The current business environment is affected by technological changes, new information technologies and new business practices. In order to meet customer expectations and meet their needs, it is necessary to create a strategy of competitive advantage (Mohammadi, 2018). Zeman and Bogdan (2019) also points to the importance of marketing strategy. According to Kotler and Keller (2013) marketing is a social process through which individuals and groups obtain what they need and want by creating, offering and freely exchanging products and services with others. In the company's success is important consumer satisfaction and education in environmental and social issues related to the business of the company, which can gain a competitive advantage, image, attract new customers and thus increase profits, through the application of the principles of corporate social responsibility (Nadanyiova and Durana, 2019). In the context of marketing, the company is an integral part of the marketing mix. It is a set of marketing tools that a company uses to achieve marketing goals in the target market. The company uses these tools to stimulate

customer activities. With a well knowledge of customer needs and expectations, the company can use the individual elements of the marketing mix to guide customer behaviour according to the company's needs. Customer relationship management includes employees, business processes and technologies to maximize customer loyalty and business profitability (Krizanova, et al. 2018). A company will only have a successful product if it has all the tools of the marketing mix harmonized (Marusic, 2019).

Product

A product in the broadest marketing sense is everything that serves to meet the needs of target or relationship groups. In this sense, products are understood as the essence of the existence of a company, without which other elements could not be effective (Vysekalova and Mikes, 2009). Janeckova and Vastikova (2001) characterize a product as anything that can be offered for purchase, use or consumption that is able to satisfy the needs, desires or requirements of customers. Birnerova and Krizanova (2013) define a product as the most important tool of the marketing mix. In relation to a product, it is important to point out two types, namely the tangible and the intangible product, which are otherwise called the terms product and service. Kotler (2007) defines products as something of a material nature that are the means of providing services. On the other hand, services are intangible products, which are activities for sale that do not bring ownership. Every customer has certain ideas and expectations regarding the properties and quality of products and services that the company should try to satisfy. Birnerova and Krzanova (2013) in the context of the product point to the importance of product policy, the essence of which is the goal and culmination of creating an offer. Depending on whether it is a manufacturing enterprise or a service enterprise, the term product policy can be replaced by the term product policy for manufacturing companies or performance policy for service enterprises. They also list the main tasks of product policy, which include demand-driven supply creation, demand-driven supply change and competition-driven supply change. It is recommended to make these changes after performing analyses that are suitable for determining the position of the assortment, such as product life cycle analysis, assortment structure analysis by age, by customers, by share of sales and by profitability. Svoboda (2009) states that the offer of products and services is the essence of the company's existence in corporate identity, and therefore it is impossible for corporate identity to be based only on corporate design, communication and culture. The correlation between an organization's product and its corporate identity is very close. One of the basic requirements for marketing is a clearly identifiable product, originating from a clearly identifiable manufacturer. The product expands its impact on the company's image and gives it an additional dimension of cohesion. For building and influencing corporate identity, such emotional properties of the product are important as: overall enjoyment of owning and using the product, personal identification with the product, satisfaction of individual taste through aesthetic properties of the product, product impact on prestige and self-satisfaction, product as a symbol enabling self-expression (Vysekalova and Mikes, 2009).

Marketing communication

According to Cihovska (2001) communication is the life-giving force of any relationship, and therefore also a commercial one, because every organization communicates. Swiatkiewicz (2018) focuses on market communication at the organizational and marketing level. Nagy (2012) points out that communication is one of the most important components of an individual's daily life, which can be described as a process of exchanging information either orally or in writing, which takes place between at least two participants. Kosiciarova (2017) sees the importance of communication mainly in the fact that it allows to influence individuals as well as groups, modify their behaviour, achieve effective changes and subsequently the relevant goals. In the

communication process, everyone expresses their ideas in a certain way and gives them a certain form. Communication is influenced by many factors based on the physical, social and cultural environment (Dedina and Odchazel, 2007). Corporate communication can be defined as the process that ensures that the corporate identity is transferred to the corporate image of the company through controlled and planned communication with key target or interest groups (Cihovska, 2001). Corporate communication represents all means of communication, a complex of all forms of behaviour by which a company shares something about itself, whether with an external or internal environment. In the context of communication in the company Dedina and Odchazel (2007) state that communication clearly directly affects the performance of the entire organization, and therefore it is necessary to pay enough attention to it. Managing communication can give a company a competitive advantage and its underestimation is likely to lead to major problems. Therefore, it is necessary to pay attention not only to classical communication, but also to communication influenced by technological changes. In the process of globalization, these are the internet, discussion groups and other new forms of communication between individuals and between organizations and the individual. The goal of marketing communication is to adequately address individual target groups so that positive attitudes to the company are created, so that marketing communication becomes an important and inseparable part of corporate identity, because without appropriate communication and presentation of strategy and company values it is not possible to create the desired image (Vysekalova a Mikes, 2009). Kosiciarova (2017) considers the main goals of marketing communication to be strengthening corporate image, providing information, stimulating and creating an offer, differentiating the product, emphasizing the value and benefit of the product and stabilizing turnover. Traditional approaches to marketing communication are based on rational consumer behaviour (Nadanyiova, 2017). The overall marketing communication program is also called the communication mix and consists of a combination of four main communication tools, including advertising, sales promotion, personal sales and public relations (Cihovska, 2001). There are several ways to classify a communication, resulting in several types of communication. First, it is possible to divide communication into two basic categories. The first is internal communication, the aim of which is to strengthen the internal integrity of the company's social system and to create a sense of responsibility of employees towards the company. The second category is external communication, which aims to inform about products, economic results, current position, future intentions and activities of the company. In connection with this division, it is important that the entire corporate communication, both internal and external, is uniform in its content (Cihovska, 2001). Balmer (2000) states that corporate communication is a system process consisting of three spheres, namely z primary, secondary and tertiary. In many societies, all three are balanced. Primary communication should present a positive image of the company and set the stage for a strong reputation. Secondary communication should be designed to support and strengthen primary communication. Tertiary communication should be positive and should result in an excellent reputation. If corporate communication is properly designed, executives who implement corporate communication can get the company to a competitive advantage. Corporate communication is particularly important in that it creates a connection between the corporate identity of the organization and the set strategic goal, and it is possible to achieve a favourable reputation of the company through it. Horakova et al. (2008) define corporate communication as a process that translates corporate identity into corporate image, through managed and planned communication with key target and interest groups. Communication is essential for all interest groups - employees, customers, shareholders and others to understand the identity of the organization, its values and strategy. Marketing communication based on a well-chosen communication mix leads to increased consumer loyalty to products and their better placement in the market. For this reason, it is also important to create and build a long-term relationship with customers through communication. Marketing communication is a term that includes all the ways in which an organization communicates with its environment and various stakeholders (Melewar and Karaosmanoglu, 2006). Communication can be divided according to the degree of formality. From this point of view, there is formal and

informal communication. While formal communication flows through officially established communication channels, informal communication takes place through informal communication channels. Petrikova (2007) points out that formal communication is based on the organizational structure of the company and determines powers and responsibilities. Communication outside the company, which in many cases is formal and official, can offer many forms, such as published company missions, logos and press releases about the company. Through formal communication, companies try to acquaint stakeholders with their strategy, goals and operational results. Informal communication is more spontaneous and does not consider formally established channels. In the context of communication Dedina and Odchazel (2007) point out the importance of electronic communication, which, despite its many forms, due to the rapid development of information technologies, it is possible to expect the emergence of its other forms. Businesses use the Internet as a global network for electronic communication and their own intranets. The Internet contains a huge amount of information about various products, companies, technologies and options, so the employee, rather than finding the problem, solves how to choose what is necessary and up to date.

Tools of marketing communication

Personal selling is included among the personal form of communication, because it takes place directly between the seller and the buyer. It is basically a presentation of a specific product or service in the presence of both parties, but it is not necessarily a physical contact. The goal of personal sales is not only to sell the product, but also to strengthen relationships with the customer and get feedback from him. (Prkrylova et al., 2019). Examples of personal sales can be sales presentation, telemarketing, face-to-face meetings, various programs, samples, etc. (Kincl et al., 2004)

Research question: What marketing communication tools do companies use?

Based on literature review, there are many tools of marketing communication. We have selected 7 tools, which we describe in more detail in the next part of the article. These selected include advertising, sales support, direct marketing, PR (Public Relations), trade fairs and exhibitions, guerilla marketing, product placement (PP)

Advertising - The task of advertising is to reach the target group of people, potential customers, either through various media or non-profit organizations and groups. Advertising is paid for and we classify it as an impersonal form of communication, because it does not take place directly between the producer and the consumer. The mission of advertising is to evoke a certain impulse in a possible future customer to buy a given product or service. (Prikrylova et al., 2019) The following are used to promote advertising: various print and broadcast advertisements, packaging design, catalogues, films, brochures, magazines, various billboards, etc. (Kincl et al., 2004).

Sales Support - In most cases, sales promotion is added to a different type of ad. The point is that existing advertising gives the customer an incentive to buy a given product or service, and sales promotion is the reason why they end up buying it. It follows from the above that it is only a kind of short-term incentive to increase the volume of sales of a product or service, which may be for example in the form of any game, competition, coupons, rebates or exhibitions (Prikrylova et al., 2019).

Direct marketing - Once direct marketing was considered a direct communication between producer and consumer, but the market and technology have evolved over time and today we can imagine direct marketing, for example, through online shopping or e-shop. This method of purchase differs from catalogue sales in that the transaction proceeds much faster, and thus the trade or bank transfer (Prikrylova et al., 2019).

PR (Public Relations) – it means relations with the public. Under this phraseology we can imagine various articles in the press, annual reports, publications or speeches (Kincl et al., 2004). PR contributes to the improvement of relationships, both inside the company (internal relations) and outside (external relations). In internal relations with the public we can include customers, suppliers, employees, in short, everyone who has a certain relationship with the company. External represent media, government bodies, teachers or high schools or universities. An important concept in PR is the so-called publicity. In this case, it is impersonal advertising, where the message, television, social network, or other form of communication refers to a product, service or person. Today, the Internet is the fastest growing medium found almost everywhere. For companies, the Internet is attractive mainly from the point of view of marketing communication, thanks to which it can quickly and easily reach potential consumers (Gajanova and Kramarova, 2016). The advantage of online marketing communication is a large impact on a wide audience, which perceives the promotion as a form of advertising (Krizanova et al., 2019). On the contrary, the disadvantage is that while the traditional consumer proves loyalty to the company for the services provided, the digital customer has several options to choose from, where the decisive factor is the purchase of time, delivery costs, product price or references (Chivu et al., 2018).

Trade fairs and exhibitions - Trade fairs and exhibitions represent a combination of personal and impersonal forms of communication, which we had the opportunity to see in previous forms of advertising (Prikrylova et al., 2019).

Guerilla marketing - A moment of surprise, this is the best way to capture the essence of guerrilla marketing. It most often uses humorous or absurd processing, which is supposed to cause a shock in people, at the same time the company tries to remind its brand at minimal cost (Wojciechowski, 2016).

Product placement (PP) - This form of advertising is essentially the placement of a specific branded product in an audio-visual work. The products themselves are not of an advertising nature unless they agree to them in clearly defined conditions. The advantage of this advertisement is that it does not act violently, the viewer perceives it as part of watching e.g. your favourite movie, where the viewer may even have a desire or need to own the product (Prikrylova et al., 2019).

In connection with technical progress and modern technologies, the necessary tools of marketing communication are the website and communication via social networks. The company's website can be the company's main means of communication with the public on the Internet. Ecommerce users' websites have very important components in gaining trust and influencing buyers when buying goods (Princes, 2019). It should contain all the important and necessary information for customers. Another tool that is in most cases essentially a necessary tool for communication are social networks, especially Facebook and Instagram. Instagram is currently the most used and, so

to speak, the latest social network. Above all, various images or series of images are shared via Instagram. In addition, however, it also offers other options: broadcast live videos, give current pictures, the so-called stories that are only visible for 24 hours, live interviews, etc. Instagram is an ideal place to promote products, and importantly - in a freeway.

Conclusion

Marketing communication is an important element, thanks to which both the customer and the company obtain the necessary information. Customer about the product and company about the customer. A serious problem is the use of the right kind of promotion of the product. Evaluate what type of promotion is most appropriate for promoting the product. Incorrectly determining the type of ad used can have a significant impact on gaining potential customers. Even though traditional methods of advertising are still used by many people today, it is important to consider technological progress. Today, the Internet is popular with many people, as it is the most dynamically developing medium. For companies, the use of communication through modern technology is a matter of course. Marketing communication is an important tool, thanks to which, when properly applied and implemented, the company can ensure effective and successful sales of the product, as well as the success of the entire company.

Abstract

Innovation and education in particular are becoming key factors for the growth of competitiveness, as well as the ability to apply the results of science, research and development in business practice. In this paper, we focus on three main areas. As the Slovak Republic is a member state of the European Union, one subchapter focuses on the level of innovation activity across the European Union and emphasizes the position of Slovakia in the ranking of all member states. However, we focused more on the innovative activity of companies operating in the Slovak Republic and the aim of this paper was to emphasize the main barriers that prevent companies from innovating. When processing the paper, we mainly used the meta-analysis to review studies by foreign authors, documents issued by the Statistical Office of the Slovak Republic and the European Union.

Keywords: innovation, innovation activity, innovating enterprises, innovation barriers.

Introduction

The natural development of the business environment of the Slovak Republic has created a great deal of pressure on the growth of the competitiveness of companies and regions. Firms' innovation activities play an important role in fostering firms' competitiveness and enhancing economic growth of regions and countries, as well as the ability to apply the results of science, research and development in business practice (Zygmunt, 2019). International competition and a competitive market environment have made it important for companies to successfully manage innovation-enhancing activities. Continuous development in areas such as education, the Internet, fast communication, contributes to the continuous improvement of companies and their growing offer of more complex and differentiated products and services.

It is the fact, that innovation is positively linked to business performance and it acts as an intermediary between organizational variables and financial performance measured by earnings achieved (Durana et al., 2020).

The level and intensity of innovation activity in individual companies does not only depend on the willingness or ability of the company to engage in innovation, but is also influenced by external factors. Identification of factors determining the innovative activity of enterprises is one of the basic directions of research on growth and economic development (Jakimowicz & Rzeczkowski, 2019). This task is extremely complex, because it is conditioned not only by the singular internal

properties of enterprises, but also by the aspects regarding the socio-economic environment (Wziątek-Kubiak et al., 2013). The impact of innovation barriers on the innovative activity of enterprises and their goals is confirmed by numerous studies (Lewandowska, 2014; Madeira Silva et al., 2017; Segarra-Blasco et al., 2008; Talegeta, 2014; Zabolotniaia et al., 2019).

In this paper, we will focus mainly on the innovative activity of companies in the Slovak Republic and on the barriers that affect their innovative activity.

Literature review

The current economic situation on the market underlines the importance of business competitiveness. An important and necessary feature of companies is a flexible response to the changing business environment and customer requirements. Efforts to meet such variable requirements create pressure for innovation (Zizlavsky, 2016). Innovation is considered a key factor for success (Akman & Yilmaz, 2008) and at the same time it is the basis for increasing economic performance and productivity. Boston Consulting Group (BCG) points out that up to 66% of executives consider innovation to be one of the top three strategic priorities (James et al., 2008). Through innovation, companies gain the ability to dictate and modify "rules of the game", allowing them to enter new markets and challenge established market leaders.

When companies wanted to increase their market competitiveness in the past, they focused on cost, time efficiency and quality improvement. At present, quality is a necessary criterion of competitiveness, but it is not enough for a company to survive and be successful (Rejeb et al. 2008; Assink, 2006; Romijn and Albaladejo, 2002). Companies should not take an emphasis only on product quality, but also quality of customer relationship is important (Krizanova et al., 2018). Businesses are therefore forced by the pressure of the market environment to constantly innovate, develop new processes and supply new products to achieve and maintain a competitive advantage (Rejeb et al. 2008).

The economic crisis that businesses will continue to face should not be a barrier to a company's ability to innovate. Simply reducing the workforce and suspending or relocating R&D to other countries will not solve the problems caused by the economic crisis. One possible solution for businesses to survive in times of economic crisis is to remain innovative. The right strategies can benefit companies and build competitive advantages. An example of the correctness of such an action is Craig Barrett, a former chairman of Intel, who was able to understand and benefit from the circumstances. He argues the following: “You cannot save on your way out of recession; but you have to invest in it,, (Little, 2009).

Carlos Moedas, European Commissioner for Research, Science and Innovation, said (2019): “Innovation is synonymous with job creation and growth. However, if the EU and its Member States are to compete globally, they must continue to invest and develop appropriate policies to further develop innovation. "

There is no denying the fact that innovation is the basis of sustainable growth in the company. On the other hand, there is no guarantee that investing in innovation will be spent effectively. Therefore, it is essential to innovate wisely and with focus. For this reason, the company should continuously evaluate current ongoing innovation projects and decide on the basis of this information whether it will continue these activities.

Unfortunately, a large number of companies are not involved in measuring the performance of innovations, despite their enormous importance in business development (Skarzynski & Gibson, 2008). Experience and research confirm that the necessary steps by top management must be: to show long-term commitment and allocate resources for innovation in order to create a lasting organizational capacity for innovation (Davila et al., 2013).

Understanding of innovation

As the Slovak Republic is part of the European Union, we will look at the definition of innovation from the perspective of the European Commission, which understands innovation as the renewal and expansion of products and services and related markets, the creation of new methods, technologies and methods of production, supply and distribution, the introduction of changes in management and organization of work, in improving working conditions and increasing the qualifications of workers.

This definition points to a comprehensive understanding of innovation, including different application procedures in the field of innovation. The European Commission does not limit the understanding of innovation to those of a technical nature; on the contrary, it increasingly emphasizes the importance of innovation in the organization and management of production processes, business quality models in production and, of course, sales promotion. It considers science, research and development to be the main source of innovation, which is naturally related to the ability to apply them in business practice and thus also to the invention, creativity and qualification of entrepreneurs and their employees.

A business that does not innovate ages and declines. At present, in a period of extreme changes, the decline is rapid. "Innovate or die," is a well-known statement by Tom Peters. The importance of innovation in business survival requires that the company's structure, organization, technologies and practices constantly meet market needs (Castellacci et al., 2005). In order for a business to continue and survive in a changing environment, it must adapt (Eisenhardt & Martin, 2000).

Innovation is important, because for many businesses it is a set of tools for generating entrepreneurial and profitable growth that will improve its performance and competitiveness (Potters, 2009). Sustainable and profitable growth in the company requires sustainable innovation activities (Michalkova et al., 2019). Before a current product or service reaches a level of maturity or technological obsolescence, companies must come up with a new business opportunity, improved product line or service to sustain growth and maintain a competitive position. Innovation helps to bring new products or services to market, retain existing customers, create new markets and promote the global competitiveness of nations (Dobrodolac et al., 2018; Elvira et al. 2019). History has shown that only companies that innovate will survive, and companies that do not innovate, are more likely to leave the market because they cannot focus on a rapidly changing market, so it is essential to drive innovation (Valaskova et al., 2018).

Many researchers are currently discussing innovation models. The research by Alani et al., 2019 provides a better understanding on the product innovation within the organizational context and the authors create a model of the relationship between strategic orientation and product innovation under the mediating effect of customer knowledge management. Innovation models have also been discussed by Oliinyk et al., 2018, where authors deal with the process of distribution of an innovative product using the Bass model. With issue of business models for sustainable innovation in Industry 4.0 dealt authors Ludbrook et al. 2019.

Companies have a strategic choice in a time of radical technological changes. Several researchers have addressed this choice in technology management, organizational education, and economics (Lee et al. 2003). The company must decide whether to use its current technology to ensure short-term survival, or it will decide to use new technologies and hope that they will have better opportunities in the long run.

Also important is the country's policy, which can support innovation in the country by allocating funds to support research and development carried out by resident companies, research institutes, universities.

Methodology

This chapter is devoted to the description of the scientific methods that the authors used to create the paper. The authors used the following scientific methods: meta-analysis and synthesis.

Meta-analysis is a scientific method that summarizes data from several sub-independent studies. The aim is to identify and quantify the prevailing trends or to identify the causes of the different conclusions of the work.

We used the scientific method of synthesis to find out the links between these earmarked elements, contradictions, their interconnections, and then we could reproduce the phenomenon under investigation with its essential features and relationships. The synthesis of knowledge consisted of joining individual parts into wholes - we combined them into individual subchapters: *Innovation activity in European Union* and *Innovation activity of Slovak companies and barriers of innovation activity*.

The literature was collected by using various sources, the main part was created by research papers from scientific databases Web of Science and Scopus. We identified such papers using the keywords “innovation”, “innovation activity”, "innovating enterprises" and “innovation barriers”. We also used documents issued by the Statistical Office of the Slovak Republic and the European Union to find out the current situation of innovation activities of Slovak companies.

Innovation activity in European Union

The European Commission has made recommendations to guide the economic policies of individual Member States. For the Slovak Republic, one of the recommendations for 2019 and 2020 is directly related to innovation: to focus investment-related economic policy on healthcare, research and innovation, transport, notably on its sustainability, digital infrastructure, energy efficiency, competitiveness of small and medium-sized enterprises, and social housing, taking into account regional disparities.

In June 2018 and March 2019, the European Council stated in its call that if Europe wants to compete on world markets, maintain and improve the European way of life, it needs to increase its innovative capacity. That is why the Juncker Commission has set more ambitious targets for the EU and its Member States and regions, and has proposed a European horizon, which is the most ambitious program in the field of research and innovation yet. These steps are intended to help keep the EU at the forefront of global research and innovation.

The 2019 European Innovation Scoreboard and the 2019 Regional Innovation Scoreboard, published by the Commission, show that the EU's innovation performance has been improving for

four consecutive years. For the first time in history, Europe has performed better than the United States in terms of innovation. However, the EU continues to lag behind Japan and South Korea, and China is fast catching up.

Regular evaluation of the level of innovation in individual EU member states is also carried out using the European Innovation Scoreboard (EIS), which provides a comparative assessment of research and innovation results across the EU. Such data can be used by Member States, regions and the EU as a whole to assess the relative strengths and weaknesses of national research and innovation systems. It also reveals areas where Member States are doing well, as well as areas where Member States need to focus their efforts to increase their innovation performance. The similar research done authors Kral and Janoskova (2019), which aim was to identify possible strengths and weaknesses of the national innovation systems of countries V4 and, thus to identify the impact of these strengths and weaknesses on the innovative position of these countries.

Based on the number of points (score) in this evaluation, EU countries are divided into four performance groups: innovation leaders, strong innovators, moderate innovators and modest innovators. We present the results of the latest evaluation for the year 2018, published in 2019. According to the division of countries into individual groups, we can see their innovative performance, as well as the classification of the Slovak Republic:

- Innovation Leaders – Denmark, Finland, the Netherlands, and Sweden perform 20% or more above the EU average;
- Strong Innovators – Austria, Belgium, Estonia, France, Germany, Ireland, Luxembourg, and the United Kingdom perform above or close to the EU average;
- Moderate Innovators – Croatia, Cyprus, Czech Republic, Greece, Hungary, Italy, Latvia, Lithuania, Malta, Poland, Portugal, Slovakia, Slovenia, and Spain show an innovation performance below the EU average;
- Modest Innovators – Bulgaria and Romania perform well below 50% of the EU average.

As we can see, Slovakia belongs to the group of moderate innovators. The following figure shows the ranking of countries according to the European Innovation Scoreboard, as well as the classification of individual countries into the four groups. The colored bars show the innovation performance in 2018, the horizontal linkers show the performance for 2017 and the gray bars the performance in 2011, all data compared to the EU average in 2011.

Innovation activity of Slovak companies and barriers of innovation activity

Enterprises with innovation activity are those that have launched new or significantly improved products or introduced new or significantly improved processes within the company, or have introduced organizational or marketing innovations. Also included are those enterprises that have had incomplete or suspended innovation activities. In the years 2014-2016, 28.7 % of enterprises in the Slovak Republic were innovatively active. In industry and selected services together (excluding construction), there were 30.7 % of them. Businesses in industry (32.7 %) had a higher innovation capacity than in services (28.4 %) (Statistical office of the Slovak Republic, 2018).

As in the previous period, the innovative activity of companies was directly proportional to their size. Compared to the period 2012-2014, innovation activity in industry increased in medium and large enterprises. In services, the increase in innovative activities compared to the previous survey was also in the group of medium-sized and large enterprises, while the most intensive increase was in the group of large enterprises. The decrease in innovation activities compared to the period 2012-2014 was in industry and services in the group of small enterprises (Statistical office of the Slovak Republic, 2018).

The low share of innovative companies in the Slovak Republic is a consequence of the action of innovation barriers preventing innovation activities in both innovative and non-innovative companies. Innovation barriers in Slovak companies are mainly cost, market and knowledge factors.

According to the results of the survey of the Statistical Office of the Slovak Republic, in the period 2014-2016, 30.7% of enterprises in industry and selected services were innovatively active. However, these companies also faced problems that prevented them from engaging in further innovation. Cost factors are considered by innovating companies to be the main factors limiting innovation activities. *Lack of internal finance for innovation* is considered to be the biggest innovation barrier by 29 % of innovating companies, *too high innovation costs* by 25.9 % and *lack*

of credit or private equity by 10.2 % of companies. Other highly important factors limiting innovation were market factors. *Difficulties in obtaining government grants or subsidies for innovation* were reported by 22.1 % of innovating companies, *too much competition in the market* by 19.5 % and *uncertain market for ideas for innovations* by 12.9 % of innovating enterprises. From the group of knowledge factors, a high degree of importance have these factors: *lack of skilled employees within enterprise* - 15 % of enterprises and *lack of collaboration partners* - 5.9 % of companies (Statistical office of the Slovak Republic, 2018). The following table provides an overview of the most important areas of factors limiting innovation activities by companies.

Table 1. The main factors limiting innovation activity in Slovak companies

Area of factors	**Type of barrier**	**Percentage of innovative enterprises indicating high importance of selected factor**
Cost factors	Lack of internal finance for innovation	29 %
	Innovation costs too high	25,9 %
	Lack of credit or private equity	10,2 %
Market factors	Difficulties in obtaining government grants or subsidies for innovation	22,1 %
	Too much competition in your market	19,5 %
	Uncertain market demand for your ideas for innovations	12,9 %
Knowledge factors	Lack of skilled employees within your enterprise	15 %
	Lack of collaboration partners	5,9 %

Tab. 2 provides an overview of innovation barriers and their impact on companies by number of employees. The data in the table show that innovation barriers are most felt by small and medium-sized enterprises, relatively less by large enterprises, which is related to the fact that the number of small and medium-sized enterprises in the economy is absolutely greater than the number of large enterprises. However, this also implies the need for greater support for innovative activities of small and medium-sized enterprises by the state. In developed economies, small and medium-sized enterprises in particular are the implementers of innovative development. To improve the innovation performance of companies and the economy as a whole, it is important to identify innovation barriers. However, this is only the first step - they must be removed. Some of the barriers can be removed at the enterprise level, through innovative management, but most of them require a society-wide solution at the state level.

Conclusion

According to the latest measurements of the European Union from 2018, the Slovak Republic belongs to the group of moderate innovators - shows an innovation performance below the EU average. The low share of innovatively active companies in the Slovak Republic (28.7 %) is also reflected in the low innovation performance of the Slovak Republic in comparison with other countries of the European Union. This result is, among other things, a consequence of the action of innovation barriers that hinder the development of innovation activities in Slovak companies. For the most important barriers limiting them innovation activities, Slovak companies consider cost factors, namely: lack of internal finance for innovation; innovation costs too high and lack of credit or private equity. However, the successful implementation of innovations is also limited by market and knowledge factors. These barriers limit innovation activities small and medium-sized enterprises in particular, therefore state support should focus in particular on these enterprises. The state must create the necessary preconditions for the successful innovative development of a certain country. This means that it should not only provide sufficient financial, human and material resources, but also create a suitable innovative business environment, enabling companies

to become more involved in innovation processes and thus contribute to increasing the innovative performance of the economy.

Acknowledgment

The contribution is an output of the project VEGA 1/0619/20 Fundamental research of quantitative and qualitative determinants of enterprise innovation potential and innovation performance in relation to increasing its competitiveness.

Abstract

The global pandemic scenario, marked by the new coronavirus (covid-19), makes evident the need for companies to react in their strategy (communication, distribution and sales). In this sense, this study aims to understand the value proposition by investing in the quality of the online sales process in the food sector based on the dimensions of service quality, identifying attributes that customers recognize value. It is intended to apply a questionnaire using the WEBQUAL model to understand the perceptions of customers on the company's website. In the end, we intend to understand the importance of the quality of the digital commerce process in companies in Portugal as a blue ocean strategy. In particular, the contribution of the quality of the digital commerce process (quality of processes) in the segment of food companies in Portugal. The research methodology is exploratory. The method used is descriptive, quantitative and based on the administration of an online questionnaire that applies the WEBQUAL model. In an interdisciplinary perspective, this study presents inputs for marketing, strategy and the quality of services. At the end, lines of future research will be presented.

Keywords: Covid-19, market orientation, Blue ocean strategy, WEBQUAL.

Introduction

The COVID-19 pandemic turned out to be a huge public health problem with an impact on companies and consumers at the national and international levels. Measures were implemented in Portugal in response to COVID-19: limitations on travel rights, closure of commercial establishments, and prohibition on holding events. Teleworking was also encouraged and distance learning was promoted. Consumers and companies had to adjust their behaviour, the mode of purchase and the place of purchase were changed. The companies took steps to continue the business because there is no knowledge of the end of the pandemic by Covid-19. They were forced to rethink strategies and processes to ensure that they have the necessary tools to remain open after the pandemic. The experience in the digital commerce process by some companies has proved to be a sustainable competitive advantage. Sustainable competitive advantage must preserve what is distinctive in a company. Digital commerce assumes itself as

an important vehicle for communication and product distribution, which is fundamental for companies today. Companies must control what they achieve, namely the portfolio of products and services to the customer. Strategy is the way to achieve the goals. Companies must follow blue ocean strategies, market space where industries that do not exist at the moment are found or blue oceans are created from innovations in red oceans with opportunities for profit and growth. There is a concern for the blue ocean strategy for technological advances and globalization. Lower barriers between commercials, product information and prices become instantly available and monopoly markets tend to disappear (Kim & Mauborgne, 2005). Strategic options are limited by the environment and the development of a corporate strategy begins with an analysis of the conditions of the industry in which it operates. To choose the strategic vision, one must consider: the structural conditions in which organizations operate, the resources and competencies and the strategic mind-set (Kim & Mauborgne, 2014). The adoption of quality (Quality Management System) is a strategic decision by an organization that can help improve global performance and provide sustainable development (NP EN ISO 9001: 2015). An organization that is focused on quality promotes a culture with processes, behaviors and attitudes that provide value in meeting the needs and expectations of relevant customers and stakeholders (NP EN ISO 9000: 2015). It is relevant to understand the quality perceived by customers to make continuous improvements and readjust strategic and operational decisions. According to Kumar, Singh and Kaur (2012), the analysis of the quality of the websites is an essential tool for the improvement of the websites and future decisions of the commercial department. Therefore, this preliminary study aims to understand the corporate strategy of companies by investing in value for quality of service in the food industry segment in Portugal, identifying attributes that customers recognize value, through the application of the WEBQUAL model.

Strategy and markets

The market consists of two spaces: the red ocean and the blue ocean (Kim & Mauborgne, 2005, 2008). Red oceans have the following characteristics: existing industries in which industry boundaries are defined and accepted; competitive rules are known; companies try to outperform their competitors; they get crowded and the profit and growth prospects are reduced. In the blue oceans are found all the industries that do not exist at the moment; untapped market space, creation and growth opportunity, highly profitable. The authors argue that some blue oceans are created beyond the existing limits of the industry, most are created from the red oceans, extending the limits of the industry to an untapped market space. Thus, the red ocean represents all the industries that exist and high competition prevails, the blue ocean considers all industries that do not yet exist, represents the unexploited market and where there are opportunities for high growth and profitability. They add that in the blue oceans there are new opportunities for profit and growth. A study was carried out on 108 companies (which started their activity) and found that the majority of businesses are located in red oceans (86% of businesses representing 62% of revenues and 39% of profits). The blue oceans represent (14% of businesses that obtain 38% of revenues and 61% of profits). The performance benefits of creating blue oceans were evident (Kim & Mauborgne, 2005).

The competitive strategy is the creation of a unique and valuable position, involving a set of different activities (Porter, 1996). It means choosing a different set of activities to provide a unique mix of value. There are three fundamental principles underlying the strategy: strategy is the creation of a unique and valuable position, involving a set of different activities; the strategy requires trade-offs* in competition to choose what not to do, the strategy involves creating an adjustment between the company's activities (Porter, 1996). Michael Porter (1996) presents three generic strategies: cost leadership, differentiation and focus.
Kim and Mauborgne (2005) argue that the “blue ocean” strategy focuses on making competition irrelevant, creating a new market space where there are no competitors. The solution to face the competition is to bet on the creation of blue oceans where innovation with value predominates (creating value for the company and buyers, making the competition obsolete) is not to compete in the red ocean environment. The authors concluded that the creation of blue oceans can be

created from the company's core business. The blue ocean strategy is achieved only when the company's entire system of utility, price and cost activities is correctly aligned. It is this system-wide approach that makes creating blue oceans a sustainable strategy. The blue ocean strategy is part of the company's range of functional and operational activities. It is a strategy that covers the entire system of activities of the company. The strategic objective, Blue Ocean, is to create new rules, to reject trade-off based on differentiation and low cost and to change strategic thinking, changing from a structuralist vision (strategic thinking based on a defensive position against the competition) to a reconstructionist that increases the value for the company and buyers (space where competition is irrelevant) (Kim & Mauborgne, 2004, 2005). The success of a strategy depends on the development and alignment of value, profit and people. The researchers also defend the concept of the blue ocean strategy strongly related to leadership in order to increase the productivity of employees: focus on the activities that leaders need to be to stimulate motivation and obtain results; keep an eye on the market and distribute leadership across all levels of management. They add the following steps to achieve blue ocean leadership: observe current leadership; develop alternative leadership profiles; select future leadership profiles; institutionalize new leadership practices. In the relationship between the leader and the led, trust and cooperation are essential (Kim and Mauborgne, 2014).

To design a blue ocean strategy, three tools are mentioned: the strategy screen, a table of the four possible actions and the relationship to eliminate, reduce, elevate and create. The strategy screen, is a diagnosis and action that aims to identify alternatives in the industry (understand what the competition is doing and identify factors to compete) and in non-customers; the framework of the four possible actions allows to redesign the strategic profile and create new value. Through identification: elimination, identifying factors in the industry that must be eliminated because they do not compete; reduction, determining the factors that must be reduced, companies can over-serve their customers and increase costs; elevation, determining the factors that they must add value according to the industry standard; and creation, identify the factors to create that the industry does not yet offer.

In elimination and reduction, companies obtain information on how to reduce costs in relation to the competition and the other two questions provide information on how to increase the value for buyers and achieve new demand (Kim, & Mauborgne, 2005). When a company applies the framework of the four possible actions to a given industry, it gets a new look at what is actually perceived. The third tool using the eliminate-reduce-increase and create ratio is a complement to the analysis of the structure of four actions that allows companies to not only ask the four questions but also to act to create a new value curve. With the application of this combination (eliminate, reduce, increase and create) it allows to obtain four immediate benefits: to look for differentiation and low costs seeking to eliminate value / cost trade-off; identify companies that are only focused on increasing and creating by raising their cost structure and designing more products and services.

The researchers applied the practical application to the wine sector in the United States and the results allowed to identify that the characteristics for a good strategy are the focus, the divergence and the slogan. The focus does not spread efforts on all factors of competition; the divergence is related to a new value curve different from that of competitors; the slogan of the strategic profile must be clear and attractive (Kim & Mauborgne, 2005). They also applied the structure of the four actions (eliminate, elevate, reduce and create) to a communication technology company in the logistics area, to the company CJ-GLS (develops an electronic logistics business model), in order to analyze how the company achieved a competitive advantage through innovative information technology that allowed to create a space in the electronic business logistics market. The rapid growth was due to the implementation of a blue ocean strategy (3PL market) and not to the attraction of competitive customers. In order to carry out this study, interviews were conducted with the directors: executive, IT, research in logistics, responsible for information and several collaborators. Success factors and problems in the implementation of the blue ocean strategy were identified. The success factors for implementing

a blue ocean strategy were mentioned: the highly motivated information systems team, strong leadership from top managers and the availability for innovation (Kim et al., 2008).

Online trends and WEBQUAL

The digital world has come to challenge companies, approaching everyone everywhere (Malheiro et al., 2019). Challenges that extend to all levels, not only economic, but also at a relational level, since the relationships themselves, and the way in which people relate and behave, have also undergone modifications. Its indefinite nature, among the news about the various unlawfulnesses that have occurred in the digital medium, make the online consumer develop a certain prudence in the use of this medium, especially in regard to their trust in it. Thus, it is clear the need for companies operating in this medium, in addition to addressing new business models and take advantage of the great benefits offered by this new digital era, including in their strategies the needs and expectations of their customers, achieving what build a reliable image (Vilas Boas et al., 2019). In the current context, strongly marked by the coronavirus pandemic, online services assume a recognized importance (as an attempt to react and respond to the health crisis, economic and social crisis). Thus, this section aims to address the importance of online services (trends and developments in the Portuguese market) and also the WebQual model as a tool for managing and improving the service provided. According to the General Directorate of Health (DGS) in Portugal, the new coronavirus, designated SARS-CoV-2, was first identified in December 2019 in China, in the city of Wuhan. This new agent has never been identified in humans before. The source of the infection is still unknown. The route of transmission is still under investigation. Person-to-person transmission has been confirmed and infection already exists in several countries and in people who had not visited the Wuhan market.

The evolution of online commerce

The most common form of trade is one that is based on the existence of a physical store, a supplier/seller, a customer and all the dynamics that derive from the interaction between the three, the so-called "brick-and-mortar" (Barnes et al., 2004). In this type of channel (traditional/offline) it is possible to expose the product, touch, smell, test, change or even return, which allows the consumer to enjoy a complete shopping experience, although limited by the operating hours and location (Vilas Boas et al., 2019). It was for many years the main form of transaction and sale of goods of the society but that quickly was transformed, not only by the evolution of the technology, but also by the needs and demands that the consumers and the own economy came to present (Koufaris, 2002). According Vilas Boas et al. (2019), online commerce brings countless advantages for consumers, such as, for example, getting alternatives at any time, compare products and compare prices (Pallant et al., 2017). 65% of respondents admitted using the Internet to compare prices in other stores, 61% to search for information about products or services and 49% to see reviews. In the first place of research by products, where 52% of consumers cited at least one channel without connection and 59% an online channel, which shows that, despite the growth of online commerce, both types of commerce still have a significant weight in the consumer purchase process (KPMG International, 2017). In the event that there is a change in the quality of the information, it should be taken into account that the use of information technology, allow stores to be able to attract and retain more consumers.

In specific Portuguese context, and according to the e-commerce barometer in Portugal, in 2014, 66% of the sites in the study said they had increased their sales volume compared to the previous year, and 24% said that this volume was over of 1 million euros (ACEPI, 2015). According to ACEPI's annual study, e-commerce and online purchases are growing in Portugal and at the end of 2016, some 873.000 Internet domains were recognized in .pt. In 2017, online purchases in Portugal amounted to 4.6 million euros, only in the B2C market, and the expectation for 2018 is for growth. Indicators for the development of the digital economy in Portugal revealed that in 2025 the percentage of the population that uses the Internet will be moved to 91, and 59 the

percentage of consumers who use the Internet to make online purchases. The fashion and clothing sector and the technology sector have the highest online sales rate, although the study also foresees a significant increase in the food and supermarket sector (ACEPI, 2018). With this change in online commerce, consumer behavior has also changed. The digital age brought with it a new profile, the online consumer profile. According to the results published recently by Statistic National Institute (INE) on the use of information and communication technologies (Vilas Boas et al., 2019), presented in Figure 1, in 2018, 79% of Portuguese families had Internet access at home (INE, 2018).

Figure 1: Proportion of households with Internet connection, Portugal (2010-2018).
Source: Vilas Boas et al. (2019).

However, and with the reality of the new coronavirus strongly felt in Europe, particularly in Portugal, online commerce is increasingly important in the first months of 2020. The results mainly in an attempt by companies, and consumers, to minimize the economic impact of the pandemic and, at the same time, have greater access to essential products and services (e.g. food and beverages, pharmacy or clothing).

WEBQUAL

Quality is a central element in corporate strategy. Companies compete for quality, customers look for quality and markets are transformed by quality (Golder et al., 2012). According to the standard (NP EN ISO 9000: 2015) the quality of an organization's products and services is determined by its ability to satisfy customers and the impact on relevant stakeholders. The quality of services is considered a determining factor for the success of companies and assumes importance due to the increase in the offer (Igreja & Sousa, 2020), the experience of the companies, the cost and the demand of customers (Parasuraman et al., 1985). Companies to be able to match or even exceed customer expectations need to understand the dimensions they value, in order to improve the services provided (Zeithaml, 1988). The technical and functional dimension constitutes Service quality. The technical dimension is related to what the customer actually receives from a service (result). The functional or process dimension concerns the way the service is delivered, the customer's perception of the interaction during the service provision (Grönroos, 1982). Technical quality affects customers' perceptions of service quality (Grönroos, 1982, 1990; Rust & Oliver, 1994). In some services, technical quality may be difficult to assess. If this dimension of quality is not possible to estimate customers, they depend on functional quality, namely on empathy and the trust transmitted by the service provider (Kang, 2006).

The WebQual model is considered a method of assessing the quality of websites that is based on the perceptions of consumers' quality on the websites. This model has been applied in several

areas of online commerce: bookstores, online auctions and small businesses (Stuart J. Barnes & Richard T. Vidgen, 2001). The researchers Loiacono et al. (2007) reached an instrument with 36 items, organized into four constructs (utility, ease of use, entertainment, complementary relationship) and 12 dimensions (Loiacono et al, 2007).

The utility construct is composed of the dimensions: adequacy of information to the task, interactivity, degree of reliability and response time. The dimension adequacy of the information to the task is related to the personalization of the information according to the objectives of the users (clear and easy to understand information). The interactivity dimension characterizes the resources available on the website in order to facilitate the user to obtain information appropriate to specific needs.

The reliability dimension is related to the respect for the privacy of users' information, technical reliability on websites and the provision of updated content in a secure environment. The response time dimension is the time to obtain a response after requesting with the website, the user must quickly access and perform any operation from his environment (Loiacono et al., 2007). The ease of use construct is made up of dimensions: ease of understanding and intuitive operations. The ease of understanding dimension is related to the pages displayed on the site being easy to read and the sections easy to understand. The intuitive operations dimension is related to the ease of use of the website.

The entertainment construct is made up of the following dimensions: visual attractiveness, degree of innovation and emotional appeal. The visual attractiveness dimension is related to the stimuli that can lead to a pleasant browsing experience and innovative character of the website. The degree of innovation, is related to the creativity and innovative design of the website, and the emotional appeal, is related with the emotional effect of using the website and with the intensity of involvement (the user feels satisfied, excited and sociable) (Loiacono et al., 2007). The complementary relationship construct consists of the following dimensions: consistent image, online integration and comparison with other sites. The consistent image dimension is related to the website providing an image consistent with the company's image. The online integration, the website must allow the user to be able to complete his online transaction. The dimension comparing with other channels, is related to the user comparing the service provided through the website with the same service provided through alternative channels (namely the fax or telephone) and the website should allow the same tasks to be performed through the Web in the best way (Loiacono et al., 2007).

Methodology and preliminary results

This study will follow, in methodological part, a stage of primary data collection and systematization in the Portuguese context (in the first half of 2020). In particular, we intend to observe the performance and responsiveness of some food companies in Portuguese (i.e. dairy products). It is intended to understand the reactive strategies of organizations in the context of the pandemic (i.e. coronavirus) and the extent to which market strategies are adopted in these unpredictable scenarios. Thus, the WebQual model will allow researchers to assess the quality of websites that is based on the perceptions of consumers' quality on the websites. In this sense, it will also be intended to develop an analysis of social networks, in order to capture good practices for responding to the covid-19 crisis (communication and response strategies with online service). See, for example, the case of the '*Lacticínios das Marinhas'*, that sells dairy products, (figure 2) that published a new home delivery service on social networks (using electronic commerce and online shopping).

On the social network, a company located in the north of Portugal (in Esposende) put the following message "During this difficult period, we don't want anything missing! Now you can receive the best Marine products in your home at no extra cost. By private message and Order now!". At the same time, check if the public organization has several posts with the message

'everything will be fine', in an attempt to create hope, empathy and positive thinking with Portuguese consumers.

Figure 2: Reaction strategy of the company '*Lacticínios das Marinhas*'' (Portugal).
Source: Facebook.

Since this strategy is relatively recent (30 days), it is too early to evaluate the results of this initiative. However, a qualitative analysis of social networks shows a high acceptance by the public, particularly with regard to the number and type of reactions and sharing with the community (viral marketing). The pandemic situation led to a greater use of the Portuguese company's digital channels, using technological means and avoiding proximity and physical contact. In particular, and due to the pandemic situation, Lacticínios das Marinhas decided to reinforce the measures of the contingency plan implemented and ensure the protection and health of employees, while maintaining the provision of services. The measures in question, came into force as of 16.03.2020 and are broadly reflected in the following:

- Lacticínios das Marinhas did not receive any supplier at its facilities until further notice.
- Elimination of sales to final consumers on the premises.
- Customers (Wholesalers and Retailers) who pick up orders at the premises should place orders via phone or e-mail and call the office as soon as they arrive and should remain in the vehicles until pickup is authorized.
- Drivers must also avoid contact with employees.
- Only accept payments for orders via MBWay, ATM or bank transfer. Cash payments were not accepted. The reactions that were manifested on social networks were positive and consumers showed a strong sense of social responsibility and a greater acceptance of the digital solutions presented by the Portuguese company. Future studies will allow us to monitor and analyze the evolution of this initiative and, consequently, measure the positive impact on sales and customer loyalty.

Conclusions and future research

The global pandemic scenario, marked by the new coronavirus (covid-19), makes evident the need for companies to react in their strategy (communication, distribution and sales). In this sense, this study aims to understand the value proposition by investing in the quality of the online sales process in the food sector based on the dimensions of service quality, identifying attributes that customers recognize value. Technological evolution is the great cause for most of the changes that have occurred, from cultural, social, political, economic, personal and even psychological changes, all of them on a global scale. The environment and the relationships that are built in it stopped happening only in physical space, happening also in a space without defined location: the virtual space. The development of technology has brought with it innumerable positive aspects: the global communication that today is fundamental; the democratization of knowledge throughout the world, made possible through the connections that information systems have acquired; the medicine that attended to great evolutions; the very world that has become a small town where everyone is connected, and endless other advantages.

The inclusion of trust and perceived risk was due to the fact that online commerce, due to its technological nature, operates in an environment of doubt and uncertainty. However, the needs and expectations of the consumer have undergone changes with these technological advances, so that companies in this sector had to reinvent themselves and, inevitably, evolve themselves as well. The improvement of behavior models originated the development of new business models, which in turn originated new forms of communication between companies and consumers, and vice versa. In specific, the WebQual model is considered a method of assessing the quality of websites that is based on the perceptions of consumers' quality on the websites. This model has been applied in several areas of online commerce: bookstores, online auctions and small businesses.

Thus, the WebQual model will allow researchers to assess the quality of websites that is based on the perceptions of consumers' quality on the websites. In this sense, it will also be intended to develop an analysis of social networks, in order to capture good practices for responding to the covid-19 crisis (communication and response strategies with online service). See, for example, the case of the '*Lacticínios das Marinhas'* that published a new home delivery service on social networks (using electronic commerce and online shopping). Since this strategy is relatively recent, it is too early to evaluate the results of this initiative. However, a qualitative analysis of social networks shows a high acceptance by the public, particularly with regard to the number and type of reactions and sharing with the community (buzz marketing). Future studies will allow us to monitor and analyze the evolution of this initiative and, consequently, measure the positive impact on sales and customer loyalty. In an interdisciplinary perspective, this study presents inputs for marketing, strategy and the quality of services. However, this study has some limitations, namely because it was developed during a coronavirus mitigation phase in Portugal. Temporary limitations prevent, for now, this manuscript from presenting more conclusive data. In view of this Public Health threat, response phases have been defined that include three levels and six sub-levels, according to the risk assessment for COVID-19 and its impact for Portugal. Currently, Portugal is in the Mitigation phase, in which there is local transmission in a closed environment, as well as community transmission. On March 19, 2020, a state of emergency was declared as a consequence of the evolution of the pandemic in Portugal. The risk assessment is constantly updated. The World Health Organization does not recommend travel, trade or product restrictions to countries with a COVID-19 outbreak. Travel bans to affected areas or denied entry to passengers from affected areas are generally not effective in preventing the importation of cases. Therefore, the approach centered on the study of online commerce is very relevant in this scientific investigation. However, it is a preliminary contribution to the management and quality of services (online) in the Portuguese context.

