a comprehensive examination of the subject of research, a socio-anthropological approach, and a structural-functional method. The empirical base of the study was information borrowed from economic theory, history, social psychology.

Discussions

The production of material goods, determining the objective premise of the constitutionalization of economic relations, is also a form of production of the subject of economic activity. Economic activity from the standpoint of man, as a subject of social relations, acts as a form of production precisely of human life in all its rich content. Considering a person as a subject of economic relations, it is imperative to take into account the fact that the individual acts not only directly in economic relations, but in the totality of relations that arise in society at each stage of its development. Economic activity acts as a system for transforming the surrounding material, subject and social environment, which entails the need to determine the forms of economic life of the individual, as well as the place and role of various social phenomena acting within the framework of the socio-economic system.

Like any scientific model, the model of the person-subject of economic relations is built on abstraction, idealization, simplification. It must be agreed that the effectiveness of any model design to explain the phenomenon as a whole is limited. It includes only the main parameters characterizing the individual, and, first of all, the motives that stimulate the activity of his economic life, goals, and the methods used to achieve the goals. Economic theory considers a person through the prism of his functions in the process of creating, distributing and using material and wealth in conditions of limited resources, the possibility of an alternative system of production and distribution, etc. The model of man in economic science proceeds from the primacy of satisfying, first of all, his material needs (level of consumption), leaving natural, social and spiritual needs secondary roles. That is why the model of "economic man" is characterized by one-sidedness, since there are many other areas of public life in which a person has the opportunity to show his qualities (Mazhikeyev A., Edwards T.H., Rizov M. 2015).

In the great variety of approaches to creating a model of the subject of economic relations, three main approaches can be distinguished. The criterion for dividing can be the level of abstracting the essential characteristics of the model from the variety of individual, personal qualities of a person. Conventionally, the first direction may be represented by the English classical school. The basis of this direction is the idea of an economic person, as a product formed by the desire to multiply their own economic resources on the basis of increasing the efficiency of their activities. Monetary interest is the main motive for the activity of an economic person. Within the framework of this model, an individual formulates his behavior in such a way as to maximize the usefulness of his own actions, to extract the maximum possible result (primarily cash income). The behavior of an individual is determined by a rationalistic attitude towards achieving his goal at minimal cost under conditions of objectively limited opportunities. A rationalized economic person, in the classical model, acts as a person who is able to determine value priorities and work out ways to achieve them in an acceptable

way. Naturally, to implement a rational model of behavior, an individual must have certain abilities, freedom of action. The contradiction between the possible and the desired is the main condition determining the form of realization of rational behavior.

The following types of rational economic behavior are distinguished: full, limited, and organic rationality. Complete rationality presupposes the absolute triumph of the "cold" mind over ethical and aesthetic experience, achieving maximum results with absolute minimization of costs. The model of complete rationality assumes the unlimited possibilities for the implementation of rationalistic attitudes.

The concept of limited rationality comes from a more realistic attitude about the limited possibilities of man. When making business decisions, a person is objectively unable to use all the information available on a given problem, which is related to the inability to get full access to it. The imprint of the difficulties of analysis, and the limited cognitive resources of the person himself. The economic person in this concept proceeds from the opportunities available to him, he strives to maximize utility, but only within the limits of the level available to him.

Organic rationality states the existence and special role in the system of economic activity of various kinds of behavioral attitudes that an economic person follows. The theory of organic rationality suggests that in the process of economic interaction the rational activity of a person - the subject of economic relations is determined by formal and informal rules of behavior. Fear of breaking established stereotypes makes people act in accordance with tradition even when they do not consciously seek to rationalize their behavior. Conversely, the correspondence of the behavior model to group attitudes is characterized as rational.

The next direction is a product of understanding the place and role of man in the Keynesian school's economic system. The basis of this direction was the awareness of the limited motivational resource of economic activity. For example, it is an oversimplification to reduce the incentives of economic activity only to multiplying a monetary resource. D.R. Keynes as a stimulator of economic activity also notes the needs of a social, spiritual nature, including group ethics, habits, traditions. In such conditions, the achievement of goals by business entities through the implementation of the mechanism of free competition is not possible. In general, the Keynesian model of economic man is close to the concept of organic rationality (Mikova N., Eichhammer W., Pfluger B. 2019).