Abstract

The innovation process, and its application to tourism, has been gradually gaining ground in the academic community as a field of study. Similarly, in recent decades, tourism has received greater attention from researchers in several sciences. The present manuscript intends to gather and sistematize the main aspects related to innovation process in specific tourism context, in particular the case of thermal tourism in Peninsular Northwest. In specific, in this region, thermal tourism still constitutes a vector of sustainable development, serving as leverage for complementary activities like healthcare and thermal tourism. The study has as purpose to provide a better understanding regarding the essence of innovation process and entrepreneurship: theoretical and practical implications. With a theoretical perspective, the manuscript aims to bring together the major components of entrepreneurship and its implications tourist perspective and relationship marketing (i.e. consumer perspective). In the end, we intend to explore the relationship with thermal tourism consumers, suggesting a conceptual model (to be tested empirically) that relates relational marketing and the result of innovation in tourism (favoring trust, commitment, quality of service, satisfaction and loyalty). A future study should include emotional factors. The new vogue of thermal tourism forces us to challenge and re-visit the power relationships that exist within contemporary tourism and the host-guest relationship.

Keywords: Innovation, Process creation, Thermal tourism.

Introduction

Tourism is an economic and social phenomenon due to its ability to create regional and cross-border development. According to Ratten et al. (2019), there has been increasing recognition of the way tourism can be innovative, particularly through creative means (e.g. thermal tourism). This is evident in new services developed that integrate technology and sustainability practices. The subject of interest for many years, the role of innovation in tourism is growing in significance. There are two main reasons for the dramatic growth. Firstly, the tourism industry has been the launchpad for new technological innovations that have created new markets and segments (e.g. thermal tourism), and secondly, the tourism industry has a large number of small-sized enterprises include tourism providers such as hotels, travel agencies or educational providers (Ratten et al., 2019). Therefore, and according to Ma and Tan (2006, p.705), "there has been an increasingly popular trend of cross-fertilization among strategic management

research and entrepreneurship research, two fields deeply concerned with wealth creation and heavily influenced by Schumpeter's seminal work on innovation and creative destruction". With regard to its proximity to the concept of innovation, Schumpeter (1934) argues that innovation can be seen as a phenomenon, including technical, non-technical aspects as well as innovations in product and process innovations (e.g. tourism industry). The creation process contributes to business success and increased competitive advantage, which is a theme that has clearly captured the attention of researchers in the field of management. The dynamic nature of this process, coupled with the constant need to invest in a highly distinctive and differentiating offering new studies have provided in order to score market position and achieve consumer satisfaction, including the level of emerging realities confirmed by new trends and desires (Costa, 2001; Buhalis & Costa, 2006). Innovation is the adoption of a change that results in something new to the organization and relevance to the environment, and the creative idea and its development is the seed germinated by innovative, effective for the market economy (Sousa & Alves, 2019). There is a large body of knowledge about innovation management but less is known from a specific thermal perspective. This is unusual as thermal management has an abundance of innovation due to its emphasis on technology and change. In this sense, innovation has attracted the attention of several scholars and entrepreneurs together with this research topic (Ratten, 2016). The present manuscript intends to contribute theoretically to the management of innovation in specific tourism contexts (i.e. thermal tourism) in Peninsular Northwest. In the end, we intend to explore the relationship with thermal tourism consumers, suggesting a conceptual model (to be tested empirically) that relates relational marketing and the result of innovation in tourism (favoring trust, commitment, quality of service, satisfaction and loyalty). The model should be tested empirically in the Peninsular Northwest. This makes it possible to open new doors and open new markets, enabling greater efficiency in business, economic growth and new ways of targeting an increasingly competitive market, in specific the case of thermal tourism contexts in Peninsular Northwest.

Innovation and relational trends

Innovation can be seen as a specific tool of entrepreneurs, the means with which exploit change as an opportunity for a different business or service, being able to be understood and, as such, to be practiced, leading to a common distinction between invention and innovation (Drucker, 1993). Almost all the innovations reflect existing knowledge, combined with new uses, suffering the concept of innovation as a shift towards emphasis on the interaction between institutions, focus on interactive for the creation, dissemination and sharing of knowledge and relevance of the role of government processes as an important actor in an innovative environment (Sousa, 2015). It is important to clarify the difference between two concepts that, for different times, tend to be confused: Process Innovation and the Innovation Process. Innovation Process is essentially related to the set of steps that tend to incorporate both the market and technology. Companies have the ability to go seizing, building your knowledge base and thus make the continuous improvement of process management (Tidd, Bessant & Pavitt, 2003). Monitor the internal and external environment and analyze the relevant signals will be the starting point. After this, we have the decision about how to respond. Finally, we will implement the project with the development of technology and the domestic and foreign market (Sousa, 2015). The Process Innovation, by the way, combines the adoption of a process view of the organization's business with the application of innovation to key processes. This is the big difference, compared with the Innovation Process, but it allows us to understand its complexity. Process Innovation encompasses the prediction of new work strategies, the actual process activity and the implementation of change in their complex human, technological and organizational dimensions (Davenport, 1993). According to Davenport (1993), in practice, companies need to combine the two concepts in a continuous quality program. Ideally, the organization will seek to stabilize the process and start continuous improvement, to later create the ambition to go on the innovation processes. The differences between these two concepts can hinder your combination, so one of the possibilities to minimize this problem may be the assignment of different roles to different managers, with high levels of cooperation. The company must be aware that the risk of innovation processes is at least proportional to the

rewards for that in reduced competitiveness continuous improvements environments may be the preferred choice. Highly competitive environments (e.g. greater balance between enterprises, reduced rate of market growth, high barriers to exit) may encourage the bet on a change with the greatest impact (process innovation). Access to information (e.g. technological innovations) and the challenge of the information revolution is also the base of the reach of competitive advantage, in order to maximize innovation in the process and, consequently, greater differentiation from competitors (Ratten, 2015).

The dynamic nature of triggering and entrepreneurial process

Entrepreneurial activity is seen as a process: includes a set of steps, is subject to tourism management, continuous and applicable in many contexts (Stevenson & Jarillo 1990). This process becomes a source of competitive advantage on a global scale. This entrepreneurial process is, as a rule, inextricably linked to certain factors that allow initial "take the leap" (circumstances, triggering events). Shindehutte et al. (2000) present a conceptual model that summarizes the dynamic nature of the triggering process in an attempt to summarize the various contributions on this topic.

The entrepreneurial process is conceptualized as a response to the awakening of the event. However, the nature of the trigger, relevance and impact depends on the dynamic interaction between the characteristics of managers/employees (e.g. personal life), firm characteristics (e.g. size, culture) and external developments of the environment (e.g. competitiveness). The different types of entrepreneurial activities are probably the result of different types of triggers.

Shindehutte et al. (2000) present a summary that reflect the main differences between conventional marketing and entrepreneurial marketing. The entrepreneurial process results in corporate contexts, rather than individual traits of an increasingly conscious need to provide the organization with innovative behavior and can, according to Sharma and Chrisman (1999), take many forms. The prospect of Schollhammer (1982) is the most cited and identifies five types of corporate entrepreneurship: administrative, opportunistic, acquisitive; incubative; imitative. Traditionally, innovation management and entrepreneurship tend to be excluded from the domain of conventional marketing department (Shindehutte et al, 2000).

The creation process in termal Tourism context

Tourism is a phenomenon that moves millions of people around the world, taking as a major driver of the global economy. Every year, much due to the frequent changes in the tourism environment, fosters competition between and within tourist destinations (Bigné & Andreu, 2004; Sousa & Rocha, 2019; Sousa, Silva & Malheiro, 2020). Moreover, tourism is a sector of great importance to the economy, responsible for creating a large number of jobs. For instance, female entrepreneurship in the tourism sector has been rather neglected as a field of study and women's employment opportunities and the segregation of occupations are the major focus of research on women's situation in the tourism context (Tajeddini, Ratten & Denisa, 2017). As a psychological phenomenon, a tourist trip is preceded by a specific need that generates a reason to travel and sets a goal for the trip, which follows the search for information (Gursoy & McCleary, 2004; Sousa & Alves, 2019). Like other emerging sectors in a modern economy, tourism is a dynamic and ever-changing industry (e.g. Wellness and thermal tourism). As such, comes an increasing need to understand the consumer behavior of thermal destinations contexts. According to Lordkipanidze et al (2005), the growth of the tourism sector and increasing demand with regard to new types of tourism, makes it even more visible and required its connection with the emerging trends in entrepreneurship (e.g. Termalism, Thalassotherapy, Spas and quality of life, Senior Thermalism). Since tourism is composed of many of small firms, they are constantly called upon to respond quickly to new trends and market demands (assuming as a source of innovation). The role of each actor in the distribution channel, within the operational management of tourism, will be critical to appreciate the range and nature of the emerging changes. The use of technology has profound implications to satisfy tourist demand

as it enables the interconnection between consumers, intermediaries and producers, providing at the same time, tools for strategic marketing development (Buhalis, 2003; Kim, Lee & Hiemstra, 2004).

According Costa, Quintela and Mendes (2015) Wellness and thermal tourism has become an emerging market segment directed not only for those who pursue solely thermal treatments but also for those seeking illness prevention, physical improvement and spiritual balance or even for those eager of cultural and relaxation programs. In this sense, this specific niche tourism has become more complex and creative, demanding high quality equipment and infrastructures, providing a wide range of products and services related not only with the diversity of spa treatments but also with complementary recreational activities regarding the connection to nature and to cultural patrimony as well as to other regional resources, creating effective links to the territory and becoming a significant force that will shape the regional development, by creating a positive pressure on local economic bases with spillover effects on the territory. For instance, and according Araujo, Paiva, Ribeiro & Coutinho (2015), thermal spa treatment is a touristic product that is highly recognized for its potential in the exploration of endogenous regional resources. Consequently, the development of new and competitive thermal tourism products can play an important role in the development of the inland regions, contributing effectively to addressing the economic asymmetries of the region. Particularly in the Galicia Northern Portugal Euroregion this activity still constitutes a vector of sustainable development, serving as leverage for complementary activities like accommodation, restaurants and transports (Ladeiras, Mota, & Pardo, 2015).

On top of this, the researchers Fleus, Azara & Michopoulou (2018), citing Bushell & Sheldon (2009, p.56) highlight the potential identified by governments and the tourism industry itself of wellness tourism – and thermal spa tourism in particular – to serve as a tool for empowering individuals and societies to adopt wellness. In a similar manner, according to Ladeiras et al. (2015), thermalism benefits the cultural industry as it helps boosting the demand for cultural products, promoting local identity and consolidating the feeling of belonging by transforming natural endogenous resources into differentiation elements for the destination and, consequently, improving the local communities' quality of life. In fact, Roget, Dominguez & Brea (2018) identify SPAs businesses as a framework of a company committed with sustainable development because these companies make use of resources without compromising their future, create jobs and generate wealth, settle populations and satisfy needs by improving people's quality of life. As thermalism goes, this activity underwent significant changes throughout the last centuries. It is referred by Del Río-Rama et al. (2014) that thermalism has moved from a tradition that focus solely on the curative purposes for a variety of health conditions – such as respiratory, gastric or rheumatic, among others – to a wider approach that highlights the properties of thermal waters and its benefits for the contemporary society. The changes underwent by thermal tourism and the subsequent diversification of its offer echoed in the type of consumer of this industry. Del Río-Rama et al. (2014) also refers to the objectives of this type of tourism: the improvement of the tourist's health status; rest, quite and relaxation; contact with nature; aesthetics and beauty. In turn, the consumer is gradually turning away from companies that focus their offer exclusively on health benefits and is now more inclined towards companies that will help him/her occupy his/her leisure time in their facilities but obtaining greater satisfaction through value proposals (Rama, et al., 2014). This shift in the tourist's positioning forces the companies that provide thermal tourism services to give him/her special attention beyond technical quality, as is stated by Rodriguez (2005), since this tourist is not seen as a patient but as a consumer (Del Río-Rama et al., 2014). According to Del Río-Rama et al. (2014), this tourist seeks treatment for his/her physical and mental diseases while, at the same time, searching for a good level of service, adequate accommodation facilities, leisure programs, cultural and sports activities and pleasant natural surroundings.

The development of dermocosmetics based on thermal water carried in nanobiotechnological systems is proposed for its contribution to the differentiation amongst local, unique and genuine products, especially relevant in the case of products with high economic impact in tourism

markets (Araujo et al., 2015). According to Portuguese Thermal Association data, „demand for wellness packages in 2005 registered a growth of 37.1% in relation to 2004, while, in the same period, classical therapeutic thermalism showed negative growth, with a 6% loss in clients. The same trend occurred in the following year, with a fall in the number of classical thermalism users, from 80,309 users in 2005 to 76,999 users in 2006, and growth in the number of wellness thermalism users, to a total of 22,049 users compared to the 17,730 seen in 2005. In 2008, there were 38 active hot springs, 19 of which were located in the centre of Portugal (50% of the total), 16 in the North (42%) and 3 in the South (8%). Wellness has become an important topic of research, as well as a rapidly increasing business. There is demonstrable growth in health and wellness tourism across Europe, as the result of a number of social circumstances" (Quintela, Correia & Antunes, 2010, p.2). Similarly, Loutraki has a long history in Spa & Thermalism. The water derived from the Loutraki natural thermal springs was characterized as "The Water of Life" since antiquity.

The geothermal springs derive from many faults of the coastal area in a 750 -m-wide zone. The natural spring hot waters, at the bottom of Mount Geraneia, are discharged from a great mineral depth. Nowadays, visitors enjoy balneology, spa treatments & wellness sessions in a luxurious environment in the modern Loutraki Thermal Spa. Similarly, wellness tourism is promoted through various services that are practiced in order to relax and rejuvenate. Hot springs have been one such effective method that has tremendously added to the dimensions of the wellness tourism. Naturally occurring hot springs and the use of their water is highly important in various wellness therapies as well as the procedures that are required to provide rejuvenating experience to the guest (Sousa & Alves, 2019). Geothermal energies and hot spring waters are the basis of the wellness therapies like balnoetherapy, thermalism etc. The water of these naturally occurring hot springs usually possesses a very high quantity of mineral content that is used extensively for clinical purposes. Spas and other wellness centers run on the mercy of these waters for these waters are the basis for nearly all the wellness therapies (Jagyasi, 2010). Also in thermal tourism context, the process of creation and innovation have been increasingly used to describe business behavior, the destinations, the tourism sector as well as all their planning (Dredge, 2009). However, tourism is going through significant changes, facing new challenges that require new perspectives and implementing ideas (Stamboulis & Skayannis, 2003).

A Peninsular Northwest perspective

Particularly, in terms of natural resources and thermalism, the Peninsular Northwest (Spain and Portugal) is one of the most important in the Iberian Peninsula, with a large number of quality springs and the richest medicinal mineral waters (Amboage, Fernández, Boga, & Fernéndez, 2019). However, because this territory is composed by two regions of two different countries, it is easily understandable that in political terms, these two regions live different realities. Cross-border regions may vary, for example, depending on the degree of cooperation (high or low intensity) or geographic extent (low or high). In particular, Euroregions tend to define themselves as micro cross-border regions, with a reduced geographical extension between contiguous spaces. In view of the above, it was intended to carry out fieldwork in the Euro-region North of Portugal and Galicia (as an integral part of the study of cross-border tourist regions), not only for the local convenience but, above all, for the contribution that will be given to it. This Euroregion belongs to two different states: In one of them an autonomous administrative level (Galicia) is created, while in the other (Northern Portugal) an administrative region with no legislative capacity is maintained (Commission for the Coordination and Development of the Region) do Norte). According to Sousa (2014), it is a Euro-region with more than 6,000,000 inhabitants, based on a space of strong social, economic and cultural interaction. The Euro-region North of Portugal and Galicia shares a significant cultural and natural heritage, with enormous tourist potential. With the opening of national borders between Member States of the European Union, regional exchange registered a clear increase, both in economic and social terms, creating highly compensatory regional synergies. This region is formed by twelve NUTS III (common nomenclature of statistical territorial units) of which five

constitute the basic border area (Pontevedra and Ourense in Galicia, Cávado, Minho-Lima and Alto Trás-os-Montes in Northern Portugal). In a study on banding and strategy in the Peninsular Northwest, Oliveira (2015) pointed out that as an autonomous region, Galicia has its own regional government with legislative and executive powers in such fields as infrastructure, environment and regional planning, while, in contrast, the Northern Portugal region lacks this autonomy and is ruled by the central government and this limits the region's decision-making capabilities. In terms of thermalism, Galicia stands out as being Europe's second largest thermal region and the city of Orense is only surpassed by Budapest in number of water reserves (Roget, Dominguez, & Brea, 2018).

According to Roget et al. (2018), Galicia possesses up to 300 water catchments and the largest part of the 116 spas in Spain. It is underlined by Roget et al. (2018) that in Galicia thermal tourism presents itself as a tourism alternative that comprises health, wellbeing and leisure. These researchers point out that a large number of Galician SPAs are located in the inlands, in rural areas characterized by a low-income population and an economic landscape where the primary sector is dominant (Roget et al., 2018). Roget et al. (2018) add that the Galician SPA play an important role of socioeconomic promoters of the municipalities where they are established. Roger et al. (2018) state that these SPAs are generally small sized, family-owned companies of Galician origins. In the beginning of this century, Nóvoa (2010) found that one fifth of all of Spanish SPAs are located in Galicia, with these SPAs generating approximately 126 million euros in wealth and being responsible for directly employing 2700 professionals in the the year of 2009, which served 140 thousand tourists in the same year (Gândara, Brea, & Manosso, 2013). The work of Solla (2012) shows us that by the beginning of the twenty first century, Galician SPAs had a rate of occupancy around 80%. This researcher argues that although a large number of SPAs' customers benefit from public subvention programs, the popularity of SPAs and the services provided in SPAs has significantly increased throughout the years (Solla, 2012). This increase in popularity of SPAs translates into a growth of this market. Roget et al. (2018), referrencing DBK (2016) show that in Spain thermalism is a 230 million euro market, with a growth trajectory. Roget et al. (2018) noticed a change in the thermal tourist's demographic profile which is becoming younger. These researchers state that the most proeeminent age interval of the thermal tourist is between the age of 46 and 60 years old which contains 46% of these consumers (Roget, Dominguez, & Brea, 2018). Roget et al. (2018) add that the contemporary themal tourist shows a greater interest for his/her health and wellbeing than before.

Over on the Portuguese side, Gustavo (2010) describes the country as a case-study for thermalism due to it abundance of hot springs and the popularity of thermalism. The work of this researchers shows that in the first decade of the twenty first century there were approximately 40 active hot springs in Portugal, most of them located in Northern Portugal and specialized in the therapeutic component of thermalism (Gustavo, 2010). Gustavo (2010) adds that, in recent years Portugal has witnessed an increase in the number of modern SPAs, mostly located in urban areas and often integrated in hotel units. In an important article on Thermal Tourism, the researchers Quintela, Correia, and Antunes (2011) demonstrated that, in 2005, the total number of visitors of Portuguese themal units was approximately 98.000, increasing to approximately 99.000 visitors in the following year. Quintela et al. (2011) also noted that Spanish tourists accounted for a little over half of foreign visitors to Portuguese traditional themal units. These researchers noted that, if on the one hand, the demand for wellness packages increased dignificantely between 2004 and 2005; on the other hand, the demand for classic thermalism in the same period shortened 6% (Quintela et al., 2011). This trend continued in the following years, as is showned by Quintela et al. (2011), however, since the increase wellness tourism was insuficient to offset the decrease in the demand for classical thermalism, portuguese thermal units suffered a decrease in business of 4,3% in that period.

Nevertheless, innovation in thermal tourism and its offer in Peninsular Northwest continued to thrive in the following in years as is shown in the works of researchers such as Roget et al. (2018). These researchers state that, in Galicia, innovative products are being introduced in the

market, integrated in a strategy combined of the public and private sector to promote the thermal sector as an innovative tourism destination for wellbeing and thermalims seekers (Roget et al., 2018). The city of Ourense and its product 'TrenBalnearios' is an example of innovation provided by Roget et al. (2018). This product comprises the mobility of tourists through seven of the province's SPAs (Roget et al., 2018). Another example provided in this article is the CERLAC – the rowing training centre of Laias, Arnoia and Castrelo de Miño – which is a 2014 inniciative of Grupo Caldaria and INORDE – Ourense's Economic Development Institute – that combines indoor nautic sports and Laia's SPA infrastructure and services (Roget et al., 2018).

Proposed conceptual model

Preliminary research was conducted in order to develop the research instrument. Details of the preliminary research are given below. After the collection of the preliminary data, empirical data would be collected through fieldwork. This study discusses the increasing phenomena of thermal tourism and the relationship marketing perspective associated to innovation. Based in the literature review, we propose a model that connects the relationship marketing dimensions (i.e. commitment, trust and cooperation) with the consequent satisfaction with thermal tourist and the behavioural intention of repeating the experience or reinforcing the experience with a euroregion marketing and niche tourism perspective. Several studies in marketing and tourism contexts have discussed the association relationship marketing to the site and consumer purchasing behaviour, including the study of satisfaction, loyalty or quality of service (Heung, Kucukusta & Song; 2010). An extensive review of the current literature reveals that no integrated theoretical framework for the holistic study of the innovation and thermal tourism industry exists. The proposed research model not only has implications for future research, but also provides useful information for practitioners in the thermalism. Several studies have shown that more brand commitment and brand trust leads to more positive satisfaction behavior (e.g. Belaid & Temessek Behi, 2011; Sousa & Alves, 2019). The theoretical framework highlights that satisfaction tends to favour the development of behavioural loyalty. These results are particularly evident in tourism contexts, as the example of the importance of satisfaction in revisiting or recommendation family or friends (Bigné et al., 2005; Prayag, 2008; Sousa & Rocha, 2019). Based on this discussion, we propose that, in a context of healthcare and thermal tourism, the increase in trust, cooperation and commitment facilitates the development of behavioural satisfaction and loyalty. The proposed model intended to contribute theoretically to the management of innovation in specific tourism contexts (i.e. thermal tourism) in cross-border tourist destinations (Portugal and Spain, specifically the Peninsular Northwest. The relationship with consumers of thermal tourism was explored, suggesting a conceptual model (to be tested empirically) that relates relational marketing and the result of innovation in tourism (favoring trust, commitment, quality of service, satisfaction and loyalty). The model should be tested empirically in the cross-border tourist area of Peninsular Northwest. Hence we propose that: P1: cooperation has a positive effect on satisfaction of healthcare and thermal tourism; P2: commitment has a positive effect on satisfaction of healthcare and thermal tourism; P3: trust has a positive effect on satisfaction of healthcare and thermal tourism; P4: Satisfaction has a positive effect on the healthcare and thermal tourism.

This study should to reveal the potentials of individual destination attributes to cause satisfaction and/or dissatisfaction, and it shed light on the most determinant and critical attributes in explaining the overall tourist experience, in specific the case of thermal tourism contexts. It is well established in the literature that the tourist's assessment of different destination attributes influences his or her overall satisfaction and, subsequently, intentions to revisit a cross-border destination. Studies typically apply linear modelling techniques in analyzing these influences, such as multiple regression analysis or structural equations modelling and focus group analysis.

Final considerations

In an increasingly global world, which tends to predominate competitiveness and change, the difference is, so often, the ability to create discontinuities in the external environment. Many times the success is the ultimate goal, which focuses on searching for new products, new markets, new organizational forms and new sources of customer value. In this field it inevitably highlights the thermal tourism as some of the examples mentioned in this paper, as vehicles of innovation, and that may prove suitable choices of context for the operationalization of the proposed study. For instance, the creation process associated with for Wellness and SPA reservation systems, mechanisms and information sharing as a form of competitive advantage over other tourist destinations (social networks), the marketing of thermal and heatlh tourism products and services as well as other related activities that can leverage the increased business synergies. It should be noted generators entrepreneurship factors that may trigger an entrepreneurial activity (particularly in thermal tourism contexts); and whose origin may be associated with internal, external factors and characteristics of the organization. The external factors are more difficult to control: political, economic, social, technological, environmental factors or legal issues. However, the combination of those factors with the intrinsic nature will form the basis of an innovative event, along with the organizational characteristics (e.g. culture, values and business traditions). Finally, and this manuscript is primarily theoretical and reflection, is expected to arise in the future some work of a practical nature that bring greater robustness to support and perspectives presented. In terms of thermalism, Peninsular Northwest stands out as being Europe's second largest thermal region and the city of Orense is only surpassed by Budapest in number of water reserves. Galicia possesses up to 300 water catchments and the largest part of the 116 spas in Spain.Iin recent years Portugal has witnessed an increase in the number of modern SPAs, mostly located in urban areas and often integrated in hotel units. The present manuscript intended to contribute theoretically to the management of innovation in specific tourism contexts (i.e. thermal tourism) in cross-border tourist destinations (Portugal and Spain, specifically the Peninsular Northwest). In the end, the relationship with consumers of thermal tourism was explored, suggesting a conceptual model that relates relational marketing and the result of innovation in tourism (favoring trust, commitment, quality of service, satisfaction and loyalty). The model should be tested empirically in the cross-border tourist area of Peninsular Northwest. We intent to show shows how these valid questions can be answered by introducing causal modelling and discussing one approach to it, structural equation modelling (SEM), which is a rigorous technique for building and testing such models. An advanced statistical methodology delivers models and results that are easy to understand and employ. We intent to confirm that a causal relationship exists (i.e. measurement over time should confirm that change in one variable precedes change in the other; a controlled experiment is required that changes a single variable; the direction of causality must be correctly specified; the relationship must not disappear when common causes of both are removed and the causal effect 'makes sense' in domain knowledge), (Elliott, 2003). This study has already identified that the global movement of tourism is seemingly showing an increased focus on the thermal tourism (niche product or niche service). In this case, the question seems to be whether the further growth in demand for healthcare management and thermal tourism. A future study should include emotional factors. The new vogue of thermal tourism forces us to challenge and re-visit the power relationships that exist within contemporary tourism and the host–guest relationship.

Abstract

This research presents a study aimed to evaluate the performance and competitiveness of tourist destinations in Portugal and Belarus within regions. The evaluation was performed under an analytical tool, Market Share Analysis proposed by Faulkner (1997). In addition, it was used some descriptive statistics. The conducted analysis concluded, with respect to the evolution of the destinations tourism that *Açores* Island is the most prosperous market for the majority of countries, because most countries staid in the zone of Performing market. North, Lisbon and Algarve regions are maturity markets for the most countries, because they stay in Stagnant markets zone. Centre and *Alentejo* regions could be attributed Emerging markets for the majority of countries once are developing markets. The major market share is occupied by Portugal practically for all regions, except islands.

Keywords*:* Rural Tourism, Competitiveness, Agritourism.

Introduction

Tourism is one of the largest economic sectors in most countries, and it also has a very competitive sector. In rural tourism, an escalating niche in the tourism market, numerous elements of environmental constructs, such as natural resources, cultural heritage, infrastructure, environmental quality and environmental preservation, fulfil a key role in promoting the sustainability and competitiveness of rural tourism destinations. Moreover, the regards of regional fellowships toward tourism extension impact its prosperity or flop.

Therefore, this research regarded rural tourism destination competitiveness in Portugal regions. The conclusions of this research also give useful data to tourism intermediaries and policy planners about the significance of environmental attributes and community maintenance in direction of the extension of tourism destination competitiveness, especially in the scope of rural tourism. The evaluation was performed under an analytical tool, Market Share Analysis (MSA), proposed by Faulkner. For the calculation of the MSA, it was used varying the overnight stays in the Portuguese rural areas, empowered by the National Institute of Statistics, for the period from 2013 to 2014.

The sections of this research are organized in the following order. Section 1 represents the general information about tourism in a whole and rural tourism in particular, as well as description of peculiarities of rural tourism in Portugal. Section 2 reviews research methodology and objective of the study, as well as description of data collection and data analysis from rural tourism context. Section 3 demonstrates the data analyses and obtained results. After that Conclusions, limitations and implications of this study as well as suggestions for future research are presented.

Background

Day by day tourism becomes more and more popular global leisure activity and has been emerged as one of the most dynamic and fastest growing industries all over the world, which represents around 6% of international trade both in goods and service and contains 30% of the world's export of commercial services (Daniloska & Hadzi Naumova-Mihalovska, 2015). In both developed and developing countries, tourism is supposed to be a vital mean of growth in economic, social and cultural activity and regions development (Hall, 1994). It is also a highly competitive environment, which forces tourism players to provide better services for customers in order to stay competitive.

Nowadays World Tourism Organization (UNWTO) gives the following general definition to this term: "Tourism is the activities of persons identified as visitors", (UNWTO, 2014). The main reason for such generalization of the term lays in huge differentiation of tourism division recently.

For example, modern society marked out around 80 different types of Tourism. Here are some of them: Adventure travel, Curative tourism, Cultural tourism, Ecotourism, Geotourism, Heritage tourism, Medical tourism, Music tourism, Rural tourism, Wine tourism, etc. (Sucheta, 2013).

Principal contextual feature of rural tourism is that it meets the needs of people, who live in cities for open area and let them fresh knowledge of nature and rural lifestyle, and therefore is in contradiction with urban area. Rural tourism is accomplished on the space that is originally used as a living and labouring area of rural population and agricultural producers that is space vestured with tillable, fallowed and populated area outside the cities. It composes of the conventional village and rural architecture, along with whole rural landscape where traditional culture, distinct cognition and capabilities, lodging, clothing, nourishment, national dances, songs and legends are cultivated and created. The unity of all these elements performs the distinguishing and essential part of the tourist importance that have to be integrated into rural tourism sentence.

Several rural villages may alleviate tourism because many countrymen are hospitable and eager to welcome (and from time to time even host) tourists. Partially it occurs because agriculture is becoming notably mechanized and consequently, needs less handheld labour. At the same time, this trend is generating economic tension on some countrymen, which in its turn produces young people to shift to urban locations. There is howsoever, a part of the urban population that is concerned in visiting the rural locations and conception of the lifestyle (Daniloska & Hadzi Naumova-Mihalovska, 2015). Rural tourism is a multi-faced performance, which takes place in an environment out of strongly urbanized locations. It is an industry segment characterized by small scope tourism business, established in locations where land use dominated by agricultural occupations, forestry or natural locations (Lane, 1994).

Consequently, in an attempt to aggregate all previously mentioned definition, rural tourism has to have following features (Roberts & Hall, 2001):

- Located in rural areas;
- Functionally rural-built on the rural world's particular characteristics of small and medium size enterprise, uncovered area, connection with nature and the natural world, inheritance, 'conventional' communities and 'conventional' practice;
- Rural in scale (e.g. either in terms of houses and locations and, consequently, usually small-scope);
- Conventional in nature, escalating deliberately and organically, and linked with regional households. It is usually very substantially managed regionally and developed for the long term of the location;
- Of many various types, representing the multipurpose pattern of rural environment, economy, history and location.

The rise of rural tourism reflects as common enlargement of all kinds of tourism as a variety of tourist experiences, tightly connected with the growth of a lifestyle-led and leisure-oriented society at the same time, and with the prevalent mobilization of tourism as a strategy for rural elaboration and recovery (Walmsley, 2003).

According to the European Union, a quarter of the EU population travels to a rural area within their holidays. Moreover, while focusing on natural and cultural resources, rural tourism provides visitors with an alternative to 'sun and sand tourism'. Recently instead of three S (sun, sea, sand) - come three L (landscape, lore, leisure). If considered in a wider environment of a destination's frame this orientation gives tourism providers the possibility to vary and supplement their offers whilst spreading the advantages of tourism more extensively (Sharpley, 2002).

From the other point of view, rural tourism should be seen as a continuum of various types of tourism subject to the region/location where it occurs. That is, the inquiry for rural tourism is immediately connected with the distinct feature of rural locations. It looks like rural regions not far from urban locations are very likely to present several urban tendencies, whereas circumferential rural locations whereas attracting lower levels of tourists can propose more possibilities for more rural-specific tourism activities. For example, farm tourism is characteristically rural, whilst cultural tourism is usually a more urban type of tourism. In contrast, wellness tourism located in the middle of these two forms of tourism (Pollermann & Neumeier, 2014).

Situated in the Western part of the Iberian Peninsula, Portugal is a country with one of the most antique and sustainable territorial frontiers of Europe (Silva & Leal, 2015). Until the end of the XXth century tourism based on the 'sun and beach' has been the main commodity of the Iberian Peninsula (Loureiro, González & Javier, 2009). The conception is determined as a paid set of activities and services provided in rural regions, in foundations with family nature aiming at sentence of a complete and varied tourism commodity in rural locations (Agapito, Mendes & Pinto, 2012).

In these latter days, western and particularly Portuguese remote rural locations are increasingly considered as multifunctional areas, where efficient activities, such as agriculture or forestry, are occasionally as prominent as the (growing) consumption-oriented activities as leisure and tourism (Figueiredo & Raschi, 2012). Besides leisure and tourism, new functions of the countryside contain environmental protection and the conservation of both customs and memories and of the built patrimony and inheritance (Silva, 2012). Those locations are nowadays 'beyond agriculture'. However, around 50% of Portuguese area may be measured as brittle and declining rural locations (Oliveira-Baptista, 2006).

In Portugal, tourism is a strategic sector in the country economy. Indeed, with a view to enhance the destination's attraction for tourism, the National Strategic Plan for Tourism (Ministério da Economia e da Inovação, 2007) pinpointed nature-based tourism as one of the ten national strategic products.

The regional fellowship also plays an active role in establishing the rural tourism experience, supporting visitors to detect and relish a keener experience of these places. Residents can share their cognition of a region's history, culture and nature inheritance, or suggest possibilities of closer binding with their way of life or with regional products (Sáez, Fuentes & Lloréns-Montes, 2007).
Nowadays in Portugal prevails several forms of rural lodging units, such as: *Turismo de habitação* - manor houses or residential houses of admitted architectural value, of adequate measuring, with character furniture and decoration; *Turismo Rural* - rustic houses having the features of the rural environment in which they are situated; *Agroturismo* - houses and the outhouses on the farm, visitors being able to participate in the work of the farm or in supplementary types of entertainment, *Turismo de Aldeia* - Villagetourism; and *Casa de Campo* - Country Cottages (Ribeiro & Marques, 2002).

Methodology

The objective of the study is comparison of situation on rural markets of Portugal and to observe the competitiveness of rural markets. The research focuses on forms of rural tourism and it is driving forces, its advantages and what makes rural tourism successful. It provides some examples of rural

tourism in Portugal. The work gives data about various geographic regions and stages of tourism development. The study also highlights some points for further research and extension of rural tourism.

To answer the main objective of the study it was fixed the follow research hypothesis (RH): There are tourism rural competitiveness between each region of Portugal.

Data was collected from web site of National Institute of Statistics of Portugal. On the base of obtained information, for Portugal in a whole and its each region in particular for the 2013-2014 period, the Top 5 countries which visitors spent the most number of nights in rural tourism areas were chosen. Eventually the whole data set included 7 countries (Portugal, Germany, France, Spain, Netherlands, United Kingdom and Belgium), because of the difference in Top 5 for each region (North, Centre, Lisbon, *Alentejo, Algarve, Açores, Madeira*).

In these research was used the following variables: Market bias index, Change index, average rate, grows rate and/market share rate.

During the data analysis of Portuguese rural tourism competitiveness, Faulkner, (1997) Market Share Model was implemented, because this type of analysis provides valuable background for verification of particular target markets and provides valuable diagnostic information for strategic planning. The base of this method is an index that repulses the movements of the marketplace and variations in the destination's performance with respect to this market, while at the same time permitting for the givens that place extensive limits on the destination's general competitiveness. This method was widely used in 1960 to compare the economic development of regions.

During the research, it was used the following dimensions of the analysis (Faulkner, 1997; Águas, Grade & Sousa, 2003; Fernandes, 2005; Fernandes & González, 2007; Fernandes et al., 2008):

- An index of market share with respect to each major market or, in other words, market bias index (B); in examined case this index means the degree to which the market share of Portuguese regions with respect to a Portugal as a whole deflects from its share of spending nights of tourists generally. This index is calculated as fallowing:

$$B_{ik} = \frac{\left(X_{ijk} \Big/ \sum_{i=1}^{n} X_{ijk} \right) - 1}{\left(\sum_{j=1}^{n} X_{ij_{(k)n}} \Big/ \sum_{i=j}^{n} \sum_{j=i}^{n} X_{ij_{(k)n}} \right)} \quad [1]$$

  Where,

  B_{ik} , Market bias index for destination *i* in year *k*;

  X_{ijk} , Tourists numbers to destination *i* from market *j* in year *k*;

  n , Number of markets (origins) and destinations.

- An index of change (C) in the tourists received from each market relative to the change in that market generally.

$$C_{0-k} = \left[\left(X_{ijk} \Big/ X_{ij1} \right) - 1 \right] - \left[\left(X_{jk} \Big/ X_{j1} \right) - 1 \right] \quad [2]$$

  Where,

  C_{0-k} , index of change of market share between moment 0 and the moment *k*;

X_{jk} , total foreign tourists from market *j* in year *k*;

X_{ijk} , tourist's quantity to destination *i* from market *j* in year *k*;

$1 \ldots k$, between year *1* until year *k*.

For analysing the competitiveness of Portugal in the sphere of rural tourism, the data was united in Tables according to year (2013 and 2014), countries (Portugal, Germany, France, Spain, Netherlands, United Kingdom and Belgium) under analysis and region (North, Centre, Lisbon, *Alentejo, Algarve, Açores, Madeira*).

The most important reason for choosing that method was a possibility to present the value of these two indices in the evaluation within graphs, where Market Bias Index (B) is on the vertical axis and the Change Index (C) is on the horizontal axis (Figure 1).

Follow it will be described the strategies for each Quadrant (Faulkner, 1997; Águas, Grade & Sousa, 2003; Fernandes, 2005; Fernandes & González, 2007; Fernandes et al., 2008): Quadrant I (B>0; C>0) - Performing Markets: origins, where the destination already had a share above average and where market continues to gain market share; Quadrant II (B>0; C<0) - Stagnant Markets: backgrounds, where the target has a quota market above average but begins to decrease; Quadrant III (B<0; C<0) - Declining Markets: backgrounds, where the target has a quota of below the market average and reducing continuous; Quadrant IV (B<0; C>0) - Emerging Markets: origins, where the destination part of a market share is below average, but that is beginning to gain market share.

Note: Market Bias Index [B]. Change Index [C].

Figure 1. Market Share Typology.

Results

It could be easily seen (Table 1), that in one year the number of visitors, who participated in rural tourism grew as for Portugal as a whole as for the North region in particular, except Netherlands towards Portugal and North region, and United Kingdom and Portugal with respect to North region. The main difference between these 2 years lays in changes in Top 5 of visiting countries; Spain reached 1 level and obtained the forth place, while Netherlands lost 1 level and lowered to the fifth place in 2014.

Table 1: Overnights spent by foreign tourists in rural areas of Portugal within North region.

2013 (10^3)		Countries	2014 (10^3)		Annual Growth Rate (%)

In the plot, presented below the bubbles formed by countries represent the Market Share, occupied by countries. It could be seen that the biggest share in North region is taken by Portugal, the smallest by Netherlands. The graph shows that only Spain is located in the zone of Performing market, while the majority of countries (France, United Kingdom and Portugal) are situated in the zone of Stagnant market or so called zone of uncertainty. Concerning Germany and Belgium, these countries laid in the zone of Declining market or failure, and Netherlands belongs to Emerging market.

The graph shows (Figure 2): that for Centre region most countries are located in the third and fourth quarter; Lisbon region all countries are located in the third and second quarter, e.g. between Stagnant (the majority of countries: Spain, France, Portugal, Netherlands and United Kingdom) and Declining (Germany, Belgium) markets; *Alentejo* region all countries, except Portugal, which is located in the Performing Market, are located in the third and fourth quarter; *Algarve* region most countries, on the contrary with *Alentejo* region, are located in the first and second quarters, except Portugal, which is located in the Declining Market, and France, which occupies Emerging market; *Açores* region the main Market Share is taken by Germany, and the smallest by Spain. Such countries as Germany, Belgium and Netherlands represent Performing Market (staying in the first quarter), while France occupy Stagnant market (second quarter); *Madeira* region the main Market Share is again, as in a case with another island region *Açores*, taken by Germany, and the smallest by Spain. Only Germany and UK were situated in the first quarter, or zone of Performing market. Such countries as France and Netherlands are located in the zone of Stagnant Market, Portugal and Spain represent Declining Market for *Madeira* region, and the Emerging Market is occupied only by Belgium.

Figure 2. Analysis of Origins in the Destination North, Centre, Lisbon, *Alentejo*, *Algarve*, *Açores* and *Madeira*.

To answer the specific objective 1, "*SO1: There are tourism rural competitiveness between each region of Portugal*", the analysis produced above showed that for each region of Portugal the rural tourism is competitive but for different countries (in connection with the quadrant in which these countries are situated).

Conclusion and Limitations

This research regarded rural tourism destination competitiveness of Portugal regions. To answer this question an analytical tool was applied, as well as Market Share Analysis, proposed by Faulkner.

During the analysis it was found that *Açores* are the most prosperous market for the majority of countries, because most countries (Germany, Belgium and Netherlands) stay in the zone of Performing market, what means that they are located in the area where shares of these countries are above average and where market continues to gain market share.

North (France, United Kingdom and Portugal), Lisbon (Spain, France, Portugal, Netherlands and United Kingdom) and *Algarve* (Spain, Netherlands and Belgium) regions could be attributed to Stagnant markets for the majority of countries located in the second quadrant. It means that the target of these countries have a quota market above average but begins to decrease.

Centre (Germany, Belgium and Netherlands) and *Alentejo* (France, Belgium and United Kingdom) regions are supposed to be developing markets for the most countries, because they stay in Emerging markets zone. Stagnant Markets are origins, where the destination part of a market share is below average, but that is beginning to gain market share.

Madeira region occupies several markets at the same time: Performing market (Germany and UK), Stagnant Market (France and Netherlands) Portugal and Spain represent Declining Market.

It was concluded that "There is tourism rural competitiveness between each region of Portugal", answering in this way to the specific objective.

It is also necessary to underline, as limitation, that the research was made only within two years (2013 and 2014), because of the lack of necessary information in previous years in INE web site.

As future lines of research is intended to monitor these indicators to see the behaviour of each one and to give this information to municipal and national decision-makers for maintain foreigners and create sustainable rural tourism.

Abstract

Earnings Management is about the use of accounting techniques in the process of financial statements creation. Financial statements are a structured presentation of the business activities and financial situation of companies. Earnings Management is thus used for the way in which accounting rules are applied and generates financial statements according to the management's wishes. Earnings management is becoming an increasingly popular topic and therefore is the subject of this paper. The objective of presented paper is to clarify alternative techniques of earnings management. It also contains presentation of the relationship between earnings and cash flow. The presented paper consists of five parts. The first part of the paper is devoted to the theoretical aspect of earnings management. It also contains, clarification of the creative nature of the earnings management. The paper deals with the options of application earnings management as well. The second part of the paper is aimed at clarifying alternative earnings management techniques. Within the issue of earnings management, increased attention is devoted to techniques like „Cookie Jar Reserve“, „Big Bath“, “Big bet on the Future”, “Flushing”, “Throw out a problem child”, “Change accounting”, “Operating versus non-operating income”. The third part of the paper focuses on analysing the relationship between earnings and cash flow. The analysis was carried out on the Slovak company. The fourth part of the paper is focused on discussion. The discussion deals with specific cases of the use of individual techniques, which have been defined parts before. A descriptive method, analysis, mathematical-statistical methods, graphic methods, comparison and synthesis were used in the processing of the submitted paper creation. The result of this paper is a comprehensive overview of the possibilities in the process of alternative earnings management techniques usage.

Keywords: earnings management techniques, cash flow, earnings, creative accounting,

Introduction

Earnings is generally an item that is part of the accounting statements. It is usually most often subjected to different calculations, forecasts or planning. It tells about the profitability of the company. The earnings values for monthly, quarterly, or annual statements are subject to comparations with an earnings-development prediction. (Svabova, Kramarova, Durica, 2018) The actual earnings values are compared with the estimated values. If the development of earnings is different to the estimated development, the price of the shares will be directed towards the decline. It is therefore evident that earnings determine the price of shares. It also gives information about whether the company will be profitable and successful in the long run. Earnings management is therefore defined as the purpose and legal management of decision-making and reporting in order to achieve stable and predictable financial results. (Eysenck, Kovalova, Machova, Konecny, 2019)

This definition is an important ingredient "legal". It emphasises the legality of this activity, in contrast to illegal accounting procedures, created for the purpose of manipulating financial statements. Illegal creative accounting practices are also referred to as “cooking the book”. Earnings Management is thus moving within the scope of the legal framework. However, it is not possible to deny the fact that Earnings Management contains creative accounting techniques. (Remenaric, Kenfelja, Mijoc, 2018) In essence, it is a creative accountant that shows the financial situation and performance of the company according to management. As a result of creative earnings management, it is possible to doubt the true and fair image of the accounting as well as the image of economic reality. (Huynh, 2019)

The creative character of earnings management is also reflected in terms such as creative accounting, the earnings game, accounting magic and window dressing. Creative accounting can be characterised as a process of manipulation with accounting data. (Susanto, Adrianne, Pirzada, 2019) The aim is to transform the accounts of the financial accounts into a form that should have a fair view of the facts. Creative accounting includes the execution of such transactions, the purpose of which is to present the desired financial position, performance or cash flows of the enterprise. (Hoang, Joseph, 2019) The earnings game concerns the wishes of companies and the steps that are taken in order to meet their quarterly forecasts of earnings. Used to describe the way companies play the game. Players in the game include companies, their accountants, analysts, etc. The essence of the game lies in the fact that companies meet the assumptions of analysts for example for one share. The reason for which this goal is referred to as "the game" is, that it is not always achieved as linear as your management may think. The magic accounting uses the term as fraud. In accounting, accountants are involved in cheating on economic realities. What they believe is really real and vice versa. (Gray-Hawkins, Michalkova, Suler, Zhuravleva 2019) The facts induced by accounting alone are physical artefacts that have an official certificate. Window dressing is a strategy used by mutual funds and other management portfolios. This is mostly the end of the year or quarter, which contribute to improving the performance of the Fund in front of its investors. Thus, window dressing are the actions that were taken before the release of the financial statements in order to improve its appearance. Based on these definitions, it is therefore difficult to establish an imaginary boundary when accounting and managerial creativity are within the limits of the law and when they no longer among its boarders. However, fraud in these contexts generally refers to the creation of transactions that have not been related. (Kliestik, Kovacova, Podhorska, Kliestikova, 2018) Alternatively, the deliberate use of unauthorized accounting practices. The goal is to deceive users of financial statements. (Craig, Smieliauskas, Amernic, 2014), (Hudakova, Masar, Luskova, Patak 2018), (McKeen, 2005)

Methods

Earnings management is thus the management of earnings through the manipulation of accounting in the company. The reason is to make the company's earnings looks better. There are a number of earnings management techniques that are not generally illegal. Primarily, because they are complying with accounting rules. But they can violate the spirit of these rules by assuming something other than an honest, objective picture of the company's finances.

„Cookie Jar Reserve“ technique

This technique results from the flexibility of the accounting framework. The essence of this technique is to 'store' the various amounts as long until it is time to increase or decrease the earnings. Mostly according to the current situation and needs of the company. If we use GAAP, IFRS and other national laws, it is necessary to estimate the role of managers and record the costs incurred from the event of the current year. Although they will become due in the future. It is the estimation of the amount of costs that brings room for profit management. If the manager chooses

the highest possible amount that can be reasonably justified, he will report higher costs than he would in the case with a lower estimate. With this decision, the manager created a "cookie jar reserve", which will be used later. Especially when it is necessary to report lower costs and possible higher earnings. However, if in the future it turns out that spending is actually in the upper range of the cookie estimate, spring reserve will be empty. Then there will be no revenue increase. Withal, if future expenditure actually appears in the middle or lower range of the estimate range, the excess in the previous period may be taken into account as earnings.

„Big bath“ technique

This technique will report all possible revenue-related expenses in the current year. This is a technique that is often used, when management change. New managers can shift responsibility for huge losses to their predecessors. The Big bath technique is used in the belief, that if it has to report bad news to management, that is the loss caused by substantial restructuring, it is better to report it at once. Given the fact that many such fees are based on estimates, it is better to estimate the parties now. The reason is to avoid any surprises. In essence, this technique practically means that if a company expects a poor profit, it will show an additional loss for even worse financial results. On the other hand, this avoids a later loss. With this technique, the time of cost recognition is affected.

“Big bet on the Future” technique

In this technique, it is about ensuring earnings growth by the fact that management literally buys the profit through acquisition. This technique is basically a combination of business earnings management methods that we have defined above. A separate acquisition is a consequence of the investment decision made by the management. The related acquisition costs may be subject for creative accounting. In practice, it works like having a company acquired by another company make a big bet on the future.

“Flushing” the investment portfolio

This technology is understood as reducing the number of securities. It mainly on the purpose of earnings/loss, depending on what needs to be achieved. In essence, this is an earnings management technique that is very good feasible in terms of time. However, this technique is not an example of creative accounting. It is part of an investment decision leading to the sale of securities that lose economic sense. One of the purposes of sales is to influence earnings. Companies often buy shares in other companies to invest excess funds. Alternatively, they have achieved some kind of strategic alliance. These investments usually are classified into one of two portfolio categories. Each of them has different accounting procedures.

“Throw out” a problem child

This technique is worthwhile, if it appears that the slowdown in profit due to the branch will increase in the near future. This technique follows from existing alternatives. Management decides on the method of disposing of the branch according to the accounting impact. If earnings are driven down by an underperforming subsidiary, the burden is expected to increase in future periods. The subsidiary company “problem child” can be a “throw out” to get rid of the pulling down. Stopping the downward pull can be done using one of the techniques including the accounting entity. The first technique is the sale of the company. Upon the sale of a subsidiary, the earnings/loss is recognized in earnings or loss statement in the current period. If reporting a large loss on sale is undesirable, a distribution should be considered. The second technique is to create a special purpose entity for financial assets. One of the available technical alternatives is the transfer

of financial assets to a qualified special purpose entity. Such assets are treated as sold and are excluded from the balance sheet. The company's management records an earnings/loss on the sale of assets. A qualified special purpose entity is not consolidated with the financial statements of the entity. The third technique is to spin off the subsidiarity. As part of this activity, the shares of the subsidiary are distributed or exchanged with the current shareholders. On the separation normally no earnings/losses are recognized and any negative effects of the subsidiary are eliminated from all financial statements.

Change accounting

If a company chooses an accounting policy, which it will use, little when they change over time. Companies that are changing they must also ensure that the stock market does not regard this change as a deterioration in the quality of returns. The reason may be, for example, that the company underestimated the share price. However, in the following circumstances, accounting policies may change without adversely affecting the share price. The first circumstance is volunteering for a new accounting standard. There is usually a period of two to three years for the adoption of a new accounting standard, which companies can accept at any time. Because voluntary early adoption can be an opportunity to manage earnings. The second circumstance is the improved revenue recognition rules. Many industries have several alternative revenue recognition rules. Some of them are better perceived as economic reality. Early adoption of a better revenue recognition rule provides an opportunity to manage earnings. The third circumstance is an improved expenditure reporting rule. For companies that record certain cash-based expenditures, a timely change of the rule may provide an opportunity to manage earnings. This change may coincide with a change in the Company's policy on the item.

Operating versus non-operating income

Comparison between operating and non-operating profit may seem like a straightforward task. However, there are items whose categorization is ambiguous. On this basis, a decision must be made as to which type of earnings these items belong to. Operating profit is characterized by regularity and is expected to be generated in the future. Although non-operating earnings are volatile and earnings is one-off. Operating profit is the starting point for determining the value of the company's shares. It is also an important accounting item for the financial statements and its components must be correctly identified. Consciously try to prevent purposeful shifting of individual types of earnings precisely in order to create a misleadingly negative picture of the financial situation of the company. The choice between posting a transaction to operating or non-operating profit is a profit management technique. It is available again due to some accounting flexibility. As a cessation of operations, extraordinary earnings/party, or the cumulative effect of a change in accounting policy.

Earnings and operating cash flow can also be used as a measure of quality earnings. We can divide it into two groups. The first measure can be:

$$QE1 = \frac{earnings\ distribution\ before\ extraordinary\ items}{operating\ cash\ flow\ dispersion} \tag{1}$$

If it is assumed that all revenues and expenses will be translated into cash flow in a given period, then earnings and cash flow will be equally variable. This means that QE1 will be exactly 1. The variance is the mean of the squares of the deviations from the arithmetic mean of the set. If the ratio is less than 1, then the variance in operating cash flow is greater than the variance in earnings. This reflects the poor quality of the earnings. If the ratio is greater than 1, the operating

cash flow deviation is less than the earnings deviation. However, this cannot be evaluated as a result of earnings management.

The relationship between earnings and operating cash flow is also expressed:

$$QE2 = correlation\ (earnings - operating\ cash\ flow) \tag{2}$$

The correlation coefficient indicates the statistical dependence of two characters. Its values are in a closed interval <-1.1>. This interval indicates how strong the two variables are linked to each other. A correlation coefficient of 1 means excellent positive and direct proportionality. And under unchanged conditions, an increase/decrease in operating cash flow leads to a decrease/increase in earnings. The correlation coefficient -1 means indirect proportionality. The operating cash flow is calculated as net income plus non-cash expenses minus the increase in working capital. The lower the correlation coefficient is, the more profit manipulations have been made.

The mentioned measures of earnings management will be applied and analysed for a specific Slovak company. The aim is to demonstrate whether academic tools for detecting manipulation of profits have real explanatory power. Whether they actually provide a claim that there have been creative interventions in accounting or not. Also finding interdependence between operating cash flow and earnings. Whether the tax model is statistically significant.

Advantages and disadvantages of using these techniques

Of course, each of the above techniques has both its advantages and disadvantages. The utility of these alternative earnings management techniques can now be combined with their benefits. The following paragraph lists some of the benefits of using the technique in earnings management. Also, the disadvantages of using these techniques in earnings management.

The advantages of using the above techniques by managers are, for example:
- manipulation of income information so that the company's managers achieve the set goal, possibility to charge financial bonuses, increase the value of society to achieve earnings, improve and adapt information on reported earnings, etc.

The disadvantages of using the above techniques by managers are, for example:
- decrease in operating performance, lower return on assets as well as equity, lower cash flows, lower earnings per share, lower price to wage ratio, etc.

Entities can use these techniques: manufacturing companies and companies with larger net operating assets, publicly traded companies, companies getting ready for major debt financing or for an IPO (Initial Public Offering), automobile industry sector mechanical engineering and electrical engineering private domestic companies, private international companies, private foreign companies, etc.

In accounting, earnings management is a method of manipulating financial records to improve the appearance of the company's financial position. In general, we can say that earnings management techniques can be used by almost all companies. Companies use earnings management to present the appearance of consistent profits and to smooth earnings' fluctuations.

Examples of entities that have used these alternative earnings management techniques and faced legal action is Cendant. Cendant announced misstated financial statements at its CUC International unit, the announcement resulted in a loss of $14 billion in market capitalization within one day of trading. It had produced a tremendous record of growth in revenues and

earnings. The second examples is Manhattan Bagel. From its initial public offering in 1994 to June 1996, the stock price of Manhattan Bagel rose from $5 per share to $29. The company grew to be the third largest bagel franchise in the United States with ambitious plans for substantial expansion. Sales and earnings were growing. The company began to expand through acquisition. The free-fall in its stock price continued and with the negative publicity and shareholder lawsuits that followed, the company was unable to sell franchises at anywhere near their previous pace. Eventually, the company was forced to seek bankruptcy protection. sell franchises at anywhere near their previous pace. Eventually, the company was forced to seek bankruptcy protection. The third example is Sunbeam. Sunbeam, a maker of small consumer appliances such as Mr.Coffee, has drawn much attention in recent years for its disappointing financial results. In mid-November 2000, the SEC concluded its investigation into accounting practices at Sunbeam. This activity was prior to the dismissal of Sunbeam's infamous CEO, who was terminated in 1998. Although not discussed in the SEC ruling, it would not be surprising if the stress of the environment contributed to the aggressive revenue recognition.

Results

In order to analyse the quality of earnings calculations, we had to obtain data directly from the company's financial statements. For better informative value, we have followed the development of earnings and operating cash flow in the last 5 years. In table 1 contains the values of earnings development and operating cash flow from 2014 to 2019. And also, the results of two earnings management quality indicators.

Table 1: Values of profit development and operating cash flow and results of indicators for measuring the quality of earnings management

	Earnings	**Operating cash flow**
2014	130929	172455
2015	7849	19149
2016	688	11892
2017	-151995	-140431
2018	377	18064
2019	462	7347
Variance	8056908553,47	9809063212,00
QE1	**0,821373905**	X
QE2	**0,995852034**	X

Source: own processing

The first measure of quality earnings (QE1) reached the value of 0.8214. This value indicates that the company was clearly managing earnings in the period. A value lower than 1 indicates from the table that the deviation of operating cash flow is greater than the deviation of earnings. Thus, we can note that in the analysed company, the possible presence of earnings management is pointed out.

The second measure of quality earnings (QE2) points to the relationship between operating cash flow and earnings. The Slovak Republic strives to detect as many frauds as possible within the framework of creative accounting and earnings manipulation. Therefore, we decided to perform a regression analysis of earnings factors and operating cash flow. As first, we set the null hypothesis that earnings and operating cash flow are linearly independent. Subsequently, an alternative hypothesis was established that earnings and operating cash flow are linearly dependent. Then it is

important to choose the level of significance α, which in our case was 0.05. The next step was to determine the relationship between earnings and operating cash flow. A Scatter / Dot-Simple Scatter graph was chosen to express the dependence. The graphical dependence of the variables is in graph 1.

Fig 1. Graphical dependence of the variables

The value of R^2 is the coefficient of determination. Determines the quality of the regression model. Thus, how many% of the variability of the dependent variable is captured by this straight line. The closer R^2 is to 1, the better the linear model captures the data. The coefficient of determination is the square of the correlation coefficient r. Thus, in our case r = 0.996. Subsequently, the correlation coefficient was calculated in the SPSS statistical program and its statistical significance was tested. The test result is shown in table 2.

Table 2: Calculation of the correlation coefficient of its statistical significance.

		Operating_Cash_Flow	**Earnings**
Operating_Cash_Flow	Pearson Correlation	1	0,996
	Sig.(2-tailed)		0,000
	N	6	11
Earnings	Pearson Correlation	0,996	1
	Sig.(2-tailed)	0,000	
	N	6	6

Source: own processing

Table 2 is an important line where it is earnings. It depends on the number of operating cash flow. Therefore, we will take into account the second cookware table. Pearson Correlation is the value of the correlation coefficient, which represents 0.996. Sig.(2-tailed) is a test of the relay significance of the correlation coefficient. If p value is < α, then the hypothesis H0 rejected and vice versa. In our case, we reject the hypothesis of zero. Correlation is statistically significant and variables are linear dependent. And thus, under unchanged conditions, it leads to an increase in operating cash flow to reduce profits. In our case, the company achieves the value of 0.996 and the less manipulations of profits have been made. If the value was lower, it would be possible to talk about greater handling of profits in society.

Discussion

In addition to the aforementioned gauges and techniques, that have been defined and analysed above, there are still several options where the Cookie techniques Jar Reserve, Big Bath, Flushing defined in methods can be used.

The authors of the paper recommend to use the technique Cookie Jar Reserve for the following reasons. The first option technique is to return goods and discounts. Claims must be accounted for in net realisable value. Thus, the value at which they are expected to be collected eventually. Therefore, all possible factors which affect the collection must be taken into account. (Caylor, Chambers, 2015) The typical ones are sales price, returns and discounts. Managers are expected to return or modify the sales price. The second option is the depreciation of inventories. The historical value, cost or cost of production must be reduced to a net realisable value. If there is a significant fall in their usefulness due to oblong, reduced and price changes. The implementation of the cost factor is also important for these methods. For example, one possibility is therefore the depreciation of the inventory into the cost. Subsequently, the possibility of applying advertising stocks.

The most common circumstances, in which a Big Bath technique can be applied, are the operational restructuring and the impairment of assets. (Valaskova, Kliestik, Kovacova, 2018) The cost of operating restructuring is the costs incurred by the company in order to reorganise its activities. The reason for this, is to increase revenue or reduce productivity. These costs are due to the temporary dismissal of employees. The posting of depreciation of assets consists in the comparations of the book value and expected future cash flows from their use and possible removal. (Svabova, Valaskova, Durana, Kliestik, 2020) If the expected cash flows are lower than the carrying amount, the asset will be a detailed deterioration. However, the loss of deterioration shall be the amount of the difference between the carrying amount of the asset and its market value. (Novak Sedlackova, Svecova, Tomova, 2019)

The Big Bet on the Future technique includes two areas, within specific usage cases. The first is to write down the ongoing costs of research and development for the company acquired. For example, this technique allows companies to depreciate a substantial portion of the purchase price against the actual profit in the acquisition year. This is because it protects future profits from these charges. In practice, this means that future earnings will be higher than they would be otherwise. The second is the incorporation of the earnings of the acquired company into the consolidated earnings of the company. (Vochozka, Rowland, Zrbka, 2016)

With Flushing technology, investment requirements that offer the opportunity to manage revenue are broken down into several techniques. (Hadaway, 2006) The first technique is the timing of sales of securities that have earned value. If additional revenues are needed, companies may sell portfolio security that has unrealised earnings. The earnings will be recognised in the operating income. The second technique is the timing of the sale of securities that have lost value. If it seems more useful to report lower income, companies sell a security that has an unrealized loss. (Svabova, Durica, 2019) The loss will be recognized in operating income. The third technique is to change the intent to holding. The company's management may decide to change its intention in relation to the security. It may reclassify from a trading securities portfolio to an available-for-sale portfolio and vice versa. The effect would be to transfer any unrealized earnings/losses to or from the income statement. (Khanh, Thu, 2019)

Conclusion

The main goal of submitted paper was to clarify the accounting techniques used in earnings management, which may lead to manipulations of earnings. Earnings management can be achieved essentially in two ways. The first is a company management decision to do some transaction with an impact on earnings. The reason is its influence. The second option is to use earnings management through the bending of accounts for the purpose of the desired result. This requires sufficient orientation in accounting. The formulation of accounting standards, principles or standards offers a fairly wide scope for earnings management. This facilitates the execution of creative accounting ideas.

In conclusion, it can be said in general that the implementation of the time factor is also an important factor in these techniques. Earnings manipulation is an important accounting and economic issue. This issue cannot be avoided due to the involvement of the human factor. Because from time to time, personal interests are subject to the detriment of the public. The elimination of this problem can be sought in the wording of the accounting-legal framework, which will not offer such flexibility to the units of account. The question remains, however, whether such a requirement could sometimes be fulfilled.

The output of the presented paper is a tool that will enable the non-recognition of earnings management techniques and the debugging of the use of these techniques in society. The paper is part of a wider project, the main output of which will be an innovative solution.

Abstract

Assessment of the organization's functioning using the EFQM Excellence Model is usually implemented as a comprehensive project to which the entire organization is a subject. This article presents the idea of using the RADAR tool, which is part of the EFQM Excellence Model, to examine the level of implementation and evaluation of a selected organizational solution related to the concept of Industry 4.0.

Keywords: The EFQM Model, business excellence, assessment, RADAR, Industry 4.0

Introduction

The concept of Industry 4.0 has become one of the main drivers of change in organizations in the world in recent years. The digitization associated with it enters the lives of almost every organization, causing changes in processes and ongoing operations. The question arises how to evaluate both the change process itself and its results. This article presents the idea of using the tool from the EFQM Excellence Model, i.e. the RADAR tool to evaluate an organizational solution in a selected factory in the automotive industry. In the following parts one can find a description of the evaluation tool and plan of research related to the evaluation of the implemented and functioning solution in the area of internal logistics of a large factory located in Poland. The purpose of this research procedure is to check if and how the RADAR tool can be used to evaluate individual organizational solutions.

1. Digital transformation

Digital transformation is a tool of industry 4.0 (the fourth industrial revolution) as well as a vision of the future for most enterprises. It is a concept of connecting the world of production machines with the world of the Internet, information technology and people. The flow of information between all these elements should be automated and connected within the digital ecosystem.

Companies of all sizes can take advantage of innovative digital solutions and transform their enterprise into a 'smart factory' - the intelligent factory of the future. Processes are carried out

automatically, production is optimized, and all areas of activity intertwine smoothly and work together to ensure maximum profit for the company. The key to this approach is, according to CG. Machado et al. [Machado et al., 2020,] is to understand the network of connections that must occur in the organization between new technologies, products, value chain and the business model of the organization. The key role is played by a broader view on processes within the organization and its structure, i.e.

- transformation of the product and service offer,
- vertical and horizontal integration of the value chain,
- optimization of customer relations,
- building a new business model

[A. Wagire et al. 2020; PWC, 2017; Deloitte, 2016; HBRP, 2019; Zielinski, 2016].

Research on the level of automation of Polish production plants prove that for the managers of Polish factories the challenges of the third industrial revolution related to microelectronic technologies remain largely valid. Only 15% of Polish factories are fully automated, [Zieliński, 2016] and 76% of respondents point to partial automation. Only a small part of factories, i.e. 6%, use IT systems for operational management and production control (Manufacturing Execution System MES class).

While analyzing the data from the reports, it can be concluded that Polish industry still has a problem with finding its place in the third industrial revolution involving the automation of individual machines and processes. This Polish delay compared to the most industrialized countries is the result of:

- lack of adequate capital,
- late opening to modern technologies,
- lack of specialized management and engineering staff,
- focus on marketing and sales in order to build market position.

If organizations want to prepare themselves to take advantage of the opportunities associated with the current, fourth industrial revolution, first of all they need full access to the technology from the previous stage, i.e. building a strong infrastructure that allows automation and computerization of production.

On the other hand, the key to the development of Polish enterprises is effective building of the value chain. The key stages of this process are: R&D, design, branding, production, distribution, promotion and maintenance services. This means that companies that focus only on production will be under pressure to lower prices. If they do not automate or build new value added in the short term, e.g. in the form of R&D and design processes, they will be eliminated from the supply chain.

It is obvious that when implementing new, breakthrough organizational solutions, it is also highly desirable to specify how the implemented solutions will be assessed. The assessment of compliance with the implementation schedule and budget seems obvious, but from the point of view of assessing the relative value generated by a given solution, this approach seems to be insufficient. A usage of an assessment tool which is a part of EFQM Business Excellence Model can fill this gap.

2. The EFQM model as a framework for assessing implemented Industry 4.0 solutions

The EFQM model is one of the methods supporting the holistic preparation of an organization for Industry 4.0. The Model of Excellence helps modern organizations measure, anticipate, monitor the needs and requirements of interested parties, and track the achievements of other organizations. The results achieved are the basis for the implementation of improvement activities in the organization. [EFQM 2013]

The evolution of the path to excellence was shown in the work by P. Hermel and J. Ramis-Puyol [Hermel and Ramis-Puyol 2003], where they anticipated the concept of integrated improvement - the so-called "Excellence 5.0". This concept is based on the integrated improvement of the organization, based on a systematic view on management, taking into account all its dimensions. [Stańczyk-Hugiet, 2014]

There are now many models that are designed to help achieving business excellence. They can be classified in three areas: global / national models; academic models, company models. Overall, Tickle et al [Tickle, 2016] identified 94 models of excellence that are used in 83 countries around the world. The basis of most is the EFQM Model.

Values and goals of the model according to Carvalho A. et al. [Carvalho et al., 2019] focus mainly on improving the competitiveness of companies on the domestic and global market, as well as emphasize the importance of flexibility, creativity and an innovative approach to management. Key areas of improvement are: leadership, employees, clients, strategy orientation, process management, etc. Strong aspects of the stakeholders, the environment and long-term orientation of the company's success are also important aspects. The organization’s performance is a key element. Socio-cultural conditions are of fundamental importance when creating the principles of excellence models. According to B. Talwar [Talwar, 2013] it is important to properly include the culture and customs of a given country in the organizational culture being built. Western countries focus mainly on individual devel-opment, developing freedom, creative thinking or entrepreneurship, while in Asian countries they focus on group development and "Eastern philosophy."

Literature analysis [Bou-Llusar et al., 2005, 2009; Boulter, Bendell, Abas, Dahlgaarh et al., 2005; George et al., 2003; Jackson & Bircher, 2002; Sanchez et al., 2006; Martusewicz, Wierzbic , 2018] indicates that the use of models of excellence facilitates the improvement of the organization by obtaining an overview of the entire organization, identifying the strengths of the organization and areas for improvement, the ability to check the effectiveness of actions taken, the ability to compare with other organizations, help in identifying and sharing best practices within the organization, increasing employee involvement in continuous improvement or improvement of internal communication and integration of various initiatives in the organization.

Thanks to self-assessment, the organization receives a picture of where it is and what is the basis for determining the path to its continuous improvement. The proposed self-assessment of enterprises based on models of excellence, compared to other assessment systems, takes into account the richer range of issues that comprehensively relate to various activities for quality and excellence.

3. The EFQM RADAR as assessment tool

In the EFQM Excellence Model 2013, the RADAR tool works in conjunction with the criteria for Enablers and Results [EFQM 2013]. The set of elements and attributes against which the assessment is made is different in relation to the two types of criteria mentioned above. In the latest version of the EFQM Model, there are three groups of criteria: Direction, Execution, Results, and the RADAR tool, similarly to the 2013 version of the Model, is adapted to each of the three groups of criteria mentioned above [EFQM, 2019]. For the purposes of this study, the tool described in the EFQM Model 2013 will be used. This choice is dictated by the fact that this version of the model is known to managers in the researched organization, as well as the fact that the organization has experience in using the Polish Quality Award model, which is very similar to EFQM Model 2013.

The RADAR tool, contrary to many popular beliefs, is not directly related to a radar chart, often used to present three or more quantitative variables on axes meeting at the starting point and stretched in the figure resulting from the number of axes, i.e. the number of presented variables. RADAR is an abbreviation of the words Results, Approach, Deployment, Assess, Refine. RADAR logic predicts that at the beginning the **results** that one want to achieve should be defined. Next, one need to design an **approach** that aims to achieve results. The next step is to **deploy**, implement the approach in reality. After that one should **assess**, evaluate both the approach itself and its implementation. The last step is to **refine**, improve the approach and its implementation. There are common points between RADAR and PDCA, but it seems that the creators of RADAR have intentionally highlighted the results to be achieved.

The figure 1 shows the flowchart of the RADAR tool.

Fig 1. RADAR, source: EFQM Model 2013

As mentioned above, the EFQM 2013 model is built based on two groups of Enablers and Results criteria, and in both groups the RADAR tool has different elements and attributes. On Figure 2 one can see the RADAR for Enablers.

Analysis of Enablers

Elements	Attributes	Guidance
Approaches	Sound	The approaches have a clear rationale, based on the relevant stakeholder needs, and are process based.
	Integrated	The approaches support strategy and are linked to other relevant approaches.
Deployment	Implemented	The approaches are implemented in relevant areas, in a timely manner.
	Structured	The execution is structured and enables flexibility and organisational agility.
Assessment & Refinement	Measurement	The effectiveness and efficiency of the approaches and their deployment are appropriately measured.
	Learning & Creativity	Learning & creativity is used to generate opportunities for improvement or innovation.
	Improvement & Innovation	Outputs from measurement, learning & creativity are used to evaluate, prioritise and implement improvements & innovations.

Fig. 2. Analysis of Enablers, source: EFQM Model 2013.

As it can be seen on fig. 2, the RADAR for Enablers is directed to four elements, i.e. _ADAR (approaches, deployment, assessment & refinement) and in the area of each of these elements attributes are defined, with which the assessment is performed.

The figure 3 shows RADAR for Results, i.e. the first letter of the acronym. Unlike RADAR for Enablers, Relevance & Usability and Performance were defined as elements, for which attributes and hints have been added.

Analysis of Results

Elements	Attributes	Guidance
Relevance & Usability	Scope & Relevance	A coherent set of results, including key results, are identified that demonstrate the performance of the organisation in terms of its strategy, objectives and the needs and expectations of the relevant stakeholders.
	Integrity	Results are timely, reliable & accurate.
	Segmentation	Results are appropriately segmented to provide meaningful insights.
Performance	Trends	Positive trends or sustained good performance over at least 3 years.
	Targets	Relevant targets are set and consistently achieved for the key results, in line with the strategic goals.
	Comparisons	Relevant external comparisons are made and are favourable for the key results, in line with the strategic goals.
	Confidence	There is confidence that performance levels will be sustained into the future, based on established cause & effect relationships.

Fig. 3. Analysis of Results, source: EFQM model 2013.

The original assessment methodology assumes awarding points for obtaining individual attributes, as well as additional restrictive conditions. For the purposes of the designed study, they will not be used, and therefore the authors have abandoned their presentation in this text.

4. Methodology of planned research

The assessment of the organization's functioning using the EFQM model is usually implemented as a comprehensive project to which the entire organization is subject. This article presents the idea of using the RADAR tool to examine the level of implementation and achieved results of a selected organizational solution. The research project will be implemented in one of the factories of a global manufacturing company operating in the automotive industry and will be treated by the team of authors as a pilot study, which aims to answer the following research questions:

- is it possible to "use" the RADAR tool to evaluate selected organizational solutions without having to implement the entire EFQM model,

- what are the determinants of this approach affecting the assessment process,

- how the assessment procedure of the selected organizational solution will be perceived by the persons participating in the assessment and by the management of the plant.

Unlike the classical organization assessment methodology developed by EFQM and being the basis for awarding distinctions and EFQM AWARD, the authors of this work decided to use a different approach. First of all, the assessment does not apply to organizations, but concerns the project of implementing organizational solutions resulting from the Industry 4.0 concept, which was implemented in the researched factory. A project from the area of internal logistics, i.e. e-kanban optimization based on RFID solutions, was selected for evaluation. The selection of the project for evaluation resulted from the recommendations of the plant management and from the fact that the project has already been formally completed and the resulting solutions are already functioning. From the point of view of the assessment method, it does not matter which project would be selected, and the key here is the use of a non-classical organization assessment method.

Respondents will be managers involved in the implementation of the evaluated e-kanban optimization project, and will be selected in consultation with the top management of the factory.

The assessment will be carried out on the basis of a questionnaire, which will be based on the presented above elements and attributes of the RADAR tool, while the assessment under the given attribute will be carried out on a scale:

- attribute not achieved,

- attribute partially achieved,

- attribute fully achieved.

In order to clarify the tool, as well as to calibrate how to understand the scale, it is planned to conduct a workshop for the participants of the assessment, in which the framework of the evaluated project will also be reminded. The second element of the research will be to ask about the usefulness of the method used to assess the implementation and results of the project, which

aims to answer whether the non-classical use of the RADAR tool is valuable and can / should be used to assess other organizational solutions or projects for their implementation.

5. Summary

The idea of using the RADAR assessment tool for evaluation of a given project instead of assessing the organization as a whole is a key aspect in the article.

The methodology of using the RADAR tool is different than in the case of the classic implementation of the EFQM Model in an organization. The fact that RADAR is applied to only one approach significantly changes the assessment process and the depth of analysis of a given issue. In the classic approach, the assessors focus on the assessment of many organizational solutions, which, even with the greatest care, reduces the amount of time and thus reduces the insight of analyzing individual solutions.

Our proposed approach also reduces a significant disadvantage of the EFQM Model as a management tool, which is the very large complexity and scale of the Model. Focusing on RADAR as an evaluation tool, and then applying it to the organizational solution which is well-known to participants of an evaluation process, can be used to get familiar with the EFQM Model and to gain a specific desire to learn it in full. This particular approach can also be used to other self-assessment tools like the one specified in ISO 9004 or in other Business Excellence Models across the world.

Once the RADAR is checked in this context the organizations will have the next, well designed, and validated tool for evaluation of projects or organizational solutions, in the Industry 4.0 area but also in others managerial scopes.

Abstract

Innovation is discussed everywhere. Ads deceive us about innovative products and companies. Professors open the door to various funds with the word "innovation", the most talked about innovations and written where they have never been done - in European offices, universities and various food agencies. It is a pity, because only innovation moves the world forward and improves it. In general, we could say that innovation adds value or benefit to the customer (performance, health, well-being, safety, comfort, satisfaction, happiness, etc.) and removes harmful functions or problems (risk, nature pollution, consumption, control complexity, costs etc.).Companies that do not know how to innovate disappear so that companies can be created better. Products that have helped people in their lives are being replaced by innovative products, which are better and have less harmful functions. Take, for example, the tools that served us for various things then and today - e.g. razor, ink pen, parchment or storytelling, trowel for tillage, ax for woodworking, animal for transporting people and materials, etc.

Keywords: Innovation. Small and medium sized enterprises. Innovation. Support of innovation.

Introduction

If we look at the S curve of the product, then at the beginning it's like a small child - it doesn't work on its own and there are many things to learn, in the next phase its functionality improves, later performance, efficiency, effectiveness, reliability and at the end of life. cycle, the cost of the product is reduced and the product disappears. If I wanted to be cynical at this point, this also reminds us a bit of old age in Slovakia - people with poor pensions, who have to reduce their living costs in old age. The product is optimized in its first phase - it improves its useful functions (eg performance, range, reliability) and eliminates useless functions (eg consumption, weight, emissions, etc.), later it is dynamized (adapted to the environment and the user in different situations), integrates functions from the environment (see functions in a modern mobile phone) and finally switches to a supersystem (eg cloud services, GPS, music from the Internet, etc.). The evolution of products also shows an interesting pattern - first it is made from a monoblock of

material (eg letters on a typewriter or a knife), which is later segmented (dot matrix printer or saw), later passed into the field (laser printers or plasma cutting).

Professor Milan Zeleny defines innovation as follows: “Innovations are those quantitative or qualitative improvements of a product, process or business model that significantly add value to the customer, the company, preferably both parties at the same time. Since value added is realized only in a market transaction, innovation itself arises on the market, at the moment of sale. It is implemented by the customer. Therefore, innovations are fundamentally different from invention, invention, patent or improvement design - they can remain unrealized, in a safe, in a warehouse, in papers, at the patent office.

Innovation connects ideas with actions in which people look for new ways of doing things and create value for customers. The only one who decides on the innovation is the customer who buys the solution or rejects it.

INNOVATION

Examples from Linet, OMS Lighting, Bernard Family Brewery, Fosfa or Brano Group show how innovation results are measured - success in the market. Profitability, margins, market position, sales, enthusiastic customers - these are the main benchmarks of innovative projects. However, there are also innovative projects whose primary goal is, for example, to attract customers or test new technologies and solutions (eg the Multicare bed in the beginnings of Linet, cooperation with Giugiaro Design and Hella in LED technology at OMS Lighting).

The results of innovation are therefore reflected in three basic areas:

1. Company image on the market - design, technological sophistication, opening doors for demanding customers.
2. Development of knowledge in the company (we can measure the knowledge account of each employee - the added value it creates by transforming knowledge into innovation) and attracting the best talent on the market. No need to look for innovators, if you play in the Champions League, they will find you.
3. Business success - new markets, new customers, vitality index - the share of sales and profits from new solutions created in innovative projects, flexibility and speed of launching new solutions on the market. You might also be encouraged to be copied by others or by litigation caused by frustrated competitors who are beginning to worry about you. You are on the right path.

When discussing the financing of innovation, EU projects, grants, subsidies, incentives and various concessions are often mentioned. It is a language unworthy of entrepreneurs and is often used by those who have never done any innovation, but would like to improve on the fact that European officials support innovation, even if they do not know what exactly it is.

Innovation is the result of talent, freedom, sometimes even defiance of generally defined rules, striving to excel, diversity, experimentation and non-traditional solutions. Asked whether the European Union's programs to support innovation are enough to make Europe competitive with the United States and Asian countries, Professor Green answers: "I don't think so. Innovation takes place in the company, not in the ministry or in EU grant bureaucracies. Promoting innovation is not a question of money, but of motivation to excel. Innovation and quality do not arise on the basis of regulations, standards and norms, but on the basis of customer care. To do this, you need to know your customer, not just "your" bureaucrat. The USA and Asia (China, Japan, Taiwan, Korea, Singapore, India) have the great advantage of not having an EU. Therefore, they have no problems with competitiveness: because they can not only compete but also cooperate, create alliance networks in order to satisfy the customer as much as possible, not just the authorities.

Imagine that there are no European funds, no grants and no tax breaks - and we start acting like real entrepreneurs and innovators. The best solutions arise when two conditions are met:

1. Restrictions (limited resources and time).
2. Concentrate on the essentials (create an exceptional solution that will save us).

So where to get money for innovation?

Is there a better investment for a business owner than investing their own dividends in a functioning innovation process in their own company? He can create grants and thus support his own company and value money in it, similar to what investors do with venture capital funds. Definitely a better investment than saving money in a bank, building a guesthouse or buying diamonds. Similarly, other collaborators can contribute to the financing of innovative projects - if they do not have the capital, for example by participating in future revenues from innovation and reducing current costs (for example, by investing in their work). The same applies to business partners, customers or external collaborators - innovation consultants, project managers, designers, etc.

In startups, the first innovations are usually financed by angel investors, and later by venture capital and standard investors. Crowdfunding systems and other Internet tools, for example, are opening up new ways of raising funds.

Some companies create an innovation fund to support innovative ideas and prototypes. This fund is created from money that brings innovation - in some companies it is up to 75% of sales and profits. Such an "innovative EPA" can continuously fill the budget for new projects. However, time and people must also be assigned to money. There are companies that allow their co-workers to devote 15-20% of their working time to their own projects and ideas (eg 3M, Google). However, this means that 15-20% of people have to pay "extra". However, we should realize that using the word "cost" in innovation would be better replaced by the word "investment." We are not only investing in a new idea (even if it is risky) but also to people who, in any innovation project, regardless of its success, move further compared to competitors. The company innovates itself in this way.

Innovation does not mean inventing something revolutionary (and expensive), but it is usually a different way of applying and applying something that already exists. Thus, innovations arise in networking and cooperation at the borders of various disciplines and specializations. And so they can be co-financed.

There are companies where customers finance innovations and will have privileged opportunities to use the new solution (this method is used, for example, by the Slovak company GA Drilling, which develops revolutionary technologies for drilling into the ground using plasma).

Innovation teams

Innovation teams are quite different from production teams, mainly in that sometimes there is not just one leader who leads others, but several strong personalities meet there. In addition to pushing hard for their opinion, they have different specializations, knowledge and often speak different languages (trade, service, production, logistics, research and development, construction, technology, industrial design, marketing, purchasing, finance, informatics, etc.) We inspect the relevant literature on the decision-making logic of big data algorithmic analytics, providing both quantitative evidence on trends and numerous in-depth empirical examples [1].

Fig 1. The ten faces of innovation

In a team, we need experienced experts who often know very well what "will definitely not work" and inexperienced enthusiasts who will push for it to "work" because they know nothing about it. We need people from inside the company and from the outside environment, young and old, experts and laymen, specialists and generalists. But most importantly - the ability to listen, mutual respect and cooperation. Although Western Europe is a global leader in innovation activities among the OECD countries, these activities are not distributed evenly across NUTS 2 regions [2].

CULTURE OF INNOVATION

Once upon a time, breakthrough technologies and revolutionary changes came more slowly, the world was not so fast and changeable. Today, it is not possible to innovate without connecting to external experts and networks. Many top people cannot even be employed by companies, not for money, but for the need for freedom.

The company should develop in its culture six basic skills in the field of innovation:

1. Ability to identify and interpret opportunities correctly.
2. Ability to create, design, project and implement innovative changes.
3. Ability to learn.
4. Ability to network with external sources of knowledge and technology.
5. Ability to collaborate and cross departments and specializations.
6. Ability to develop an innovative culture.

Innovative management principles are a culture of delegating decision-making and responsibility downwards, supporting staff initiative and opportunities to find one's own way, a culture of accepting the mistakes that arise when people experiment and look for new solutions. Criticism of mistakes kills initiative and support for experimentation and invention, for which everyone should have 15% of their time at work (Google today uses a similar principle - 20%).

What mistakes to watch out for?

Be careful not to confuse innovation with brainstorming and generating ideas that make people have fun coming up but stay on the wall. According to the results, the most demanding job is that of couriers, followed by postal clerks and call center operators [3].

Don't get carried away by many interesting ideas and don't work on a large number of projects at the same time. Many kinds of research has suggested that innovation is positively linked to business performance and that it acts as an intermediary between organizational variables and financial performance measured by earnings achieved [4].

Don't let people on the team spend time and energy on negative discussions about how something isn't going and how difficult it is. Innovative activity is an important source of competitiveness, economic growth, as well as the image of each country [5].

Don't let an innovative project revolve around a technical solution, deal with all elements of the business model. n the era of industrial digitalization, companies are increasingly investing in tools and solutions that allow their processes, machines, employees, and even the products themselves, to be integrated into a single integrated network for data collection, data analysis, the evaluation of company development, and performance improvement [6].

Don't let people on the team talk instead of the customer, gather experiences and suggestions directly from customers, get to know their environment, work, problems and plans in detail.

Solve details, go deeper and deeper into the problem, do not avoid contradictions and "unsolvable" problems. The main objective of the contribution is to create the CRM (Customer Relationship Management) level and performance measurement model [7].

Simplify the customer's journey to purchase your solution - from their search, through selection, configuration, purchase, installation, use and service. Business management plays a vital role in building processes, structures, and the business environment to make the business innovative and to motivate individuals and teams to innovate [8].

Learn your customer's language and use it - define the value and quality of your solution in his words. Developments in data and communication systems provide massive prospects for supply

chain intelligence and self-determination setting up means of advancement for Industry 4.0 supply chains [9].

Accept the mistakes that arise from innovations, do not be afraid to go back, change the assignment or redesign the whole solution, if necessary. The article deals with the process of distribution of an innovative product using the Bass model [10].

Don't be influenced by impressive presentations, ask for prototypes, facts, real customer experiences and not abstract analyzes. An analysis of the results of empirical studies of the relationship between economic growth and income inequality shows that the results largely depend on the choice of the model specification and the quality of the data used [11].

In innovation, we must be fast and slow, bold and careful, creative and disciplined - innovation is about contradictions and contradictions. We need time for many solutions, many breakthrough technologies need to mature and need the right infrastructure to function. On the other hand, sometimes the time is important - to be the first on the market, to have the first feedback and customer experience, etc. When you come to the market with an interesting solution, "Run Forrest Run" yells at you and you have to run - faster than others. When no one is interested in your "amazing" solution, you have a chance to ask why and fix it. A consumer considers a large number of brands to meet their needs, one of which are private label brands. They became a part of the Slovak consumer market with the arrival of foreign retail chains, and the name of most private label products is closely related to the name of the given retail chain [12].

Innovation needs the right people, environment and conditions. Many companies are trying to give people creative offices, freedom to work, excellent infrastructure and financial resources - and yet, the results are not coming. Innovation requires motivation and the desire to change the world. The question is whether this energy is generated more in an environment of scarcity and obstacles or in a comfortable incubator, where people have a good time but do not innovate. Firms' innovation activities play an important role in fostering firms' competitiveness and enhancing economic growth of regions and countries. Regarding the significance of the issue, it is essential to explore indicators of firms' innovation activities [13].

People in high positions in companies sometimes argue that they do not have time for strategic things and innovations. It's nonsense. I think there are only three reasons why they don't do it - they are incompetent, they are scared or they are lazy. And then the question is whether they are sitting in the right places. They deal with operations and pettiness, instead of addressing issues that will secure the company's future.

Small businesses are usually innovative because they would not otherwise be able to survive. However, sometimes their problem is that they have to deal with many things at once and do not have enough people, money and knowledge to innovate. We are therefore looking for ways to connect smaller companies and innovate together. We meet at regular intervals, work on several projects and it turns out that the heterogeneity of the team and the diversity of views on the problem is an advantage. It also works out more financially, the only problem can be that some internal ideas and strategies can get out.

CONCLUSION

For companies that have chosen an innovation strategy, is characterized by the so-called innovative corporate culture, which is characterized by change, learning, flexibility, creativity, development. The business environment is a profound concern for the state and institutions to make it encouraging to boost entrepreneurship. Given such relevance of the business environment [14].

Not all companies that have a strategy have it planned and formulated in writing. There are also companies with a strategy that works, employees understand it and implement it, but there is no formal strategic plan. Such a strategy has not been purposefully developed and chosen, it was created unplanned in response to customer wishes, or as a support for the most profitable activities, or as a result of the activity of a leader who is charismatic and naturally innovative. In

order for this situation to occur, there must be a precondition in the company in the form of a certain content of organizational culture, favorable for the progress of the given strategic focus.

Abstract

If we start to analyse the possibilities of using technical indicators of technical analysis, we come across two basic groups of these indicators. These two groups differ in part in their basic characteristics and possibilities of use. Our article will take a closer look at these two groups, which are the oscillator and the trend indicators of technical analysis. The aim of our article is to theoretically identify the basic characteristics of these two groups of indicators, their advantages and disadvantages and then verify them on the basis of real market data. In the element of the chapter of our paper, we will focus on the basic definitions and trend indicators and oscillators, an explanation of their operation and a detailed description of some indicators from these groups. In the following chapter, we identify the basic characteristics, advantages and disadvantages of these two groups of indicators. In the third chapter we present the obtained results of verification of these facts on real market data and in the last chapter we interpret the obtained results and findings and outline the next possible direction of research in this area.

Keywords: oscillators, trend indicators, trading

Introduction

If we decide to be interested in the issue of technical analysis, we will come across a wide range of mathematical indicators. In our article we will compare the basic characteristics of the two main groups of indicators of technical analysis, namely oscillators and trend indicators. The aim of our article is to theoretically identify the basic characteristics of these two groups of indicators, their advantages and disadvantages and then verify them on the basis of real market data. In the first chapter of the article, we elaborated in detail the theoretical basis of the problem. In the following chapter, we identified the basic characteristics of the two basic groups of indicators. In the third chapter, we then determined and described the rules of the application and the settings of individual indicators, saw the results of the application and interpreted them.

The theoretical basis

Currently with the development of various scientific mathematical and statistical methods there are an incredibly large number of indicators of technical analysis and each the trader can also create his own technical indicator according to his own requirements and his own trading approach. Today traders or researchers at universities use various complexities in the construction of technical indicators methods such as neural networks, linear programming, support vector machines, Bayesian statistics, fuzzy set theories, logistic regression (logit, probit) and many others. As there are currently a large number of technical indicators, it only depends on the preferences of the trader, which indicator he chooses for his needs, or what combination of which technical indicators he decides to use. It is not quite easy to choose the right indicators that a trader should incorporate into his trading system. The same indicator has a different explanatory power in different markets and for different assets in the same market. After studying several publications dealing with technical analysis, we can

say that there is no uniform classification of technical indicators that would be generally accepted. During the historical development of technical indicators, several divisions were gradually created and are still being created today. For the needs of this paper, we have chosen the following comprehensive structure of the division of technical indicators:

Table 1: Example of individual types of indicators

Technical indicators	
Trend indicators	**Oscillators**
• Moving averages	• Relative Strength Index (RSI)
• Bollinger bands	• Commodity Chanel Index (CCI)
• Moving Averages Convergence Divergence (MACD)	• Average True Range (ATR)

Source: Own processing

Trend Indicators

This type of indicators is designed primarily to identify the direction and strength of the trend. We can also identify them as delaying indicators. This means that trend indicators try to identify and confirm a trend that, of course, already exists on the market. It follows from their very nature that they are used in situations where the trader needs to find out whether a clear price trend has appeared on the market and also in the case of determining the strength of this already existing price trend. For a closer understanding of the essence of trend indicators, we will elaborate in detail the characteristics of some of them in the following subchapters.

Moving Average

Moving averages are among the most popular and most used indicators of technical analysis. They are based on the idea that they provide the trader with information on the average price of the monitored asset over a certain period of time from the past. The time interval always starts with the current, current price of the asset and continues into the past. The length of the selected time interval depends on the requirements of a specific trader (it is arbitrary). Also, the price of the monitored asset can be used opening, closing, maximum, or minimum in the selected time frame. As for the mathematical calculation of the indicator itself, we can choose from several different procedures. In general, Simple Moving Average (SMA), Exponential Moving Average (EMA) and Weighted Moving Average calculations are known and widely used. As its name implies, the moving average is the average that moves. Old data is dropped because new data is available [2,3]. This causes the average to move over time. If those prices are *PM, PM-1, PM-2, … , PM-(n-1)* then the calculation formula is:

$$\begin{aligned}\bar{p}_{\mathrm{SM}} &= \frac{p_M + p_{M-1} + \cdots + p_{M-(n-1)}}{n} \\ &= \frac{1}{n}\sum_{i=0}^{n-1} p_{M-i}.\end{aligned} \tag{1}$$

When calculating successive values, a new value comes into the sum, and the oldest value drops out, meaning that a full summation each time is unnecessary for this simple case:

$$\bar{p}_{\mathrm{SM}} = \bar{p}_{\mathrm{SM,prev}} + \frac{1}{n}(p_M - p_{M-n}) \tag{2}$$

The SMA calculation formula is as follows:

$$\mathrm{EMA}_{\mathrm{today}} = \mathrm{EMA}_{\mathrm{yesterday}} + \alpha\left[\mathrm{price}_{\mathrm{today}} - \mathrm{EMA}_{\mathrm{yesterday}}\right] \tag{3}$$

Expanding out $EMA_{yesterday}$ each time results in the following power series, showing how the weighting factor on each datum point p_1, p_2, etc., decreases exponentially:

$$\mathrm{EMA}_{\mathrm{today}} = \alpha\left[p_1 + (1-\alpha)p_2 + (1-\alpha)^2 p_3 + (1-\alpha)^3 p_4 + \cdots\right] \tag{4}$$

Where:

p_1 is price today,

p_2 is price yesterday,

and so on.

The weighted moving average calculation formula is as follows:

$$\mathrm{WMA}_M = \frac{np_M + (n-1)p_{M-1} + \cdots + 2p_{(M-n+2)} + p_{(M-n+1)}}{n + (n-1) + \cdots + 2 + 1} \tag{5}$$

Oscillators

The name oscillators is based on the fact that they oscillate (similar to a sine wave) around a horizontal line called the equilibrium line. This applies to price points and zero momentum, which is the point at which momentum does not increase or decrease. If this were the case, we can say that the market is stable and that the trend is still to be followed. To better understand the nature of oscillators, we will elaborate some of them in the following subchapters.

Relative Strength Index (RSI)

RSI is a technical momentum indicator that compares the extent of recent gains and recent losses to determine when an underlying asset is repurchased or resold. In general, it should signal when a potential correction of a recent movement may occur. RSI is probably the most common oscillator and is typically used for a period of 14 days. The RSI value, which falls in the range 0 to 30, signals that the market is oversold. Traders anticipate that the oversold currency pair indicates that the downward trend is likely to reverse and may be considered a buying opportunity. On the other hand, an RSI value falling in the range of 70-100 signals market overbought. This signal indicates that the resistance level for the instrument is close to or has been reached and the rate is likely to fall; traders would interpret this as a sales opportunity. For example, if you see that the RSI for EURUSD has risen above 70, a sell signal is generated and a currency pair can be sold. The calculation formula for calculating the RSI is as follows:

1. Calculation of the opening and closing price difference for each one rising candle (U) and for the falling candle (D).

$$U = CLOSE_i - CLOSE_{i-1} \ldots \textit{for each growing candle} \tag{5}$$

$$D = CLOSE_i - CLOSE_{i-1} \ldots \textit{for each falling candle} \quad (6)$$

2. Calculation of exponential moving averages from U and D values for a selected time period.

3. RS calculation.

$$RS = EMA\ (U) / EMA\ (D) \quad (7)$$

4. Quantification of RSI

$$RSI = 100 - 100\ x\ (1 / 1 + RS) \quad (8)$$

Theoretical comparison of basic characteristics

The main characteristics of oscillators include:

- Determines when the price is prone to correction (when the market is exhausted in the prevailing trend).
- Provides a signal to sell in the oversold zone and a signal to buy in the oversold zone.
- It shows the divergence between the oscillator and the price, which is useful in making trading decisions.