Another direction is represented by the interpretation of an economic person as a carrier of diverse, constantly changing needs, from the desire to improve the quality of life, to the need for freedom of expression through the implementation of economic activities. This model assumes a dynamic society based on pluralistic principles, with a high level of social mobility, suggesting the possibility of a free transition from one social group to another. Making his choice in a world of limited resources, a person in any economic system seeks to minimize costs and maximize benefits. The universality of this principle allowed G. Becker to formulate the theory of "economic imperialism", the essence of which is the application of the principles of economic rationality to analyze the lives of people outside the economic sphere.

The presented models of an economic person make it possible in an extremely general form to reflect the main characteristics inherent in human behavior in the process of implementing economic activity. Activities in the economic sphere in particular, and in general, as a kind of human activity, always acts as a social product, being a form of reproduction and development of the subject, a form of satisfying needs. The dialectics of the objective and subjective in the process of production of material values (economic activity) is manifested in the social property of the produced values and in the personal properties of their producer. Personal qualities are manifested in the process of creation, and in the emotional attitude to reality, and in its creative transformation. Moreover, both the organizers and managers of production and the direct producers act as the active subject of production relations.

Results

The concept of production we cultivate as the reproduction of not only a system of things, but also of a person, provides the basis for characterizing economic activity and as a form of meeting the needs of a higher order. Successful economic activity can satisfy the needs of a social and spiritual nature. The difference in the system of value priorities of social communities is the basis of pluralism of forms and methods of solving economic problems. The effectiveness of the economic system is directly determined by the level of acceptance by its subjects of economic activity, the degree of positively assessed changes. The ability of certain things to satisfy the needs of a person must be realized by him. An emotional assessment of economic phenomena is based on the correspondence of the phenomena of economic life to public ideas about an ideal economic system. The socio-economic ideal is a unity of the ultimate goals (values) and ways to achieve them, including the form of ownership and the form of organization of the economic system, and the way of distribution of benefits, etc.

Ideas about the ideal form the oldest element of the social worldview. In the scientific community, the term "ideal" means the following: "An ideal is what constitutes the highest goal of activity, aspiration, the perfect embodiment of something." The undisputed authority in the study of this problem is I. Kant, who speaks of the ideal as a state of perfection achieved, which we presented today. It cannot be practically realized in reality. In human material activity, the ideal acts as an a priori understood "regulatory principle". Fichte claims: "We know that ideals cannot exist in the real world, we only argue that they should judge reality and the latter is changed by those who feel within themselves the strength for this" (Moriconi S., Peri G. 2019).

By socio-economic social ideal, we understand the idea of a certain institution that is perfect and desirable for the whole society to organize production, distribution and consumption, material wealth, and create a type of existence on this basis. The socio-economic ideal is a kind of projection of social needs, in which there is no place for everything insignificant, unstable, random. The economic ideal is that image of perfect production and consumption of material values, which, from the point of view of the majority of members of a social group, is most consistent with their ideas of higher justice. The social ideal as a whole seems to be a multifaceted phenomenon, in this case it is right to speak of relatively independent economic, political, moral, aesthetic ideals. It should be noted that each of them does not exist in isolation from each other, but represents peculiar forms of manifestation of a single social ideal. The economic ideal captures the characteristics of production relations and productive forces, reflects the need for society to improve the economic structure of society, all aspects of its organization, all manifestations of its life. The idea of a perfect economic system is that social ideal that stimulates the progressive development of the economy, inspires people to realize their desired future (Agnello L., Fazio G., Sousa R.M. 2016).

The socio-economic ideal certainly carries with it the significance of the moral ideal, since it is based on public opinion and includes a positive moral assessment of the ideas about the desired order of economic relations and ties in this society. This gives the economic ideal a serious transformative moral force. Ideas about the ideal are influenced by constant moods, feelings, desires, various kinds of fantasies, dreams, etc. The ideas developed by the mentality are formed into a special formula of the ideal, the components of which are all kinds of value preferences, priorities, multiplied by a constantly stable emotional psychological condition. The solution of the question of the economic social ideal should be determined by the general, of course, recognized values of the phenomenon under consideration. We have in mind the idea of society about the ideal, which regardless of time and socio-economic situation is always the same, and the pursuit of which is the truth and the meaning of the existence of the national community as a whole.