The main characteristics of oscillators include:

- Identifies the existence of a trend in price development or a trendless situation.
- Identifies the direction of the identified trend.
- Can determine the strength of an identified trend.

Technical indicators and oscillators are useful tools. They can show when it would be possible to open a store and in which direction it could go. However, it must be remembered that they are based on the past, not the future. This means that from time to time they can generate a false signal which can lead to loss. Therefore, the responsible trader should not always trust them 100%, but use them as confirmation or negation of his signal.

Results

For the purpose of verifying the identified basic characteristics of oscillators and trend indicators, we carried out the following research. From each group of indicators, we chose a typical representative of indicators, which is commonly used by traders. We chose a simple moving average for the group of trend indicators. For the calculation of the simple moving average, we chose the time period 25, because it is a common and basic setting of this indicator. We chose the Relative Strength Index (RSI) indicator for the group of oscillators. We used time period 5 to set the calculation of this indicator. The reason for setting this time period into the indicator calculation is that the indicator with this setting can respond more quickly and sharply to the price changes of the financial instrument. In the case of a moving average, we will consider the crossing of the indicator line with the price of the asset to be the signal of entry into the position. If the price breaks above the moving average, we will enter a long position, and if it does, and vice versa. The detailed rules for finding divergences are as follows:

- The divergence is only valid after the candle has been closed.
- The divergence that appears below the zero line on the indicator is always traded as a long position.
- We enter a long position to break through the high candle, where the divergence has been confirmed.
- The divergence that is created above the zero line on the indicator is always traded as a short position.
- We enter the short position to break through the low candle, where the divergence was confirmed.
- If we denote the vertices of the divergence in the graph and the indicator, their lines must always have a visible slope.

The application of the indicators will take place on the futures price chart for the S & P500. The reason for the choice is that it brings together and represents the 500 largest publicly traded joint-stock companies in the USA, is traded with a high volume and shows the direction of development of the entire sector of the economy. To collect the necessary data and apply the indicators, we chose the time interval from 1.1.2019 to 31.12.2019. The reason for the selection is that we consider this period to be long enough to collect a sufficient amount of data, it will reflect seasonality and also part of the economic cycle. We will apply the moving average to the candlestick price chart of this asset with a time frame of 1 day. The reason for the choice is that this time frame can filter out insignificant intraday price fluctuations and we can generate a sufficient amount of data with it. We will also apply the RSI indicator on the same interval of the candlestick price chart of this asset, but with a time frame of 4 hours. The primary intention was to implement the application on the same time frames, but RSI cannot generate a sufficient number of data for us with a time frame of 1 day. The results of applying the indicators with the given setting are as follows:

Source: Own processing

Based on the research, we can state that during the specified time interval, we identified 23 entry signals on the basis of SMA on the selected market and 41 signals on the basis of RSI. During the period under review, we identified a strong and clear Up trend in this market. As there was a strong and clear trend in the market, we expected that the trend indicator would give better results, but it generated 18 input signals less than the RSI oscillator during the year. Of the inputs generated on the basis of SMA, 10 (which are 43.5% of the total number of signals) were sales signals. These signals are anti-trend in the long term. The question of the number of profit signals cannot be commented on in the case of a moving average. The reason is that in the case of crossing the price of the asset and the indicator line, there has always been a certain, albeit minimal, movement in the direction of the signal. In such a case, it depends on the setting of the trader's trading system, which then determines which trades would be profitable and which would be loss-making. However, the average point gain of the signal indicated based on the SMA is 84.74 points. The RSI indicator generated 41 valid signals for us, which is more than 78% more than the SMA indicator, despite the fact that a strong up trend was indicated on the market. Of these, 35% of the identified signals predicted a change of trend from UP to down trend and the other 65% of signals identified an inflection point after which the trend should have reversed towards UP. The average point gain per signal indicating a change in the UP direction was 313.91 points and the average gain per signal indicating a downward change was 30.9 points. This fact agrees with the fact that a strong up trend was indicated on the market during the year. Based on the above, we can conclude that signals generated based on RSI divergences have a potentially higher success rate, despite the fact that it is an oscillator, which according to its basic characteristics should show better results in the trendless market and show more false signals in case of trend. The reason for the greater efficiency of this oscillator than SMA may be the fact that the oscillator predicts the inflection point of the market and can indicate the reversal of the trend at the moment of its emergence, unlike SMA, which is significantly delayed and does not change the trend until some time after. We can state that despite the basic characteristics that result from the very nature of the indicator design, oscillators can show better results than trend indicators in a market with a strong long-term trend.

Conclusion

The aim of our article was to theoretically identify the basic characteristics of these two groups of indicators, their advantages and disadvantages and then verify them on the basis of real market data. In the first chapter, we elaborated on the theoretical basis needed for further research. We have presented in detail the mathematical procedures for calculating individual indicators. In the following chapter, we theoretically identified and defined the basic characteristics of two groups of indicators. In the last part, we determined the basic variables of the application of selected indicators, we defined the market, time interval and input variables. They then presented the measured data and interpreted our findings. We consider the goal of the paper to be fulfilled and we hope that our article will be a valuable contribution to research in this area.

Abstract

The present work intends to study Rural Tourism. More specifically: regional policy of Rural Tourism development. Purpose of this research is creation of innovative qualitative model of regional policy of Rural Tourism development. The results showed that the highest rural houses availability is in Western geographical region. Other regions have low level of rural houses availability. However, analysis of resources needed for successful Rural Tourism development showed, that all geographical regions are attractive for organizing Rural Tourism activity. Based on this information an innovative qualitative model of Rural Tourism development was created.

Keywords: Rural tourism, Innovative approaches, Innovative model.

Introduction

Nowadays, market of tourism services is one of the most intensive growing sectors of global economy. The rapid pace of branch development leads to search of new approaches of tourism services providing. As a result -new subtypes of tourism developing. One of the most specific and most rapidly grooving subtypes of tourism is Rural Tourism.

At the very beginning of development Rural Tourism was called to find out from economic depression and for revitalization of rural areas. Today Rural Tourism is a popular kind of tourism, which has in purpose rest from crowded urban areas, rural areas cognition, renovation and preservation of culture. That is why correct approach of its development can solve not only economic, but cultural and social problems as well.
In this regard, creation of innovative qualitative model of regional policy of Rural Tourism development for Ukraine become an aim of scientific research.

In question of creation of innovative qualitative model of development firstly is important to learn experience of creation of regional policy of Rural Tourism development in countries, where Rural Tourism has long development history and is an essential part of tourism industry. Moreover, it is important to study experience of countries, where Rural Tourism developed during short time, however has rapid growth dynamics. In total this data gives an opportunity to create a vision of Rural Tourism development opportunities in Ukraine and reach a purpose of research.

In section of research methodology was described the methodology of research. Analysis decided to make in three stages. On first stage was formed purpose, subject, object and methods of analysis. Second stage had in purpose collecting and analysis of data. Results of analysis of first group called to understand present

development level of Rural Tourism. Meanwhile, goal of second part's analysis was to find most attractive destinations for Rural Tourism development in Ukraine.

During research were used following methods of analysis: methods of statistical analysis, grouping, comparison method and mapping. Last stage of methodology is about creating of innovative qualitative model of regional policy of Rural Tourism development for Ukraine, basing on data, received from theoretical part and on results of analysis. Except theoretical justification of model, suggested structure of Rural Tourism services and designed examples of Rural Tourism networks based on innovative qualitative model of regional policy of Rural Tourism development for Ukraine. At the end conclusions were made about results of research.

Rural Tourism and its significance in development of region

World nowadays develops fast. Especially cities. Concentration of capitals in cities leads to theirs fast development. In the same time rural areas develops much slowly. It has negative aspects and positive as well. Negative aspects displays in absence of new work places in rural areas. As a result – citizens leaves rural areas and go to the cities. On other side, non-urban territory gives an opportunity to save authentic rural life, traditions, culture and nature of area. This is positive thing. At the same time questions appears: "What kind of preferences it gives? How it can be used? How to transform depressive rural territories in attractive for investment areas?" The only answer: "Share it with the world using tourism as a fast growing world economy's branch of services".

Rural areas as human built environment, is a form order of life, which contains the physical elements of spatial as an activity space and non-physical elements in form of values as well as the accumulation of community activities. There are three elements, which form a rural: region/territory, residents and life system (Vitasurya, 2016). Moreover, rural tourism depends on the natural, geographic and ethnological features of each country (Guzman-Parra et al., 2015).

It makes sense to transform unique rural areas with its advantages in unique touristic product, which cares inside itself cultural and historical heritage and going to attract the ones, who want to rest of urban territories. This kind of tourism named "Rural Tourism".

Question of development of Rural Tourism as a sector of Global Tourism attracts more and more attention of governments of different countries. With their active support, people in rural area can develop their own business in Rural Tourism sphere and develop a state market of Rural Tourism. In next turn, scientists, gives their support in branch development by describing processes, analysing market of Rural Tourism services and giving recommendations about future development opportunities. That is why it is important to review some of them.

Rural tourism can make full use of tourism resources in rural areas to adjust and optimize rural industrial structures, extend the agricultural industrial chain, develop rural tourism services, promote non-agricultural employment in rural areas, increase the incomes of farmers, and create a better economic base for the new rural construction, (Zhang, 2012).

Rural tourism, with its year after year increasing, is a significantly important asset for the European economy (Buhalis & Deimezi, 2004). Its evolution represents a key tool in sustainable economic development and an alternative to the traditional offer of sun, sea and sand, encouraging diversification towards new destinations, and redistributing demand to form sustainable rural tourism destinations (Polo Peña, Jamilena & Molina, 2012). Rural tourism has been promoted across several regions in Southern Europe as an alternative to the traditional mass tourism industry. For example, several programs, regulations and plans have been implemented in Spain (Barke, 2004), Portugal (Kastenholz et al., 2012), Lithuania (Barkauskas et al., 2015), Cyprus (Sharpley, 2002), Greece (Kizos & Iosifides, 2007) and others. Aside from pursuing the socioeconomic revitalization in rural areas, the diversification strategy of the industry is justified by tourism, environmental and economic reasons. Aims of this politic are:

-reduce seasonality in the tourist industry;

-look for higher-spending markets which leave a higher share of economic benefits to the local inland population;

-adapt the supply to an increasing demand for destinations with high environmental quality (Hernández et al., 2016).

From an environmental perspective, the promotion of new attractions (natural or cultural inland) also pursued to lessen pressure on the environment in the concentrated coastal areas (Sharpley, 2002).

In opinion of Roberts and Hall (2001), main characteristics of rural areas are: low population density; rural land usage; traditional rural culture. Rural tourists are different, but these characteristics forms the main goal to visit the destination.

During a short period of time, rural tourism managed to become very popular and actively used by the rural citizens. Although rural tourism occupies only a small part of the global tourism market, it is one of the most rapidly developing sectors. Rural tourism can serve as a tool for diversification of the local economy, helping to conquer new markets for local products, as well as an additional source of income for farmers and other agriculture-related people (Barkauskas et al., 2015). Moreover, rural tourism promotes rural development, thus contributing to the overall growth of economy of whole country (Irshad, 2010). Thus, it has influence on many areas. Rural Tourism benefits presented on Figure 1.

Figure 1. Rural Tourism benefits.
Source: Author's own elaboration based on Barkauskas et al. (2015, p. 168).

Research Methodology

Ukrainian Rural Tourism has low level of development. Reason hidden in absence of strategic vision on its development. There is no model developed and applied. Purpose of this research is to fill this gap and form an innovative qualitative model of regional policy of Rural Tourism development. Other goal is to create examples of Rural Tourism networks based on usage of developed model.

To answer the main objective of study we used statistical information about areas covered by agricultural lands, lands covered by forests, lands covered by water resources and quantity of cultural and historical resources by regions. Information collected from Statistical Yearbook of Ukraine, Statistical Digest "Regions of Ukraine" and analysed by author. For analysis was used data collection about rural houses availability by regions of Ukraine from Statistical Bulletin "Touristic Activity in Ukraine". This statistical data is important for understanding which regions started to develop Rural Tourism as separated tourism activity.

On first stage of analysis was decided to divide data from 25 administrative regions to 5 geographical regions, namely Western, Eastern, Northern, Southern and Central, with aim of achieving collaboration between administrative regions on way of developing successful Rural Tourism market. Map of geographical regions represented in Figure 2. To make it possible, was used grouping method. Different type of indicators forced to

use different types of analysis. For comparison of data of first group was used Gross Rate. This made it possible to see the changes in the structure of indicators.

For second part of analysis was used the same division on groups and as a result the same way to group data. However, for analysis of availability of resources needed for successful Rural Tourism activity was important to know a share of resource in total area of the region and share of resource in total area of Ukraine. That is why Share of the Total formula was used. List of formulas shown on table below.

Table 1. List of formulas.

Name	Formula	
Arithmetic mean	$A = \frac{1}{n}\sum_{i=1}^{n} a_i$	[1]
Gross Rate	$\frac{Gross\ Profit_{n-1} - Gross\ Profit_n}{Gross\ Profit_n}$	[2]
Share of the Total	$\frac{Part\ of\ Resource}{Total\ Resource} \cdot 100\%$	[3]

Figure 2. Map of geographical regions of Ukraine.

Analysis and Presentation of Results

Analysis of statistical information about rural houses availability

According to literature, accommodation is the most important services, which can be provided to visitors of Rural Tourism. Accommodation service provided in rural houses and from their quantity and capacity depended how many tourist can visit rural areas and gross of branch of Rural Tourism. That is why analysis begins from this case. It is quite important for research to understand how many rural houses, which provides services in Rural Tourism available in Ukraine, capacity of houses, their placement by regions and changes in structure during analysed period.

For analysis used data from period of 2012-2014 years. Statistical Bulletin "Touristic Activity in Ukraine" gives us data from everyone from 25 administrative regions of Ukraine. However, for analysis was decided to

group administrative regions in 5 geographical regions, namely Western, Eastern, Northern, Southern and Central. It is reasonable for aim of forming innovative model of Rural Tourism development and helps to deepen links between administrative regions. 4 indicators going to be analysed, such as number of rural houses, their average capacity, number of persons placed and area of rural houses. These indicators should help to understand situation with availability of rural houses in Ukraine in total and by geographical regions specifically. To see quantitative change in indicators used to analyse rural houses was used Gross Rate. Table 2 and

In 2014 took a place change in total number of rural houses (Table 3). This had reflection in decrease of rate (-0,1825 gross rate). Gross Rate for number of persons placed decreased as well and was (-0,2129). Reason was decreasing of number of rural houses at all geographical regions except Northern, where Gross Rate was 100%. Structure of location of rural houses by geographical regions almost has not changed, that is why big decrease of Gross Rate of number of rural houses at Western geographical region caused significant decrease of rate for indicator in total. As well, significant increase of rate of number of persons placed in Northern geographical region did not make big difference in total result of this indicator's rate. Decrease of Gross Rate in total number of persons placed was more significant as in previous year and was 21,29%.

Table 3 represents results. Results show, that Gross Rate of Number of rural houses is 0,2391, what in percentage means 23,91% gross or that 2013 year have 123,91% of 2012 houses. Average capacity of rural houses increased as well and this gross is 14,54%. Nevertheless, number of persons placed decreased on 1,53%. This changes caused by several reasons. As well as number of rural houses at Southern and Central geographical regions increased (Gross Rate for Southern region equal to 2,3(3) and gross rate for Central region equal to 1,2857), number of persons placed in these geographical regions increased (it shows by gross rate of 2,3901 and 2,4613). However, gross rate of number of persons placed in Western geographical region of (-0,0687) caused decrease in total gross rate for Ukraine of (-0,0152). The reason is, that general part of rural houses and, as a result, number of persons placed situated in Western geographical region, so small decrease of visiting of this region causes significant change gross rate for whole country.

Table 2. Gross Rate 2012/2013

Geographical Region	Number of rural houses, units	Average capacity of rural houses, places	Number of persons placed	Area of rural houses, m^2.	
				Total	Dwelling place
Ukraine	0,239130	0,145455	-0,015298	0,333855	0,442611
Western Region	0,163636	0,354545	-0,068768	0,224931	0,287463
Eastern Region	-	-	-	-	-
Northern Region	-	-	-	-	-
Southern Region	2,333333	0,420968	2,390152	2,258113	2,998354
Central Region	1,285714	1,800000	2,461326	0,372531	0,819869

Source: Author's own elaboration.

In 2014 took a place change in total number of rural houses (Table 3). This had reflection in decrease of rate (-0,1825 gross rate). Gross Rate for number of persons placed decreased as well and was (-0,2129). Reason was decreasing of number of rural houses at all geographical regions except Northern, where Gross Rate was 100%. Structure of location of rural houses by geographical regions almost has not changed, that is why big decrease of Gross Rate of number of rural houses at Western geographical region caused significant decrease of rate for indicator in total. As well, significant increase of rate of number of persons placed in Northern geographical region did not make big difference in total result of this indicator's rate. Decrease of Gross Rate in total number of persons placed was more significant as in previous year and was 21,29%.

Table 3. Gross Rate 2013/2014.

Geographical Region	Number of rural houses	Average capacity of rural houses	Number of persons placed	Area of rural houses	
				Total	Dwelling place
Ukraine	-0,182456	0,071429	-0,212961	0,080123	-0,214455
Western Region	-0,148438	0,041107	-0,217316	0,051093	-0,135617

Eastern Region	-1,000000	-1,000000	-1,000000	-1,000000	-1,000000
Northern Region	1,000000	0,850000	7,108333	33,333333	4,136250
Southern Region	-0,900000	-0,829739	-0,989385	-0,826268	-0,897077
Central Region	-0,250000	-0,069328	0,593775	-0,041948	-0,223405

Source: Author's own elaboration.

Based on results of this part of analysis can be made conclusions, that branch of Rural Tourism in Ukraine nowadays is low developed. General part of rural Houses situated in one geographical region. Smart regional policy of Rural Tourism development and development of innovative qualitative model of Rural Tourism development can change this situation and will help to expand Rural Tourism activity in all regions.

Analysis of resources needed for successful Rural Tourism activity

On first part of work was found, that rural area with its natural landscapes is one of the biggest motivators for tourists to take a part in Rural Tourism. Rural areas considered to be a destination for one's who want to rest away from crowded urban areas in calm and peace environment. Extrapolating these findings on Ukraine forces us to think about resources Ukraine have and can provide for usage of Rural Tourism needs. These resources are agricultural lands, lands covered by forests, lands covered by water and cultural and historical resources.

For analysis was used data collected from Statistical Yearbooks. Was decided to divide data from 25 administrative regions in 5 geographical regions, namely Western, Eastern, Northern, Southern and Central regions. It is possible to do because of similar climate and natural conditions. As well, such collaboration, as factor of success, contributes to economical connections between administrative regions and promote its common economic development. Such development is one of the main goals of regional policy of Rural Tourism development for Ukraine.

Other goal of analysis is to determine more attractive regions for Rural Tourism development by comparing them with each other. Moreover, it is crucial to have basis of analysis with average values for comparison analysis making. The average area of agricultural lands is 72790,8 km^2, what is equal to 60,45%. Quantity of area covered by forests is much lower and equal to 19147,8 km^2 and therefore, 15,814%. Share of lands covered by water is 8,85% and it results to 10 888 sq. km. Regions of Ukraine have 8 159,8 units of cultural and historical resources in average. This data needed for comparing values of regions with average values. Bigger values of resources in regions represents higher attractiveness of geographical region for organizing Rural Tourism activities.

Analysis of areas covered by agricultural lands and areas covered by forests followed by analysis of areas covered by water resources. Ukraine is rich in water resources. Network of rivers in country is highly developed. Biggest Ukrainian river is flowing through three geographical regions, namely Northern, Central and Southern in is important in historical aspect. Some regions have many lakes and swamps, especially Western and Northern. Moreover, two seas forms southern border of Ukrainian territory, but in context of Rural Tourism it is not crucial for development of this kind of tourism activity.

Analysed last, but not with lowest importance, cultural and historical resources closes a part of analysis of resources needed for successful Rural Tourism development. **Error! Reference source not found.**6 shows high availability of cultural and historical resources in Western region and consist 13769 units, what is equal to 33,75% of total quantity of resources in Ukraine. Northern region with its 7084 units of resource has the lowest quantity of resource in compare with other regions.

Summarizing results of analysis the Western and Central geographical regions are the most attractive destinations (leaders in three of four groups of resources analysed) followed by Northern geographical region. Less attractive are Eastern and Southern geographical regions. These results are useful for applying model, which will be formed in next part of research.

Creating an innovative qualitative model of regional policy of Rural Tourism development

Modelling a system of Rural Tourism services

Availability of services in tourism industry forces tourists to stay in place of refreshment for longer time. Providing of services depends on level of infrastructure development and desire of hosts to provide exclusive touristic services. As well it depends on specification of tourism branch. After studying of international approaches of regional policy of Rural Tourism development can be concluded, that Rural Tourism have specific structure of services. Moreover, exists some similarities in services structure in studied countries, but in general they are different and reflects specific of nation's rurality.
With the aim of creating an innovative qualitative model of regional policy of Rural Tourism development, such system of services can be useful as an additional case of specification of model. Such services as accommodation, catering and transportation represented in every studied countries, that is why they considered to be combined in group of 'Main Services'.

Other group of services cannot be specified easily, because it depends on level of infrastructure development and have to reflect national self-determination. It makes development of Rural Tourism easier, in one hand, and harder in other hand. Easier, because service's providers can use available infrastructure to provide self-developed structure of services. Harder, because opportunity to provide some kinds of services depends on availability of resources, such as one's, which considered to be crucial for Rural Tourism development: agricultural lands, lands covered by forests, lands covered by water resources and cultural and historical resources. However, combination of them with aim of usage for providing services of Rural Tourism gives an opportunity to provide a big amount of services and makes destination more attractive for visitors.

Group of 'Main Services' is more important, than group of 'Additional Services', because it forms environment for visitors and help to feel themselves as a part of rural area. To provide 'Main services' hosts need such resource as agricultural land and own rural house. Role of 'Additional Services' is to immerse visitors in the environment and open its beauty. To provide them more resources needed, such as lands covered by forests, lands covered by water resources and cultural and historical resources. Also, for organizing and providing them community support needed.

Structure of Rural Tourism services presented on Figure 3 and it includes groups of 'Main Services' and 'Additional services'. 'Main Services' are divided in accommodation, catering and transportation. 'Additional Services' are divided in subgroups of Refreshment which can be active and passive; Taking a part in cultural and entertainment events; Attracting in rural work (depended on vacation time) with work at houses, harvesting, gardening, stockbreeding and agriculture.

Developed structure is just an example of services, which can be provided by Ukrainian Rural Tourism hosts and it is not a full version. Approximately, it reflects services, which could be provided using resources needed. There is a place for expend by additional services in this scheme and it depends on region and desires of each services provider. As well, from recommended services provider can chose that one's, which in his opinion can meet the needs of most consumers. Their total providing is not relevant. Moreover, consumer always have a choice what services he want to try and this totally depended on his desire.

Figure 2. Structure of Rural Tourism services.
Source: Author's own elaboration.

Examples of Ukrainian Rural Tourism networks

Good model is good when it supported by examples. That is why in the end of chapter of analysis described a few networks of Rural Tourism, based on developed model, which is possible to organize.

Some example of Rural Tourism network:

- "Ukrainian village-Home of Poetry". There are many Ukrainian poets, which were born in villages, that is why was decided to organize such network. Main advantage of this network is its coverage of big area of Ukrainian territory. Contrary to the opinion, that this example of network is massive with its combination of 32 destination, it should be noted, that Ukraine is a big country (Biggest in Europe) with total number of 28441 villages. Moreover, for network was used just home villages of most significant Ukrainian poets. This network going to be interesting for ones, who like poetry and interested in beloved poet's biography. It will help to develop not only Rural Tourism network, but also repair or open new Museum-Estates of born in villages' poets;

- "Republic of Kholodnyi Yar". This network, as well as this region, can be interesting for ones, who like history. Originally Republic of Kholodnyi Yar is a name of territory where was organized rebel movement after collapse of Russian empire and one of the centres of struggle for independence of Ukraine. After defeat of the army of UNR, fight of rebels in this area continued. Republic of Kholodnyi Yar become a symbol of the indestructibility of the spirit of Ukrainian nation. Firstly, this network based on cultural and historical resources as resources needed for successful Rural Tourism activity. However, natural resources, namely forest, important as well for this network as a place where main battles took place. Advantages of this network are its small area of occupation; link to important historical events; beautiful natural landscapes; good communication system helps in transportation from one village to another;

- on Figure4 presented an example of organization of network in borders of one administrative region, namely Volyn' region. It is situated in Western geographical region and rich in natural resources such as water resources (general part of lakes situated in region, as well as swamps) and forests, so Rural Tourism network calls to promote Rural Tourism services connected with usage of these resources. As a result for network were used villages, which have both of these resources and beautiful natural landscapes. However, Rural Tourism aims to promote whole region as touristic destination, so it is important to represent in network all interesting places. That is why to network were added important not only for regional history places, but for national history as well, such as Berestechko, Zymne and Selets villages. Promotion of networks should be done on national level and be supported by state, its ministries and department of tourism and, as well, by Association of Promotion of Rural Tourism.

Figure 4. Example of Rural Tourism Network in borders of one administrative region.

Conclusions, Limitations and Future Research Lines

Summarising made research, can be concluded that purpose of study, namely creation of innovative qualitative model of regional policy of Rural Tourism development for Ukraine, was reached. Results of analysis of rural houses availability showed strong displacement in availability of this resource to Western geographical region. Received results confirmed idea of necessity to create an innovative qualitative model of regional policy of Rural Tourism development with purpose of finding approaches, which would help to develop Rural Tourism equally in every geographical region.

Analysis of resources needed for successful rural tourism development showed different availability of resources in different geographical regions. However, analysis did not show any region totally provided with all kind of resources with bigger than average value of indicators. Other words, some geographical regions have higher level of availability of one resource and some regions – of others. It gives an opportunity of development of different sets of Rural Tourism services in different geographical regions and be competitive. Particularly for supporting of this idea was created a structure of Rural Tourism services. On last stage of analysis, according with the results received from analytical part, was developed innovative qualitative model of regional policy of Rural Tourism development.

During research problem of collecting data appeared. Although statistical data about tourism in Ukraine is much specified, there is a lack of statistic data about Rural Tourism, caused by low level of development of this kind of tourism activity. The only data possible to collect was data about rural houses availability by regions of Ukraine. Collection of this data by State agency of statistics started only at 2012 and exists just for three years from 2012 to 2014. Nevertheless,

this data was useful for analysis and gave an opportunity to understand positioning of rural houses in regions of Ukraine.

This research was called to create an innovative qualitative model of regional policy of Rural Tourism and as a result basing on international approaches of regional policy of Rural Tourism development was selected key approaches, which determines the framework of development. Moreover, in addition to qualitative model was developed structure of Rural Tourism services according to national Ukrainian characteristics and exemplified by developed, in accordance to model, Rural Tourism networks. Despite the fact, that made research gives clearly image of qualitative model of development, it is not specified and has many gaps, such as: legislative regulation of the branch and role of state in process of development, level of participation in process and functions of state; ways of promotion of Rural Tourism as national touristic product among citizens and foreigners and used in this purpose instruments etc. This work has big impact on development of regional policy of Rural Tourism development in Ukraine and gives wide field for future research in sphere of regional policy of Rural Tourism development.

Abstract:

This article covers reflection and constitute a synthetic analysis in the area of security challenges in the context of technology development. The paper presents results of a research which are of a reflective nature due to the changes of selected aspects of security resulting from the industrial revolution known as Industry 4.0. with examples of selected challenges and threats arising from the development of technology. In the research process, was made extensive use of qualitative research methods, including analyses and methods: analysis and logical construction, generalization and implication. In turn, among quantitative research methods, intensively was used statistical analysis. A systematic literature of open access studies and specialist journals papers was the key method applied in the research.

Keywords: Industry 4.0, technological threats, artificial intelligence, big data, technological challenges.

Method

A systematic review and analysis of literature and analysis of statistic of IT and ICT threats was the key method applied in the research. There are mainly institutions research results referenced to the specificity of the research problem of this article. The paper contains a broad review of scientific literature relating to the following thesis: development range of industry 4.0. determines the emergence of new types of threats. Conducted research allowed to examine the outline of the scope of the impact of development of Industry 4.0, identify selected types of threats and challenges related to the use of this industry.

Introduction - new technological revolution

The beginning of the 2020s abounds in evidence of the beginning of another industrial revolution. After technological revolutions related to the development of technology based on steam,

electric current, and then computer technology, the factor determining the competitive advantage is the efficiency and speed of information flow. This observation prompts the authors of the paper to try to take a broad look at the challenges and threats that arise from the development of technology in the context of security and defense of countries at a global level. Sources of a compatible, new revolution called "Revolution 4.0" - "Industry 4.0" are increasingly effective ways of using the possibilities of the Internet and computing centers, co-creating the so-called clouds (Kodym, O. Kubac L.et al. 2020). Until now, for the first 40 years of the Internet's existence, its functionality was rather limited to connected personal computers, servers or other large systems connected to the telecommunications infrastructure and connections for data exchange between them, the so-called communication protocols.

This gave the opportunity to develop an idea in which soon any utility object in the manufacturing process will be equipped with appropriate micro-chips having the functionality of a wireless network adapter connecting to the Internet. It is strived for such devices to make connections autonomously and, if necessary, to communicate with other "machines-to-machine (M2M)". This concept is called "Internet of Things" (IoT) (Miller, M. 2016). At this point, it should be emphasized that IoT alone is not enough to trigger another revolutionary technological leap. Currently, intensive work is underway on the development of new tools. Budgets for the development of tools for processing large amounts of data (BDA), which are already achieving their first successes, are growing significantly. An example here is the controversy related to the use of BDA to influence voter preferences in the United States in the last presidential election in 2016 (election staffs used the services of a specialized company Cambridge Analytica, which based in its studies on data from about 87 million Facebook user accounts'). It is also worth adding that a particularly important part in the BDA are issues related to the so-called artificial intelligence (AI) (Walsh, T. 2018). To a large simplification, it consists in extending the existing possibilities of electronics and the software that controls it with selected cognitive functions, i.e. those that are (or were) so far only available to living organisms, e.g. related to learning. Contemporary types of self-learning AI are based, among others for analysis and synthesis of natural languages (e.g. speech synthesizers and translators, including some functions currently being developed so-called virtual assistants); logical reasoning (inference based on knowledge and reasoning algorithms, and thus the processing of information from the database); neural networks and broadly understood machine learning involving independent decision making based on a knowledge base and algorithms. There are more and more companies earning from BDA processing, and the estimated total value of the global AI market is expected to exceed USD 10 billion in 2020 (Markets and Markets, 2018).

According to Forrester Research, the vast majority of business leaders in the European region agree that the Internet of Things (IoT) will revolutionize business. The trend report estimates that 50 billion devices will be connected to the Internet by the end of 2020, compared to 15 billion today. The third key element affecting the dynamics and scope of the impact of the 4.0 revolution is progress in miniaturization and automation. The flagship example of progress in this area is the

MEMS (Micro-electromechanical Systems) technology, which boils down to the integration of mechanics, sensors, actuators and generally electronics in one sub-millimeter system. The rapid development of technology therefore already applies to all components of the Revolution 4.0, ranging from miniaturization and Internet infrastructure, to the most advanced methods of data processing. They are gaining an increasing share of the global market for goods and services, giving countries that have decided to take part in this race to raise their position in the global economic system (Angelopoulos, A. Michailidis E.T. et al. 2020).

Threats

Each new solution brings new challenges and threats. The ecosystem in which objects equipped with sensors communicate with computers is also subject to such laws. The scale of application of IoT solutions (from miniature clothing accessories, through intelligent home appliances, building automation and intelligent cities to defense systems) - allows you to visualize the scale of challenges at the same time and the risks associated with them. In general, digital threats will be the dominant threats to IoT. Although the nature of digital threats may not be noticeable in the entry phase - its effects can have a measurable and very real nature in the initial phase (from financial losses to destabilization or shutdown of specific systems, e.g. energy distribution). Threats will therefore be any destructive (intentional and unintentional) actions in the form of undesirable: disclosure, distortion, modification, damage, destruction or preventing the processing of information functioning in a given system / information flow that may result in loss. The main threats to data processed in ICT systems will be: threats to the security of data processing devices and systems, threats to electronic data, and threats to data transmission in ICT networks (devices and media, etc.) (Yu,W.J. Dillon T. et al. 2020).

In turn, the threats to the systems:

- disruption of systems / disruption of data flows,
- disabling: sending, processing / storing information,
- system damage,
- taking control of systems,
- destruction of systems.

However, threats to digitized data:

- disturbance,
- interception,
- theft - manipulation,
- damage, deformation,
- destruction.

The consequences of the above threats may be e.g. loss of control over devices, their destruction or use for destructive purposes, the use of data / information to demand cyber-purchase or to take total control. According to a study conducted in 2016, as many as 42% of entities were attacked within 12 months, of which 32% paid cyber-coup, but 1/5 of them did not recover data, while 67% of infected

entities lost some or all of their data - and ¼ spent several weeks restoring access to blocked resources (Security Bulletin, 2016). It is worth noting that the scope of use of devices connected to smart-systems - apart from the undoubted benefits and improvements that increase daily efficiency, also bring measurable threats in the context of privacy. The so-called: *Information sensitivity* is a measure of the importance attached to information / given by the decision maker or owner / holder - to indicate the need to protect it. Increasingly frequent events (incidents) related to the transfer and use of users' data without their consent and knowledge, whether the unlawful processing of these data have become the regulatory basis of Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 *on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46 / EC* (General Data Protection Regulation). The issue of control and its lack of data applies not only to services processed in the cloud, but to all types of services and applications - in particular those installed in mobile devices, e.g. mobile phones. Currently, the manufacturer is free to consider and evaluate information as "important" or "critical" that the device must send, and the user has absolutely no control over his device in this regard. It is also not able to determine at what moment and which data is transmitted by the device owned and used by it. This problem applies to any utility tool equipped with an operating system and applications / utilities that have technical networking capabilities. The problem of privacy and data processing is also associated with the awareness and operation of the users themselves - both by the fact of sharing information about themselves, including in social media, as well as consenting to data processing and profiling for received profits (e.g. discounts on purchases or additional discounts). Statistics on the loss of identity or access to accounts (electronic banking, social media, etc.) illustrate the scale of challenges and potential threats also for individual users. An example would be related controversy with Samsung Smart TVs, which according to reports include British The Telegraph were to have implemented code fragments, allowing the capture of audio-video stream from built-in cameras and microphones, also when the TV is in sleep mode (Singh, M. 2015). Statistics of companies specializing in IT systems security programs indicate that criminals are increasingly using social engineering methods instead of complex algorithms and scripts, using the users' ignorance (in terms of digital security and based on human behavior, e.g. rush). In the EY20 report: in the area of vulnerability and threats, the most serious were: carelessness or lack of awareness employees (55%), malware (52%), phishing (51%). Examples of employee / user activities and behavior include:

a.) opening a dangerous link or file received in an e-mail - resulting in the encryption of data on the computer / network / or preventing the use of from the system;

b.) transfer to a fake bank account sent in a crafted message by people impersonating an existing contractor;

c.) providing sensitive information about the company in publicly available places (e.g. social networking site).

The most common social engineering methods include:

a.) providing dangerous content of the attachment under the pretext of relevant information (e.g. courier service, alleged call to cease unfair competition, call or request for payment of invoice). The effect of this action is most often blocking access to the resources of the device on which the malware was installed along with a ransom payment request (so-called cyber- extortion) for unblocking the access (often payment does not restore functionality);

b.) false impersonation of an enterprise or institution, and then sending in a crafted message information about the alleged change of the existing business account, to which payments should be made (use of the entity's real data);

c.) swindling money for allegedly blocking a user's account and requesting payment of a certain amount for unblocking access.

It is worth noting that the more frequent attacks are the so-called spear-phishing attacks (personalized attacks aimed at a specific person, e.g. an employee of the company, preceded by careful network intelligence). In 2017, as much as 48.2% of phishing emails were opened by the user-target (recipient of the message), 31.5% clicked on the malicious attachment or link to the infected site, and 7.9% provided information, making the attack successful. According to the SANS Institute, 95% of all attacks on enterprise networks are the result of successful spear phishing.

Examples of social engineering methods used in the titles of electronic messages:

- Re: official,
- Re: invoice,
- *Re: document scan,*
- *Re: photos,*
- *PD (or Fwd): invoice payment,*
- *demand for payment.*

According to the Webroot Threat Report, nearly 1.5 million new phishing sites are created each month. The number of phishing emails containing a form of ransomware grew to 97.25% since 2016. According to FAU researchers, 78% of people claim to be aware of the risks of unknown links in emails. And yet they click anyway.

Referring to the mainstream considerations, it is worth pointing out that as much as 57% of IoT devices are vulnerable to medium- or high-severity attacks, 41% of attacks exploit device vulnerabilities, as IT-borne attacks scan through network-connected devices in an attempt to exploit known weaknesses. At the end of 2016, the Mirai worm attacked Internet of Things (IoT) devices. Its propagation was based on guessing the default passwords in these devices and - after correct logging and infection - scanning the network for more potential victims. The attack disrupted many large global Internet services: services such as Twitter, Netflix, Spotify, Airbnb, Reddit, Etsy and SoundCloud. The main problem and the reason for the effectiveness of the attacks was the lack of change in the default logins and passwords of devices assigned by manufacturers, but the history of Mirai proves that the Internet of Things can become a threat on a large scale. It is enough to point out the attack on March 13 in Brno, which not only delayed the operation of the hospital, but also the

examination of COVID-19 samples. Director of the hospital Štěrba said: "There are laboratories, hematology, microbiology, biochemistry and more sophisticated laboratories for tumor diagnostics, radiological systems work, but there is no possibility of transferring information from these laboratories to the database system". “We are able to investigate patients, but we are not yet able to store data. Patient care is maintained, and we are working to be able to store data in hours” he added. Leaving without comment the moral issues of this type of attack during the global fight against COVID-19 disease, the attack shows a wider scale of the problem in the future, even in the field of medicine. Potentially more threat in the future may be the use of AI in conflict / war. If a high level of sophistication is achieved in this technology, it would be possible to use systems without any ethical barriers to control people by precisely applying crowd psychology based on individual personality profiles constantly updated via the Internet. If in this type of attack, the algorithms would have access to a huge amount of information from every moment of the life of the attacked people collected through IoT technology and the constantly updated psychological profile, one could speak of perfect mass-scale manipulation. At this point, it is worth recalling that the previously mentioned problems related to the illegal collection of sensitive data by consumer electronics already occur (Fernandez, G.P. and Brito, A. 2019).

Challenges

The development of technology is most often caused by the stimulus for some market needs or its artificial creation. It brings some improvement, improvement of the technical fragment of our reality, while affecting the modification of other aspects of it. In other words, it can be said that the process of technological change causes an avalanche of changes in as many areas of reality as there are numerous aspects of human life and the environment that it affects. Because any such modification introduces a change in the balance of power and capabilities at various levels - it can be seen as both an opportunity and a threat. Since the first chance to become a real beneficiary of such a change is the one who first introduces it in a "thoughtful" way, the desire to take a privileged position provokes competition, manifested in the so-called "Technological race" (Bostrom, N. 2019).

Therefore, security challenges in the context of having technology should be viewed from the perspective of what areas of technology we have currently mastered. The problem therefore concerns not only raw materials or access to factories, but more and more often the availability of highly qualified personnel. This issue is one of the most critical because without specialized human resources with expert knowledge and experience, vulnerability to future threats may turn out to be much higher. In the technical layer, therefore, the challenges will undoubtedly also include: design based on accepted standards and protection of user data, but above all - product protection and safety.

Conclusions

The above examples do not even exhaust the huge range of various threats related to the development of technique and technology. One could, however, be tempted to generalize to the Fourth Industrial Revolution, the beginning of which we are experiencing. Namely, almost every

field today has received powerful tools in the form of supercomputers, the Internet, BDA and other innovative solutions, and the security of countries or organizations increasingly depends on the technological potential. This means that the development possibilities of the potential of states or organizations decide on the position and actual defense capabilities against the challenges of the future. Referring to the modern phenomenon of Big Data, it can be said that not only humans, but also information generates information. Therefore, it can also be assumed that not only humans, but also technology will potentially be able to generate technology, hence "keeping pace" and implementation of modern solutions becomes an exponent of the possibility of ensuring security of functioning and development. Thus, it may turn out that "human intelligence, the driving force of which is creativity and the ability to logically describe the environment, has led us to a stage that can be a dead end of evolution - with all the accompanying consequences" (Pasieka,T. 2018). This statement becomes the main challenge for the security of modern human civilization.

A Process of Investigating ToRepublic Hacker Forum

Rafał KASPRZYK

Faculty of Cybernetics, Military University of Technology, 2 Kaliskiego st. 00-908 Warsaw, Poland, rafal.kasprzyk@wat.edu.pl

Abstract

The article discusses the analysis of the *ToRepublic* hacker forum as an example of the practical application of graph and network theory and *BigData* tools. The issue of analyzing data on criminals' activities in cyberspace is extremely in good standing. Recently, we can see the "arms race in cyberspace", which requires not only very specialized technical knowledge, but also knowledge in the field of operational research and experience in the construction of IT systems used for advanced analytics.

Keywords: criminal organizations, *DarkNet*, graph and network theory, *Big Data*

Introduction

There is a growing interest in the research on the systems that may be modeled using the theory of graphs and networks (Korzan, 1978). In the surrounding reality, the networks understood as sets of nodes and branches (edges, arcs and loops) representing various relations between such nodes are omnipresent. Some of the examples of the network-modeled systems include, among other things, the Internet, WWW network of pages, transport networks, telecommunications networks, power networks or, at last, social groups, including criminal and terrorist networks. Due to the number of nodes and links in the above-mentioned systems, they are referred to as complex, large scale or broad networks. An apparent increase in the interest of the systems that may be modeled using the theory of graphs and networks results from the growing importance of the actual large-scale networks (Kasprzyk, 2012).

ToRepublic dataset

ToRepublic is a Polish hacker forum, which was launched on June 8, 2013 and remained active almost by the end of 2015. Due to unknown reasons, the *database dump* (also known as SQL *dump* which means data that can be used for either backing up or duplicating a database) of the forum was created on December 19, 2015 and allowed competent authorities to identify key forum users, many of whom were taken into custody and charged in connection with a number of allegations (Ed. Niebezpiecznik.pl, 2015a; Ed. Niebezpiecznik.pl, 2015b; Haertle, 2015). The *Hydra* forum replaced *ToRepublic* in the *Polish DarkNet* for some period of time. The forum was created by the user under the nickname Mbank_konsultant, who first logged in on June 8, 2013, at 09:31:49 PM. The last login was by the user under the nickname ay79 on December 16, 2015 at 10:38:25 PM. The database dump of *ToRepublic* include 35 tables, which are shown in figure no. 1.

The approach outlined in this paper consists in the analysis (exploration, including visualization) of the *ToRepublic* hacker forum, using models and methods related to the theory of graphs and networks, for the purpose of investigating the role of individual forum users in the hacking activities.

Fig 1. Dump of *ToRepublic* database. Source: Own elaboration.

The concept of analysis of *ToRepublic* forum

The concept of analysis of *ToRepublic* is based on using the models of methods related to the theory of graphs and networks for the purpose of quantitative evaluation of the role of individual forum users in the hacking activity. Additionally, the article describes an expert method allowing interactive visualization of the network's topology. Nowadays, such interactive visualization of the network system is considered an important element of its analysis. It is of great practical importance, as the lack of graphic illustration of the results makes it difficult or even impossible to draw the correct conclusions.

The concept of the network visualization, i.e. "the technique of creating graphs, figures, diagrams or animation of the network systems" is currently inherently connected with the collection, storage and processing of often very large data sets, thus, it is entirely consistent with the area of *Big Data* and *Data Science*. The process of visualization of the network data may be divided into the following three fundamental stages:

- import of **abstract data** into the application;
- transformation of abstract data into their **visual equivalents**;

- presentation of the final picture (**interactive visualization** is preferred instead of static pictures).

Fig 2. Process of data visualization. *Source: Own elaboration.*

Even though the technologies used for the visualization of information have actually proven indispensable to analyze large sets of data, their application is not common. It is due to the fact that successful applications in the area of the network data visualization are not easy. The purpose of such visualization of information is to increase learning possibilities of an analyst. Therefore, on the basis of abstract data, the analyst may reach interesting conclusions. The visualization of data extends the range of perception by allowing to "control" larger amounts of such data. The above-mentioned analyses make it possible to study the structure of the examined networks in a truly intuitive manner. On the basis thereof, it is easier to identify key nodes, analyze potential means of communication across the network and perform many more activities. The relationships diagrams may be also used to present and analyze large amounts of data concerning, among other things, telephone conversations, transactions on bank accounts or network traffic. In such cases, the diagrams may be implemented to easily identify common elements, groups of closely interrelated elements or indirect links. Apart from explicit learning opportunities, the visualization of complex networks may be also seen as a form of art.

Description of ETL (*Extract*, *Transform* and *Load*)

The ETL process - starting from the dump of *ToRepublic* database, through ***Neo4j*** graph database used for quantitative analysis of network data, and ending with *GraphML* files, i.e. input data for the network visualization - is shown in figure no. 4.

Fig 4. ETL process for *ToRepublic* forum data. *Source: Own elaboration.*

The key *BigData* technology in the described process is *Neo4j* graph database, which is considered one of the most popular and mature solutions among graph databases. *Neo4j* constitutes the database used to implement a transaction model ACID (*Atomicity*, *Consistency*, *Isolation*, *Durability*). The data are stored as nodes and relations between them. The database has its own declarative and intuitive DML (*Data Manipulation Language*) called *Cypher*, which has been developed to process graph data. To analyze substantial sets of network data in the aforesaid process, the *Mazerunner* tool was used, which extends *Neo4j* by allowing queries in the form of tasks executed by *Apache Spark*. The location of *Mazerunner* is shown in figure 5.

Fig 5. Location of *Mazerunner* in the analysis of substantial network data. *Source: Own elaboration based on (Boyd, 2016).*

In the ETL process, the data of the *ToRepublic* databases are in the following three formats:

- source data – *dump* (copy) of the *ToRepublic* forum database (*forum.sql* file, type of database: MySQL). The forum was running on the *punBB script*;
- intermediate data– *.csv files including processed data from the selected tables (e.g. *posts*, *pun_karma*, *pun_pm_messages*, *topics*, *users_reputation*);
- output data – **.graphml* files with graphs representing structures of the selected networks generated by user activities on the *ToRepublic* forum, including quantitative characteristics of individual nodes.

The ETL process of the *ToRepublic* database consists of the following five basic stages:

1) Import of the *ToRepublic* forum dump to relational database

The file including the forum *dump* constitutes the set of SQL queries, which create the structure of the database and supplement it with relevant data. The "raw" file is difficult to "read" by the analyst. To facilitate quick review of the file, the file was imported to the relational database. The data were accessed using *PhpMyAdmin* and *MySQL Workbench*. On the basis of data from the *ToRepublic* forum *dump*, the "candidates" for nodes and relations between them in the form of arcs for the graph model – representing the network structures created by user activities on the *ToRepublic* forum – have been identified:

- Nodes:
  - *User* (1972 – number of accounts on the *ToRepublic* forum);
  - *Post* (31044 – number of posts on the *ToRepublic* forum);
  - *Topic* (4643 – number of topics on the *ToRepublic* forum).
- Arcs:
  - INVITES (*User->User*);
  - MESSAGED (*User->User*);
  - RATED (*User->User*);
  - POSTED (*User->Post*);
  - GIVES_KARMA (*User->Post*);
  - CREATED (*User->Topic*);
  - POSTED_IN (*Post->Topic*).

2) Export of selected tables to CSV files

After analyzing the data, the selected tables, which constitute the grounds for subsequent generation of the network structures created by the user activities on the *ToRepublic* forum were exported to CSV files. The tables included i.a.: posts and topics, karma (user ratings), direct messages and reputations (set per *Post* by users).

3) Import of CSV files to *Neo4j* database to build graph model

Another step was the import of data to *Neo4j* to build the graph model of the database on the *ToRepublic* forum. The task was executed through a database command line interface (*neo4j-shell*) by subsequently importing CSV files exported in the previous step. For instance, by importing users, the following command was launched:

```
using periodic commit
load csv with headers from "file:///users.csv" as csvLine
create (u:User
        { userId: toInt(csvLine.id),
          username: csvLine.username,
          email: csvLine.email,
          registered: toInt(csvLine.registered),
          invitedBy: csvLine.invitedBy,
          pgpKey: csvLine.pubkey })
match (a:User), (b:User {invitedBy: a.username}) create (a) - [:INVITES] -> (b)
```

First, the CSV file was loaded with headers, and then a *User*-type node including specific attributes was created for each line. Second, the INVITES relation, joining two nodes when a given user invited another user to the forum, and the MESSAGED relation, joining two nodes when a given user wrote to another user on the forum.

Fig 6. INVITES (*User→User*). *Source: Own elaboration.*

Fig 7. MESSAGED (*User→User*). *Source: Own elaboration.*

The above-mentioned form of data allows to observe certain correlations, such as "sequence of invites", or the users who send each other messages most often. The data loaded to *Neo4j* were subject to quantitative analysis, using the *Cypher* language and *Mazerunner* tool, with the aim to show a possibility of analyzing large sets of network data (*Big Data*). The results of such quantitative analyses were presented in the subsequent part of this paper, in the section entitled: "Selected quantitative analyses and visualization of *ToRepublic* network".

4) Export of data from *Neo4j* to **.graphml* files

For the purpose of further and often easier analysis of network data, the graphs selected from the *Neo4j* database were converted into the *GraphML* format, which is one of the standard formats used for storing

network data. Such files may be downloaded to many analytical tools or easily used in own applications. Due to the implemented version of *Neo4j* (2.3.3), it was necessary to use the database extension called *neo4j-shell-tools*, which allowed to export the results of queries in the *Cypher* language to *GraphML*. Examples of queries:

- export of entire database:

export-graphml -t -r -o full.graphml

- export of users and INVITES relations between them:

export-graphml -t -r -o invites.graphml match ()-[r:INVITES]->() return r

- export of users and MESSAGED relations between them:

export-graphml -t -r -o messages.graphml match ()-[r:MESSAGED]->() return r

5) Exploration of data in third party programs

The processed *GraphML* files formed basis for additional exploration of network data, including their visualization in specialist analytical tools. The *Gephi* platform was used, which is an interactive modular framework for exploration of graphs and networks, available as *open source* (Bastian, Heymann and Jacomy, 2009).

Selected quantitative analysis and visualization of *ToRepublic* network

From the point of view of analysts in the units responsible for cyber security in the police force for the purpose for which the analysis of *ToRepublic* described in this chapter was performed, the most interesting was the visualization of evolution of the following graphs over time. However, it is impossible to present this part in a synthetic manner in the chapter of the standard (paper) monograph.

In the first week of the activity of the forum, 107 accounts were created. The Venom Inside invited dez0r and lucypher. dez0r invited several other users, whereas lucypher invited Pocket, who then invited 22 users. There were also smaller clots around Mala_Mi, OneAnother, krang, dez0r, gonzobonanza, okp, …

Fig 8. Graph of invitations – INVITES (*User→User*). *Source: Own elaboration.*

Table 1: Users sorted according to the number of invitations sent

No.	User	Number of invitations
1.	Mbank_konsultant	172
2.	The Venom Inside	36
3.	Polsilver	30
4.	Pocket	22
5.	Mala_Mi	11
6.	OneAnother	9
7.	krang	7
8.	dez0r	7
9.	gonzobonanza	5
10.	okp	5
…		

Summary

Big Data significantly changed the approach to the management of companies of any size - both at strategic and operational level. Currently, analytics constitutes the area without which it is difficult to imagine an efficiently operating enterprise. It is something that supports the decision-making process at any level in the organizational hierarchy of the company in a manner not seen before. In case of the decision-making process, it is worth mentioning the potential of *Big Data* in the field of national security and defense. The above-mentioned area is especially interesting for employees at the Institute of Computer and Information Systems, Military University of Technology in Warsaw. Different entities responsible for national security in each of the critical areas thereof, such as, among other things, armed forces, police, fire services, border guards collect substantial amounts of data, whose analysis using the *Big Data* revolution may prove beneficial to the country and its citizens. The *Big Data* technologies are of key importance to create the so-called *Situation Awareness* and *Common Operational Picture* for cyberspace.

An Overview of Information Warfare Models

Rafał KASPRZYK

Faculty of Cybernetics, Military University of Technology, 2 Kaliskiego st. 00-908 Warsaw, Poland,
rafal.kasprzyk@wat.edu.pl

Abstract

The article presents different models to be used while describing the information warfare. The author focused on quantitative models and methods to draw attention to a possibility of applying operations research in the field which has been dominated by the qualitative studies. In the paper, emphasis is put on discussing mathematical models of information warfare (or information operations) seeing that: game theory, hypergame theory, information theory, theory of reflexive control and last but not least theory of disinformation complete with models of information diffusion.

Keywords: information warfare, game theory, hypergame theory, information theory, reflexive control, theory of disinformation, information diffusion

Introduction

The "*wars of the future*" will be mainly carried out in cyberspace, which constitutes a key element of the modern information environment. Additionally, the "traditional" cybernetic operations – *CyberOps* (Joint Publication 3-12, 2018) will be more and more often synchronized with the information operations – *InfoOps* (Joint Publication 3-13, 2014), creating *de facto* one collective operation in cyberspace. The battlefield will be information and data processing systems, thus, not only hard ICT infrastructure (*CyberOps*), but everything that is "connected" thereto, including people – i.e. "*brains performing cognitive processes*" (*InfoOps*). While awareness of technical threats is consistently increasing and being managed, the awareness of the seriousness of threats at the information level is still insufficient. Due to wide availability of the Internet, social media started to play more significant role in the shaping of public opinion on basically every topic and have broad impact on the way the world is perceived by people, social groups or whole societies. Therefore, the paper centers around this burning issue, focusing on formal models suitable for describing this phenomenon.

Models of information warfare

Game theory

One of the methods for describing the phenomenon of information warfare is game theory (Ameljańczyk, 1987; Jormakka and Mölsä, 2005; Von Neumann and Morgenstern, 1944). The traditional game theory is based on a number of assumptions, which make it difficult to use the game-theory model while analyzing the actual scenarios of information operations. Basically, the arbitrary assumption that all conflict participants (players) are reasonable and "play the same game" is accepted. On the other hand, the game models are classified using different criteria, e.g. the number of conflict participants (players), the count

of the set of strategies, competitiveness (zero-sum or non-zero sum), possibility of cooperation, completeness of information, etc. The game theory, despite some assumptions that may be at times really difficult to achieve, provides a lot of interesting and practical concepts and conclusions, e.g. the concept of dominant and dominated strategies, pure and mixed strategies, reasons for constant domination of one of the players, benefits from using mixed strategies in both offensive and defensive.

The assumptions of traditional game theory that are difficult to make are modified for the purposes of modeling the information warfare, for example, by introducing the concept of meta-strategy (Jormakka and Mölsä, 2005), which allows to describe the impact on the perception of game rules (e.g. list of strategies, payments for particular players in different situations) by the opponent and hence the course of the decision-making process by individual players. Therefore, the aforementioned meta-strategies allow to include the process of manipulating the situational awareness of the opponent in the conflict situation model, which may be treated as the modeling of impact of disinformation on the adaptive decision-making model, i.e. OODA-*loop* (*Observe-Orient-Decide-Act-loop*).

Hypergame theory

One of the theories allowing to model the conflict situations with incomplete information, thus, in particular, the information warfare, is the hypergame theory. The theory assumes that the players may see the game rules and course in a different manner (Bennett, 1977; Kopp, 2003; Kovach, Gibson and Lamont, 2015; Mateski, Mazzuchi and Sarkani, 2010). Additionally, their knowledge and opinions may also differ, which has impact on their choices. In other words, the reasonable choice of one player may seem completely unreasonable to the other. Such differences may cause, for example, misunderstanding of the intentions and goals of other players, lack of information about all of the potential moves to be used by other players, lack of knowledge regarding the participation of all conflict participants (players) in the game.

The hypergame theory assumes that the players make reasonable decisions to maximize their payments (benefits), however, not on the basis of the common picture of the conflict situation, but subjective opinions resulting from the aforementioned differences between the players. Therefore, the hypergame theory allows to model the process of manipulating the situational awareness of the opponent in a far more precise manner than meta-strategies, which occur in the models based on the traditional game theory. With the above in mind, it may be stated that the hypergame theory is a very promising approach to the modeling of the impact of disinformation on the adaptive decision-making model, i.e. OODA-*loop* (*Observe-Orient-Decide-Act-loop*). The first two stages of the OODA-*loop* model are related to the creation of the subjective picture of the situation by the player, whereas the other two concern the choice of the strategy, which allows the player to maximize their benefits based on the created picture of the situation. Figure 1 shows basic differences in the modeling of the conflict situation on the basis of the game theory and hypergame theory.

Fig 1. Comparison of theories and hypergame theories. *Source: Own elaboration based on (Kopp, 2003).*

Information theory

Another approach to the modeling of the information warfare is to use the Shannon–Weaver model of communication channel. In the most fundamental context, the information warfare means the manipulation of the communication channel to achieve a certain purpose (Kopp, 2003). Figure 2 shows the aforesaid model.

Fig 2. The Shannon–Weaver model of communication channel. *Source: Own elaboration based on (Kopp, 2003).*

Four basic methods of attack on the model of communication channel are distinguished in the described approach to the modeling of the offensive information warfare (Kopp, 2003): 1) adding the additional source of controlled noise to the model by the attacker; 2) adding the additional source of information and transmitter controlled by the attacker to the communication channel, which facilitates the insertion (injection) of disinformation to the channel for the purpose of misleading the recipient; 3) disruption or damage of the receiver; 4) adding the additional source of information and transmitter controlled by the attacker to the communication model, which facilitates the insertion (injection) of disinformation to the channel for the purpose of initiating self-destructive processes at the recipient.

Apart from the four above-mentioned methods of attack, which affect the availability or integrity of information, the attack on the information confidentiality should also be mentioned at this point. The method means that additional receiver controlled by the attacker is introduced to collect information. The modeling of the information warfare, using the information theory, allows to describe the manipulation of the information attributes (availability, integrity, confidentiality) by the opponent in a relatively precise manner. However, the information theory does not give a direct answer to the question how the said manipulation of the information affects the behavior of both parties to the conflict.

Theory of reflexive control

Another way of modeling the information warfare is the theory of reflexive control developed in the USSR by Vladimir Levebvre (Lefebvre, 1965; Lefebvre, Baranov and Lepsky, 2969; Lefebvre, 2001; Lefebvre, 2010) in the 1960s. The concept is similar to the hypergame theory, however, with a much more developed formal apparatus and suggested taxonomy of manipulation techniques allowing the process of having control over the opponent. The starting point of the reflexive control process is to build a specific model for the object to be controlled. The object is usually a person, i.e. the object that thinks (is reflexive), hence, creates subjective images (models) describing the world. The foundations of the construction of such a specific model are connected with the concept of ***reflexion*** understood as the ability to adopt a perspective of an observer of one's own knowledge, beliefs, desires and intentions. The so defined *reflexion* is the ***reflexion of the first kind*** or ***self-reflexion***. The core of *reflexion* is its recursive character. The concept of *reflexion* was generalized by Lefebvre and, in the context of the ***reflexive control***, it is understood as the ability to adopt the perspective of the observer of one's own and another reflective object's knowledge, beliefs, desires and intentions. The so defined *reflexion* is the ***reflexion of the second kind***, which leads to the concept of the ***hierarchy of realities***.

Fig 3. ***Reflexion of the first kind*** **(left);** ***Reflexion of the second kind*** **(right).** *Source: Own elaboration.*

When building the model of the object subject to the reflexive control process, it is of key importance to include the aforesaid concept of *reflexion* of the modeled object. Object X that wants to control object Y constructs the model of the world image (model), which is built by object Y at a specific level of the

hierarchy of realities. On the basis of such a model, object X prepares ***information disorders*** (any kind of information used in the process of manipulation) dedicated to object Y, aimed at encouraging object Y to make the decision as expected by object X and in such a manner so that object Y is convinced that they make this decision independently and that the decision will be the best possible choice for object Y. **The essence of reflexive control is to change the approach from an attempt to predict the decision-making processes of the opponent to influence the decision-making processes of the opponent by using *information disorders*** (Kasprzyk, 2019; Kasprzyk, 2020; Thomas, 2004).

If the process of *reflexive control* is executed secretly and object X properly "read" the subjective world image of object Y, then each portion of *information disorders* (Wardle and Derakhshan, 2017), marked as *id* in Fig. 4, sent from object X to object Y constitutes additional information for object X about object Y. It is also interesting that object Y may reverse the process so that it is possible to abandon the role of the controlled object and assume the role of the object controlling object X, while still confirming object X in its belief that it has control of the *reflexive control* process.

Fig 4. The concept of *reflexive control* process.

Theory of disinformation and models of information diffusion

The information warfare may be carried out by using different communication channels, among other things, through physical contact between people, traditional media or social media. Potential communication channels create a complex information environment, in which every player (aware or unaware of this fact) may be both the recipient and creator of information disorders, thus, play the role of both the controlled and controlling object (in line with the theory of reflexive control). In such case, it is helpful to use the ***theory of disinformation*** developed by Vladimir Volkoff (Volkoff, 1999), according to which different actors play certain roles in the disinformation process:

- *Commissioning Party* (*Client*) – a person or a group of persons that derives benefits from the disinformation process;
- *Agent of Influence* – an entity executing the commissioned disinformation process;
- *Theme* (*Leitmotif*) – the main *idée fixe* being a specific narrative for the purpose of the disinformation process;
- *Supports* (*Props*) – events (true or false) that are "fuel" for the disinformation process;

- *Transmitters* (*Carriers*) – objects (including media) connected with the *Commissioning Party* or the *Agent of Influence* and intentionally propagating *information disorders*;

- *Resonators* – objects (including media) not connected with the *Commissioning Party* or the *Agent of Influence* and unintentionally propagating *information disorders*;

- *Target Group* (*Intended Audience*) – a person or a group of persons being the target of the disinformation process.

In case of *Social Media*, many objects playing different roles participate in the disinformation process. What is also important is the fact that in this information environment, it is very easy to reach people who propagate *information disorders* on the basis of the *Resonators*. It is equally easy to obtain *Transmitters* via ***social bots*** and whole ***social botnets***, which may be constructed in a relatively easy manner, with little technical knowledge, or which may be bought in the form of a service. Due to the *Web3.0* "culture", the so-called *Resonators* are widely available and have actual impact on the disinformation process - due to their number, they may often completely take over the role of *Transmitters*.

Fig 5. Diffusion of *information disorders* in *Social Media*.

The main issue in case of the modeling of information warfare is to understand the dissemination (diffusion) process of the information disorders (Kasprzyk, 2012; Kasprzyk, 2019; Kasprzyk, 2020) including assessment of the role and significance of particular "nodes" in the network (creating the information environment) and forecast of diffusion dynamics and reach of the information disorders. It is also contemplated issues how two or more opposing views (contrary beliefs) diffuse in the information environment, i.e. the information confrontation concept (Mikhailov and Marevtseva, 2012), including the position adopted by particular persons (Petrov, Maslov and Tsaplin, 2016).

Summary

The reality at the information level is more and more difficult to verify and easier to manipulate because of cyberspace. Due to wide availability of the Internet, social media started to play more significant role in the shaping of public opinion on basically every topic and have broad impact on the way the world is perceived by people, social groups or whole societies. The awareness of risks at the information level is still limited. The character of information wars will be strictly dependent on the development of science

and technologies. This is an interdisciplinary and multi-faceted issue, which further complicates its effective analysis. The studies of this phenomenon are essential to understand, identify related threats and establish methods of prevention.

The theory of reflexive control facilitates the analysis of the decision-making process with respect to both own and the opponent's decisions due to a possibility of manipulating the situation awareness. The theory enjoys quite a rich history and strong position among analysts of national security both in Russia and the United States. Many Western analysts see theory of reflexive control as the Russian alternative to game theory. At this point, it should be noted that the hypergame theory also referred to as metagames or higher-order games, which first appeared in the 1970s, may be perceived as the Western response to the theory of reflexive control. Nowadays, the theory of reflexive control is being developed - to a certain degree - independently by several research groups that propose a different formal apparatus to describe and analyze reflexive control (Novikov and Chkhartishvili, 2014; Shreider, 1999; Taran, 1998). One of the branches may be the aforementioned hypergame theory. At the same time, information operations are also modeling using the traditional game theory.

Abstract

Rapid development of information technologies determines the need in usage of various digital solutions in order to conduct operational analysis and processing of large amounts of information. In today's age, the introduction of digital solutions is especially relevant in the healthcare system. The development of conditions for such analysis of information is one of the main tasks of digitalization of the healthcare system. Nowadays, there is no significant experience in conducting digital data analysis in the field of healthcare. Because of that, it is highly beneficial to study the experience of various non-medical organizations in this field, including the ones that effectively use Business Intelligence technologies for such tasks.
Thus, this article explores data storage and analysis tools, as well as the market of existing BI-systems and the specifics of the application of these systems in the healthcare sector are examined.

Keywords: Business Intelligence, Healthcare, Business Analytics, Digital Technologies, Data Analysis

Introduction

Nowadays, the Russian Federation has adopted and is implementing the federal project "Digital Technologies", which is a part of the state program "Digital Economy of the Russian Federation" (until 2024), as well as the state program "Development of Health Care" (until 2020) [1]. These programs determine the development and digital transformation of priority sectors of the economy based on end-to-end digital technologies.

Main goals of the Digital Technology project are following:

- "providing support to the leading high-tech companies on the Russian market, the ones developing products, services and platform solutions based on end-to-end digital technologies aimed at digital transformation of priority sectors of the economy and social sphere, with focus on domestic developments";
- "providing support for projects aimed at scaling technological solutions based on "end-to-end" digital technologies used in priority sectors of the economy and social sphere" [2].

Implementation of a unified state healthcare information system provides a solid basis for the creation of a system intended to collect and sort indicators of regional healthcare systems. However, it is necessary to develop the means of effective support in managerial decision-making in the healthcare sector both at the level of individual medical organizations and at the regional and country-wide levels [3]. Business Intelligence (BI) systems provide said means of effective support in managerial decision-making and present an ideal tool for the health indicators analysis of Russia's federal subjects. One of the main advantages of such systems is the ability to create visual tools for making both strategic and operational decisions at various levels of the medical structures.

This article explores the concept of the term Business Intelligence from the point of view of various authors and research organizations, highlights the key features of Business Intelligence, and also presents the advantages and disadvantages of using Business Intelligence technology. In addition to that, the article discusses data storage and analysis tools and examines the market of existing BI-systems and the specifics of the application of these systems in the healthcare sector.

Materials and Methods

The rapid development of technologies, including the ones used in the healthcare system, determines the need for the usage of various IT-solutions for conducting multi-aspect operational analysis of the available information.

One of the main goals of digitalization of the healthcare system is the development of proper conditions required for such analysis. Active implementation of the National Healthcare Project and the "Creating a Unified Digital Circuit Based on EHISS" Federal Project allows to create a convenient environment for analytics but the current level of experience of medical staff and executive authorities in the healthcare sector highlights the lack of ready-made, well-established IT-solutions and significant experience in conducting digital data analysis [4][5].

Consequently, it is highly beneficial to study the experience in the field of data analysis and the creation of proper conditions for decision-making in organizations of various non-medical areas of activity. Most organizations effectively use Business Intelligence (BI) technologies to solve such problems.

The term Business Intelligence was first used by Hans Peter Lun in 1958 in the article "A Business Intelligence System", published in IBM System Journal. The author divided this term into components and characterized them separately. Lun described Business as a set of various activities undertaken in science, technology, commerce, industry, legislative activity, defense, etc. Various communication systems that provided and supported these types of activities he called "intelligence system". In general, term "intelligence" Lun defined as the ability to establish a relationship between the representations of individual facts in order to better solve the goals and objectives.

Late in the 1980s, Gartner analysts under the leadership of Howard Dresner gave a broader definition of the term – "user-oriented process, which allows access and research of information, its analysis, development of an understanding, which, in turn, leads to improved and informed decision-making". Later in 1996, Dresner added the following to the definition: "Business Intelligence is a tool for analyzing data, creating reports and queries that can help business users to overcome the large quantities of data in order to synthesize meaningful information from it" [6].

There are other interpretations of this term. The Data Warehousin Institute, an organization that studies the analysis and storage of data, gives the following definition: "Business intelligence allows to turn data into knowledge, and then that knowledge is used to formulate business actions ensuring profit." Forrester Research defines Business Intelligence as "a set of methodologies, processes, architectures and technologies for processing primary data into meaningful and useful information used by management teams to better understand business processes and make informed decisions at the strategic, tactical and operational levels" [7].

So, despite slight differences in definitions, a number of common attributes of Business Intelligence can be distinguished. Today BI-solutions are not only used for to conduct analytics and form reports, but also for data collection and quality management.

Based on previous statements, it can be concluded that business analytics, in the broad sense of the word, means:

1. The process of turning data into information and knowledge about the business in order to ensure improved decision-making;
2. Information technologies, methods and tools for data collection and information consolidation;
3. Business knowledge gained from in-depth data analysis.

The presented technology is based on the principles of end-user access to the analysis of structured data. This creates an integration process, allows end users to interprete transactional business information in the most simple, understandable way suitable to be the basis for business analysis and development of an effective strategy for changing the organization. Business Intelligence has a wide range of users, including both ordinary employees, as well as analysts and managers at various levels. In relation to medical organizations, it should be noted that Business Intelligence technologies are of interest both to doctors of various departments, as well as to heads of departments, statisticians and heads of organization [8].

Nowadays, the categories of BI-products are usually divided into: BI-tools and BI-applications. BI-tools, in turn, are classified into the following types:

1. Query and report generators – desktop tools that provide users with access to databases, perform analysis and generate reports;
2. Developed BI-tools (most impotantly, OLAP analytical processing tools);
3. Enterprise BI Sets (EBIS) – a set of BI-tools that were previously presented as separate products;
4. BI-platforms – sets of tools for creating, implementing, supporting and maintaining BI-applications [6].

Given the diversity of various types of BI-solutions used for working with typical tasks, it is easier to talk about the typical blocks of modern BI-systems. The main capabilities of Business Intelligence systems are focused in the following directions: storage, integration, analysis and presentation of data.

Data Storage

To store the data used by BI-systems throuout their work, special storages called data warehouse are organized. The stored information should present a valid, real and comprehensive view of the organization because of that the data is collected from various operating systems. For a more efficient analysis, the data storage structure is formed in a way most suited for creating and processing various requests, while in ordinary databases, optimization of the execution time of transactions is often more important.

It should be noted that if the data size is too large, specific subsets of information can be formed, called data marts, in order to solve narrow, specific tasks.

There are several different approaches to data integration. The so-called data warehouse management tools, ETL tools, are used to form and maintain the data warehouse. The ETL abbreviation itself stands for Extract, Transform, Load, which is a brief description of the function of these tools. Thus, ETL tools are tools that allow to extract, transform and convert data to a specific required format. These tools are used for uploading data to the repository or another database.

Alongside ETL tools, BI-systems include tools that allow to wotk with a programming language used to manage real-life databases in database management systems (DBMS). One of the most common ones is the Microsoft DBMS – SQL Server. The abbreviation "SQL" stands for structured query language, which means that is allows users to directly access the data.

It should be noted that recently the tools for generating and processing requests have become more geared towards unprepared users, rather than on qualified IT specialists [9].

Data analysis and visualization

Modern BI systems cannot be imagined without using OLAP (Online Analytical Processing) technologies for data analysis. This technology involves the acceleration of the processing speed of large data arrays by structuring information according to a multidimensional principle. Storing information in separate database tables often leads to an increase in the complexity of processing multi-table queries. Because of this an OLAP structure of joining tables in the "star pattern" or "snowflake pattern" is currently used in BI systems.

The presented tools allow to quickly generate the required data slices, and then visualize the given information in a numder of different ways such as graphs, charts, reports, all customizable according to various parameters. Using the OLAP structure allows to quickly make changes to the presented data [9].

It should also be noted that a number of the most developed BI-solutions support the data mining technology. This usually means as a group of tools designed to facilitate the search for hidden, unknown and non-trivial patterns. This group of tools includes various modeling and forecasting methods based on neural networks, the decision tree, Bayesian networks, regression and correlation analysis, and various other methods. Data mining technologies are designed to facilitate the analysis of huge amounts of information, as well as to ensure the competence of strategic decision-making by using the analysis of various event scenarios.

Dashboards and scorecards are the most widespread and generally accepted means of displaying data in modern BI-systems. Information panels are visual solutions on which the main parameters are displayed in the form of charts, scales and indicators. These tools allow users to both evaluate and monitor the current values of the parameters, as well as making the comparisons with the various values of the indicator and, as a result, identifying the existing risks and threats.

Scorecards are a visual solution directly related to the analysis of key indicators (KPI – key performance indicator). In this case, we are talking about a comparison with the target indicator values. These cards are the simplest and most convenient form of studying and preventing the risk of not achieving the planned values of indicators [10].

Benefits of using Business Intelligence Technology

The usage of BI-systems makes it possible to solve a very wide range of tasks, including monitoring and analysis of the current values of indicators, as well as determining strategic and operational goals of the organization's development. Among the advantages of using BI-systems there are:

1. creation of a support system for the development of existing business processes and structural changes in the organization;
2. the emergence of opportunities for modeling business cases;
3. creation of conditions for operational analysis and work with non-standard query forms;
4. redirection of human resources from routine analytical activities and filling out reporting documentation to deeper analytical work;
5. the growth in the volume of processed and analyzed information due to the possibility of scaling the system.

Also, the use of BI-solutions provides some additional opportunities in the field of strategic development. They include:

1. evaluation of the effectiveness of various activities;
2. operational and continuous monitoring of the attainability of key goals and objectives;
3. the formation of a method for assessing the effectiveness of the use of available resources;
4. calculation of the effectiveness of financial activities;
5. cost and investment management [6].

According to experts from MiPro Consulting, the use of a BI-system in the organization has a number of significant advantages compared to the use of standard analytical tools integrated into the organization's existing information systems. These benefits include:

1. improving the visibility and increasing the convenience of working with data;
2. the possibility of using several analytical solutions, depending on the nature of the problem and the direction of activity of a particular unit of the organization;
3. the ability to work with various data sources and data types;
4. continuous development and improvement of existing BI-platforms;
5. high level of scalability, performance and efficiency of the analysis of indicators;
6. the emergence of conditions for building and supporting end-to-end procedures throughout the organization;
7. the possibility of creating analytical centers responsible for studying information about the organization's activities;
8. variety and flexibility of analytical tools for solving tasks;
9. the ability to provide users with data and analytical tools in accordance with their access rights.

It is important to note that the use of analytical tools integrated into the other information systems that are not directly intended for analytical activities usually has a number of limitations:

1. the lack of differentiation of user access rights to analytical tools;
2. extremely limited set of analytical tools;
3. the necessity to export and analyze data in other software products, for example, in the Microsoft Office Excel package because of disadvantages of the built-in tools for visualization and analysis of the information;
4. inability to work with external data sources is not available;
5. the limit on the number of users using the analytical extension of the information system, due to the fact that the widespread use of this product can significantly impair the work of the application for other employees of the organization;
6. limitations on the formation of flexible, non-standard queries;
7. the use of large amounts of historical information is limited [11].

Disadvantages of using Business Intelligence Technology

In practice, in the process of forming a BI solution, the first task is to organize a scheme for collecting information and creating a unified database of the organization as the main information space of the institution. The storage of the BI-system should provide for the possibility of the receipt of information from any available, including external sources. In reality, the tasks of implementing an immediate solution fade compared with the tasks of creating a integrated digital space within the organization.

Standard reports are only a small part of the capabilities of BI-systems. These solutions have significant potential for creating a powerful analytical tool that will provide an opportunity to analyze all the activities of the company. And it does not even require the implementation of new independent programs to solve individual problems. However, the presented positive side carries a number of dis-

advantages. BI-systems are tools built on rapidly changing technologies. Significant pace of development and improvement of existing solutions require constant monitoring of existing BI-systems.

Another important risk of the practical use of BI-systems is the performance degradation with insufficient data quality. If the data are not properly processed and cleared, then none of the possible BI-tools will not achieve significant results in the analysis of information. This situation is not always clearly presented to the main stakeholders, and BI-solutions are often associated with inefficient work of the analytical group, and not with problems with the data collection structure. BI-technology itself is not able to comprehensively solve these problems, and neglect of them returns to information anarchy [6].

Result

Market overview of existing BI-systems

According to Gartner, in 2018, the explosive development of the business analytics industry was recorded, which was largely due to the development of machine learning technologies and neural networks. Today, there is every reason to argue that the trend of increasing influence of the new generation BI-platforms continues.

Gartner analysts urge suppliers of all BI-systems to pay attention to the realities of the information space and radically revise their point of view on working with data: BI-systems can no longer rely on standard data mining methods. The rest of the technology world is moving to bring machine learning, NLP and AI to customers, so BI-industry must do the same.

One of the easiest ways to form an idea of market leaders is to present the magic square of market leaders used by the Gartner analytical agency. So, at the beginning of 2018, there are three main leaders on the market: Qlik, Tableu and Microsoft with its Power BI solution [8].

Market overview of BI-systems in healthcare

According to Marketsand Markets, the global healthcare BI market amounted to about $ 2.38 billion in 2013. And in 2019, it is expected to reach $ 4.74 billion (average annual growth of 14.8%). In the medical market, technology is dominated by traditional Business Intelligence, while cloud-based BI and mobile BI represent great potential for growth: on the one hand, hospitals, in the face of limited economic resources, need more accessible, flexible, transformable and scalable forms of business intelligence, and on the other hand, the demand of medical institutions for mobile solutions is growing [12].

The further market growth can go mainly due to the implementation of BI solutions directly in medical organizations. However, it should be noted the importance of using BI systems in executive bodies in the field of healthcare management.

There are a lot of vendors of analytical solutions in the healthcare sector. Among them, the largest include IBM, Information Builders, Microsoft, MicroStrategy, Oracle, Qlik Technologies, SAP, SAS, TIBCO Software, Tableau Software, Computer Sciences Corporation, Dimensional Insight, Jaspersoft, Klipfolio, Perficient, Agilum Healthcare Intelligence, Siemens Healthcare, Tata Consultancy Services, Infosys, Wipro Limited, Hexaware Technologies Limited and others [13].

Let's take a closer look at the solutions that are recognized as market leaders.

1. QlikView from Qlik company

This platform focuses on the needs of the user as the ultimate recipient of data. There is a high flexibility to study and visualize data, as well as the presence of a relationship between the data and the

dip function, which allows obtaining detailed information about each studied parameter. Key product features are:

1. opportunities to create advanced dashboards based on data from a variety of sources;
2. the presence of a tool for automatic recognition of relationships between data, which can significantly simplify the work of the end user in the process of creating reports and dashboards;
3. data storage in the server RAM, which speeds up the process of query execution when working with a large data array;
4. QlikView reports and dashboards have a low entry threshold, which allows even beginners to use these functions. However, the process of creating dashboards itself requires advanced development and SQL skills, as well as the presence of certain practices in the QlikView programming language.

It should be noted that when using QlikView, the main thing is a clear understanding of current goals and objectives, as well as a vision of the final result. This solution allows to demonstrate amazing results with a clear consistent course and its implementation.

2. Tableau

As a BI solution, Tableau's main focus is the presentation of data through visualization. The system makes it easy to create interactive dashboards, with a dip function and transitions to trend indicators. It should be noted the wide possibilities of the visual library, which includes word clouds, bubble and tree diagrams, and other tools. Also there is a function of combining elements, which allows you to reduce and overlap various visual solutions, which is especially important in view of the need to save work space in the monitor space.

The main difference between this solution and competitors is the ability to mix data from different databases and sources, as well as the ability to work with a significant number of different types of data.

It should also be noted that the functionality of the program allows simultaneous use by several users in real time.

It is important to note that Tableau is relatively loyal to beginners who were not previously interested in data visualization issues. There is an intuitive interface, well-described technical guidance and assistance. It is convenient to work with the program both from the side of the user creating the report, and from the end-user studying the result and making strategic decisions.

3. Power BI by Microsoft

A service developed by Microsoft as an extension of the existing functionality of Microsoft Office Excel. The solution is characterized by a relatively simple and intuitive interface, as well as the presence of many functions similar to the apparatus of the latest version of Microsoft Office Excel. In addition, the system is as friendly and compatible with another development of Microsoft – the SQL Server hardware product.

However, it should be noted that there are certain limitations in the examples of data visualization, and the program also notes a relatively small number of tools for cleaning and processing data [13].

The specifics of BI-systems in healthcare

It should be noted that the use of Business Intelligence technologies in healthcare has a number of features.

Medical organizations operate with various layers of data: personal information about patients, test results, radiological and computer images, video recordings of studies, as well as information from management systems and others. For quick and timely decision-making in the presence of such an array of data, careful collection and analysis of information is necessary. Automation of medical analytics requires taking this feature into account [14].

It is also important to remember that medical activity is associated with the concept of medical confidentiality. So, according to Article 13 of the Federal Law of November 21, 2011 No. 323-FL (as amended on May 29, 2019) "On the Basics of Protecting the Health of Citizens in the Russian Federation" [15] information about a citizen's appeal for medical assistance, his state of health and diagnosis, or other information obtained during his medical examination and treatment, constitutes medical confidentiality and it is not allowed to disclose information constituting medical confidentiality, with the exception of cases established by parts 3 and 4 of this article. It should also be noted that there is a significant amount of depersonalized data that is not a medical confidentiality, but has a limited level of access, since its wide dissemination can influence on the security of the Russian Federation [16].

An essential feature of medical organizations is that usually two types of BI are required by healthcare institutions. Firstly, this is analytics aimed at supporting the healing process, and secondly, managerial analytics. These two systems solve different problems, determined during the treatment process at various levels and practically do not intersect. It should also be noted that organizations responsible for studying existing health systems can be is interested in a separate type of management analytics [17].

Conclusion

The quality of decisions made by the management of medical organizations and state bodies of the healthcare system depends on the corresponding information support, which is directly related to BI-systems. Today, BI technology allows to better understand the structure of medical care and increase the speed of informed decisions. BI is not only a business analysis of information, but also work with big data from different sources, their processing, testing, presentation and servicing of requests for this information. It is important to automate the processing of information, because it will reduce the time to perform routine operations and receive relevant quality information.

The article discusses market leaders. It is a QlikView platform that focuses on the needs of the user as the ultimate recipient of data. The platform has high flexibility to study and visualize data, as well as the presence of a relationship between data and a dip function. The Tableau system is characterized by the presentation of data through visualization and the ability to work with a significant number of different types of data. Power BI service is characterized by a relatively simple and intuitive interface, as well as the presence of many features similar to the apparatus of the latest version of Microsoft Office Excel.

The article also considered a number of features in the healthcare system when using Business Intelligence technologies. Thus, medical organizations work with large amounts of data, which require careful collection and analysis of information presented in the form of reports and forecast models. Often, such data is the personal information of patients and is not subject to disclosure. An essential feature of medical organizations is that healthcare institutions require two types of BI - analytics aimed at supporting the treatment process, and managerial analytics. These two systems solve different problems that are determined during the treatment process at different levels and practically do not intersect.

Abstract

Any economic activity is inextricably linked with its information support. One of the key indicators of the efficiency of the economic system is the decision-making and information processing time, which reflects the effectiveness of the company. Characteristics of information systems have a significant effect on management of technologies and business processes of business entities. Production is one of the most complex spheres in terms of the volume of information and the requirements for the speed of decision-making. Any production process is implemented within the framework of resource, time and technical limitations, which imposes its requirements on its planning and management.

This article presents the features of application of multi-agent technologies for performing the tasks of operational production planning and draws a comparison between the basic production planning methodologies. The present study highlights problems faced by companies implementing automated operational production planning and indicates the key advantages of using multi-agent technologies for meeting the tasks of planning and production dispatching.

Keywords: Production, operational planning, multi-agent technologies, APS, MRP2

Introduction

At the end of the 20th century, many mathematically sound models and methods of information processing originated, which have just begun to be applied in various fields, such as finance, manufacturing, the service sector, etc [4]. Recently there has been a significant amount of interest in models that allow building long-term and medium-term economic forecasts, use historical and operational data on the activities of the company for self-training and, as a result, make effective management decisions, as well as solve complex tasks for a limited amount of time.[3]

A multi-agent approach to managing company resources is the main driver for the development of adaptive information systems that can adapt to the rapidly changing external environment as quickly as possible. Multi-agent technologies make it possible to solve problems in such technologically challenging areas as production, logistics [26], e-commerce, etc. Production is one of the most complex spheres in terms of the volume of information and the requirements for the speed of decision-making. Any production process is implemented within the framework of resource, time and technical limitations, which imposes its requirements on its planning and management. The work of planning and operation management departments is faced with such tasks as effective planning of execution of orders for delivery in the shortest possible time using the optimum amount of material within the technological process [5]. Moreover, as a rule, there are several technological processes for manufacturing the same product, and each of them is effective depending on the current capacity of work centers or priorities for a specific order. Large and medium-sized industrial holdings can receive several thousand orders a day and each of them must be completed by the due date. The multi-agent approach allows to search in real-time mode for solutions that are close enough to optimal within the framework of the task of planning production orders.

The conflict of interests of participants and elements of the production planning process, the high complexity of technological processes, the large number of orders and the need for real-time decision making determine the relevance of the multi-agent approach in production planning.

Setting the objective of operational planning and supervision of production

The main objective of operational planning in production is to ensure the output of products in specified quantities, within the specified time, in compliance with the production procedures and with optimal use of workcenters.

To solve this problem, coordinated work of all production sites is necessary, which systems and methods of operational planning and dispatching are called upon to ensure. Different enterprises use operational planning processes based on various methods or groups of methods, such as: volumetric method, calendar method, volumetric-calendar method, volumetric-dynamic method, etc., which directly depends on the needs for a certain type of operational planning: operational-calendar one, intershop, intrashop, etc. The need for a particular type of operational planning is associated with the type of production and the form of the production process. The algorithm for operational production planning can be outlined as follows:

1) Annual plan break down with determining the start-up and release dates by product type. Annual plan division into quarterly or monthly ones. Distribution of scheduled tasks by division.

2) Operational planning with a horizon defined at the first stage. The input is a set of production orders with specified deadlines within the horizon: month, decade, weeks, days, and shifts.

3) The ongoing planning or supervision, which consists in monitoring and control of the production process, is carried out at the intershop and intrashop levels.

Effective operational planning and supervision is necessary to meet the following objectives:

1) Define the annual production program. Distribute efficiently the work between own production facilities and the external ones.

2) Optimize the distribution of operations across workcenters, taking into account sets of criteria for optimization and restrictions in order to use them effectively

3) Timely respond to external and internal events, fast schedule changeover for the purpose of maintaining the progress of the production process

4) Achieve coordinated work of all parts of production

Depending on the type of production, large-scale, medium-scale, small-scale, single-unit, approaches to operational planning may differ significantly. In case of a large-scale production, the production plan development is a linear function that implements, for instance, the 'planning by tact' approach, which relies upon the availability of a complete group of orders by the beginning of the planning and the assumption of their guaranteed sales. However, in the case of medium-scale, small-scale and single-unit production, the orders may be received after the production plan is formed, which forces the responsible departments to revise the schedule upon the arrival of each new order. Each new order can lead to conflicts, uneven equipment loads, and more expenses for the changeovers and transportation. The operational planning system should meet the needs of the operations control department in terms of rescheduling, as well as build a reliable and efficient schedule in terms of allocating operations to workcenters. There are various optimization criteria to distribute operations across the workcenters effectively. For various types of productions, certain optimization criteria may be prioritized. In this paper, we will consider quite common criteria that are used in both medium-scale and small-scale productions:

1) Minimization of the number of changeover operations
2) Minimization of the maximum interoperability stay of the part with the guaranteed level of interoperability stay specified
3) Minimization of the risk to not fulfil the production order

Problem statement

We are given a set of resources:$\{r_1,\dots,r_n\} \in R$ set of products: $\{p_1,\dots,p_n\} \in P$, set of process operations: $\{o_1,\dots,o_n\} \in O$, set of types of operations$\{ot_1,\dots,ot_n\} \in OT$, set of processes: $\{tp_1,\dots,tp_n\} \in TP$ and a set of orders:$\{po,\dots,po_n\} \in PO$. Resources $\{r_1,\dots,r_n\}$provide their capacity for production of the orders from the set PO according to the range of manufactured items (products) from the set P by performing process operations$\{o_1,\dots,o_n\}$. The order production po_i implies that resources of R perform a finite number of operations (>0) of O in a certain sequence determined by the specific process tp_i according to which the product p_i is manufactured. A single resource r_i can only execute one operation o_i at a time $t > 0$, just as a single operation o_i at a time can only be performed by a single resource r_i. Each resource r_i can only perform operations of a certain type from OT, which is determined by the type of equipment. The ratio of transitions from the operation o_i of type ot_i to operation o_j of type ot_j is expressed duration $\square t$ and cost c. Each such ratio forms a new operation $oc_i \in OC$- a set of changeover procedures. It is required to find such a distribution of operations$\{o_1,\dots,o_n\}$ across the resources$\{r_1,\dots,r_n\}$ in order to plan the orders $\{po,\dots,po_n\}$ based on the product range $\{p_1,\dots,p_n\}$ according to the process map $\{tp_1,\dots,tp_n\}$, where:

$$\left\{\begin{array}{l} \sum_{i=1}^{n}(po_i^{due} - po_i^{end}) -> \max, \mathrm{n} \in \mathrm{N} \\ \sum_{i=1}^{n}\sum_{j=1}^{m}(\mathrm{o}_{i,j}^{start} - \mathrm{o}_{i,j-1}^{end}) -> \max, \mathrm{n} \in \mathrm{N}, m \in \mathrm{N} \\ \sum_{i=1}^{n}(oc_i^{dur}) -> \min, \mathrm{n} \in \mathrm{N} \end{array}\right\}$$

$$\text{constrained:} \left\{\begin{array}{l} po_i^{due} - po_i^{end} \geq 0 \\ o_{i,j}^{start} - \mathrm{o}_{i,j-1}^{end} > 0 \\ oc_i^{dur} > 0 \\ o_i^{dur} > 0 \\ \sum_{j=1}^{m} o_j^{start} - \mathrm{o}_{j-1}^{end} \leq mis \end{array}\right\}$$

Where: R – a set of resources, P – a set of products, O – a set of process operations, OT– a set of types of process operations, TP – a set of processes, PO– a set of production orders, OC – a set of changeover operations,

po_i^{due} - date of order i transfer to production, po_i^{end} - actual execution period of the order i, $\mathrm{o}_{i,j}^{start}$ - start time of the operation j of the order i, $\mathrm{o}_{i,j-1}^{end}$ - end time of the operation (j-1) of the order i, oc_i^{dur} - duration of the changeover operation i, o_i^{dur} - duration of the process i, mis - maximum interoperability stay for each of the orders of m.

Optimization criteria:

$\sum_{i=1}^{n}(po_i^{due} - po_i^{end}) -> \max$ - increase of the period between the orders production date and the orders delivery dates.

$\sum_{i=1}^{n}\sum_{j=1}^{m}(o_{i,j}^{start} - o_{i,j-1}^{end}) -> \max$ - increase of the maximum interoperability stay of the part

$\sum_{i=1}^{n}(oc_i^{dur}) -> \min$ - minimization of total time of changeover operations

Restrictions:

$po_i^{due} - po_i^{end} \geq 0$ - production order shall be completed no later than by the deadline po_i^{due} for delivery of the order

$o_{i,j}^{start} - o_{i,j-1}^{end} > 0$ - process operations during the product fabrication as per the production order cannot overlap in time

$oc_i^{dur} > 0$ - time of the changeover operation i is strictly greater than 0

$o_i^{dur} > 0$ - time of the process operation i is strictly greater than 0

$\sum_{j=1}^{m} o_j^{start} - o_{j-1}^{end} \leq mis$ - time of the maximum interoperability stay of one part should not exceed the setting mis - (maximum interoperability stay)

The problem is a multi-criteria type, NP-hard problem of finding a route for the production of the order po_i of the product p_i according to the process tp_iagainst competition for resources with the other orders. Obviously, due to the multi-criteria nature of the problem, there is not only one optimal solution for distributing operations among the workcenters. It is also worth noting that it is almost impossible to solve this problem using the exhaustive method, simplex method, branch and bound method, if one of the convolution methods is used, using the Pareto set, or the global criterion method, for the case when the potency of sets$|R|,|P|,|O|,|TP|,|PO|$ is comparable to the actual parameters of production, that is, is quite large. It is important to emphasize that each order po_i can be manufactured using different production routes. Production route is a route of the part across the workcenters with the time intervals specified for the operations. To determine all possible routes, it is essential to formulate the Cartesian product of sets of possibilities for performing the $o_i$operation. The number of such sets of possibilities depends on the number of process operations that need to be performed to manufacture the product p_i.
Let us assume that tp_i consist of 2 consecutive operations o_i, $o_{i+1}$of different resources of R. Then there are 2 sets: A and B, where A is all options of performing operation i, and B is all options of performing operation (i+1).We get an ordered pair that allows us to define the Cartesian product of sets: $A \times B = \{(a; b) \mid a \in A, b \in B\}$. By filtering out routes that do not match the production processtp_i, we get a final set of routes, each of which can be evaluated separately. Let us assume that duration of all operations for the product p_i is 1 minute and each operation o_i is performed by only one, yet any resource r_i. Let us assume that the parameters of the problem are as follows:$|R| = 4$, $|P|=1$, $|O|$

=4, $|TP|$ =1, $|PO|$ =1, Δt =24*60 = 1440, where Δt is the planning horizon in minutes. Then the total number of routes is described as ~ $\Delta t^{|R|}$ or $1440^4 \approx 4\ 299\ 816\ 960\ 000$ options. It is obvious that some of these routes do not correspond to any of the processes of TP, since they break the time limits of the operations, but the order of the existing number of options remains significant. If we assume that the time to evaluate a single route according to the optimization criteria and restrictions is 1 millisecond, then the total time for the optimum search using the exhaustive method would take about 1194393.6 hours $\approx$ 136 years. It is also worth noting that the RAM in this example is assumed to be unlimited, and the search is carried out without parallel processing, within a single physical flow. Exhaustive search is not the most effective method of finding the optimal solution. However, for instance, in case of the branch and bound method, we would first need to solve a linearized problem using a greedy algorithm to discard the known "bad" options, and then solve a block problem using the exhaustive schemes to correct some variables. At that, each step would require the upper bounds to be calculated, which requires solving a linearized block problem with new initial conditions. The second stage needs be repeated multiple times, which leads to pseudopolynomial complexity. It is also possible to use dynamic programming by means of the so-called breadth-first search (BFS) [18]. However, while it is possible to reduce the search time for a solution using exhaustive search, the order will remain substantial, less and less deviating from the time spent on exhaustive search as the complexity of the problem increases. As per the needs of the management of the production complex, development of the work plan should be carried out in a fairly short time, which cannot be achieved using the above methods without introducing permissible errors and simplifying the problem, which ultimately can adversely affect the schedule.

Furthermore, it shall be noted that in case a new order is received, equipment breaks down, or other events occur that may affect the plan, with the schedule already in place, the operator should provide complete re-adjustments or make re-adjustments manually. This allows two conclusions about the possibility of solving the problem using "standard" methods:

1) The search for an optimal or a set of suboptimal placement solutions can lead to a combinatorial explosion; the search for solution can take such a long time that by the time it is completed, this solution will no longer be reasonable. Furthermore, a lot of computing resources are required to perform the calculation.

2) The obtained schedule is not adaptive in a sense that in order to correct it, it is necessary to solve the problem once more with an account for the new input data.

To solve the first problem, heuristic algorithms based on informed search methods can be used. A heuristic algorithm is a problem-solving algorithm that includes a practical method and which is not guaranteed to be accurate or optimal, but is sufficient to solve the problem. [23]

From a business point of view, management does not always require to determine the optimal plan. More often, a search for a schedule close to the optimal one is required, with the possibility of further optimization. Heuristic algorithms allow us to search for such solutions in a short time, however sacrificing the search for the optimal solution, although theoretically the latter could also be found. Since the operator works with the operational plan and is personally responsible for its correctness, the resulting schedule is anyway passed through its filter, and situations when the developed schedule is automatically used for generating tasks are rarely practically possible.

At its core, these algorithms apply the knowledge of the problem being solved, which allows solving it more “directionally” than using a universal method, such as the method of branch and bound. There are the following types of heuristic algorithms: greedy algorithms, local search, restricted search, random search, A* algorithm, etc.