Awareness of the social ideal by society is nothing more than an awareness of the path of one's own civilizational development as a whole and the methods of economic production as well. The social ideal, as a form of manifestation of the collective spirit, is the value core of the social worldview, which determines the strategic guidelines of the social and spiritual existence of society. Without an idea of collective ideals, a person will be unable to realize his own social identification, to determine

the direction of his development. In our opinion, the main idea on which the ideas about the national social economic ideal in the social spaces of Eurasia are based is the idea of social justice. It is in economic relations within the collective that justice acts as an appraisal phenomenon, an all-encompassing measure of retribution or moral claims against the results and methods of economic activity. Achieving justice is an essential component of the collectivist aspect in the spiritual Russian tradition, which, in fact, is based on national ideas about freedom (will and justice). Justice, in the understanding of the Eurasians, seems to be a materialization in the social relations of the biblical formulas of retribution - “to each his own” and “to each and every reward”. Moreover, justice is not perceived as a ready-made system of measures, acts, regulations, actions. They feel it in the fatum of events that contain the practical implementation of the above formulas (Guo H., Bao A., Liu T., Jiapaer G., Ndayisaba F., Jiang L., Kurban A., Maeyer P. 2018).

In the concept of “justice” in Russia they have been investing and are investing in understanding and evaluating events and actions of the individual from the point of view of historically established ideas about the correct order of things, in such an order that corresponds to popular beliefs about the truth. In this regard, the concept of “justice” for Russians is very consonant with the concept of “equality”. The presence of property and legal inequality and, above all, violation of the principle of equitable distribution is perceived by the mass national consciousness as extremely painful. The whole inner nature of the Russian ethnic group initially seeks to overcome any manifestations of this kind, which is reflected in folk tales, legends and songs dedicated to this topic, which expressed the innermost aspirations and dreams of a just social being. In many national fairy tales, one can track the path of people's hope in their spiritual searches and in the belief in the existence of a mythical country of happiness, where all people live in harmony among themselves, based, including on material wealth, which in turn was the result of an equitable distribution of responsibilities on the production of wealth and which is the basis for public well-being. In the national tales of the peoples of Russia, a wonderful, happy, collective consciousness was associated, first of all, with the active life position of a working man. Often, the main characters, despite the presence of magic items, prefer to live on their own natural abilities and labor skills, and use magical power only in the interests of the whole society. The leading characters of national everyday tales are ordinary people living on funds obtained by their own labor, people who, even for big money, do not want to renounce their professional skills that benefit people and respect their countrymen. A man who earns a living by physical labor is endowed in the tales of the peoples of Russia with the right to rejoice for restoring public justice, and has all the qualities necessary for this: resourcefulness, great quick wit, sharpness of mind and language, which helps him overcome the stupidity, greed and nonsense of egoists. The latter are often exposed as lazy people, for which they bear a fair and severe punishment - the loss of authority in society (Ploeg F., Poelhekke S. 2008).

Thus, justice in the Russian mentality was perceived primarily as a social category. “From each according to his abilities and to each according to his merits” - it is in this principle-thesis that the essence of the Russian national idea of social justice is expressed. Undoubtedly, social justice in the national sense is a problem, first of all, socio-economic. At the same time, the content in it of a real spiritual foundation is not in doubt since any violation of the principles of justice is reflected in the moral and spiritual-emotional state of any team. The idea of justice is the connecting spiritual link of a person with other people. Violating its principles, a person rejects the ideals of the collective, and therefore turns out to be spiritually and physically divorced from society (which was especially clearly manifested in the primitive history of mankind). The question of the social ideal is closely connected with the problem of the production of material goods, which, as you know, are created in the process of labor activity. Any work, even the most difficult, was, according to the people, the best way to distract from various vicious and difficult thoughts. Only in labor can a man be able to make happiness, only labor gives him true joy, only labor will provide comfort in grief: “Evil gruin - work will dissipate”, “Friendly work amuses the soul”. In labor, the Russian ethnos saw a means of satisfying its needs, since it is as a result of production activities that the physical, moral, creative and mental strengths of a person are revealed. This effect of labor on the individual is explained by the creative and creative nature of labor. Strength, wisdom, ingenuity, skills and abilities are invested in the material products of labor, the material embodiment of which cannot but please a person, giving him a sense of his own superiority over nature.