To solve the second problem related to the non-adaptability of the schedule, we need to look at the original problem statement from a different angle. It may be assumed that there is a developed work schedule. In case of a new order, the operator of the supervision department can manually add this order to the schedule, while resolving all local conflicts between the planned operations. The operator can re-arrange the schedule by making local changes, having sufficient knowledge to do so. In fact, to

get an adaptive schedule, we need to build a system where a new order will be self-included in the existing schedule and resolving conflicts with the other orders, similar to how the supervision department operator does it. To be able to implement such self-sufficient control, each element in the system, including the controller, needs to have sufficient knowledge and restrictions according to which the interaction will be performed. Systems of this kind can be implemented by means of simulation modeling methods (agent-based approach in particular), which allow to describe the actual system with sufficient accuracy. From the perspective of operational planning, a production, a group of workshops, or a specific shop, depending on the objectives set by management, can be the actual system.

Features of production planning by means of multi-agent approach

To this date, most operational planning tasks are solved using approaches that focus on any one optimization criteria, for example: forward in time, back in time, right on time, as cheap as possible of others. These approaches are based on various kinds of methods: exhaustive search, ant colony algorithm, local search method, branch and bound method, and other "greedy" algorithms [2]. These algorithms are quite demanding of technical resources on the basis of which planning is carried out, and also take a significant amount of time when calculating a schedule within a large number of work centers, equipment, technological processes and orders. It is also worth noting that any drawn up plan loses its accuracy in direct proportion to the planning horizon, which requires constant re-calculation of the entire schedule or its parts with manual control of interfacing. The number of possible options for planning a specific order with a large number of work centers, technological processes, equipment and product complexity can reach several million combinations, not to mention the fact that there are many orders and they all compete for resources. The requirements for modern planning systems reside in the fact that a correctly calculated schedule is required at any given time and the business depends on it, since errors in operational planning can lead to delays in order fulfillment, to an incorrectly planned amount of materials for its execution, as well as to a conflict of the whole schedule, which can affect the production process and the image of the company [7]. Commonly the use of standard heuristics for operational planning in large-scale production leads to the fact that the calculation of the annual production plan can take several weeks and any operational interventions in the constructed plan require either full re-planning or manual adjustments, which can negatively affect the overall picture, and sometimes lead to collapse in production.

In turn, multi-agent systems offer a completely new approach to operational planning of production, which is based not on clearly determined algorithms that allow you to find the optimal solution to the problem, but on finding one of the solutions satisfying the conditions which results from the interaction of many intelligent system elements - agents [6]. A graphical representation of the discrete algorithm and multi-agent system can be seen in Fig. 1. In the past ten years, the agent paradigm has received a huge boost in its development, which affected the publication of many scientific works and various projects implementation.

Discrete algorithm	Multi agent system
	
Fig 1. Graphic representation of a discrete algorithm and multi-agent system

Multi-agent system is a set of intelligent agents having such properties as self-sufficiency, reactivity, proactivity, and sociality. Each agent has a goal, its intentions, obligations and restrictions. Each agent has a communication tool, which allows him to aim at solving a specific problem, interacting both with the outside world and with other agents. Within the entire system, there is one or several global tasks that are decomposed into many sub-tasks each of which is solved by an agent [7]. The main form of interaction between agents is cooperation, which consists of a set of messages, a communication protocol and direct agent relationships. The enlarged structure of the agent is shown in Figure 2

Fig 2. Enlarged Agent Structure

Multi-agent systems can be distributed: different agent communities can be based on its own virtual or physical servers, which allows building a cluster architecture, balancing the capacity and allocating significant and similar subtasks into the framework of one subsystem, thereby reducing the cost of task solution [9]. The agent system identifies each agent with a unique key, which allows disabling selected program units. At the same time, agents can clone each other for an unlimited number of times and therefore form their own resources to solve new problems if necessary, which allows them to adapt to the external environment. Figure 3 shows the enlarged architecture of the core of a multi-agent system.

Fig 3. Integrated multi-agent system core architecture

The high adaptability of multi-agent systems allows them to be effectively used in the operational planning of production. Such events as equipment failure, the arrival of a priority order, the delay in the delivery of materials and the cancellation of an order are frequent within the production process.

The agent approach allows you to respond to such events instantly, realigning the plan in real time mode, taking into account the current stage of production, workloads of work centers, equipment work schedules and many other restrictions. This happens due to the fact that each resource and operation within the framework of the technological process receives its own intelligent agents who build private schedules that are included into the global one. Instead of trying to find a solution to the problem using one of the types of "greedy" algorithms, agents interact with each other in order to reach a compromise solution, which, in turn, satisfies general restrictions in terms of delivery dates, material requirements, etc. As a result of agent interaction, the schedule is constantly being rebuilt, adapting to changes in external factors [1].

For the multi-agent approach to work efficiently for operational production planning, it is necessary to have a formalized principle of event notification, integration with PDM systems and instructions for managing such system.

Thus, the differentiating features of multi-agent systems are:

- reactivity: the ability of the system to adaptively perceive the state of the external environment and timely respond to changes;
- activity: the ability of the system to independently generate goals and act rationally to achieve them, and not just passively respond to external events;
- self-learning: the system is able to use its experience in solving emerging problems;
- productivity: instead of combinatorial search, the system uses many intelligent agents who jointly look for solutions close to optimal using a minimum amount of time.

Comparison of MRP2, APS and multi-agent approach in terms of the effectiveness of solving production-planning problems

To this day, most of the production planning modules that make up ERP solutions are based on MRP2 methodologies and APS class systems. Within the framework of the MRP2 methodology, iterative volume-calendar production planning is carried out by processing incoming information about the needs for finished products and planning requirements for semi-finished products and materials, which ultimately forms a work center loading plan. This approach to production planning has several disadvantages, the severity of which increases with the complexity of production processes. First of all, it is worth noting the following problems:

- Production planning without a deep understanding of technological processes;
- Focusing on production and procurement planning without understanding the entire supply chain;
- Significant amounts of time spent on planning process, which does not allow to flexibly respond to external changes;
- Focusing on discrete production without the possibility of planning continuously running production.

Working in a highly competitive market, the company must keep a high level of service maintenance, which affects information systems that provide support in decision-making. Today, the systems based on the MRP2 methodology are being replaced by APS class systems, which take into account the entire supply chain when planning, not just the production itself, and also allow to conduct the detailed planning, taking into account the features of equipment operation, the operation hours of the enterprise and the priority of customer orders.

APS class systems are focused on the integration of planning of all parts of the supply chain, taking into account all factors and production details, which can be achieved by building models that reflect all the capabilities and limitations of work centers. The main distinguishing features of APS systems is the ability to flexibly configure the models on the basis of which planning will be carried out, as well as the flexibility of the planning stage itself. In case of planning within the framework of the MRP2 methodology, a human cannot influence the planning stage. In the case of working with an APS class system, it becomes possible to partially re-plan both a single order and an order portfolio.

Fig 4. Supply chains of the enterprise with which the APS system works

Preactor, Ortems, Adexa eGPS are the key players in the market of industrial APS systems. Each of the systems integrates with the ERP solution and replaces standard planning tools based on the MRP2 methodology.

Despite the fact that APS class systems are a breakthrough in terms of continuity and speed of production planning, they have several disadvantages:

- The need to reschedule the entire planning schedule when receiving a new order, the terms of which affect the area of high workload of work centers
- Low adaptability and scalability of the system. Planning heuristics have to constantly be revised and refined, which takes up a significant amount of time
- Low planning speed at a large number of parts and assembly units and complex production relationships. It results in appearance of the excessive decomposition in the modeling process, which does not always positively affect the planning results.

In terms of planning with the use of APS, the human factor impact is lower than in the framework of the MRP2 methodology, however, it remains quite high, as it is impossible to define all the possible scenarios of the impact of a single order on the entire plan in the framework of the planning heuristic. It is also worth noting that heuristics rely on solving massive integer linear programming problems, which results from planning from the top approach and can take up a significant amount of time.

The multi-agent approach to production planning, unlike MRP2 and APS, allows you to separate a specific element of the system, whether it is a work center, technological operation, or material, from knowledge of the entire system as a whole. Each element of the system can be represented as an intelligent agent that solves its own local problem within its scope, which ultimately affects the entire schedule. Each agent or group of agents can change over time depending on the new data that the system receives, as well as quickly adapt to changes due to the interaction of agents. In this case planning is carried out in real time mode and each new production order, in the event of a conflict, will itself find out from other already planned orders, whether they can reconsider their priorities, as well as interview agents of work centers of the possibility of allocating resources to them for a certain time at specified deadlines. This approach determines the reactivity of the system and at every moment in time the system is active, agents are negotiating about the possibility of improving their own time and cost characteristics. If the newly prepared plan suits the planning department, it is fixed and becomes basic. Further changes to the basic plan are only possible with the approval of the dispatcher.

Applying the multi-agent approach to form schedules as a part of operational planning and supervision of production

To solve the stated problem with an account for a possible extension or change of the optimization criteria, it is possible to use the architecture of the agent-based environment: agent-metaagent-agent, designed by the authors using the principles of Gaia and MAS-Common KADS methodologies.

Table 1: agent-metaagent-agent model

Component	Objectives	Required set of knowledge
Resource agent	• Maximizing capacity utilization of the resource • Minimizing the number of changeovers • Minimizing the risk of underutilization of the resource capacity	• Algorithm determining the cost of the operation booking and the penalty charged for cancelling the booking for a period of time T, taking into account the current resource load and operation parameters • Data about the resource and its restrictions • Data on the cost of changeover operations • Data on shifts
Order agent	• Minimizing the cost of the order completion • Minimizing the risk of the order non-fulfilment • Minimizing the time dependence of operations in the sequence (achieving a guaranteed level of interoperability stay of the part)	• Algorithm for searching for a route close to the optimal order completion route • Algorithm for determining the cost and penalty for reassignment • Information about the order and its restrictions • Process chart
Scene	• Achieving an equilibrium state in the system	• Data about all agents in the system • Agents interaction protocol • Macro-parameters of environment

The multi-agent problem statement as a part of the presented model is as follows: a set of resources is given:$\{r_1, \ldots, r_n\} \in R$ as well as a set of orders: $\{po, \ldots, po_n\} \in PO$. Resources$\{r_1, \ldots, r_n\}$provide their capacities, which are time intervals $\square t$ within the scope of the model, for producing the orders from the set PO according to the range of the manufactured items (products). An agent ra_i is assigned to each resource r_i , and an agent apo_i is assigned to each order po_i.

The problem involves finding such a placement of process operations in the resources´ time intervals that will maximize or minimize the specified optimization criteria for each of the agents.

In this paper we will consider the order agent in more detail. The agent's lifetime in the system can be divided into 3 stages:

- Emerging of a new order and initial planning
- Optimization of current booking, interaction with other agents and the scene, etc.
- Recording the results of the agent's operations after the work time has started

The agent appears in the system when a new order emerges. The agent interacts with a scene component for the purpose of initial planning of process operations defined according to the process of product manufacture, in order to produce the order taking into account its parameters and restrictions. After the initial planning, the agent goes into the search mode for a more optimal placement of process operations, and is also in a waiting mode for notifications, for example, on the impossibility to carry out a controlled operation or the request of another order agent on the possibility of rebooking with a obtaining a premium. After the order delivery due date, the scene informs the order agent on the successful implementation of the order, records the results of its own activities and is destroyed.

After appearing in the system, the agent has data on process operations that shall be performed to complete the order. The agent receives these data from the process map depending on the item that needs to be produced.The process is a set of stages of the part processing in a certain sequence, which has to be performed. Each stage is a process operation. Each operation can be performed using either only one possible workcenter, or several. This data is the identification type within the scope of which each type of workcenter is associated with many operations it can perform, with a given cost per minute of work. The order agent has access to the current work schedule of each of the resource agents. The set of free time intervals of the workcenter at each of the process stages forms the set of possible options for planning an order or routes. Let us put the case that there are many sets of possibilities in the form of a directed acyclic graph (V^n, C^n), where the vertices are time intervals within which it is possible to perform a given process operation of a certain stage, and the edges are the connections between them. The number of levels of vertices corresponds to the number of operations within the process, and the number of vertices within one level corresponds to the set of possibilities for the implementation of a certain operation.

Fig 5. Set of possibilities for the order implementation

Objective function of the order agent:

$$\left\{\begin{array}{l} po_i^{due} - o_{last}^{end} -> \max \\ \sum_{i=1}^{n}(\mathrm{o}_i^{start} - \mathrm{o}_{\mathrm{i-1}}^{end}) -> \max, \mathrm{n} \in \mathrm{N} \\ \sum_{i=1}^{n}(o_i^{\cos t}) -> \min, \mathrm{n} \in \mathrm{N} \end{array}\right\}$$

Subject to the constraints: $$\left\{\begin{array}{l} po_i^{due} - o_{last}^{end} \geq 0 \\ o_i^{start} - \mathrm{o}_{\mathrm{i-1}}^{end} > 0 \\ o_i^{dur} > 0 \\ o_i^{\cos t} \geq 0 \\ \sum_{i=1}^{m} o_i^{start} - \mathrm{o}_{i-1}^{end} \leq mis \end{array}\right\}$$

Where po_i^{due} - is the due date of order i putting into production, o_{last}^{end} - actual date of the last production operation as per the process flow chart, o_i^{start} - start of operation i, $\mathrm{o}_{\mathrm{i-1}}^{end}$ - end of preceding (i-1) operation, $o_i^{\cos t}$ - cost of operation i, o_i^{dur} - duration of operation i, mis - maximum interoperability stay for any order of m.

Optimization criteria:

$po_i^{due} - o_{last}^{end} -> \max$ - increase to the maximum extent the period between the planned orders production date and the orders delivery dates.

$\sum_{i=1}^{n}(\mathrm{o}_i^{start} - \mathrm{o}_{\mathrm{i-1}}^{end}) -> \max$ - increase in the maximum interoperability stay of the part.

$\sum_{i=1}^{n}(o_i^{\cos t}) -> \min$ - minimize the cost of process operations

Restrictions:

$po_i^{due} - o_{last}^{end} \geq 0$ - production order shall be completed no later than by the deadline po_i^{due} for delivery of the order

$o_i^{start} - o_{i-1}^{end} > 0$ - process operations during the product fabrication as per the production order cannot overlap in time

$o_i^{dur} > 0$ - time of the changeover operation i is strictly greater than 0

$o_i^{\cos t} \geq 0$ - the cost of implementing process operation i is greater or equal to 0

$\sum_{i=1}^{m} o_i^{start} - o_{i-1}^{end} \leq mis$ - time of the maximum interoperability stay of one part should not exceed the setting mis - (maximum interoperability stay)

$o_i^{\cos t}$ - is a pre-defined value for the order agent. It appears only when a request to the resource agent is processed.

The principles of its definition are defined within the framework of the resource agent architecture; this is an external information for the order agent.

Life cycle of the agent is represented by the set of possible statuses of the agent at time *t* defined by the following list: $\{\text{new}; \text{opitimizes}, \text{sleep}\}$. Each of the listing items represents the current status of the agent. At the time of occurrence the agent has the status '*new'*. After the initial booking of operations, the agent moves to the status '*optimizes'*. After exceeding the specified number of attempts to optimize the current placement, the agent enters the '*sleep'* status. Each action of the agent is initiated by the scene. As part of the definition of the action, the current status and the actions to be performed within the current iteration are determined. When the agent has the status '*optimizes'*, a search is made for a new agent placement, which correlates to the basic one. The search for a new placement consists in starting the main search algorithm for the route for the order implementation with a shifted primary operation start date in the framework of the process.

The features of the problem being solved are as follows:

1) The graph has a large number of vertices, which makes the search using algorithms based on sequential vertex search difficult.
2) The length of the route of the order implementation is characterized not only by the length (time), but also by the cost, the coefficient of in-process queue, which requires expressing the weight of the edges not through scalar values, but through some vector indicator.
3) The weights of the edges are not determined, which is associated with a large number of calculations necessary to define it.
4) Due to the multi-criteria nature of the problem, there is not only one route

Search algorithm for the order production route is presented in Appendix 1.

An example of solving a scheduling problem using a multi-agent model

Let us define the global production parameters to build a multi-agent model of operational planning of the parts machining workshop:

Table 2: global production parameters

Type of production	Single-unit and serial
Types of machines	General-purpose, special, automated
Principles of design of processes	Concentrated and differentiated
Form of work organization	Single unit and multiproduct
Main types of works performed	Turning, milling, grinding, cutting, planing, etc.
Manufactured parts	Shafts, bearings, gears, cutting tools
Working hours (shifts per day)	2 shifts
Duration of work shift	3 hours

For the purpose of modeling the process of operational planning of production we will define the following set of the processes:

Table 3: Technical processes

Detail A		**Detail B**		**Detail C**	
Operation name	**Operation number**	**Operation name**	**Operation number**	**Operation name**	**Operation number**
Lathe	005	Cutting	005	Detachable	005
Boring	010	Drilling	010	Milling	010
Boring	015	Drilling	015	Milling	015
Milling	020	Core-drilling	020	Lathe	020
Milling	025	Lathe	025	Lathe	025
Drilling	030	Broaching	030	Lathe	030
Drilling	035	Broaching	035	Lathe	035
Sanding	040	Lathe	040	Thread-cutting	040
Sanding	045	Lathe	045	Thread-cutting	045
Sanding	050	Sanding	050	Lathe	050

According to the process, operations are carried out using special equipment:

Table 4: equipment

Process operation	Time of operation (min)	Cost of the operation (RUB)	Machine
Lathe	5	110	Engine lathe 16K20
Boring	3	42	Radial-drilling 2A55, 2m55
Milling	4	56	Milling CM 1325
Drilling	3	42	Radial-drilling 2A55, 2m55
Sanding	3	54	Sanding machine STUDER S33
Core-drilling	7	98	Radial-drilling 2A55, 2m55
Cutting	3	21	Grinding machine SM300
Broaching	5	80	Horizontal-broaching 7B55
Detachable	3	27	Sanding machine STUDER S33
Thread-cutting	4	20	Thread-cutting Rothenberger 50R

If there are several resources of the same type, they are grouped together:

Table 5: equipment groups

Set of operations	Group	Resources, Pcs.
Boring, Drilling, Core-drilling	Radial-drilling machines	2
Lathe	Screw-cutting lathes	2
Milling	Milling machines	2
Broaching	Horizontal broaching machines	2
Thread-cutting	Thread-cutting machine	2

Thus, there are 5 groups of equipment from a perspective of the ability to perform certain process operations. The shift and duration of one shift are determined by the general production parameters, which are identical for all equipment groups: from 09:00 to 12:00 and from 13:00 to 16:00.

Generation and planning of orders

1) Generating the set number of production orders and their scheduling

a. Create five production orders for each type of product. Delivery deadline - 10.01.2000.

A* - orders for the production of item A, B* - orders for the production of item B, C* - orders for the production of item C. Total: 15 orders.

b. Transfer created orders to the component: "Scene", which creates agents for each order

c. Initiate the start of the "Scene" component operation: start of interaction between agents for the purpose of developing the schedule. Expecting the signal when the schedule is ready.

d. Obtain results in a form of Gantt's chart:

Fig 6. orders planning result

The sequence of operations can be seen as exemplified by one specific order.

Fig 7. orders planning result: specific order route

Results of generating and planning of 15 orders:

- Deadline for completion of the last order: 14:00
- Time spent formulating the Gantt chart: 3.284 seconds.
- Number of interactions between agents: 54
- Average maximum interoperability stay of the part: 6 minutes

Simulation of a breakdown in one of the workcenters, automatic resetting of the schedule based on this failure

Using the schedule obtained after modeling at stage 1, we will conduct an experiment to simulate the failure of the resource "Radial-drilling 2A55, 2m55_2". After the hardware is disabled, the diagram representation is as follows:

Fig 8. orders planning result: schedule after rebuilding

As seen from the diagram, all operations from the resource "Radial-drilling 2A55, 2m55_2" were moved to the resource Radial-drilling 2A55, 2m55.

Results of simulation of resource 1 failure:

- Deadline for completion of the last order: 15:21
- Time spent formulating the Gantt chart: 4.674 seconds.
- Number of interactions between agents: 22
- Average maximum interoperability stay of the part: 8 minutes

In can be noted that the latest order fabrication period has increased, as well as the average time of interoperability stay, which is associated with a serious rearrangement of the schedule, due to the breakdown.

The resulting multi-agent model is adaptive, and the generated schedule can be used for tasks issuing to the production.

Conclusion

The application of the ideas of artificial intelligence has proven its practical value in solving a number of economic problems. This article examined the use of multi-agent technologies as a new approach to operational production planning.

The paper is dedicated to the study of the history of the creation of multi-agent technologies and their application in industry, which allows us to understand how this type of artificial intelligence will develop in the future. The analysis of the multi-agent approach in the context of its application in operational-production planning was conducted. The main elements of the system construction were reflected.

The use of an agent-based approach to production planning allows achieving high results from both technical and economic points of view. From a technical point of view, multi-agent technologies can increase the speed of operational planning, increase the adaptability of the system, and reduce the influence of the human factor in the formation of the plan. From an economic point of view, the multi-agent approach allows to increase production efficiency, which is reflected in the fulfillment of a larger number of orders with the involvement of fewer resources, it allows to reduce production costs of non-optimal use of materials and non-optimal planning of such expensive operations as readjustment, it also allows to increase control over operational planning and to reduce the cost of developing an integrated planning system.

An important advantage of the multi-agent approach is its event-significant component, which allows you to respond to the most serious changes in terms of the operational plan in the shortest possible time. If a client submits an application for a priority order, the company should be able to include this order in the current operational plan with minimal costs for other orders and maintaining the structure of the annual plan. In the event of equipment failure, the company's management should be able to immediately estimate how critical this is for the group of orders that was using this work center as part of its production technology[10]. In case of cancellation of the order, operational re-planning is necessary, which should optimally load the freed up resources

It can be concluded that the multi-agent paradigm is at the source of the further development and application for solving problems of operational production planning.

Appendix 1. Search algorithm of the production route of the order

Search algorithm of the production route of the order

It is suggested to use a step-by-step search with optimization criteria sorted by priority. To minimize the route search time, it is suggested to define a subgraph from the given graph of possibilities. It is assumed that within the scope of the operational planning of production, the highest priority is to determine the possibility of building a plan, which is expressed by the ability to perform the operation o_{last}^{end} within the due dates po_i^{due}. The maximization criterion of interoperability stay time (elasticity) with a restriction is a further approximation to the optimum for any of the rt_i routes, provided that the value of each possibility at the graph level i is the same, and therefore we can assume that any rt_i route without prior optimization with the elasticity criterion can be improved by finding a new route from the basic one. Therefore we will specify the priority of each of the optimization criteria:

1) $po_i^{due} - o_{last}^{end} -> \max$

2) $\sum_{i=1}^{n}(o_i^{\cos t}) -> \min$

3) $\sum_{i=1}^{n}(\mathrm{o}_i^{start} - \mathrm{o}_{\mathrm{i}-1}^{end}) -> \max$

The algorithm consists of initially determination of the basic route rt_i^{basis} and further attempts to improve it. After finding the best of the limited set of routes rt_i^{best} in the specified search area, this route is gradually changed in order to maximize the time of interoperability stay with the specified restriction.

The graph of possibilities (V, C) is represented as a set of subsets of vertices $V = \{V^1, V^2, ..., V^n\}$, where each subset is a set of possibilities (time intervals t) to implement operation o_i from the set of operations O. Time intervals $\{\mathrm{t}_1, ..., \mathrm{t}_n\}$ are arranged in ascending order. No additional graph transformation is required, since the original graph is already presented as a set of subsets or levels If the time interval is taken or partly taken, it is marked by 1, if it is not occupied – by 0.

The algorithm can be represented as follows:

1) Find the basis route rt^{basis} using algorithm **AlgoSearchBasisRoute,** the most distant in time from po_i^{due}

2) If the basis route is found, we follow the point 3. Otherwise the order po_i cannot be planned.
Go to point 10.

3) At each level of the graph, select all the vertices marked with "transition". This marking indicates that this vertex is transitional, that is, a previously performed operation of a certain type was replaced by an operation of a different type, and therefore the equipment had to be readjusted. Denote the set of vertices found by X^i, where i is the current level of the graph.

4) Go sequentially through each of the points within the set X^i. Find the vertex closest in time to the transition point, request the implementation cost from the resource agent and evaluate it using the criterion that combines the first and second optimization criteria with the given weights. (**EstimateRoute** weighting algorithm).

5) At each level of the graph, select the points with the highest estimate in the quantity determined by the system operator. Denote this number of points as m. Set of sets of capacity possibilities | m | obtained.

6) Using sets of possibilities develop routes formulating them as the Cartesian product. Exclude technologically impossible routes, when operation with number i + 1 in a sequence is performed earlier than the operation i. The set of routes is a subgraph of the original possibility graph (V, C).

   Using the algorithm **EstimateRoute** find the route rt^{best} with the highest estimates.

7) Compare rt^{best} and rt^{basis}: evaluate the route rt^{basis} using **EstimateRoute**. If $rt^{basis}_{weight} \geq rt^{best}_{weight}$, then $rt^{best} = rt^{basis}$

8) Using the **GetElongatedRoute** algorithm, get the modified route $rt^{best}_{elongated}$. Revised route will be obtained only if its estimates as per **EstimateRoute** are better than the estimates of the current route rt^{best}

9) Route rt^{best} is accepted as the basis. End.

10) Determine the number of the operation in the sequence for which no booking opportunities could be found. Denote it as U. If the operation U is the first in the sequence, then L = CurrentModelTime (current time within the model), thus, go to step 12. Otherwise, go to step 11.

11) Find the route using the **AlgoSearchBasisRoute** algorithm excluding all subsequent operations,
including U. The end time of the last operation in the shortened sequence is to be denoted as L.

12) If the number of the rebooking attempts exceeds maximum permitted one, rebookingAttempts $\geq$ maxRebookingAttempts – order failed to be booked, the end. Otherwise: rebookingAttempts = rebookingAttempts+1.

    Request the scene for the ID of the agent that booked the interval from (L; L+ $o^{duration}$). Denote the agent having the booking of the interval of interest as ao^{reserv} .

13) Addressing the ao^{reserv} and requesting the possibility to free the occupied time interval and the amount of the premium that ao^{reserv} is expecting to receive for rebooking

14) If ao^{reserv} agrees with rebooking (the algorithm for determining whether an operation can be rebooked - **contract Algorithm**), determine the possibility of paying the premium. If the payment is within the range of a certain order budget - accept the rebooking. ao^{reserv} frees the operation. Go to point 1. Otherwise – L = L+ $o^{duration}$, go to step 12.

Basis route search algorithm AlgoSearchBasisRoute:

Input data: set of possibilities: $\{V^1, V^2, \ldots, V^n\}$. i=1, $i \in \{1, 2, \ldots \mathrm{n}\}$, where n= $|\mathrm{V}|$, t $\in \{1, 2, \ldots \mathrm{m}\}$, where m = $|V^i|$. rt^{basis} = $\{\mathrm{o}_1, \ldots, \mathrm{o}_n\}$, o^{end}_{last} =0 (end time of last operation of the process). There may be several alternative sets of possibilities for each level, which is associated with the possibilities of various resources to perform the operation. The number of subsets at one level denotes as V^iC .

1) Find such a vertex at the level i of the graph of opportunities, within which the time interval for the period $\square t$ = 0 (is free (unoccupied)) and

FOR (i=0; i$\leq$n; i=i+1)

FOR (k=0; k$\leq$ V^iC ; k=k+1)

i. FOR (j=0;j$\leq$m;j=j+1)

1. If $V^i_k[\mathrm{j}]$=0 and $V^i_k[\mathrm{j}]^{start} \geq rt^{current}[\mathrm{i}-1]$, then $rt^{current}[\mathrm{i}]$ = $V^i_k[\mathrm{j}]$, go to point ii

2. Otherwise, if j=m and k= V^iC - go to point 2

ii. If i=n, go to point c, otherwise - go to point b

b. Moving to the next level of the graph, go to point 1 (i=i+1).

2) rt^{basis} = $rt^{current}$,

Output data: route rt^{basis}.

Route estimation algorithm EstimateRoute

Input data: set of operations: $\{o_1, \ldots, o_n\}$, defining the route to be estimated, po_i^{due} - order due date.

The evaluation function is a combination of optimization criteria 1 and 2 with given weights. Weight is an expert estimate. To combine two criteria into one, let us bring the criterion

$\sum_{i=1}^{n}(o_i^{\cos t}) -> \min$ to the maximization problem.

$$routeWeight = w_1(po_i^{due} - o_{last}^{end}) - w_2 \sum_{i=1}^{n}(o_i^{\cos t})$$

Where w_1 - weight of criterion 1; w_2 - weight of criterion 2.

Output data: **routeWeight**

Search algorithm of the elongated route GetElongatedRoute

Input data: set of operations: $\{o_1, \ldots, o_n\}$ route rt^{basis} to be changed, mip – maximum number (in minutes) of mip $\in$ N interoperability stay, n – number of operations within the route rt^{basis}, shift – size of the shift within a single iteration.

CurrentRouteWeight = rt_{weight}^{basis}, $rt^{current}$ = rt^{basis}

FOR (j=0; j$\leq$mip; j=j+1)

FOR (i=0; i$\leq$n; i=i+1)

If i=0, then $rt^{current}$ [i] = rt^{basis} [i]

If i = n-1, then $rt^{current}$ [i] = rt^{basis} [i] + shift

Otherwise, $rt^{current}$ [i] = $rt^{current}$ [i-1] * (rt^{basis} [i]*100/ rt^{basis} [i+1])

END FOR

CurrentWeight = **EstimateRoute** ($rt^{current}$, po_i^{due}).

If CurrentWeight > CurrentRouteWeight, then CurrentRouteWeight= CurrentWeight

Otherwise - exit the loop

END FOR

Output data: $rt^{current}$

Algorithm for determining the possibility of the time interval transference: contract Algorithm

Input data: time interval t : $\{t^{start}; t^{end}\}$, n – number of operations within the planned route, set of operations: $\{o_1, \ldots, o_n\}$ of the route rt^{basis} , premium – premium rate paid by the initiator agent in case of the agreement is reached, w – the weight with which the premium rate affects the route estimation

Rescheduling = false

1) Let us define the time interval within which the new location should be found. Let us define the desired interval as: $\{f^{start}; f^{end}\}$

   LeftBorder = CurrentTime;
   FOR (i=0; i $\leq$ n; i=i+1)

   If $t^{start} \geq o_i^{start}$ or $t^{end} \leq o_i^{end}$, then:

   f^{start} = LeftBorder

   $f^{end} = o_i^{start}$

   Otherwise, LeftBorder = o_i^{end}

   END FOR

2) Form the virtual process $rt^{contract}$ from one operation. Start general route search algorithm for a virtual order. If the route is not determined – end. No rebooking possible.

3) Route for $rt^{contract}$ obtained. Form the new route consisting of previously planned operations and new operation. Name the route: rt^{new}

4) Let us determine the efficiency of a possible rebooking, taking into account the amount of premium that can be received by the agent.

If $rt_{weight}^{current} \leq w * premium$ + **EstimateRoute** (rt^{new} , po_i^{due}), then:

Rescheduling = true

Output data: Rescheduling

Implementation of Project and Process Management In Mining Enterprises

Abstract

The article considers and justifies the necessity of project and process approach in development of mineral deposits. Each approach has a number of advantages and disadvantages, and in practice is applied separately. This often leads to the fact that they not only do not complement each other, but in the case of illiterate use, thereby reducing the efficiency of both the mine development and the management of the mining enterprise as a whole. The authors propose to change this situation by combining the project and process approach and considering these approaches as a single management system. The proposed approach (model) allows to build a management system in real conditions for a mining enterprise consisting of both a single mine and a system of deposits (hub). Its universality is that it is applicable to all stages of its development: preparatory, construction and operation. In addition, the methodology allows to assess the contribution of mineral reserves and resources to the total market value of the mining enterprise.

Keywords: Mine Development; Investment; Project Approach; Process Approach.

Introduction

The development of mineral deposits is an organizationally complex and costly activity. This imposes a certain responsibility on the subsoil user and requires him, on the one hand, to invest significantly in launching and on the other hand, to be flexible and appropriate to the time and nature of the management system. Increasing competition caused by rising prices for mining products, development of complex and hard-to-reach deposits, resulting in an increase in unit capital costs, is a powerful incentive to improve the management system.

The development of an approach (model) of the management of the mine individually and of a mining enterprise, which would allow a potential investor to effectively manage all resources, is of great importance both in our country and abroad.

Existing hierarchical practices tend to try to interact and resolve issues through reports and letters to management, committees and meetings, without trying to establish a clear system and algorithms of decision-making. This approach, based primarily on the functions of the division and performer, is suitable for a small organization. But over time, an organization can grow and grow organizationally, and therefore needs a systematic approach to management. These are two approaches: project and process management. This raises the question: Which of the approaches to be applied at the mining enterprise, which one is preferred given the stages of development of the mine.
The mining enterprise is a complex and dynamic system. As a rule, it may include several mines implemented within the framework of projects, and in turn several sites where repetitive processes occur continuously: extraction, transportation, processing. At the same time, mining operations change

in time and space, so the activity of the operating enterprise can be characterized by two types of activity:

- recurring processes.
- single processes that will no longer repeat in this form.

The first type of activity is a process, the second one is a project. That is, the business process, unlike the project, is a certain kind of conveyor to perform certain functions, whereas the project is repeated only once. Thus, managing a company's activity means managing its processes (Process Management) within the project. In practice, it is quite common for project activities to become project activities and vice versa.

Thus, for the effective management of the mining enterprise in the implementation of projects, clearly defined processes are necessary. This work is devoted to finding the optimal combination of process and project management approaches in the implementation of mining projects.

Methodology

In order to understand project and process management, it is necessary to define their definitions.
The concept of a business process, like a project, is interpreted differently, but in this case it can be based on the definition given in ISO 9000: Process - a set of interconnected and interacting operations (actions) that transform inputs into outputs. Processes can be standardized because any methodology contains the following controls: initiation, planning, execution, analysis, management, completion. The approach, when the resources and activities of an organization are managed as a process, is called a process. In practice, a functional approach is most often used when the functions of the entity are the objects of control. However, in the case of a process approach, the objects of control are processes that focus on achieving intermediate results. The most commonly used standardized methodologies, including project management processes, include: PMI PMBOK, OGC PRINCE2 and APM APMBOK.

There are several definitions of the concept of the project, but the most comprehensive is the following: The project is a set of measures and activities aimed at changing a system by achieving certain goals, under resource and time constraints. [2,3,5]. In other words, the project is a unique process, consisting of a set of one-time activities, as a result of which a unique product is created. Projects can be divided into two categories: development projects and ongoing projects. The projects of the first category are aimed at the creation of new assets, which can include the construction of processing facilities and the development of new mines. In turn, the projects in the second category are aimed at modernization and reconstruction of already existing assets as well as active processes of the management system. In essence, each project is a unique activity and can differ in the scale, complexity, composition and number of participants, terms of implementation, goals and tasks, object of investment activity, requirements for quality and ways of its provision. When the project is managed, it is a project approach.

For some elements, the project and the business process are similar:

Table 1: Compare common project and process elements

Element	Process	Project
activity	repeating	one-time
term	unlimited	limited
content	implementation	planning, implementation, control, completion
assignment	converting resources to a product	creation of new assets, development of existing projects and functions, converting resources to a product
uniqueness	missing	present

Conclusion: Process management focuses on the implementation stage and project management at all stages of the life cycle.

The composition of the organization's processes and projects depends on the nature of its activities. A trade organization, for example, is process-oriented because its activities are based on purchase-sale processes. And it may not change for years. At the same time, the construction organization, rather in its activity, is guided by the project approach. As a rule, a new construction facility may differ in its location and complexity. But there are organizations where the project and process approach will work together. Such organizations include mining enterprises. This enterprise is a unique project by definition, as each mine is created by nature itself and cannot be repeated. The mines or group of mines form a project, the management and development of which is based on a process basis. In this case, the mining management model can be considered as a process-based project model. In terms of the tasks to be solved, the project defines the development strategy of the organization, while the process is a tactical tool for its implementation. Thus, processes are a project component and the process approach complements the project approach. In this case, we can see the addition and promotion of two approaches. A well-built management system can create synergies.

Many researchers ([Lankhorst], [Kalyanov], [TOGAF]) more or less explicitly note the need to include in the enterprise architecture a component responsible for working with changes and transformations. The [TOGAF] emphasizes that the enterprise architecture among other elements should include "transition processes to implement new technologies in response to changing business needs." Because the enterprise architecture is a dynamic management tool, it requires a built-in mechanism for change management that differs from routine operating processes. These arguments prove the necessity of introducing the project slice into the model of the business architecture of the enterprise.

Results

The efficiency of any enterprise is based on the choice of its process management tools. One such management tool is the value chain. The value chain is a strategic analysis tool aimed at detailed analysis of the business for strategic planning purposes. The author of the concept is Professor Michael Porter, who has determined that it is the value chain that is the best helper in the choice of the strategy of enterprise development. This is because the concept allows us to understand what is happening in the organization, who is responsible for it, and what is the final product. Analysis and reorganization of the value chain allows to determine the efficiency of the business model of the enterprise/project as a whole, to analyze the processes separately, to highlight the necessary modernization, to increase the competitiveness of the enterprise, its profit, and return on capital. Based on the results of the analysis, the decision can be made to create additional value chains as well as to make changes to the organizational structure of the enterprise.

The process of development of the mine involves the following value chain based on the stages of its industrial development:

Scheme 1- Industrial development stages

The scheme is a process of four stages, each of which can be considered separately. This is a simplified scheme, since during the mine's processing, the processes specified in the scheme can be carried out, for example, at one of its sites. Each step is independent but not independent. The fact is that without exploration it is impossible to determine the value and value of the mine itself. The absence of reliable information on reserves and potential resources of the deposit, mining-geological, mining and technical conditions and other conditions, it is impossible to make decisions on its industrial development, to start designing, construction, extraction and processing. Each of these processes has a responsible functional manager, thus it directly influences the result of the organization's activity as a whole. On the one hand, the area of his responsibility ends where his business process ends, on the other hand, the activity of one unit can affect the other, and lead to the reduction of its performance. In this regard, in the mining enterprise it is particularly necessary to coordinate the actions of all the participants of the process. In the project approach, each project has a manager who is responsible for the final result. At the same time, not only the functional units responsible for the main processes under the scheme 1, but also the units supporting the activities of the enterprise in the areas of personnel management, logistics, technology development and infrastructure can participate in the project.

Analysis of investment projects shows that these are complex and long-term projects, implementation of which requires management in order to be effective implementation Business project management methodology can be considered at the main stages of the project life cycle:

- Development of project proposal;
- Project planning and preparation;
- Project implementation;
- Close the project.

Thus, the life cycle stages fully reflect the development stages of the mine. The lifecycle involves tracking and directing the project at all stages of the life cycle before its completion to achieve the intended outcome.

In addition to the current activities the company regularly implements development projects, it seems advisable to create a permanent unit in the organizational structure responsible for the implementation of project activities - a project office. To manage such projects, it may be much easier to apply the appropriate project office model.

A team of project executives led by the project manager is formed by the project office from among the company's employees or external specialists depending on the directions and competences required for project implementation.

The supervisor of the project office is the person responsible for allocating resources for the project implementation. These powers are vested in the head of the company.

The head of the project office is the person who manages its activities in the interests of society in the part of:

- project activity administration - workflow,
- project competences management-methodical support.
-analysis of projects for feasibility of implementation and formation of a balanced portfolio of projects;
- Resource management-planning, allocation, monitoring, monitoring and analysis of the use of resources for current and potential projects;
- interaction with performers (design, expert analysis), contractors (construction, outsourcing services), representatives of authorities, including when receiving tax benefits within the framework of the project being implemented, for example, TOSER, RIP.

The functional model of the company's project office is as follows:

Scheme 2: The functional model of the company's project office.

The project office will allow to manage individual projects, portfolio of projects (project programs) in the company. Depending on the size and complexity of the projects, the project office may create project management units of a particular type, such as IT projects. The listed functions must be presented in the project (software) office.

The creation of a process office should help to increase the operational efficiency of the business, as well as for the successful implementation of projects and programs. The main objective of the office is to improve processes, as well as to monitor and build business process performance reports for the relevant process owners and senior management. The process office can be located inside and outside the company, working on outsourcing, which is determined by the scale of the company's organizational structure. In practice, however, there is more often a mixed method of organization, where there is a small internal division that knows the specifics of the enterprise, and external expertise and resources are used to solve certain tasks.

Conclusion: Project approach combined with process management is the most

suitable for a mining enterprise.

Conclusion

In previous decades, the project's success has been linked to three variables: cost, time and quality. However, the modern world is not standing still and new variables related to governance are beginning to appear in the projects. They are mainly the result of model studies that have yet to be tested in various organizational and cultural settings. In this regard, it can be argued that in order to achieve the necessary results and sustainable development the enterprise needs to form an effective management system. In this regard, it is most appropriate to organize operational activities as well as ongoing mining projects based on business processes within the project (mines). The development of the enterprise, connected with the development of new mines and construction of processing capacities, is more convenient to build on the project approach. All this in the complex will allow faster development and commissioning of deposits.

Abstract

In the era of business digital transformation and the implementation of information and communication technologies in both production and management processes the role of the human factor in the formation of an enterprise's development strategy significantly changes. The personal staff characteristics which are reflecting the teamwork skills, creativity and the ability to think out of box while solving management tasks are becoming increasingly important.
The article talks about the role of human capital management in a modern organization and sets the personal and professional competencies for the personnel that are necessary in the formation and implementation of the enterprise development strategy in the digital business transformation. The result of the work was the development of a "personal" business model based on the transformation of the classic business model of A. Osterwalder and Y. Pigneur where the main factor in the transformation is human capital, its multifunctional adaptability to changing business conditions and personalization. The proposed "personal" business model has a wide range of practical applications both in the formation and implementation of an enterprise development strategy and in the human resource management, in particular in the recruiting and development of new information and communication technologies and platforms for increasing the synergistic effect of working in cross-functional teams by finding new opportunities for cooperation and achieving effective results.

Keywords: Business model, Osterwalder, enterprise development strategy, digitalization, human resource management

Introduction

The second half of the XX and the beginning of the XXI century was marked by various changes and targeted reactive actions in the face of uncertainty in the external and internal environment, which served as a change in the views of scientists, futurologists, public figures, entrepreneurs, heads of organizations and industrial enterprises on the role of personnel in organizational and economic activities, which is based on the human factor with given professional skills and personal skills. The traditional concept of "personnel" is collective, an individual person in the enterprise was considered as a resource involved in production, while in the 21st century a person with his intensified evolution

of moral, intellectual and spiritual development, as well as taking into account the introduction of a corporate code in a number of organizations, began to synthesize in such subject areas as human resource management, strategic management, emotional intelligence, goal setting and the formation of a vision for the future organization, including After that, it has become a significant element in the digital transformation.

Modern management is focused not so much on the creation of values and meanings in the field of science and education, the practice of making and implementing managerial decisions, but how to master the art of human resource management. The human factor and its role in forming a development strategy in the context of digital business transformation is considered paramount, where human resources management needs advanced methods and tools that would ensure the transition from reactive management to proactive (program-targeted) management of an organization from -for the rapid development of the scientific and technological revolution in relation to the nature, content and division of human labor. Human labor, to a greater extent, requires a person to have high soft-skills rather than hard-skills, since working conditions change and cease to be mechanical, i.e. routine, which leads to the need for quick adaptation to changing environmental conditions. Modern gadgets, information technology, lifestyle makes you consider a person not only and not so much from the point of view of technocracy, but also with the possibility of having a high share of intellectual training in him and operating with a large amount of data, thereby personifying him more and more in a digital environment.

The importance of the human factor in the current conditions plays an important role in shaping a development strategy, where the leadership of the organization changes the ability to control employees in order to increase the importance of self-control due to established performance indicators for each employee. Therefore, the role of each employee in the implementation of the organization's strategy is growing significantly due to the constant search for new, non-trivial and effective solutions, the implementation of performance indicators in achieving strategic goals through the synthesis of intra-company entrepreneurship and creativity, i.e. Constant creation of the birth of an idea that can strengthen the organization's competitive position. In dynamically changing conditions, it is necessary to constantly monitor emerging technologies, consumer preferences, social trends, which directly affect the competition and become decisive in choosing the right business model for the organization. The analysis of sources on the features of construction, the possibilities of applying and adapting business models to solve socio-economic problems showed that the most convenient, universal and popular business model is the model of A. Osterwalder and I. Pigne, since this model contributes to the idea of how the organization intends to act and generate ideas, increase the value of its product, reflect the organization's abilities, the list of partners required to create, promote and transfer this value are finite m consumers, correlate the capital necessary to obtain sustainable financial flows, as well as assist in the formation and development of personal and business qualities, determine the positioning, skills, competencies, potential of the entire staff and each individually by conducting a timely assessment and analysis of verbal, numerical and abstract abilities. The choice of this business model is due to the fact that successfully created technological products in the conditions of digital business transformation are no longer a guarantee of stability and long-term success in the market, as they undergo permanent changes in the external and internal environment, therefore the use of monitoring, analysis and subsequent design of an improved version of the product is relevant and binding.

Changes occur in the operational activities of the product, in terms of resource optimization and staff rotation due to the development of human, information and organizational capital, which are associated with the agile philosophy, where, on the one hand, there is awareness of future requests and active adaptation of products and services under the uncertainty of the macro and micro environment, on the other hand, the need to attract talented, entrepreneurial and creative employees who are able to build organizational activities with elements of decentral called control, i.e. the formation of a horizontal management structure, based on self-organizing teams, in which all significant professions, the necessary competencies and skills to achieve the final result are concentrated. The most common case of a horizontal control structure is the Zappos shoe online store. In 2013, the company introduced holacracy - a horizontal management structure where there are no middle managers, that is, the entire company has areas of responsibility in the form of "circles" that exchange ideas, tasks and information about their implementation. Organizational management is carried out not through managers, but

through selected reputable employees within the "circle", which colleagues have chosen as leaders of their groups. The main idea of the CEO, Tony Shea, was that all employees show high involvement and effectiveness, work as entrepreneurs - independently generate ideas and make various decisions with a collective mind.

In order to be a highly qualified, significant and progressive employee, you must be able to work in a team, find your weaknesses, strengthen your strengths, assess opportunities and mitigate emerging risks, and, as a conclusion, join the idea that work is not only a source of everyday life On the contrary, it is an instrument of personal and professional development in solving complex problems.

It is necessary to summarize that, at present, it's not only the choice and effective implementation of the business model that is important, now it is especially important to constantly monitor the level of development or degradation of the public masses, the validity of the human factor to changing environmental conditions, which goes into a stage of unique self-expression when objective career factors (social status, welfare) are increasingly giving way to subjective factors (satisfaction from work done).

Materials and Methods

The first steps in designing a business model were considered as a step-by-step tool for strategic and innovative management, which appeared in the 70s, when project management needed a structural analysis and design methodology SADT (Structured Analysis and Design Technique). Then, programs and projects aimed at medium and long-term development within the framework of strengthening and increasing the competitiveness of the organization's strategies, designed to solve organizational issues of management or business modeling, were singled out in a separate segment, which was called BMS (Business Modeling Software) in the international community. Since the 90s. of the last century, a certain trajectory of the development of research on the concept of business modeling is traced - from the definition of the conceptual apparatus "business model" to the application of the concept of a business model to study various trends, characteristics and phenomena. Using the approaches proposed by A. Osterwalder and I. Pigne, in which it is proposed to determine the stages of the concept of a "business model" and to identify five stages of the evolution of cognition of the concept of a business model:

1. definition and classification of a business model;

2. highlighting the elements of a business model;

3. study of the elements of the general system;

4. development of basic models and categories;

5. development of tools for analysis and application of the concept of a business model.

It should be noted that the authors did the theoretical and instrumental work on the construction of the sixth stage, which is characterized by the adaptation of the business model and its transformation into a more progressive form of development associated with the identification of human capital in the organization.

Business models have become widely popular in the era of the formation and development of technological entrepreneurship and venture financing, since this tool provides an opportunity for a certain period of time to form, evaluate and select the proposed initiatives or subject of the study area. This tool is a tool for rethinking the traditional business paradigm in the research branch, filled with a wide range of tasks, among which are: understanding the logic of the subject under study and its scope; designing an instrumental form for adapting an organization to functional changes; basis for strategic planning and development; business process modeling; assessment and selection of strategic alternatives; creation of a single communication platform in the context of the mission, organization goals and digital business transformation. Thus, the modern practice of applying business models extends to many areas of activity and extends far beyond the boundaries of the business environment.