The problem of searching for a social ideal becomes especially relevant during periods of people's awareness of the loss of the meaning of their existence, which ceases to be whole and graceful, loses its universally significant goals for the majority of the nation, which in turn threatens the complete destruction of the traditional system of being. Based solely on the national archetype, on popular beliefs about the possibility of a fair socio-economic structure in Russia, the socialist idea managed to take root. In Bolshevik socialism, people have found hope that they will achieve a perfect model of economic structure, an image that meets their existential expectations, in which there is no exploitation of man by man, an unfair distribution of the goods produced, and their inefficient use. The society had the same hopes at the beginning of the reforms of the second half of the 80s of the XX century.

Conclusion and Recommendations

The economic ideal is a spiritual-worldview category and is recognized by society as an image of truth, goodness, culture. Society cannot and should not abstract from those traditional aspirations that in different historical epochs determined the essence of national ideals. The Russian national economic idea should first of all reflect the fundamental values of the national traditions of the economic life of all its peoples, become for them a single consolidating principle, its essence should be the idea of saving and developing the people. The main priorities of this idea should be the idea of collective norms of socio-economic justice. Economic life is an organized system that is the result of the ordered activities of subjects of economic relations, with their conscious activity, with their ability to establish connections between the interacting phenomena of economic reality, to construct a model of their behavior and even in the most general way to foresee the consequences of their actions.

Thus, the economic system is a special sociocultural phenomenon, which on the one hand is organizationally included in the spiritual and moral potential of society, and on the other hand, it is initially influenced by its cultural priorities. Potential opportunities and models of social ideals are projected onto a complex of methods of economic interaction. The large-scale changes experienced by Russia over the past century in all spheres of public life and in the economy in particular, unique in its complexity natural and economic conditions, undoubtedly need to be generalized and theorized. The deconstruction of the Soviet socio-economic system, and the subsequent destruction of the Russian economy, clearly demonstrated the characteristic aspects of real reality, which urgently required a review of the paradigms of economic theories traditional for official science.

Legal and Organizational Problems of Industrial Development in the Russian Federation

In modern Russia steps have been taken towards regulating industrial production. However, the development of industrial business in the Russian Federation still faces numerous problems, among which are the following:
- lack of effective financial and credit mechanisms, material and resource support of the industrial sector development;

- gaps in the current legislation;

- complexity of access to business information - information about the product, competitor, etc .;

- unresolved issues arising from protection of the rights of workers employed in industrial business;

- instability of an economic situation in the country;

- dishonesty of big business;

- access to credit resources and a high rate of lending;

- lengthy paperwork, especially on land, etc.

Persons carrying out activities in the industry also note the problem of too high tax rates, the complexity of the tax system, the complexity and imperfection of legislation that registers enterprises that regulate their activities, for example, product certification, licensing and so on. Obstacles to business are called “administrative barriers” [1].

Leaders of industrial companies consider the imperfection of state regulation to be the main problem in doing business.

Many managers of chemical enterprises also note the imperfection of state regulation. Manufacturers are concerned with high electricity tariffs and industry taxes, which negatively affect the industry.

Equipment manufacturers are in need of government funding, subsidies and investments. They, along with enterprises in the chemical industry, consider government funding the most attractive [2].