The business model, initiated by A. Osterwalder and I. Pigne, is modern, used by leading companies in the USA and Europe, including IBM, Ericsson, Deloitte, which have established themselves as winners in the competition. This business model in these organizations has a conceptual approach and is a tool in creating values for consumers, employees, partners and shareholders. The authors conducted research to identify experimental hypotheses and established themselves that the business model of A. Osterwalder and I. Pigne has a number of transformational changes, one of which is the separation of the business model in order to form more efficient activities of the head and functional units, using the example changes in the practical value of the use of human capital in the organization. The application of the business model of A. Osterwalder and I. Pigne can also be applied to an individual person, because a person with his set of knowledge, skills and competencies is a representative of the organization, provides services and goods to customers, therefore, forms the organization's profit and own income. Using the business model of A. Osterwalder and I. Pigne as an example of a person, one can find points of concentrated growth, and, conversely, abandon destructive attitudes and habits that do not bring moral satisfaction and success in the organization. This approach allows you to define and transform a business model into a functional (personal), i.e. how to more effectively use your skills, competencies and talents for personal and professional development. The ability to reflect on one's own experience, characterization of retrospective, current and perspective areas of a person will reveal causal relationships between events, namely, will lead to the establishment of how to remain a sought-after, unique and competitive employee in dynamically changing environmental conditions. The fact is that in the modern world there is a frequent change in the context of events, and organizations, like employees, are aimed at long-term improvement in order to remain as competitive as possible in their type of activity.

To continue further research and its significance, it is necessary to compare the traditional business model, in which the human factor influences the organization's operational processes, with a functional (personal) model that includes the practical value of using a person's knowledge, skills and competencies in favor of the organization. A graphical interpretation of the template of the business model of A. Osterwalder and I. Pigne, consisting of nine structural blocks, is presented in Fig. 1. A graphical interpretation of the "personal business model" is presented in Fig. 2. It should be noted that all elements and parts are in interaction with each other, establish causal relationships and dependencies of the analyzed object and subject. These templates represent a universal language for describing, presenting, analyzing and transforming business models for special tasks. The business model has nine blocks that allow systematically and centrally presenting the organization's activities and the practical value of a person on one sheet.

The Customer segments block in the organization exists thanks to customers. Each organization is able to serve different types of customers. An example is an online store that focuses on working with individuals and legal entities, providing corporate packages of services and goods. If we are talking about a person and hired work, then the same people in the organization can be clients. That in one, that in another case, services are provided.

The "Value Proposition" block in the organization is to provide unique value - this is the main reason why customers express their preference for a company that is focused on such an offer. Examples of unique value range from novelty, low price and performance to privileged status, brand positioning, and lower investment risks. In a personal business model, this is the answer to the question of how to provide assistance in performing work for the organization's clients.

The "Channels" block in the organization is focused on the value propositions of the organization that come to the client through a combination of information and communication sales channels. Public distribution channels may include personal and business contacts, a website, social networks, digital instant messengers, etc. With this approach, this increases the client's awareness of the organization's goods and services, evaluates the organization's value propositions, allows the consumer to purchase goods and services, etc. Promotion channels represent five stages of goods receipt to a client:

– Informational (how does the client's awareness of the goods and services of the organization increase?)
– Evaluation (how is the help to clients arranged in evaluating the value propositions of the organization?

- Sales (how is the customer provided with the opportunity to purchase certain goods and services?)
- Delivery (how is the delivery of our value propositions to the client?)
- After-sales (how is the after-sales service provided to the customer?)

In a personalized business model, "Distribution Channels" refers to positioning regarding how unique value is delivered to a customer.

The "Customer relationships" block describes the types of relationships that an organization establishes based on consumer segments. The organization clearly defines what type of relationship it intends to establish in relation to a particular consumer segment, in addition, they can vary from personal to automated. There are several types of customer relationships that exist within the framework of several consumer segments: personal support, privileged support, self-service, online communities and co-creation of a product like "seller-buyer", for example, involving customers in creating product designs or producing content. This gives the right to believe on the basis of which methods and approaches new customers are acquired, how existing products are held and how products can be diversified. The data block in the personal business model shows exactly how the employee needs to interact with customers.

The Revenue streams block in the organization arises as a result of the successful implementation of value propositions to various consumer segments. This block includes the profit that the organization receives from various consumer sources. The organization must know for sure why the client is ready to give money and provide a convenient payment method that will be preferable to the client. There are a number of ways to create cash flows: selling assets, usage fees, subscription fees, licenses, brokerage, advertising. A distinctive feature of the personal business model will be the entry into the incomes of an individual not only material income, but also intangible, in which such concepts as job satisfaction, recognition, social and social contribution are concentrated.

The Business Model Canvas

Fig. 1: Template of the traditional business model of A. Ostervalder and I. Pigne

Fig. 2: Template for the "personal" business model of A. Ostervalder and I. Pigne

The Key Resources block in the organization is represented by the most important assets necessary for the functioning of the business model. Key assets can be expressed in the form of value propositions, have a market position, maintain contact with consumers and generate profit. Key resources can be characterized by the following classification: production resources, intellectual property, human resources, financial resources. In a personal business model, a person's key resources are his interests, knowledge, competencies, skills, personal qualities, experience, business contacts, and other intangible or material resources.

The Key Activities block is focused on the practical actions that are necessary to implement a business model. Key activities can be classified as follows: product architecture, problem solving, product placement platform. In other words, the key activity is that with the help of which value propositions of the organization are created and implemented for certain consumer segments. In a personal business model, key activities project the work and benefit of a person, i.e., actions performed in the interests of the organization's client.

The Key Partners block describes the base of suppliers and partners, thanks to which the business model functions. The organization is interested in building partnerships to optimize the business model, mitigate risks and obtain appropriate resources. There are several types of partnerships: strategic cooperation, joint ventures in the form of a manufacturer and a lead supplier. The motive for such synergy may be, for example, optimization of production, reduction of risks and uncertainty conditions, and supply of resources below the market price. In the personal business model, this block is one of the fundamental, since it is important to have like-minded people to successfully carry out joint work and aspirations. This category includes professional mentor, organization employee, family, friends.

The Cost Structure block shows the most significant expenses incurred as part of the business model. Expenses are easy to predict if you identify key resources, activities and key partners. In contrast to the organization's business model, the costs of a single person are presented in material and intangible aspects, i.e. stress, time, energy and money.

Results

Thus, the development of a traditional and functional (personal) business model should be considered as the first step towards transforming the organization into an innovative concept for creating practice-oriented solutions and proposals based on self-organizing personnel. In the table. Figures 3 and 4 show the traditional and functional (personal) business models created and proposed by the authors in the framework of this study.

In the formation of a number of requirements for personnel (person) on the basis of a professional team, the choice is associated with the appearance of the following features, which must be taken into account:

1. A disciplinary, synthesizing, or creative type of thinking may be established in an employee's activity that requires certain knowledge and skills to collect, analyze, and master cross-sectional data.

2. Knowledge has its practical relevance and belonging only if it corresponds to the level of development of the economic system, and therefore, it is necessary to constantly update and increase through the collection of alternative opinions, facts and suggestions to ensure a high level of personality development.

3. The quality of acquired knowledge of a modern employee has its own value and time, but in order for knowledge not to lose its relevance and reality, it is necessary to monitor emerging trends and development programs at an interdisciplinary level, that is, to establish causal relationships between the studied disciplines, to conduct a multifaceted analysis and assessment of the practical reliability of information to ensure a new influx of knowledge and competencies.

Table 3: The traditional business model of A. Osterwalder and I. Pigne on the example of the development of the practical value of human capital in an organization

Key Partners	*Key competencies*	*Value Proposals-*	*Employee Relations*	*Consumer segments*
- founders; - leaders; - professional teams; - specialists.	- instrumental (cognitive, methodological, technological, communicative abilities); - interpersonal (individual abilities as social skills (social interactions and cooperation); - systemic (abilities and skills).	advanced education; corporate university; -health and nutrition; - flexible form of employment; - motivation to work (the possibility of self-realization, option program, job satisfaction, the implementation of their own initiatives and projects); - culture and leisure; - providing staff with business literature, valuable contacts and resources; - ecology and healthy lifestyle.	-internal communication (involvement in the labor process, teamwork, team-building); - establishing long-term relationships ("Declaration of values"); - issue of a monthly newsletter, which indicates the latest company news and development prospects; - corporate identification (personal approach).	- scientific staff; - technical staff; - technological staff; -management staff (specialists, managers, administrators).

	Key resources - the effectiveness of the system of interaction between shareholders, management and structural divisions; (professional teams, informal leaders, agile, scrum methodology, remote workstations, use of artificial intelligence) - motivation to work; -qualified management.		*Sales channels* - information systems (ERP, CRM); - instant messengers; - platforms; - mobile applications; - social networks.	
Cost structure -HR resources (selection, training, social programs, improving internal communications); - financing of scientific research of educational institutions.		*Revenue streams* - contribution to the development of new research areas; - contribution to the increase in company revenues; - contribution to the development of relations with customers; - contribution to the coordination of activities of units; - contribution to the successful development of a horizontal management structure; - contribution to the development of informal relationships between structural divisions.		

Table 4: Functional (personal) business model of A. Ostervalder and I. Pigne on the example of the informal leader of a professional team

Who helps you *(key partners)* *-a family;* *- managers;* *-specialists;* *-other professional teams*	**What are your responsibilities** *(key activities)* *-management of team business processes;* *-Human resources management;* *-initiation;* *-planning;* *-realization; monitoring;* *-the control;* *-analysis.*	**How do you help** *(value propositions)* - providing team members with the necessary literature, valuable contacts and resources to create a product; - the ability to listen to a team to implement their needs and needs; -motivation;	**How do you interact with employees** *(customer relationship)* -informal communication in a team (involvement in the process, team approach); -establishing friendships; - corporate identification (personal approach).	**Who do you help** *(consumer segments)* -organizations; - members of a professional team; - to other specialists;

	Who you are and what skills, competencies you own *(key resources)* *Soft skills* - verbal communication; - ability to manage time and stress; - the ability to make decisions; - identification, definition and resolution of problems; - stimulation and motivation of other team members; - delegation of authority; - setting goals and formulating a vision of the future organization; - introspection; - Creation of teams for relevant goals and objectives; - Conflict Management.	- mentoring (mentoring, coaching); - situational leadership.	**How you spread yourself and how you deliver value** *(sales channels)* - information systems (ERP, CRM); - instant messengers; - platforms; - mobile applications; - social networks.	
What do you invest *(cost structure)* - personal qualities (extraversion - a warm attitude towards others, sociability, self-confidence, activity, a sense of joy, optimism and positive emotions); - moral beliefs; - foundations and values; - time.		**What are you getting** *(revenue streams)* - realized idea; - achievement of the result; - increase the synergistic effect of structural units, professional teams that provide organizational and economic development of the organization; - material incentives for the leader and team;		

Conclusion

Thus, the authors found that the development of a traditional and functional (personal) business model has a positive tendency to develop a wide range of innovative solutions that form the basis of the organization for strategic planning and development. The art of human resource management has a high development potential and forms new information and communication technologies and platforms that are verified on traditional and functional business models in specialized organizations, where industry units based serving one or more types of activities are based. Such companies have a certain organizational structure, consisting of professional teams that are constantly generating options, tacking between creativity and decision-making speed in conditions of rapid adaptability, moving between other teams and ongoing projects, increasing the role of the human factor for creating new opportunities and effective results.

Abstract

A precise and justified assessment of assets plays an important role for successful investments in the real estate market. A significant influence on the result of the market cost is provided by the capitalisation ratio, which is used in the direct capitalisation method and to determine the cost of reversion in the method of discounting cash flows. The article considers the hypothesis about the possibility of predicting the capitalisation ratio, which is topical for reducing uncertainty in making managerial decisions. Authors developed a model that allows effectively predict the capitalisation ratio. The study has the inspection of the received model using objects of office real estate of St. Petersburg and a simulation modelling. Moreover, the article has comparison of the market capitalisation ratio of St. Petersburg and other major cities of the world. Next, the study analysed the influence of the chosen model technique of calculating the capitalisation ratio on the result of the valuation with a review of the main advantages and disadvantages of such model techniques. In order to determine the validity of using model techniques for real estate appraisal the cost of a hypothetical office building based on retrospective data of the St. Petersburg market in accordance with each model was calculated. The study presents comparison of the obtained results with a real dynamic row of the cost. In addition, it provides an alternative model for the calculation of value within the income approach to valuation, which gives results that are more accurate. The results of the study are the model for predicting the capitalisation ratio with a probability of 95% and recommendations for the effective use of model techniques for calculating the capitalisation ratio.

Keywords: Real Estate Appraisal; Income Approach To Evaluation; Capitalisation Ratio; Forecast Model; Model Techniques For Calculation Of The Capitalisation Ratio.

Introduction

Decision-making in the real estate market is hampered by the limited information on actual transactions of rent and sale of properties, as well as the lack of statistical data. In particular, the generally accepted capitalisation ratio is used to make decisions about investments in the market. It characterises the ratio of annual income to the initially invested capital. This ratio is used in the direct capitalisation method for the real estate appraisal.

The income direct capitalisation method converts the net (annual) operating income I_o into the market value V_o of the property by dividing this income onto the corresponding market rate of return (cap rate or total capitalisation ratio) R_o. Capitalisation ratio is a critical variable in commercial real estate valuations (Alesinskaya et al., 2017; An & Deng, 2009; Clayton et al., 2009). The income capitalisation formula is as follows:

$$V_o = \frac{I_o}{R_o}. \quad (1)$$

This method is most often used for the approximate assessment of the property's market value on the valuation date or to estimate the value of reversion (return of the invested capital) at the end of the forecast period when building cash flows in the income capitalisation method. In this case, the projected change in income by periods is approximately taken into account by the structure of the overall capitalisation ratio within the framework of model techniques, which will be discussed below. In (Glascock & Cunningham, 1983; Ellerman, 1994; Artemenkov et al., 2018; Atanasov et al., 2017; Battisti & Campo, 2019; Bril et al., 2018; Gribovsky, 2001 & 2007; Gribovsky et al., 2005; Kucharska – Stasiak, 2019; Ilin et al., 2014) the following models are proposed to use for determining the capitalisation ratio:

- Ellwood's model: $R_O = Y_O - \Delta \bullet \frac{Y_O}{(1+Y_O)^k - 1}$, (2)
- Inwood's model: $R_O = Y_O + \frac{Y_O}{(1+Y_O)^k - 1}$, (3)
- Hoskold's model: $R_O = Y_O + \frac{Y_{rf}}{(1+Y_{rf})^k - 1}$, (4)
- Ring's model: $R_o = Y_o - \Delta/k$, (5)
- Gordon's model: $R_o = Y_o - q$, (6)

Where

R_o – the reversion capitalisation ratio,
Y_o – the rate of return on capital corresponding to the return on the investment in similar real estate,
Y_{rf} – the risk-free rate of return on capital,
k – the period after which the wear level of the improvement will be 100%,
q – the growth rate of annual income in the post-forecast period,
Δ – the change in total property value for the forecast period.

Note that full depreciation techniques are rarely used in real estate valuation, although they have their supporters. Here, one should keep in mind the internal inconsistency of the Inwood's and Hoskold's models noted in (Ozerov, 2007; Laskin et al., 2016): they use the basic assumption of the Ellwood's model (2) about the immutability of income, which is difficult to agree with the assumption of the full depreciation of the object. The Ring's model (5) is formally free from this inconsistency because it suggests linear depreciation. The Gordon's model (6) is strictly implemented if incomes and prices for real estate grow with a constant inflation rate equal to q. There is no doubt that this model can be used in the valuation of land as an asset that is not physically depreciated. However, when choosing a model for estimating the value of improvements, one must take into account physical, functional and economic depreciation, which may not necessarily be less than inflation or other cost increases (Lee et al., 2014).

In the practice of assessment with the income approach, it is more appropriate to use the discounted cash flow model (DCF model), which assumes that the value of reversion at the end of the forecast period is determined by the capitalisation of income of the first post-forecast period. That is, the value of reversion is determined by the model techniques by capitalising the income of a post-forecast period using the accepted capitalisation ratio. Thus, in the DCF model, the result of the real estate market value depends on:

- the level of market income;
- the accepted dynamics of changes in income;
- the accepted discount rate (rate of return on capital);
- the selected reversion value calculation model (Leifer, 2006).

Additionally, to the above models, the value of the real estate object at the valuation date can be determined "model" without determining the reversion by the formula (7) presented in (Leifer, 2010; Gribovskiy et al., 2005):

$$V_O = \sum_{i=1}^{n} \frac{I_{oi}}{(1+Y_O)^i} \Bigg/ \left(1 - \frac{(1+\Delta)}{(1+Y_O)^i}\right), \tag{7}$$

Where

n – the period of operation,
V_o – the current value of the object,
Y_o – the rate of return on capital,
I_o – the net operating income,
Δ – the change in value for the forecast period.

The analysis of existing model techniques shows that the issue of justification the rationale capitalisation ratio and the choice of the model technique for the reversion assessment is relevant for appraisers, since the resulting value of this coefficient significantly affects the determined value of the object. Taking into consideration the lack of information and the importance of overcoming the uncertainty for making certain decisions it is necessary to continue the research works of the authors (Ilin et al., 2018; Kozlov et al., 2017; Leifer, 2010; Mochulaev, 2010; Sivitanides, 2003; Bril et al., 2017), and to provide the ability to predict the capitalisation rate.

The purpose of the presented paper is to provide a model allowing to forecast capitalisation ratio and to determine depending of the object's market value on the chosen assessment model technique for cap rate calculation when evaluating reversion.

Methodology

The indicators characterising the office real estate market of St. Petersburg were used as initial data for building the model (Ozerov et al., 2017). Based on the available information on rental prices and sales of office property in St. Petersburg over the eighteen-year period, the corresponding time-series data were constructed. To implement the forecasting, the main trend of each series was identified by alignment using analytical formulas. The tendency of development of indicators in both cases is characterised by power dependence:

- for rental market: $A_m = 2259 \times t^{0,53}$;
- for the app price market: $P = 4233 \times t^{1,13}$,

Where

A_m – the average market rental rate of the office real estate (roubles per sq. m per year),
P – average market price of the offer on the real estate market (roubles per sq. m),
t – serial number of the year (t = 1 for 2002, t = 19 for 2020).

The existing values of the price characteristics of office real estate in the rental and sale markets in St. Petersburg, as well as the underutilisation coefficient (K_v) adopted at the average market level of 5%, and the ratio of operating expenses (K_{oe}) equalled to 35 % were taking into account. Capitalisation rate was calculated using the formula (Ozerov, 2007, p. 217; Rusakov et al., 2016):

$$R_o = (1 - K_{oe}) / M_{eg}, \tag{8}$$

where M_{eg} is the effective gross income multiplier obtained as the ratio of the price of real estate to the income from the lease minus underloading. The derived values of R_o over a long period create a dynamic range, which also has a power form of the trend:

$$R_o = 0.302 \times t^{-0.604}, \quad (9)$$

where t is a serial number of the year (t = 1 for 2002, t = 19 for 2020).

In order to take into account the uncertainty in the source data as possible deviations in the values of underload coefficient and operating expenses ratio, rental payment rates and cost of facilities, it is necessary to investigate the influence of these factors on the predicted values of the capitalisation ratio. Such deviations can be estimated by applying the Monte-Carlo simulation method (Gribovskiy et al., 2005; Poljanskihh et al., 2018; Saveliev, 2013; Zaychenko et al., 2018). This method is based on the opportunities of obtaining a distribution of indicator values for a large number of combinations of determining factors. In each such combination, the values of the factors are randomly selected from the predetermined ranges (see Table 1).

In this case, the total capitalisation ratio acts as the resulting variable, and the above model (1) describes the relationship between the source data and the result. A uniform distribution was chosen for all key factors. The number of tests (simulated scenarios) is assumed to be 10,000. Multicollinearity between factors is absent. Corresponding capitalisation ratio is defined for each scenario. Its average value and statistical indicators characterising the degree of the individual deviations from the mean values are calculated (see Table 1).

Table 1: The results of the risk analysis

Indicator (factor)	**Minimum**	**Maximum**
Rental payment rate, roubles per sq. m per year	9490	12323
Underload coefficient	5%	10%
Operating expenses ratio	30%	40%
Value, roubles per sq. m	95,493	165,967
Average capitalisation ratio	0.051	
Standard deviation	0.009	
The coefficient of variation	0.182	

Possible values of R_o can be represented graphically (see fig. 1). According to the results of 10,000 tests it was revealed that the most common value is $R_o = 5\%$, which corresponds to the previously predicted value of the coefficient. It also can be seen that the calculated values of the capitalisation ratio for chosen business centres “SetlCentre” and “Obvodny Dvor” fall within the range of possible values of the studied indicator.

Thus, the model (1) with a probability of 95% allows predicting the market capitalisation ratio based on the multiplier values obtained from monitoring and the operating expenses ratio.

The obtained market capitalisation ratio can be used in the future for management purposes.

Fig. 1: The distribution of the capitalisation ratio values

Discussion of results

Such a forecast allows taking into account various options for changing market conditions; in particular, some future risks associated with price changes in real estate market. In addition, it simplifies the process of adjusting the expected values of the cap rate.

It is worth noting that the capitalisation ratio acts as a characteristic of the profitability of the property, and therefore, the desired level of the indicator should be higher. However, at equal prices preferable object should be with a smaller cap rate, since, despite the lower revenue, the object is estimated as high as bringing more income. This means that at a lower capitalisation ratio in the present case the object value management will be more effective. These findings are supported by the comparison of cap rate values in developing and developed countries (for the latter – ratio is usually lower). Thus, a comparison of the obtained indicators with world values in this case allows us more fully assess the tendency of the indicator under consideration.

To achieve this goal, a hypothetical office property with an average rental rate was chosen. Value of the project is known to calculate, as of June 2018 years, so as to have the actual data changes in rental rates and the property value over the forecast period (when writing the paper the retro-period is taken from 2012 to 2018). For the calculation of model, it is noted:

- The rental rate of the object of study at the average market level equal to 8273 roubles for the sq. m per year;
- A period of operation is 6 years (retro-period is from 2012 to 2018);
- A change in income dynamics equal to the actual change in rental income for the analysed period 2012-2018 (see fig. 2);
- The forecast of rental rate increase according to the trend shown in fig. 2;
- The underload coefficient is at the average market level of 5%;
- The rate of return on capital is at a minimum level of 11%, proposed for member banks of the Association of Banks of the North West in (Pupentsova and Livintsova, 2018).

Therefore, in the DCF model all indicators including changes in cash flows were taken as actual for the period under review. The result of the object value can only vary depending on the selected model for calculating the reversion. The object area is not used in the model. The calculation is made for 1 sq. m of the office real estate. The assumption is accepted that physical and functional obsolescence will not be able to affect either annual revenues or the reversion value, since timely scheduled repairs

are taken into account in the reserve for replacement. For model (7), the actual change in value (Δ) for the analysed period was taken at the level of 39% (see Fig. 2). The trend is transferred to the post-forecast period, so the change in value (Δ) for models (2) and (5) is also taken at the level of 39%.

The results obtained are compared with the average values aligning them with the actual value of a number of dynamic office real estate for the analysed period 2012-2018 years (see Fig. 2).

Fig. 2: The influence of the chosen modelling technique for calculating the reversal capitalisation ratio on the object value

Dynamic range based on market data for the indicated period with the application of the value of the object as of the estimated valuation date 2012 and the value of reversion, obtained by model techniques for 2018 is smoothed by a linear trend. The equation of this trend is shown in Figure 2.

Analysis of the current situation and the above calculations allow to conclude that with a 95% probability the market value of the object at the valuation date is in the range of 72,000–108,000 roubles per sq. m. Value of the object obtained by the DCF method using the formula (7) is inside confidence interval. Comparable results were obtained by the DCF method, where the capitalisation ratio for reversion was determined according to the Ring's model (5) and the "forecast" model using the operating expenses ratio and the market multiplier (8). Other reversion models led to an underestimation of the value and falling out of the confidence interval of the estimated value. It should be noted that in this paper the derived market trends for the rental rate were used for modelling the net operating income, while the losses, underload and operating expenses were given by market average coefficients. More accurate results would have been obtained by collecting retro statistics and forecasting changes for each item of operating expenses.

Conclusion

The results of this research show that the ready model (1) has been obtained from the above analysis. This model allows to predict the possible capitalisation ratio value with probability of 95% and to use it further for management purposes.

The calculations presented in this paper suggest that today due to the lack of stable prerequisites for long-term forecasting and stagnation in the rental market of the real estate it is illogical to use

Inwood's model (3), Hoskold's model (4) and Gordon's model (6) to calculate the reversion value in the method of discounted cash flows. The use of the Ellwood's model (2) for calculating the reversion allows obtaining objects value comparable to the lower limit of the confidence interval.

The coincidence of the estimated object value with the actual market data demonstrated following modelling techniques of the capitalisation ratio calculation for reversion:

- The "forecast" using the operating expenses ratio and market multiplier (1);
- Ring's model (5).

The analysis allows to recommend to appraisers using the model (7) at the income approach without defining reversion focusing on the justification of the market changes of the object value (Δ) over the forecast period.

Abstract

In modern conditions, enterprises even in traditional industries are faced with the need to maintain competitiveness based on the use of information technologies not only in the processes of organizing economic activities, but also with the need to transform the entire business model. This determines the real topicality of developing an indicator reflecting the company's readiness for a digital transformation. The authors propose a definition of the term "digital potential" and an approach to quantifying the digital potential of an industrial enterprise as an integrated indicator that allows assessing the resources and capabilities of the enterprise to transform business processes, taking into account the action of environmental factors in the process of digitization of the economy. The integrated indicator includes two groups of characteristics that reflect the state of the external and internal business environment of the enterprise. The list of indicators is proposed. All indicators can be quantified from the company's official reports. The article offers a formula for determining the integral indicator of the digital potential as a convolution of separate indicators. The proposed approach allows us to analyze not only the current level of digitalization of business processes in the enterprise, but also the possibilities of increasing the digital potential.

Keywords: Digital Transformation, Digital Potential, Industrial Enterprise, Assessment Method

Introduction

The competitiveness of modern industrial enterprises is mostly defined by the level of digitalization of all business processes. Moreover, the concept of Industry 4.0 (www.plattform-i40.de, 2020) implies not only an end-to-end digital transformation of all stages of product value creation, but also further integration of the enterprise's digital environment together with contractors participating in the value chain into a single "digital ecosystem". Results of the researches show that the development of digital technologies requires the transformation of the business model even in traditional industries (Andal-Ancion et al 2003). Thus, an industrial enterprise aimed at successful activity in the long term is forced to restructure its activities in all areas, including the processes of development and promotion of the company's products, the production process itself, the procurement process, logistics, and management accounting. The result may be an additional economic effect from increasing the effectiveness of interaction with stakeholders.

Adaptation of the company to the emerging new conditions and requirements of economic activity requires the selection of indicators allowing to evaluate the effectiveness of activities. This assessment can take place in two ways, each of which has its own advantages and disadvantages:

- the formation of a balanced system of indicators (BSC) that allows you to collectively analyze the results achieved (Kaplan and Norton, 2004);
- defining an integrated indicator that can be used as a digital potential of economic system (region, enterprise, corporation, etc.).

The issues of building BSC of various economic systems are widely and in detail discussed by the scientific community, including the inclusion of indicators that reflect the level of their digitalization (Kozlov et al, 2016) .The concept of "digital potential" and methods of its definition in relation to economic systems attract much less attention of researchers at the present time. Therefore, the problem of determining the digital potential as an integral indicator that allows you to assess the ability of an enterprise to transform business processes in the digitization of the economy becomes relevant. The digital potential of an enterprise is a relatively new concept for both Russian and foreign scientific society. Until now, scientists ' interest has focused on the concept of "Innovative potential", for example, publications Erygin Y.V. et al, (2019) and Kalenov O. et al (2019). This is partly due to the fact that the concept of "digital economy" was introduced into scientific circulation relatively recently, at the end of the 20th century (Negroponte, N. 1995). The problems of company digitalization are relevant in various industries (Maydanova et al, 2019; Zaychenko et al, 2018).

The information and innovation potential of an enterprise is not a substitute for digital potential. Information potential characterizes the processes of information interaction in the enterprise, not fully taking into account one of the important factors that is noted in all methods - the qualification of employees of the enterprise. In addition, digitalization involves not only the introduction of information technologies in management processes, but also changing the business development strategy. Innovation potential involves evaluating the company's ability to implement innovations, including those that are not related to the digitization of business processes. It means the digital potential is an indicator that reflects the new challenges and opportunities that have appeared in the company in the conditions of intensive digitalization of business processes.

Thus, the article goal is to improve methodology of the digital potential of industrial enterprise valuing.

There are definite tasks to be done to achieve the goal.

1. To develop the advanced approach to formulation of the term “digital potential of industrial enterprise”.
2. To propose the method for the digital potential of industrial enterprise calculation based on the performance indicators of that specific type of enterprises.
3. To identify the industrial enterprise performance indicators presented in official reports
4. To propose the formula for the digital potential of industrial enterprise calculation.
5. To verify the workability of the formula for the digital potential of industrial enterprise calculation

Literature Review

The term “digital potential” is used in the scientific literature, but it is not defined clearly enough and is interpreted in two senses. The most common approach is to define the concept of "digital potential" as a characteristic of the capabilities of economic systems to use digital technologies, and it is used to describe the situation with the use of digital technologies in regional markets and territories (Tsukerman et al, 2017) or industries, i.e. chemical (Porter et al, 2016), or agricultural (Fabregas et al, 2019). The most advanced approaches are developed for valuating of the level of development of digital technologies in individual countries. To assess the readiness of individual countries ' economies for digital transformation, a number of indicators (indexes) are used to assess the level of development of digital technologies in individual countries. The most relevant ones are:

- Networked Readiness Index (NRI), published since 2002 by the world economic forum and INSEAD international business school (Baller, S. et al, 2016).
- ICT Development Index (IDI), proposed by the International Telecommunication Union (ITU) in 2007. The index is calculated based on 11 indicators grouped into 3 large groups: access, usage, and skills (www.itu.int).
- Information Society Index (ISI) calculated by World Times and IDC (international data Corporation), describes the level of development of information technologies and availability of

information in individual countries (https://www.idc.com). The index is calculated based on 15 indicators grouped into 4 groups: computers; telecommunications; Internet; social development.

There are also known methods for evaluating the potential of business digitalization in various industries. The most interesting indicator is the Industry Digitalization Index (IDI), proposed by McKinsey & Company, which allows us to assess changes in the field of digitalization of individual industries, digitization of processes of general business activity. The index includes the list of indicators grouped into 4 groups: input, processing, output, and underlying infrastructure (strategyand.pwc.com, 2020).

Among Russian studies in this area, we highlight the rating of readiness of industries for the digital economy (Popov and Semyachkov, 2017). The rating assumes the calculation of 22 indicators that are combined into 3 sub-indices: equipment availability; software; human resources potential of industries. The overall rating is defined as the weighted average of the three sub-indices.

The method fully corresponds to the authors 'interpretation of the concept of "digital potential of the enterprise", given above, i.e. it takes into account only resources, but not opportunities.
Note that the considered indicators differ significantly in the structure and number of their components (both quantitative and qualitative), as well as in the calculation method. They provide an opportunity to analyze cross-country, regional, or cross-industry digital development. However, despite the completeness of the presented approaches and their testing in determining the digital potential of industries and other economic systems, they cannot be fully used to assess the digital potential of an individual enterprise, because, firstly, they do not take into account the specifics of the individual enterprise, as well as its ability to implement and apply information technologies.

Secondly, it is not possible to determine the potential as the level of development of digital and information and communication technologies, and in this sense, the digital potential indicator can serve as a tool for managing the innovative development of an enterprise.

In relation to an enterprise, the concept of digital potential in the first sense is used to describe the possibility of building a more effective information management system by expanding the use of computer programs, improving the information literacy of personnel (Granado, Romero and Rodríguez, 2015) or introducing digital technologies into the production process (Scrimshaw, 2009). The authors Popov E.V., Semyachkov K.A. and Moskalenko J.A. (2019) proposed the method of digital potential of enterprise assessment based on two indices , namely the Networked Readiness Index and the global ICT Development Index for mini-economic level of management. Kozlov A. and Teslya A. (2019) present the approach and the method of digital potential of industrial enterprise calculation as an integrated indicator. The method is based on including of te two groups of characteristics reflecting the state of the external and internal business environment of the enterprise. The authors figured the characteristics of the external and internal environment out. However the study doesn't propose the justified formula for integrated indicator calculation, presenting some options for the readers.

Results

The idea of taking into account two groups of indicators for calculating of the digital potential of an enterprise reflecting internal and external factors seems the most justified. However the factors of the first group are not homogenous. It is reasonable to distinguish firstly, factors and corresponding indicators characterizing the company's current resources, secondly, the factors and corresponding indicators characterizing the capabilities of an enterprise to implement digital technologies.

All this allows us to identify the main groups of indicators that can be used to assess the digital potential of the enterprise.

1. The state of a business environment.
1.1 A group of indicators that reflect the industry's objective readiness to form a digital economy.

An integral indicator, such as McKinsey & Company, can be used here, or a Rating of industry readiness for the digital economy that takes into account Russian specifics.

1.2 Indicators taking into account the readiness of specific key stakeholders of the company to interact when implementing digital technologies.
This section may contain indicators that reflect the readiness of resource and service providers to use new digital technologies, and their readiness to interact in new conditions. You can also add indicators that take into account the ability of the company to find new suppliers and contractors in the absence of readiness for interaction.

1.3 The indicators reflecting the goodwill of consumers of the company's products when using the interaction options offered by digital technologies.
Indicators should reflect the level of digital literacy of consumers, their skills in using digital technologies, their loyalty to changes, and the ability to form feedback in order to adapt products for specific consumers and ability of interaction of the enterprise with new groups of consumers.

1.4. State activity.
The state can influence the growth rate of digitalization of the industry. For example, the high level of digital potential in the field of education in the Russian Federation is largely due to the purposeful actions of the state that encourage educational institutions to introduce digital technologies in the organization of the educational process. This section may contain indicators that reflect the level of state activity in the field of lawmaking to enhance the digitalization of the industry, as well as the possibility of obtaining additional funding for the development and implementation of new technologies.

Indicators of the internal environment of the enterprise

2.1 The indicators reflecting the company's current resources
2.1.1 Indicators of enterprise ICT security.
There can be indicators that reflect the cost of it assets of the enterprise (computers, servers), the share of expenses for ICT equipment in the total expenses of the enterprise.

2.1.2 Indicators of information technology security of the enterprise (indicators that characterize the cost of software in the enterprise, as well as the share of total expenses for software or IT services.

2.1.3 The indicators reflecting reflect the level of use of digital technologies in various areas of internal activity of the enterprise (when planning, organizing accounting, organizing interaction of departments for large companies, when organizing the production process).

2.1.4 Indicators that reflect the level of use of digital technologies in the organization of interaction with stakeholders (when organizing purchases, conducting calculations, etc.).

2.1.5 The indicators reflecting the level of use of digital technologies for interaction with consumers (share of online sales in total revenue of the enterprise, the process of the feedback with consumers through social networks and other services, the level of use of information for marketing).
2.1.6 The indicators reflecting the level of digitalization of labor activity. For example, the share of employees employed in the field of information technology (programmers, developers) engaged in the analysis of information obtained through the use of IT technologies in the enterprise, the share of employees who use IT technologies in performing their functions, the share of costs for IT technologies and ICT equipment per employee.

2.1.7 The indicators reflecting the financial stability of the company (indicators of financial stability and liquidity of the company's assets).

2.2 The indicators reflecting the capabilities of an enterprise to implement digital technologies.

2.2.1 Indicators of the possibility of implementing information technologies in the company's activities. This section may include indicators that characterize the share of new information programs and equipment implemented by the company's employees during the reporting period.

2.2.2 The indicators reflecting the possibilities of creating your own information technologies. This section may include indicators that characterize the share of new information systems created or modified by the enterprise. As well as indicators reflecting the integration of information technologies with systems already used.

2.2.3 The indicators reflecting the possibilities of promoting information technologies for interaction with stakeholders. This section may include indicators that characterize the number of information technologies implemented when interacting with suppliers, contractors, and consumers. As well as the company's ability to further support the technologies used.

2.2.4 The indicators reflecting the readiness of the company's staff to further implement digital technologies in the enterprise. Indicators in this section may reflect the ability of the company's staff to train or the ability to attract new staff with the required level of digital competences development, as well as indicators of the staff's ability to ensure information security of the company's activities.

2.2.5 The indicators reflecting the financial capabilities of the company. Here it is advisable to present indicators that reflect the growth rate of key performance indicators (profit, revenue, etc.) depending on the industry, as well as the company's ability to attract external financial resources.
Thus, section 2.1 is represented by stock indicators that are determined at the time of evaluating the enterprise's digital potential. Indicators in section 2.2 are flow indicators that can be determined based on the company's current reporting and development plans. Indicators can be supplemented for each individual enterprise, taking into account the specifics of the industry, the specific conditions of the enterprise. A different set of indicators for assessing the digital potential of individual enterprises in different industries is not a problem, since it is not about comparing the performance of individual enterprises, but about the dynamics of the development of an individual enterprise.

The digital potential of the enterprise, formed according to the proposed method, reflects various aspects of the enterprise's activity and requires taking into account various indicators that have different dimensions. To obtain a single integral indicator, they must be brought to a single scale of measurement, which can be achieved by normalizing.

Since the significance of each group of indicators in the development of the enterprise's digital potential may differ significantly, it is necessary to take into account the priority (weight) of indicators. Coefficients of importance of criteria can be obtained using formal procedures or using expert assessments. The digital potential (*DP*) using the additive approach can be calculated as

$$DP = \alpha \sum_1^{n_1} {P_{1i}}/{n_1} + \beta \sum_1^{n_2} {P_{2i}}/{n_2} + \gamma \sum_1^{n_3} {P_{3i}}/{n_3} \quad ,$$

where: P_{ji} - the normalized values of individual indicator *i* of the group *j* (*j*=1, 2, 3);
n_j – the number of indicators of the group j;
α , β, γ - coefficients of the significance (weight) of the 1st , 2nd and 3rd group of indicators, correspondingly.
Within each group, indicators can be taken equal or ranked based on their significance.

Some other more complicated models, such as the parametric entropy method, the Saati method, and the principal component method, can also be used to obtain a numerical assessment of the integral indicator - the digital potential. In this case, the absolute value of the obtained indicator is not significant. However, the calculation of the digital potential over several periods will allow you to track the dynamics of changes in the level of use of digital technologies in the enterprise, as well as the effectiveness and expediency of the activities carried out. It is possible to perform a numerical assessment using several methods to confirm the reliability of the changes obtained based on the results of the activities carried out.

Conclusions

The further development of the digital economy will affect all aspects of the company's activity, its competitiveness, and relationships with suppliers, contractors, and consumers. The readiness of the enterprise to accept new transformational changes requires not the introduction of information technologies in the organization of economic activity of the enterprise, but changes in the entire business model. This, in turn, requires the formation of a criterion that allows you to track these changes, as well as evaluate their feasibility. This indicator can be the digital potential of the enterprise.

The proposed approach to assessing the digital potential allows the top managers to analyze not only the current level of digitalization of business processes in the enterprise, but also the possibilities of increasing the digital potential. The proposed approach took into account different levels of readiness of economic sectors to use digital technologies when including indicators that reflect the degree of benevolence of the external environment of the enterprise to digital changes, as well as their demand by external stakeholders of the enterprise. Thus, the authors included indicators that reflect the industry's readiness to form a digital environment, indicators taking into account the readiness of specific key stakeholders of the enterprise to interact, characteristics of the level of goodwill of consumers of the company's products when using the interaction options offered by digital technologies, as well as the degree of state support for digitalization processes in this industry. The indicators of the internal environment include two groups of characteristics that reflect, first, the resources of the enterprise at the moment, and secondly, indicators that reflect the future capabilities of the enterprise to implement digital technologies, in particular, indicators of the possibility of introducing information technologies in the enterprise's activities, that is, indicators that characterize the share of new information programs and equipment introduced by employees of the enterprise during the reporting period, further indicators that reflect the possibility of creating their own information technologies, promotion of information technologies for interaction with stakeholders, readiness of the company's personnel for further implementation of digital technologies in the enterprise and indicators that reflect the financial capabilities of the enterprise. A formula for determining the integral indicator of the digital potential as a convolution of separate indicators is presented.

In the future, the study will be aimed at adapting the proposed methodology for enterprises of individual industries or regions. Indicators that form separate groups can be updated or changed; workability of the methods is to be proved. The article does not regard the issues of forming a strategy for managing the development of the enterprise's digital potential, which may be a separate area for further research.

Abstract

The goal of the study is figuring out the perceptions and approaches of the Russian universities' students regarding the preferable channels of communication with their teachers in study process: based on modern digital technologies or face to face direct communications and tracing the dynamics of these perceptions and approaches in the period of 2017-2019. The target group of the study is students of Peter the Great St. Petersburg Polytechnic University. For the comparative analysis were used results of the previous researches conducted in Murmansk region and Krasnodar Territory of the Russian Federation. The questionnaire developed for interviewing consists of 4 sections and 21 questions and was presented in hard copies and in on-line version in Google Forms. The total number of respondents was 243 students of Peter the Great St. Petersburg Polytechnic University (276 in the year 2017 and 67 in the year 2019. The study reveals the positive dynamics in use of the modern educational platforms and electronic databases by the students. The main influencing factor is recommendations of their teachers. However, the research discovers the fact that an essential part of students can be described as rather conservative creatures in their approach to usage of e-learning, information and digital technologies in studying. The percentage of these conservators can be valuated as app. 30-35 % of the whole sample. Finally the authors indicate the study limitations and directions of the future investigations.

Keywords: University Students, Communication Channels, Information And Communication Technologies In Education, Digital Learning

Introduction

The prosperity of human society, the effectiveness and productivity of workforce in the digital future depends on quality of education provided by modern universities (Ilin et al, 2016). The key subject of educational process in universities is a teacher. The ability of the university teachers to communicate with students sharing their knowledge and developing skills is a crucial factor for successful educational process and formation of necessary competences of universities' graduates. The new channels of communication between teachers and students presented by modern information and communication technologies (ICT) give opportunities for both actors of an educational process to choose the most appropriate tools of communication. This situation generates the raw of questions which are as follows.

- What are the students' perceptions and preferences in using of communication channels with their teachers?
- What are the most comfortable and attractive from students' point of view tools for bridging students and teachers?
- In what extend modern information and communication technologies are able to replace traditional lectures, seminars and practical class exercises?
- Do the students prefer face to face classroom sessions or online ways of communication?
- What is the dynamics of the students' perceptions and preferences in using of communication channels with their teachers in the course of time (2017-2019)?

These questions are applicable to the most of the countries of the world. However the due to current social and economic problems in Russia, low level of economic growth (average +0,75% annual GDP growth for the last four years (and vital necessity of digital transformation of Russian economy the problem has a particular importance for the Russian Federation.

Thus, the goal of the article is figuring out the perceptions and approaches of the Russian universities' students regarding the preferable channels of communication with their teachers in study process: based on modern digital technologies or face to face direct communications and tracing the dynamics of these perceptions and approaches during the period of 2017-2019.

To achieve the goal the following tasks are to be realized.

1. Development of questionnaire focused on the identification of the perceptions and approaches of the Russian universities' students regarding the preferable channels of communication with their teachers
2. The determination of the target groups for interviewing (location, sample of respondents, etc.).
3. Organizing the interviewing process in university located in different regions of Russian Federation.
4. Analysis of the interviewing results, interpretation, and comparison of the results obtained in different regions.
5. Formulation of recommendations regarding the communications of Russian university students with their teachers.

Literature Review

The approach to education at Russian universities is changing; there is an ever closer relationship between universities and real business (Kankovskaya et al, 2018). The requirements for digital competencies of university graduates are growing at enterprises of various industries (Iljashenko et al, 2019; Zaychenko et al, 2019). The development of digital technologies has identified modern opportunities for universities to access to information sources and knowledge bases, including global best practices. One of the trends of modern Russian higher education has been the reduction of hours for face to face classroom sessions, which are to be replaced by distance education using ICT. Despite the fact that this trend is actively supported by the administration of universities, students are not always satisfied with the inability to use traditional formats of interaction with teachers, including: lectures, consultations, and practical classes since ICTs violate the traditional teaching methods. Undoubtedly, the technologies of knowledge sharing (KS) have become an important research area especially in the context of knowledge management (KM) (Salloum et al, 2016).

What communication channels do students prefer? According to a study Tan and McWilliam (2013), presenting the results of students interacting with digital technologies in an institutional school environment, new opportunities are more attractive for students who are internally focused on learning new things, acquiring qualitatively new skills. At the same time, students primarily focused on getting the right answer and an external positive assessment from the teacher, they are more likely to resist the use of new technologies.

The search for communication channels between students and lecturers is a new problem for Russian universities, so we will pay most attention to the analysis of foreign experience. Consider a study Santos et al (2019.) to find out for what tasks and situations students and teachers use ICT and also whether the expectations regarding the use of ICT for teachers and students coincide. A large-scale questionnaire survey covered 570 responses of students (and 172 responses from lecturers. It showed that communication through e-mail and collaborative technologies remain the preferred forms of interaction, while institutional support for the availability of communication tools is important. We also note that, despite the fact that expectations from the use of ICT are the same, lecturers more often recognize the presence of information and communication overload.

Researchers from both developed and developing countries, including such as United Kingdom, Turkey, Jordan (Al-Gamal et al, 2016), Malaysia (Yussiff et al, 2013), Nigeria (Omekwu et al, 2014), Australia (Romeo et al, 2012) share the experience of using ICT in education. Work on this topic is often based on targeted surveys of students. Many articles are devoted to the analysis of the positive experience of using social networks, including the study of a foreign language, as it allows you to stimulate interaction between students, communication in the target language (Baföz, 2016; Aydin, 2013).

A large number of articles are devoted to the role of social media in higher education (Tess, 2013), the possibilities and limitations (Al-Qaysi et al, 2018) of using social networks to improve interaction between students, as well as students and teachers. This trend is also observed in Russia, where professors turn to modern technologies to mediate and improve their learning, as well as to stimulate active student learning. Most students recognize the importance of social networks and their impact on their daily lives (Mahadi et al, 2016).

Ambika P. et al (2016) note that microblogging, implemented on Twitter and Facebook, is an important channel for students to interact. At universities, microblogging can be used as a back channel during lectures, creating the feeling of online learning on the forum. Facebook is one of the popular platforms, and a large number of studies are devoted to its role in the organization of training. (Habes et al, 2018; Roblyer et al, 2010). According to Roblyer et al (2010), students more likely than professors prefer to use Facebook and significantly more open to using Facebook and similar technologies to support classroom work. Professors have a predisposition to use more “traditional" technologies, such as email.

But positive reviews are not unambiguous. Selwyn N. (2009) examined the Facebook “wall” using in-depth qualitative analysis. More than 900 students were anonymously interviewed, the analysis of the records showed that the use of the application was mainly based on either retrospective criticism of the educational experience and events, the exchange of information about the teaching and assessment requirements, requests and moral support regarding assessment or training, etc. Thus, the use of Facebook seems more like a tool for solving everyday problems or conflicts in the learning process than a source of additional knowledge.

Conducted in Balakrishnan (2017), the analysis revealed six factors that affect intention to use social media for learning. These are: personality, information and communication technology facility, collectivism, communication functionality, effort / influence and performance). The impact of ICT facility and collectivism is negligible. The results also showed that, although their intention to use learning on social networks is the most important factor. Students do not actually use networks for learning unless they are encouraged or implemented policies that use social networks as part of teaching and learning.

The notable is the study of the prevalence of internet addiction (IA) and its association with psychological distress and coping strategies among university students in Jordan (Al-Gamal et al, 2016). The prevalence of Internet addiction was 40% among students, which is associated with a high level of student stress. The authors note that IA is a potential problem for this population.

Omekwu C.O., Eke H.N. and Odoh N.J. (2014) focused on the negative aspects of the use of social networks by students. According to the recommendations, universities should organize seminars to educate students about the negative aspects of using social networking sites as a means of interaction. Emphasis is placed on the importance of face-to-face communication, including at the workshops.