In our opinion, the law “On Industrial Policy in the Russian Federation” is too general. It lacks specificity both regarding the order of reflecting development priorities of domestic industry and regarding the forms of its support. The disadvantages include the following:

- in the goals and objectives of industrial policy there have nowhere been reflected how the state will specify the priorities of domestic industry development and what, in fact, will be understood as

priorities. This is not even fixed in the basic concepts with which the law operates. In our opinion, these priorities should include individual sectors (intersectoral complexes), as well as forms of territorial organization of the industry, which are designed to ensure the country's competitiveness and dominance in specific foreign markets;

- since the law on the country's industrial policy reflects strategic principles and directions of industrial development, it should be linked to the current legislation in strategic planning. Since July 2014, the RF law "On strategic planning in the Russian Federation" has been in force. It spells out in detail the levels of strategic planning and the types of strategic and program documents developed at each level. The law on industrial policy abounds in inconsistency of those documents, which should reflect the main provisions of industrial policy, to those documents that represent the basis of the strategic planning system in the country. For example, there are no inter-regional (district) strategies and programs for the development of the industry that are specified in the law on strategic planning;

- the law extremely poorly spells out directions, forms and specific mechanisms of state support for industrial development. It is not clear what is considered a priority for the state: providing support to specific industrial entities (enterprises), creating new advanced forms of territorial organization of the industry (clusters, industrial agglomerations, etc.), supporting development of industrial infrastructure or ensuring equal competitive opportunities for industrial entities. As for the latter, the law does not answer the question of whether it is necessary to ensure equal competitive opportunities for all industrial entities (domestic and non-domestic);

- the law does not affect mechanisms of public-private partnership in industrial development. They are largely spelled out in the RF law on PPPs and a number of other legislative acts. But in industrial policy (especially in industries that are strategically important for the country), such mechanisms should take their rightful place, taking into account their specific features;

- the law does not reflect the issues caused by development of national standardization and certification systems in the industry, adaptation to international production standards systems. The competitiveness of domestic industrial products in foreign markets and competitiveness of industrial enterprises themselves largely depend on this.

An important issue in regulating the safe handling of chemical products in the Russian Federation is considered to be inconsistent under the conditions of the legislation in force in this area.

Prior to the CU Agreement entry into force , the conformity of products to sanitary and epidemiological conditions was regulated by Federal Law No. 52 "On the sanitary and epidemiological welfare of the population", according to which the products were allowed to be circulated in accordance to sanitary and epidemiological conclusions or state registration certificates (old type). According to the information currently available on the official website of Rospotrebnadzor, for products that were previously subject to sanitary and epidemiological examination with the issuing sanitary and epidemiological conclusions, but which are now not included in the list of products that must be subject to state registration, documents will also be issued confirming product safety, mainly in the form of declarations of conformity. However, the question of how to draw up such documents remains open.

Another problem of this kind can be disagreements in the classification systems for chemical products existing in the Russian Federation. In Russia today, several conflicting classification systems operate simultaneously. This is due to the fact that the basic norms and rules containing conditions for ensuring safe handling of chemical products are reflected in various departmental regulatory documents: those of Rostekhnadzor, Ministry of Transport, Ministry of Health and Social Development, Ministry of Agriculture, Rosstandart, as well as in a number of federal laws of the Russian Federation, such as: Federal Law No. 7 , Federal Law No. 116 "On Industrial Safety", Federal Law No. 52, etc. It should be noted that absence of a law linking these documents into a single system has led to the fact that some documents of the above departments often duplicate each other or conflict with each other.

The same inconsistency is observed in the land law. The optimal, in our opinion, is considered to be a combination of the current land law provisions for regulating the sale of land and other natural objects in circulation with specific land law and other environmental regulations and restrictions that govern the use of land, other natural resources and environmental protection.

Over the past decade, we have seen rather slow development of Russian legislation in subsoil use. There are many problems, some relate more to economic issues than to jurisprudence, but in general we can say about the absence of a clearly defined concept for the development of legislation in this area.

You can also track two trends in the development of this area: the development of the system of administrative regulation and the development of the system of contractual relations. The administrative legal regime and civil legal regimes of subsoil use are reflected in "On the procedure for licensing subsoil use " and "On production sharing agreements," respectively. These two legislative acts represent two different subsoil use regimes, which speaks of the unresolved problem of choosing the path along which the system of regulation of subsoil use should develop.

Changing the current legislation on a contractual basis can be a way out to solve many of the problems that currently exist.

Currently, interactions in subsoil use are regulated by administrative methods. But the state does not take into account investors` interests and does not assume any obligations. But if we take into account the high risks of the subsoil user, the huge costs, as well as very long payback periods of invested money, there is a clear need for a more flexible approach regarding subsoil users.

A sharp reduction in investment is facilitated by the strengthening of state administrative measures, as well as the depletion of deposits. These reasons can lead to the transition of a number of areas to the category of unprofitable.

The current legislation does not specify the basic principles for the existence of state and municipal property, its role in a market economy, its subjects and objects.

If you pay attention to the regulation of subsoil use in other countries, then the legislation there is based mainly on a contractual basis, which includes a set of rules of business law, which is based on the rules of civil law.

In Russia, in turn, a license for the right to use subsoil is considered an administrative act and the concluded license agreements do not contain mutual consideration of interests of both parties to civil-law interactions. In fact, administrative regulation in subsoil use is fixed in the licensing procedure in the current legislation on subsoil.

Comparing the contractual procedure of relations in mining in foreign countries with the licensing of this activity in the Russian Federation, some experts talk about positive changes in subsoil use, if the contractual procedure is developed instead of the licensed one.

However, one can understand the state's fears regarding the application of the contractual procedure for subsoil use, which may not provide full protection of public interests, which is exacerbated by the lack of legislation for the effective application of a public contract.

In defense of contractual interactions, it can be said that such public contract may contain the same conditions as a license, but interactions between the parties vary significantly. These contracts are used as regulatory tools, which include administrative and legal methods of influence, but at the same time, although with certain restrictions, the principles of contractual relations. For example, in Germany, in accordance with their current legislation, the state requires subsoil users to provide a number of documents, among which there are various plans: mining and industrial activities of an enterprise, two-year plans and others. In addition, it is worth mentioning that in foreign countries there is no administrative regulation.

Foreign market investment may also be facilitated by certain market mechanisms: assignment of subsoil use rights, a pledge that can serve to receive additional loans or additional monetary resources, lease of a subsoil land provided for use, as well as trust management, albeit under state control. This will not only attract investment, but also attract subsoil land to economic turnover.

It is advisable to note that characteristics of contractual relations in mining can be considered solely from the standpoint of the fact that subsoil land cannot be removed from the state ownership. Factors such as the possibility of illegitimate seizure of the user's property, the impossibility to provide judicial protection of non-observed rights, as well as the restoration of such rights, the inability to challenge decisions of state bodies that do not comply with the law, the lack of compensation for damage caused by unlawful actions of state bodies, the absence of penalties regarding officials who did not comply with the current legislation hinder the development of the sector in question.

All these factors lead to the idea of introducing contractual relations into the current legislation, when the contract becomes an instrument for developing conditions agreed by the parties and will be based on the equality of participants in the relations. All these changes will allow large-scale project financing of Russian economy, as well as increase taxation.

However, the contractual procedure for cooperation in mining should contain a number of measures aimed at protecting state interests:

- a competitive way to select subsoil users;

- a clear procurement procedure regulated by law;

- clearly defined parameters for bidders selection, common to all;

- an approved list of possible additional conditions;

- approval of the standard form of the contract, where the boundaries of the site, the duration of the contract, the beginning and the end of work, the procedure for payments, other parameters for the extraction of raw materials, including schedules for extraction and construction of infrastructure, the procedure of completing the production process, conservation and restoration are prescribed [3].

It is also necessary to create specialized state structures, for example, the Ministry of Oil and Gas.

If we talk about the ideal solution to the mentioned shortcomings and problems of the current legislation, then the codification of legislation in all stages of development, production, storage and transportation would be a solution to these problems. It can be proposed to start the changes with a simple one, for example, by amending the current federal law No. 2395-1 "On Subsurface Resources" to define essential conditions for a license to use subsoil resources.

Based on the problem of a deficiency of the current legislation regarding this issue, we propose to supplement Article 12 with the sixth part of the following content: "The essential conditions for a license to use subsoil are: 1) the deadline for the commencement of work (preparation of a technical project, reaching full capacity, submitting geological information to the state examination); 2) forms, terms and conditions of payments for the right to use subsoil; 3) an agreed level of mining; 4) the terms of disposal of the extracted minerals; 5) the conditions for the protection of the subsoil and the environment, the safe conduct of work.

The introduction of these changes will allow subsoil users to clearly understand which license conditions are considered essential and, in addition, this will reduce the risk that the court will be able to interpret the concept of "essential conditions" differently.

As regards the regulation of light industry, the situation in the field of sale of industrial products is characterized by significant volumes of illegally imported products.

Federal Law of July 23, 2013 No. 195-FZ in Articles 81 and 82 of the Code of Criminal Procedure and Articles 29.10 and 32.4 of the Code of Administrative Offenses included rules according to which products of light industry removed from illegitimate sale are subject to destruction.

However, in practice, the implementation of these standards is difficult. In particular, the court decision on destruction of light industry products seized from illegitimate sales must contain information on the products to be destroyed with the indication of OKPD 2 codes. At the same time, the body authorized to reflect and assign the corresponding OKPD 2 codes to the seized from illegitimate sales was not assigned. The bodies that carry out the withdrawal from illegitimate sales of light industry products cannot independently assign the product OKPD codes 2 without conducting additional examinations.

Destruction is one of the most costly components after storing property. However, such products are considered the subject or object of misconduct or crime and must be destroyed. Assigning codes to such products, turning them into state ownership and allocating federal budget funds for the purpose of subsequent destruction is inappropriate.

We propose to attribute the costs of destruction of light industry products removed from the illegitimate sale to the procedural costs. This will allow the most efficient destruction of such products and will help reduce the cost of their storage.

The procedure for the destruction of light industry products seized from illegitimate sales should be regulated by a legislative act of the Government of Russia.

We also propose amendments to the Code of Administrative Offenses regarding the non-use of confiscation of the instrument of implementation or the subject of administrative misconduct as both the main and additional administrative punishment for administrative misconduct.

It is also proposed to exclude from the CAO the provisions on the list of products removed from the illegitimate sale of light industry, which must be destroyed. At the same time, it is proposed to consolidate the duty of a person who is liable to reimburse the costs of administrative misconduct in connection with the destruction of light industry products seized from illegitimate sales.

Also, amendments should be made to the Federal Law “On Customs Regulation in the Russian Federation”, recognizing as invalid the rules of destruction of light industry products confiscated or federalized, providing a simple and understandable procedure for the destruction of light industry products removed from illegitimate sale, which will be established by the Government of Russia.

At the same time, it is proposed to consolidate the duty of a person on whom the responsibility is imposed, to reimburse the procedural costs caused by the destruction of light industry products removed from the illegitimate sale.

At present, the strategic goal of modern Russia development is to achieve the level of economic and social development corresponding to the status of Russia as a leading world power of the 21st century, which occupies leading positions in global economic competition and reliably ensures national security and realization of constitutional rights of citizens. In 2015-2020, Russia should be among the five leading countries in terms of gross domestic product (purchasing power parity).

We will try to assess how the system of proposed measures and industrial policy actions in the main industry documents of the Ministry of Industry and Trade and the Order of the Government of the Russian Federation dated November 17, 2008 No. 1662-r (as amended on September 28, 2018) “On the Concept of Long-Term Socio-Economic Development of the Russian Federation in the period until 2020” is consistent with the goal (hereinafter referred to as Strategy 2020) [4].

Assessing these documents in terms of principles of strategic planning, we would like to note the following:

- the availability of these documents satisfies the principle of the need for planning, since a clearly formulated strategy, with clearly defined goals and developed tools for their achievement reduces uncertainty in industrial development and stimulates commercial activity in this sector of economy;

- non-observance of the principle of unity (according to R. Ackoff - holism) has led to the fact that the planned document Strategy 2020 of a higher level does not correspond in structure to industry documents of a lower level. So, in the development strategy of the aviation industry, developed by the Ministry of Industry and Trade, and Strategy 2020, neither the planning horizon nor the target indicators nor the values of the target indicators coincide;

- the principle of participation that has not been fully implemented, casts doubt on the choice of the target audience for which this strategy has been developed. The civil society, on which the success of the implementation of the goals and objectives will depend, is not familiar with these documents and investors understand the ambiguity and riskiness of these documents, since the country has a very short time to make such radical changes;

- using the principle of continuity, the strategic planning system is gradually expanding its horizons, but, unfortunately, these documents do not adequately reflect the basic conditions for the strategy implementation. Comparison of documents of different years, different in structure, as well as reports of various ministries on the implementation of the strategy does not give a complete picture of the achievement of planned indicators;

- the principle of accuracy is implemented in strategic plans for the development of the industry in the form of goals that are of a qualitative nature, the uncertainty of the external environment and the ambiguity of assessment of the available information increase;

- these strategies also comply with the principle of flexibility, are regularly discussed and adjusted: the Strategy for the socio-economic development of Russia until 2020 was developed in 2006-2007 by the Ministry of Economic Development in accordance with the instruction of the President of the Russian Federation V.V. Putin, in 2011 it was finalized by the Higher School of Economics, the Russian Academy of National Economy and public services.

The developed Strategy 2020 covers many aspects of the country's economic, political, social life, gives a clearer picture of the government's vision of the country development. Many targets of Strategy 2020 are unreasonably optimistic: a twofold increase in GDP, a four-fold increase in labor productivity, a two-fold decrease in the energy intensity of products and all this with a multiple increase in tariffs for energy resources and transportation. Moreover, the concept does not take into account many realities of modern society and its development: deterioration of the quality of education, a decrease of the population, social, political degradation of a society. But the fact that this document can serve as a motivation factor for a new generation, can cause loyalty to modern state power, become the basis for formation and maintenance of political power in the long term, is considered an indisputable fact.

Currently, the following national projects in the field of industry have been approved in the Russian Federation, developed by the Ministry of Industry and Trade of Russia pursuant to Decree of the President of the Russian Federation dated May 7, 2018 No. 204 "On National Goals and Strategic Tasks of the Development of the Russian Federation for the Period until 2024" [5]:

1. The national project "International Cooperation and Export" (approved by the Presidium of the Presidential Council for Strategic Development and National Projects (administrative misconduct act dated December 24, 2018 No. 16), providing for the solution of the following tasks:

- orientation of industrial policy, including the applied state support mechanisms, towards achieving the international competitiveness of Russian products in order to ensure their presence in foreign markets;

- reduction of administrative procedures and barriers in international trade;

- creation of a flexible line of financial instruments for export support (by 2021), including expanded pre-export, export and equity financing, leasing and long-term support measures;

- elimination of logistic restrictions when exporting products using rail, road and sea transport, as well as construction (modernization) of checkpoints across the state border of the Russian Federation;

- creation of a unified system of export promotion institutions, providing for the modernization of trade missions of the Russian Federation abroad;

- formation within the Eurasian Economic Union of common markets for products, services, capital and labor, including final elimination of barriers, restrictions and the abolition of exemptions in economic cooperation, while actively using mechanisms of joint project activities.

2. The national project "Labor Productivity and Support for Employment" (approved by the Presidium of the Presidential Council for Strategic Development and Priority Projects (administrative misconduct act of September 24, 2018, No. 12). It should solve the following tasks:

- stimulating introduction of advanced managerial, organizational and technological solutions to increase labor productivity and modernization of fixed assets, including provision of tax preferences;

- reduction of legislative and administrative restrictions that impede labor productivity growth, as well as replacement of obsolete and unproductive jobs;

- formation of a system of methodological and organizational support for increasing labor productivity in enterprises;

- formation of a training system aimed at teaching the basics of increasing labor productivity, including the use of digital technologies and platform solutions.

In conclusion, the legislative regulation of industrial sphere is considered the most important component of the state economic policy. In our opinion, the question of appropriateness of regulating the industrial development of business entities is especially relevant at the present time, when many Russian enterprises face problems posed by the global nature of modern economy. In this case, government intervention through the adoption of new and improvement of existing legislative acts in the industry will reduce the loss of transition from the use of the old portfolio of resources close to exhaustion, to a new one, the formation of which requires time and serious support from the state.