Thus, the problem of choosing forms of interaction between professors and students is relevant for universities in different countries. Despite the fact that the most of researchers have a positive attitude to the use of modern information and communication technologies, questions are raised about the limitations and negative consequences of their use, in particular social networks, in the learning process. Note that the work does not fully disclose the question of students' preferences when choosing one form or another of interaction with a lecturer in the process of studying a given course. And also, we are not talking about a complete rejection of direct face-to-face interaction and the transition only to distance learning.

Some differences in the work of researchers led to the conclusion that it is advisable to take into account country and regional specifics (which is relevant for such a large country as Russia, with high level of regional diversity). The foregoing makes the proposed study below relevant. Hence, the literature review confirmed the topicality of the study its goal of the article.

Methodology

This study is a continuation of the research started in spring of 2018 with students of Peter the Great St.Petersburg Polytechnic University as a target group. The first results were presented in the article (Kozlov et al, 2019a) with focus on the problems of the digital competences formation for Industry 4.0 workforce. The next phase of the study conducted in 2019 has covered more students of Peter the Great St.Petersburg Polytechnic University, students of the Murmansk Arctic State University (branch in the town of Apatity) and Kuban State Technological University Krasnodar and some other universities of Krasnodar Territory (Sothern Federal District of Russian Federation). All the studies are using the same research methods which are based on classical interviewing technology with survey developed and following analysis of the results. The analysis is based on usage of general qualitative scientific methods, such as comparative, content, and systemic analysis, and quantitative ones typical for empirical data analysis.

Thus, the study's process consists of the following steps.

1. Formulating of the purpose of the study.
2. Identification of the target groups, in our particular study, students of Peter the Great St. Petersburg Polytechnic University.
3. Adaptation of the survey to the study purpose.
4. Printing of hard copies for face to face interviewing and publishing the online version of the survey via Google Forms.
5. Interviewing of representatives of the target group using the combination of on line and face to face techniques. The total number of respondents was 243 students of Peter the Great St. Petersburg Polytechnic University (276 in the year 2017 and 67 in the year 2019).
6. Conducting the comparative analysis of the results obtained. Comparison with results of studies conducted earlier in Murmansk region, and Krasnodar Territory.
7. Formulation of conclusions and recommendations.

Results

The investigation was conducted at Peter the Great St. Petersburg Polytechnic University during three academic years among students of the Institute of Industrial Management, Economics and Trade. The sample design corresponds to the structure of the general set of students of the Institute of Industrial Management, Economics and Trade: 70% of them are students of the bachelor programs, 30% are studying at the master level. Gender distribution is as follows: 40% of interviewees are males, 60%

are females. The majority of respondents are citizens of the Russian Federation (68% in 2017, 80% in 2019), the rest are foreign students. The total number of respondents was 250.

The most important results of interviewing are the following.

In 2017 only 63% of respondents used educational platforms (EP) in the educational process, but in 2019 their share increased to 91% (Fig.1).

Fig.1: The use of educational platforms

The most popular educational platform is OpenEdu (43,2% in 2017, 62,69% in 2019) – the Russian educational platform that offers MOOC of leading Russian universities. Peter the Great St. Petersburg Polytechnic University is one of the leaders of open education in Russia with an active MOOC implementation strategy. Teachers actively participate in the development of MOOCs, actively use them in the educational process and popularize them among students. Coursera, whose share was only 5.81% in 2017, has 23.88% in 2019. The university's active policy to attract foreign teachers and integrate the university into international open education explains such a sharp increase. Studies Kozlov, (2019b) of digital competencies of students conducted in universities of the Murmansk region [1] and the Krasnodar Territory (Kozlov, 2019c) confirm the hypothesis about the impact of the university's strategy and the activity of teachers on student involvement in the use of educational platforms: in the case of the university's passive e-learning policy, the share of students using educational platforms does not exceed 55%.

The modern educational process presupposes the active use of databases. For the period 2017-2019 noticeable changes were found in the choice of databases. Google Books are the most popular for self-study. This fact can be explained by the opportunity to get acquainted with a large number of publications and choose the most relevant to their interests and research field (Fig.2).

Fig.2: The use of databases

Consultant Plus is a Russian legislative database, structured and updated daily. E-Library (the Scientific Electronic Library) is a bibliographic database of scientific publications in Russia. Students note the use of these databases for self-study; however, the choice of these bases is done by them due to previously received recommendations from teachers.

It should be noted that the competence of teachers in the use of foreign databases has grown for two years. They began to recommend them more often: for example, Scopus in 2017 was recommended by 13.46%, in 2019 - 44.78%. This led to a corresponding increase in student awareness from 3, 85% in 2017 to 17.91 in 2019. The situation with WoS is close to be the same.

For 3 years the same changes happened in the students' assessment of the teacher's role: 85% (the close percentage, 79% was in 2017) consider it necessary to have a personal communication with the lecturer for the performance of practical tasks and term papers; 34% in 2019 (for comparison – 43% in 2017) consider it necessary in lectures and only a few consider that a personal communication with the lecturer is not needed. The importance of face-to-face communication for students was confirmed by the highest valuation of this communication channel (3,2 from 5 in 2017 and 3,33 from 5 in 2019) among others (emails, messengers and social networks). Studies Kozlov et al (2019bc) show a similar percentage of those who need in contact with a teacher in practice, but the percentage of those who need it in lectures exceeds 50%. This decrease in the percentage of students who need teachers in a lecture may be associated with an increase in the opportunity to work with the material of lectures themselves in MOOC and other e-courses.

Fig.3: The use of social networks.

VK is the most popular social network in Russia, and the proportion of those who prefer communication in VK does not change - 52-56% of the total (Fig.3). The proportion of those who do not use social networks to communicate with teachers is practically unchanged at 24%.

Fig.4: The use of messengers

WhatsApp is the most popular messenger (nearby 46%), the proportion of those who do not use messengers decreased from 45% to 31% (Fig.4). Since students actively use instant messengers for personal purposes, we can explain this dynamic by the growth of digital competencies of teachers.

However, the research discovers the fact that an essential part of students can be described as rather conservative creatures in their approach to usage of e-learning, information and digital technologies in studying. The percentage of these conservators can be valuated as app. 30-35 % of the whole sample. They don't use modern tools in the educational process and prefer to communicate with teachers directly and use social networks at the first rate for private personal communication not for

educational purposes. They prefer to communicate with lecturers on the issues of study by e-mail or in person.

The study revealed, on the one hand, a very high conservativeness of students in the use of distance education, and on the other hand, a noticeable role of teachers in the formation of digital competencies of students. Russian universities, including SPbPU, are at the beginning of the y-e-education process, but an active policy and true goal-setting will allow them to proceed this way further.

The most important recommendation for increasing of students' involvement into usage of digital technologies in educational process is training, developing and motivating of university teachers in ICT, since teachers influence was distinguished as a really important stimulating factor.

Conclusions

Thus, the results of study revealed some dynamics in students' perceptions and approaches towards of ICT usage in educational process. For example only 63% of respondents used educational platforms (EP) in the educational process in 2017, but in 2019 their share increased to 91%. The main factor of this phenomena identified by the study is influence of university teachers and their recommendations regarding usage of some definite ICT tools. It confirmed the fact that the competence of teachers in the use of foreign databases, educational platforms and other digital tools has grown for two years essentially. They began to recommend them to their students more often.

Social networks are to be used by students for private communications mostly. The students are using social networks and messengers for communication with teachers, however they valuated these communication channels as not so appropriate (1,15-1,29 according 1, negative – 5, positive scale). The importance of face-to-face communication for students was confirmed by the highest valuation of this communication channel (3,2 from 5 in 2017 and 3,33 from 5 in 2019) among others (emails, messengers and social networks).

The presented in the article study and its results have some limitations. It is at the first rate the limitation of the study regarding dynamics of the students' perceptions and approaches since all the respondents are representatives of the same Peter the Great St. Petersburg Polytechnic University. Moreover the data covers the period of two years only. Secondly, the limitation is connected with the confined samples of the target groups for comparative study taken from Murmansk region and Krasnodar Territory while the Russian Federation consists of 85 federal regions.

The directions of the future research are defined by limitations mentioned above. It's firstly, the increasing of number of respondents through coverage of students of other universities located in other regions of Russian Federation, i.e. Siberia and Far East. It helps to receive more justified and substantiated results and conclusions. Moreover the continuation of the same study allows tracing a longer period of time for discovering of dynamics of the process.

The interesting direction of the future research may be comparative study of perception and approaches of students in different countries. It allows interpreting results taking into consideration cultural differences and peculiarities of national educational systems.

One more perspective direction of the future study may be research with focus at the other party of educational process, namely university teachers. What are their perceptions, preferences and approaches to ways of communications with their students? However the implementation of this idea needs in development of a new questionnaire and organizing the process of interviewing of teachers.

Implementing Electronic Health Records on Blockchain Based Architecture of Medical Organizations

Oksana Yu. ILIASHENKO, Igor V. Ilin and Darya S. TOPALSKAYA

Higher School of Business and Management, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russia, ioy120878@gmail.com

Abstract

Today, blockchain is one of the most promising technologies with great potential. The possibilities of the blockchain in the future are quite extensive and are able to solve a number of tasks facing a person in a modern rapidly developing society. This is especially relevant for the medical sector, which is faced primarily with the problems of Big Data managing, processing and security. The article is devoted to the review of changes in the IT architecture of the clinic in the interactions between the patient and the employee of a medical organization when introducing an electronic medical record based on blockchain technology. The article also provides a brief overview of the possibilities and challenges of using blockchain technology in documented medical support, as well as an overview of currently existing projects.

Keywords: blockchain-based architecture, electronic health records, medical organization, digital transformation.

1. Introduction

Our century was marked by the beginning of the transition of society to the era of digitalization. Such a transformation represents a transition from the traditional to the computerized industry, characterized by a more flexible personalized approach to each person, at the same time adapting to and forming a certain lifestyle of both the individual and the whole of humanity. This is made possible thanks to the rapid development of various technologies that provide wide and comprehensive access to information. At present, the success of any organization in the most significant way depends on the technologies used, primarily digital technologies. Blockchain technology is one of 9 cross-cutting strategic digital technologies for digital economy development in Russia. In this case, the choice of a technological solution is usually carried out in one of two ways: either a practical problem is formulated and a way to solve it is found, or the potential of already developed technologies is identified in solving current problems. It is the second path that is characteristic of blockchain technology. Created initially for decentralized generation of currencies, over the 10 years of its existence it has spread to many areas of activity: government, intellectual property protection, etc. Today we are talking about blockchain 3.0. If blockchain 1.0 is cryptocurrencies, 2.0 is smart contracts, then 3.0 are the most diverse applications. The use of this technology in the activities of medical organizations is seen as especially large-scale, since it is capable of solving the problems of document support of the industry at a new level.

At the moment, in medical organizations there is a wide variety of medical information systems, including the implementation of various modules: registry, admissions department, statistics, medical records, etc. The latter is one of the most important aspects of providing quality medical care. However, local MISs are not able to ensure the integrity of patient data due to the lack of integration of IP at the level of medical facilities and the possibility of malfunctions in the system or the introduction of corrections [1], [2]. Also, the confidentiality of data that is personal or constituting a medical secret is called into question. The emerging problems can be solved by a distributed database built on the basis of blockchain technology. A blockchain is a connected chain of blocks, each of which contains information about sequentially executed transactions. This information is decentralized and open, and the transmitted message is encrypted. Thus, a patient with a unique key can provide temporary access to his medical record to the attending physician, who, in turn, can get acquainted with the patient's entire medical history in chronological order, the results of tests ever done, heredity, etc. regardless of

the territorial location of the medical facility. Entered records cannot be changed or falsified. It is precisely such aspects of blockchain technology as reliability, transparency and decentralization that can improve the quality of services provided in the medical field.
In some countries, projects are already being implemented that develop the possibilities of applying this technology, including in medical documents.
In Russia, so far, only the conditions for the future transformation of the methods of organizing the healthcare sector and the provision of medical care using modern technologies within the framework of the state project "Digital Health" [3] are being created.

2. Methods

During the study, the following methods were applied:
1. Analysis. An analysis was made of the existing process of interaction with a medical record in a medical institution and identified changes in this process that could entail the introduction of blockchain technology. The article also analyzes the barriers that currently impede the widespread adoption of this technology in medical institutions.
2. The architectural approach. This method is the basis of the study. It is this approach that allows us to trace the relationship between business processes and IT architecture within a given enterprise. This is especially important in the context of rapidly developing technologies, which are able to find their application in the context of improving the business and ensuring competitive advantages. A feature of the architectural approach is the ability to consider business processes at the level of functions and organizational units, and the technological layer in the form of supporting applications, an interface, etc. Currently, there are four main approaches to the development of enterprise architecture, one of which is TOGAF, proposed in 1995 by the Open Group. Originally focusing on IT architecture, TOGAF now offers a wide range of models, standards, reference models and diagrams and is one of the most common framework in the world. In the research framework, TOGAF was chosen as a tool for building the architecture "AS IS" and "TO BE ", reflecting changes in the architecture of the medical institution with the introduction of electronic medical records based on blockchain technology [4].

3. Results and Discussion

Blockchain technology has become attractive to the healthcare industry due to its ability to ensure the safety of patient medical data. The issue of data security is one of the most important in this area, as every year the number of hacker attacks on medical data is growing [5]. The ability of the blockchain to maintain a decentralized, transparent journal of patient data, while at the same time ensuring their confidentiality thanks to sophisticated secure codes. The decentralized nature of the system allows the transfer of medical data between the patient and representatives of the healthcare sector. All this led to the idea of creating electronic medical records based on blockchain technology.

3.1. Overview of existing projects using blockchain to create EMC sphere

At the moment, there are not so many projects aimed at using the blockchain as a technology for storing and managing data in medicine. Conventionally, they can be divided into independent startups, which for the most part are applications that implement limited functionality and large-scale projects developed by large companies and / or the state. Below we will consider some significant projects that are currently being implemented or are being implemented.

eHealth

The program, launched in Estonia back in 2005, provided citizens with an electronic medical card, and after the conclusion of the government’s cooperation with Simply Vital HealthInc, a recognized technology leader and operating applications based on blockchain technology. One of their developments is the Health Nexus blockchain protocol, which provides an exchange process between authorized users. In the future, it is also considered the possibility for patients to sell their medical data

to research institutes and other medical institutions [6]. Thus, this cooperation will allow in the future not only to protect the medical data of citizens, due to the transparency of updating and access to data, but also to create some platform for the sale of medical information. To date, the eHealth system is the most global project in which blockchain technology is being introduced to protect patients' medical records [7].

Medicalchain

In 2018, MedicalChain, a company developing blockchain-based solutions, began to collaborate with a large American clinic Mayo Clinic to implement a number of projects based on this technology. One of them is the creation of a decentralized patient data distribution system. The blockchain solution involves the use of Ethereum and Hyperledger structures that provide multi-level data access and transactions.
The software will be able to work via the Internet on various platforms, and will also become a platform for its own services such as telemedicine [8].

Longenesis

In 2019, several South Korean medical centers entered into a partnership with Longenesis, providing modular blockchain-based solutions. The main required functionality is the ability to obtain patient consent for medical intervention, as well as the ability of pharmaceutical companies and research institutes to request patient data or invite them to participate in research, tests [9].

MediBond

The system was created with the aim of changing the traditional interaction between medical institutions, insurance and patients by creating a secure encrypted data stream. Also, in this project, the involvement of the neural network, which analyzes patient data and provides medical personnel with more accurate information for diagnosing and determining treatment methods, is noteworthy [10].

In Russia, in 2017, a decree was signed on digitalization of the healthcare sector and the transition to electronic medical records based on blockchain. By 2020, only 4% of medical facilities switched to electronic medical records due to various barriers. Thus, we can judge the impossibility at the moment of using blockchain in this area at the global level.

3.2. Medical Organization Architecture Model

The introduction of any new technology requires changes at various levels of enterprise architecture. The introduction of blockchain technology for the transfer and storage of medical data of patients in the form of electronic cards also requires transformations both at the IT level and at the business layer. At the moment, there is a blockchain based architecture model, which is used as a reference for Western realities and reflects the features of the use of blockchain technology in E-health [11]. However, now such a model is not applicable in the framework of Russian healthcare due to the specifics of Russian legislation, the level of digitalization and technological capabilities. Prior to the possibility of implementing the reference model, intermediate steps, such architectural models that will work in the Russian healthcare sector, will be needed. Consideration of such a possible model is made further.
To depict the situation of “AS-IS”, a city polyclinic was analyzed, which has information systems that allow you to create and use electronic medical records and built a model using the TOGAF methodology. Below Figure 1 shows simplified model of IT-architecture. Bbusiness layer that reflects the main stages of the interaction between the patient and the staff of the medical institution. The application layer provides the functionality displayed on the business layer. Here are indicated the implemented services based on two integrated information systems ArchiMed + and 1C: ECM. The technical layer displays the servers and databases that ensure the operation of the earlier systems.

Figure 1 – Architecture AS-IS

The TO-BE architectural model is significantly different from the previous model, although it considers the same processes of circulation, primary and secondary circulation, and clinical research (Figure 2). An application built on blockchain technology will simplify a number of processes by reducing the number of unnecessary actions. An application based on blockchain technology allows the patient to register for an appointment through their personal account, after coordinating the time, the patient receives an electronic coupon. Further, when visiting a doctor, the patient provides access to his electronic medical record through the use of a unique cryptographic key as a confirmation of data transfer; for his part, the doctor also uses a cryptographic key to confirm the transfer. Access is provided for a certain period of time for the doctor to make the necessary entries. It is also possible to provide access only to certain parts of the medical data necessary in a particular case for examination and diagnosis. The entries are stored on distributed servers using blockchain technology, so they cannot be

changed or deleted [12]. When you visit again, the algorithm repeats, while the doctor can also write out electronic sick leave, certificates, etc. Thus, the patient's data remains protected, and a single database is created containing the entire patient's medical history, which can be presented to any medical institution at the request of the patient.

When conducting clinical trials, access to a medical electronic chart is also requested, which includes the doctor's opinion and referral for tests, and the test results are also entered there. Also, as part of expanding the capabilities of the interaction platform between medical institutions and patients, it is possible to sell personal medical data to research institutes.

However, such a system requires access to the Internet and appropriate software that supports the work required by the service for all participants in this process.

Figure 2– Architecture TO-BE

3.3. Blockchain-based electronical medical cards barriers

At the moment, the technology is still far from the possibilities of its widespread use in connection with a certain number of barriers that can be divided into the following areas [13]:
1. Technical and economic
Creating a global scalable system will require a large investment in hardware. Also, the introduction of a new technology will lead to the need for reengineering business processes at the level of all medical institutions included in a single system, which is a laborious and lengthy process. Moreover, the lack of experience in introducing the technology itself in this area raises a number of questions regarding its application, namely the issue of data protection, in connection with the possible leakage of information or their interception, key management problems in a patient incapacity situation, etc.
2. Social
In connection with the relative "youth" of this technology, society treats it with distrust, associating it with illegal activities. Also, the introduction of a blockchain-based system will require the adaptation of users: both patients and employees of medical institutions and insurance organizations.
3. Legal
At present, a structural legal approach has not yet been developed with respect to blockchain technology, there are no prescribed rules defining the parameters of records in the blockchain, and the question remains of the legal significance of blockchain records, which is critical in connection with the legal responsibility of doctors for the patient's life.

3.4. Steps to Overcome Barriers

From innovation to its widespread adoption lies a long way. The transition to the use of electronic medical records based on blockchain technology requires the implementation of large, working private projects that can prove themselves and fully show their advantages and disadvantages using private clinics as an example. Further, investments and stimulation by the state are necessary, first of all, to provide technical capabilities for digitalization of processes in medical institutions at all levels and to carry out comprehensive reengineering of processes at all levels of the healthcare sector, as well as training necessary specialists in the IT field and advanced training of health workers with the aim of their familiarization and training on the use of new platforms. Moreover, it will be necessary to develop a motivation system to attract and adapt citizens to the new system. Equally important is the consolidation of the legal status of this technology. All this requires the development of detailed and long-term government programs that can gradually make the transition from complex architectural solutions with the integration of various systems or paperwork to a laconic unified healthcare system, where the patient is an equal participant in the system like insurance companies, medical institutions, research institutions.

4. Conclusion

1. A review of significant existing projects for the application of blockchain technology in healthcare was carried out, as well as barriers to the development of this technology on a global scale were identified and actions to overcome them were proposed.
2. The process of interaction between the patient and the medical institution on the platform using blockchain technology to protect the personal medical data of patients was considered. To do this, IT architecture models were developed according to the TOGAF methodology, reflecting the transformation into the business, service and technological layer in connection with the introduction of electronic medical records based on the blockchain.

Abstract

The paper is based on a project of an information system security audit for a service company when identifying existing threats to information security. Assessments of the information system's compliance with information security standards are given. The company's activities were analyzed, the necessary information was collected for conducting a security audit of the information system, and the data obtained was analyzed. Recommendations were developed to reduce the risks of information security threats. Implementation of the developed countermeasures to eliminate information security vulnerabilities will help the company reduce the risks of information security threats to protect important data stored in the information system, as well as to prevent possible financial losses and damage to the company's reputation.

Keywords: Digital transformation, the security of information systems, project, business process.

Introduction

Currently, information systems play a key role in ensuring the efficiency of the enterprises, especially those who has chosen the path of digital transformation. The widespread use of information systems for storing, processing and transmitting information makes the problems of their protection urgent, especially taking into account the global trend towards an increase in the number of information attacks, which lead to significant financial and reputational losses (Amirova et al., 2019). To effectively protect against attacks, companies need an objective assessment of the security level of the information system, especially in view of ongoing digital transformation (Dubgorn et al., 2019). This is exactly what security audits are used for.

Currently, there is no single standard for organizing and conducting an information system security audit. Drawing up an audit plan is not a trivial task, since it requires the auditor to have experience in the methods of building such plans, and also depends on the objectives of the audit and the characteristics of the information system being examined.

For a company (for example, a medical organization), it is necessary to identify existing vulnerabilities and possible security threats against information system resources, as well as suggest appropriate countermeasures to improve the current level of information system security.

To achieve this goal, you need to solve the following tasks (Bolsunovskaya et al., 2019):

1. Collect all necessary information about the company, the information system used, important business processes, and the current information security system.

2. Analyze the existing types of information systems audit, the methods used to identify threats and countermeasures. Compare them and choose the most suitable ones.
3. conduct a security audit of the company's information system, taking into account the selected methods. Identify and analyze existing threats to information security.
4. Develop recommendations to eliminate existing threats to information security for the company.

The security audit of the company's information assets allows you to get an idea of the security status of the infrastructure and information security management processes. Information security audit is a test of the ability to successfully resist threats to information security.

Conducting an independent audit allows you to identify threats to information security in a timely manner and objectively assess the compliance of parameters that characterize the information security regime with the required level.

There are a number of treats to information security:

1. This can be a privacy risk (unauthorized access to information). In this case, the information becomes known to someone who does not have access rights to this information.
2. Threats of illegal data changes. They are related to the probability of changing the information stored in the information system. This can be, for example, deliberate actions of personnel, equipment failure.

We can define 2 types of threats – natural (the impact of physical processes that do not depend on the human will) and artificial ones. Among the artificial threats, in turn, there are:

- Unintentional (accidental) threats — software and personnel errors, system failures, computer and communication equipment failures;
- Deliberate (deliberate) threats that are caused by the actions of people.

The carriers of threats to information security are the sources of threats. All sources of information security threats are divided into three main groups:

- Caused by the actions of the subject. These sources can be predicted and appropriate measures can be taken.
- Caused by technical means (technogenic sources).
- Natural sources. Such sources of threats are completely unpredictable and, therefore, measures against them should always be applied.

Let's look at the goals of conducting a security audit. These include:

- analysis of risks related to the possibility of security threats against information system resources;
- assessment of the current level of security of the information system;
- localization of bottlenecks in the information system security system;
- assessment of compliance of the information system with existing standards in the field of information security;
- development of recommendations for implementing new and improving the effectiveness of existing information system security mechanisms.

Justification of the need to conduct an information system security audit

The company uses a CRM system in its activities. Since the CRM system was recently implemented, it is necessary to analyze possible security threats to the information system.

Conducting a comprehensive information security audit includes:

- Research of the information system and business processes of the company (as objects of protection), analysis and construction of a model of interaction of components of information systems used in providing business processes of the organization;
- Determining the value and identifying the most important components and nodes of information systems to ensure the operation of business processes;
- Identification of requirements to the existing information security system, analysis of the structure, functions and features of the existing information security system in the company's automated system, analysis of settings of standard security tools, operating systems of servers and communication equipment;
- Conducting penetration tests for the company's information environment;
- Assessment of risks associated with the implementation of information security threats aimed at the most significant assets;
- Analysis of the existing information security system for the identified requirements and preparation of a conclusion.

Development of recommendations aimed at improving the current level of information security of the organization in accordance with the requirements and development of proposals to reduce information security risks.

In this paper, based on the task of auditing the security of information systems, was selected as a comprehensive audit, since it allows to obtain an integrated vision of security of the information system of the company and also combines the benefits of other types of audit, such as the basic requirements of information security has been taken from standards and additional was identified during the risk analysis it security, given the unique structure of the system and the point of view of the company's management on critical assets and threats.

Regardless of the type of audit used, in General, the information system security audit process consists of the following stages:

- initiating the audit procedure;
- collecting information for an audit;
- data analysis;
- making recommendations and preparing an audit report.

Based on the results of the analysis, at the last stage, recommendations are being developed to improve the level of protection of the information system from information security threats. Recommendations are determined by the approach used, the characteristics of the information system under review, the state of information security, and the level of detail used during the audit.

The company uses a CRM system, namely vTiger CRM-an open source customer relationship management system. The vTiger CRM system has been specially modified to meet the company's requirements and tasks.it has added modules, reports, and functions that are not provided in the standard system solution.

In order for each employee to have access only to the information that they need to perform their duties, roles are created in the information system (I. Ilin et al., 2018). For each role, the available modules and available actions with the records of these modules are set.

The main business processes of the company according to the company's management include the following business processes:

- selling a product to a customer;
- providing services to the client;

- make an appointment with a specialist for clients;
- purchase of consumables for professionals (Levina et al., 2018).

For the company to work effectively, it is necessary that data from the information system is available to employees who have access to it, so that this data is reliable, not distorted and confidential. For this purpose, it is necessary to ensure the security of the company's information system.

Research Methodology

In service-oriented architecture, an important role is played by the analysis of the architecture, which allows to Depending on the selected audit approach, different methods or approaches are used to identify threats and countermeasures. Here is a comparison in table 1.

Table 1: Comparison of the types of audit Criterion Type of audit Tools and methods of verification Result of checking

Criterion / Type of audit	Verification tools and methods	Result of the test	The ideal with which the result of the test is compared
Active audit	Conducting real attacks on the information system by experts using special software and special methods	It is aimed at identifying and fixing the vulnerabilities of the system's software and hardware	Set of known vulnerabilities in the software and the expected test result
Expert audit	Collection and analysis of information on IS, analysis of organizational and administrative documents and information flows of the enterprise	Identifying global errors in the corporate network topology, using security tools, identifying vulnerabilities of information system (I. V. Ilin, Iliashenko, et al., 2017)	Requirements of the company's management for protection, as well as the auditor's own experience
Audit of compliance with standards	Collection and analysis of information on IS and subsequent comparison with the description of the standard (Khudyakova & Shmidt, 2019)	The degree of compliance of the tested IS with the selected standards, as well as recommendations for bringing the security of the IS in accordance with standards	Abstract description of the state of information security which given in the standards
Complex audit	Depends on the set of procedures that will be implemented during this audit		

We will describe in more detail each of the approaches:

- The approach based on risk analysis. This approach uses risk analysis methods, and the auditor determines an individual set of security requirements for the information system.
- An approach based on the use of information security standards. As part of this approach, an information security standard is selected for compliance with which the information system will be checked.
- Combined approach (combining the first two approaches). The basic set of security requirements that apply to an information system is defined by the standard. Additional requirements that take

into account the specifics of the functioning of this information system are formed on the basis of risk analysis.

In this work, we used a combined approach of data analysis during the audit, because this approach is simpler than the first, because most of the requirements for information security are defined by the standard, but it does not have the disadvantages of the second approach, because the features of the information system are taken into account.

Results

Based on the information security standards, a basic set of requirements for the information system was identified. These requirements were divided into the following groups:

1. Physical access control and monitoring of premises;
2. Hardware information system;
3. Network support of the information system;
4. System software;
5. Application software;
6. Organizational support (I. V. Ilin et al., 2017; I. Ilin et al., 2019; Krasnov et al., 2019).

This approach is based on risk analysis methods and the chosen method for data analysis will affect the final result and its quality. When choosing a risk analysis method, it is necessary to take into account the features of the information system, the environment in which it operates, the applicability of this method to the information system under consideration, and other aspects (Zharova et al., 2019).

This approach is quite time-consuming and requires a high level of qualification from the auditor. In the course of using this method, an individual set of information system security requirements is identified.

Risk analysis is a study of the security of an information system, in order to determine the assets that are important to the company, from which threats it is necessary to protect them, if necessary. The development of adequate countermeasures to protect these assets takes place in the course of risk management. At the same time, you need to understand which resources need to be protected and which do not, and also take into account the fact that the cost of the information security system should not exceed the cost of the protected information (Schepinin & Bataev, 2019).

When conducting an audit, it is not enough to simply assess the risks; it is necessary to analyze the result and, if necessary, take appropriate measures to reduce them, for example.

During the risk assessment and analysis, the following steps are highlighted:

1. Defining the organization's key assets;
2. Analysis of which key assets need to be protected;
3. Forming a set of possible threats to information security and vulnerabilities that may cause these threats to occur;
4. Assessing the likelihood of realization of threats to security;
5. Evaluation of impact level with the involvement of employees (business units);
6. Calculation of risk (qualitatively or quantitatively);
7. Analysis of the results obtained.

Risk management is the next necessary step after the risk analysis, during which recommendations are made to eliminate risks, reduce them, or transfer them to third-party organizations (Maydanova & Ilin, 2018).

This can be:

- information resources that ensure the execution of business processes;
- system and application software;
- hardware (servers, workstations, active network equipment, etc.);
- premises where information is stored and processed;
- paper media;
- electronic information carriers.

At the same time, employees of the audited company help the auditor identify risks.

The importance or value of an asset is determined by the amount of damage that will be caused if the confidentiality, availability, or integrity of the asset is violated. Generally, the following types of damage are considered:

- Disclosure, deletion, modification, or unavailability of data;
- Damage or destruction of equipment;
- Violation of the integrity of the software.

It is also worth noting that the risk assessment can be performed:

- quality;
- quantitatively.

At the same time, most companies usually choose a qualitative risk assessment, since this is an easier way to assess risks. In this case, the damage levels from the implementation of the attack, as well as the level of probability of the threat of the attack itself, are also qualitatively evaluated. An example of a qualitative scale for assessing the level of damage (depending on the damage to the company's reputation and loss of tangible assets) (Chernikova et al., 2019).

Now let's look at ways to manage risks. The most common are:

- reducing the risk to the level acceptable by the company's management through the use of various technical and organizational means;
- accepting risk if it has an acceptable level;
- transfer of risk to a third-party company.

The most widely used methods of risk analysis are the following:

- CRAMM;
- RiskWatch
- FRAP;
- OCTAVE.

This list presents methods that perform qualitative, quantitative, and comprehensive risk assessment. It will also describe one method that is used only in the framework of internal audit.

Based on the analysis of existing risk analysis methods, FRAP was chosen because IT is suitable for external audit (as opposed to OCTAVE), and because it is based on a qualitative risk assessment (as opposed to RiskWatch and CRAMM), which is easier to use, and because in this case a qualitative risk assessment is sufficient.

Identify possible threats

Possible threats to information security for previously defined resources were identified by brainstorming the company's employees. As a result of the discussion, possible threats to each of the resources were identified. Let's look at them in more detail.

Possible threats to servers where information is stored and processed:

- malicious server damage or destruction;
- server failure due to technical reasons;
- destruction of the server by a natural disaster, such as fire.

Possible threats to the database where all the information necessary for the organization's operation is stored:

- unintentional modification or deletion of information from the database by company employees;
- leakage of confidential information as a result of copying information from a database using an external electronic medium.

Possible threats to electronic media that store copies of contracts and agreements with customers and suppliers:

- destruction or damage of electronic media by an attacker, resulting in data loss;
- destruction of electronic media due to fire.

To reduce the risk associated with the destruction of electronic media that stores copies of contracts and agreements with customers and suppliers, you can use the same information security tools as to protect servers from fire, but this is not mandatory, because the damage from the threat is estimated as low and most likely the cost of implementing protection will be higher than the damage caused.

The risk of destruction or damage to electronic media by an attacker, resulting in data loss, is low. The damage is also assessed as low, so there is no need to take any measures to manage this risk at this time.

Recommendations

After the audit of the company's information security, a list of recommendations was compiled:

- Recommended organizational level measures;
- Recommended measures of the software and technical level.

Organizational measures are administrative and procedural measures that regulate the functioning of the data processing system, the use of its resources, and the activities of service personnel. Organizational measures determine how users and service personnel interact with the system in such a way as to make it more difficult or impossible to implement security threats or reduce the amount of losses if they are implemented.

The recommended measures of the organizational level include:

- Regularly review the security policy when making changes to the company's system;
- Assign responsibility for ensuring the security of the company's valuable information resources;
- Include responsibility for ensuring information security in the job responsibilities of managers;
- Include in the job responsibilities of all employees the task of ensuring information security;
- The IT service checks the personnel being hired;
- Remind an employee of the company that they have signed an agreement to comply with the trade secret regime;
- Regularly send information about incidents and viruses to all employees of the company;
- Create a forum to discuss various issues related to information security;
- Conduct training on information security issues for all employees of the company every six months;
- When creating a company's information security system, you need to consider the option that the company's employees have sufficient knowledge to perform unauthorized access to information when they have the opportunity;
- Place the equipment in rooms that cannot be accessed by persons who are not connected with the maintenance of this room;
- In the event of a hard disk failure, call a representative of the supplier and inspect the damage in the presence of responsible representatives of the company;
- Update antivirus databases every day;
- As often as possible to keep track of new vulnerabilities in the software you use;
- Regularly monitor the integrity of critical data and the software that processes this data;
- Organizational and physical protection measures for backups must match the level of protection of the main storage media;
- Keep system event logs on computers with critical information;
- Update the software and install security update packages as often as possible;
- Document user rights that correspond to the business tasks assigned to them;
- Regularly check the adequacy of the rights assigned to the user;
- Conduct regular third-party security audits of the company, as well as penetration tests performed by independent experts
- Regularly use the vulnerability scanner to track changes in the security of the company's information system;
- Ensure that the company's information system meets any published security standard;
- Use only certified local and network security tools in the company;
- Exclude the presence of service personnel in the company's office without the presence of controlling persons;
- Develop a list of documents and recommendations on non-disclosure of confidential information by employees.

Conclusions and Discussions

To assess the course of the work, the following goals were achieved:

1. Collected and analyzed information about the company. Important business processes of the company include the processes of selling products to customers, providing services to customers. For effective operation of these business processes, up-to-date information from the information system is necessary, access to which should not be difficult for authorized persons. Also, the information must be securely protected from access by unauthorized persons. To ensure these requirements, it is necessary to conduct a security audit of the information system.
2. Possible types of information system security audits are analyzed. A review of methods for identifying threats and countermeasures is made: an approach based on risk analysis, an approach based on information security standards, and a combined approach. We selected a comprehensive audit with a combined approach to identifying threats and countermeasures. The ISO/IEC 27001 standard was chosen as the information security standard, which describes the requirements for information security. FRAP was chosen as the risk analysis method.
3. The company's information system security audit was conducted taking into account the selected procedure. Existing threats to information security were identified and analyzed. The most important of them are: overheating of important server elements due to the lack of air conditioning, as well as copying information to external removable media for further disclosure.
4. Developed recommendations to eliminate existing threats to information security for the company. The most important implementation recommendations are the purchase and installation of an air conditioning and fire alarm system in the server room, as well as the implementation of a DLP system designed to prevent leaks of confidential information outside the corporate network. In addition, the cost of all recommended information security measures for threats found was 183,000 rubles, which is included in the company's acceptable information security budget of 210,000 rubles. If these recommendations are implemented (organizational and software-technical), the security of the information system will increase, and the risks of threats found will decrease, which will allow the company to avoid financial and reputational losses in the future.

Acknowledgment

The reported study was funded by RSCF according to the research project № 19-18-00452.

Possibilities and Challenges of Leading BI Platforms Application in The Medical Sector Companies

Oksana Yu. ILIASHENKO, Victoriia M. ILIASHENKO and Alexandra D. Borremans

Higher School of Business and Management, Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russia, ioy120878@gmail.com

Abstract.

The article describes the existing BI systems that allow solving data analytics issues, making forecasts based on the analysis of the main KPI companies, and developing business process systems in a single information environment. The article provides an analysis of the market for BI platforms, a review of implemented analytical solutions in foreign and Russian companies in the medical sector. The article presents the system architectures of BI platforms, as well as their comparative characteristics. Models of healthcare solutions are presented using the Qlik platform as an example. The main research methods in the article are an overview of modern BI platforms with the further goal of analyzing the main advantages and disadvantages of each of them, and an architectural approach as well. The result of the study is the formed requirements for business platforms for the analysis of the main KPI of a medical company.

Keywords: BI-platforms, medical organizations, system architecture, key performance indicators.

1. Introduction

At the present stage of information-analytical systems development, companies, in particular medical organizations, have an urgent need to introduce modern BI-platforms for the analysis of key performance indicators of their activities. Analytical solutions allow you to perform data analysis in various sections in real time, build KPI systems for each of the company's departments, make a forecast based on current values of indicators. One of the main advantages of analytical platforms is the ability to aggregate data of various formats from various sources of information that characterize the work of the organization as a whole. Companies can build visual statistical and dynamic reports, graphs, charts, and other data visualization elements with business analysis systems. The basic component of business analysis technologies is the ability to analyze structured end data in a visual form to end users. This aspect is one of the main criteria for end users when working with analytical reporting systems.

The key advantages of implementing business analysis systems in enterprises are [1, 2]:

- the accuracy of the performance indicators values of the company in reporting systems;
- real-time data analysis and forecasting;
- support for the development of business processes and structural changes of the enterprise;
- ability to simulate various business situations in a single information environment;
- operational analysis of non-standard user requests;
- reducing the routine load on staff;
- increasing the amount of time for deeper analytical work;
- stable operation with a large amount of data entering the system.

In addition to the key advantages described above for using BI systems, in particular in the healthcare sector, it should be noted that the developed analytical system should combine information from various sources in its database, including remote regional medical systems, information systems at the level of a medical organization, various data sources in electronic format [3].

2. Methods

The research methods, which we use in this article are:

1. Analysis. It is the methodological basis of the study. The article analyzes the system architectures of BI platforms, as well as their comparative characteristics. Also, the article analyzed existing practices of using business analysis platforms in medical companies, Qlik Healthcare Solution Models. We use analysis for developing a system of indicators for assessing the performance of a medical organization
2. Architectural approach. This approach is a methodological basis for the designing of BI platform architecture model. The use of this approach is relevant in connection with the rapidly growing dependence of doing business with implemented IT support. It allows to make an alignment between the business and IT development strategies of medical companies. The architectural approach allows us to reflect in detail various elements such as business processes, functional and organizational structure, the level of information services and applications, as well as the technological layer [4, 5]. Moreover, this approach is flexible in relation to changes in the external and internal business environment. Using this approach, we formulate requirements for business platforms for the analysis of the main KPI of a medical company.

3. Results and Discussion

To formulate the requirements for the BI platform, we review the most popular BI systems, consider pactices of using business analysis platforms in medical companies, and compile performance indicators of medical companies that we plan to analyze using BI platforms.

3.1. Overview of system architectures for BI platforms

Consider the leading analytical reporting systems: QlikView / QlikSence, Tableau, PowerBI.

Solutions on the Qlik platform are the most popular in the Russian Federation in various fields of activity - financial, industrial, oil and gas. Medical companies are no exception. The QlikView platform is one of the most powerful tools for data visualization, which does not require additional installation of a set of software products at a high price, as with traditional BI solutions. QlikView system allows you to build business solutions based on a simple data architecture, the integrity of which stabilizes the work of all components of the Qlik platform. The main advantage of the platform is its customer focus. QlikView analytics is customizable, not the other way around.

Figure 1 shows the architecture of the QlikView platform. It includes three main blocks: QlikView Developer, QlikView Server, QlikView Publisher.

The QlikView Developer block includes tools for uploading, transforming, and loading data (ETL process), which allows you to perform complex operations on data to load it from various sources of information: BW, ERP databases, data marts, corporate portals, XML and Excel files.

The QlikView Server block is responsible for the integrity of the data, ensures the security of its storage, and allows updating data in all reports of the QlikView system.

The QlikPublisher block is a specialized tool for administering data for analytical applications that are available to the end user. The advantage of this unit is the ability to split access to applications by categories of user groups, as well as the ability to deliver analytical reports to personal emails in PDF format.

Figure 1 – Architecture of the QlikView platform (FB Consult. QlikView Architecture [Electronic resource], [6]).

The Tableau analytic platform is a fast and powerful data visualization tool that does not require training of business users and does not include costly implementation at the enterprise. The main advantage of the system is the ability to process data of any format together with a high speed of obtaining the result. Tableau is based on two main technologies [7]:

- VizQL (allows you to create high-level data visualizations);
- Data Engine (provides second analysis of a large number of rows).

Figure 2 shows the architecture of the Tableau interactive business intelligence system. It includes 5 main components:

- a data server that allows the Tableau system to connect to multiple data sources;
- data connector, which is an interface for connecting external data sources to the Tableau data server;
- Tableau server components;
- network gateway designed to send requests from users to Tableau components;
- platforms with which you can edit and view visualizations and dashboards on the Tableau server. The platforms are a web browser, mobile applications and a desktop version of Tableau.

Figure 2 – Architecture of the Tableau platform (Tableau Architecture [Electronic resource], [8]).

Microsoft's Power BI analytic platform is designed for business intelligence with the ability to connect a variety of data sources and third-party applications. One of the advantages of the Power BI platform is the ability to support many ways to import data (for example, cloud services, streaming data, Excel documents and external applications). The architecture of the Power BI platform is shown in Figure 3.

Figure 2 – Architecture of the Microsoft Power BI platform (Allison Fisher. How the Interns Hacked Power BI: A New Tool for Versatile Real- Time Dashboards [Electronic resource], [9]).

The Power BI architecture consists of three phases. The first two phases partially use ETL (extraction, transformation and loading) for data processing.

1. Data Integration. This phase includes the processing of data from various sources of information in order to further combine them into a standard format and save them in the intermediate area.
2. Data processing. The data processing phase includes the processing and purification of data, after which business rules are applied to them and they are converted into presentable data. Then the data is loaded into the data warehouse (CD).

3. Data presentation. The phase of data presentation is necessary for data visualization using various interface toolbars for visual presentation of reports.

3.2. Practices of using business analysis platforms in medical companies

The use of business analysis platforms as a tool for data analytics in medical companies is valuable in terms of studying clinical, financial and operational data. In turn, this helps to improve the quality of medical care and reduce costs. For example, the QlikView and QlikSence platforms allow hospitals to support three basic data types:

- clinical data;
- corporate data;
- transaction data.

In the United States, some medical organizations have up to fifty Qlik reports to visualize the necessary data. The main tasks that the Qlik platform helps hospitals cope with are:

- analysis of the use of operating rooms;
- quantitative analysis of ambulance calls;
- identification and elimination of bottlenecks;
- identification of clinical changes.

In the UK, one of the medical institutions using the analytical system helped to identify how an increase in the chamber load (by 1%) will increase the weekly income (up to $ 15,000). Also in the UK, a government order has been issued that says that it takes less than four hours to examine and treat each patient. Qlik shows how often a medical institution violates this decree. Moreover, the system gives an idea of the peak time when the largest number of patients enters the emergency department. Also, the visualization panel shows the number of patients that goes to the hospital.

Atlanta hospitals, including Children's Healthsouth Rehabilitation and Allina Health, use analytical systems to measure HCAHPS, CGCAHPS, outpatient quality assurance, and the number of potentially preventable rehospitalizations. Business intelligence systems offer users to see visualized information on patients, their age, attending physicians, time of arrival at a medical institution.

Table 1 presents models of healthcare solutions using the Qlik platform as an example.

Table 1. Decision models in healthcare based on the Qlik platform.

	Model of the solution	Functionality	Solution options
Value-Based Healthcare Delivery	Clincal Domain	Operating Room	The ability to make decisions throughout the entire operational process
		Emergency Department	Real-time operational management of ambulance processes
		Clinical Benchmarking	Comparison of large volumes of diverse data for making decisions about the choice of treatment methods for patients
	Healthcare Operations	Workforce Optimisation	Improving the efficiency of personnel management based on monitoring staff load
		Supply chain	Analysis of the results of the implementation of the end-to-end supply chain management process
	Corporate Domain	Financial Management	Compilation of comprehensive financial statements for various indicators
		Performance Visualization	Visualization of cross-system analysis of indicators on various aspects of the medical organization

3.3. Formation of a system of indicators for assessing the performance of a medical organization.

Some indicators are common to most medical organizations, others are specific to various health care profiles. Based on the analysis of the activities of large Russian medical centers, we identified the following general indicators that are important when evaluating the activities of a medical organization.

General indicators:

- berth turnover;
- implementation of the bed work plan for the period (%);
- average duration (median) of the patient's stay in the department (days)
- bed downtime (time between discharge and hospitalization per bed (in days);
- the number of complications by nosology (acute myocardial infarction, stroke, community-acquired pneumonia, femoral neck fracture, coronary artery bypass grafting, asthma, diabetes mellitus, etc.);
- the proportion of patients with complications in nosology (acute myocardial infarction, stroke, community-acquired pneumonia, femoral neck fracture, coronary artery bypass grafting, asthma, diabetes mellitus, etc.) (%);
- the proportion of patients with an unplanned return to the operating room (within 48, 72 hours) (%);
- the proportion of patients with an unplanned return to OARIT (within 48, 72 hours) (%);
- average waiting time (median) from the moment of diagnosis to the first nosology treatment (acute myocardial infarction, stroke, community-acquired pneumonia, femoral neck fracture, coronary artery bypass grafting, asthma, diabetes mellitus, etc.) (min.);
- the number of transfers to other departments;
- load of the doctor in the department (bed);
- result of hospitalization;
- frequency of re-hospitalization (%);
- hospital mortality by nosology (%) (acute myocardial infarction, stroke, community-acquired pneumonia, femoral neck fracture, coronary artery bypass grafting, asthma, diabetes mellitus, etc.);
- specific gravity of emergency hospitalization (%);
- the share of acquired hospital infections (by type);
- the number of discrepancies between clinical diagnoses and pathological anatomical.

We also give an example of specific indicators (depending on the profile):

- the number of patients with a certain type of nosology, for example, with arterial hypertension, having reached the target blood pressure level <= 140/90 mm per episode of inpatient treatment;
- the number of patients with a certain type of pathology who died on the first day of admission to the hospital;
- the number of discrepancies in diagnoses in pathological and forensic autopsies of patients with a certain type of pathology who died on the first day of admission to the hospital;
- 30-day hospital mortality with a certain type of pathology (%);
- hospital mortality in a certain pathology in patients of working age (%).

Monitoring the values of these indicators is important for assessing the performance of a medical organization. Using specialized software allows to reduce time costs and increase the efficiency and quality of work performed.

3.4. Development of requirements and design of BI solutions.

The development of requirements for a BI solution involves:

- analysis of the situation in the medical company. The introduction of the BI platform involves preliminary preparation. It is necessary to conduct an analysis of the business processes of the medical company, to determine the principles for making managerial decisions. These data will allow an analysis of the current situation in the company.

- development of requirements for a BI solution, which ends with the formation of a technical task [10].
- Choice of BI system.
- Designing.

To choose the right BI system, we have to:

- determine the goals and objectives of the implementation of BI systems;
- formulate requirements for the structure of data storage, determine the possibilities of data manipulation [11];
- define data integration functions [12];
- identify visualization capabilities. For each person, ideal BI analytics looks different, and the system should satisfy the needs of each user;
- versatility or narrow specialization. In the world there are systems aimed at a specific industry, as well as universal solutions that allow you to collect information in any context;
- determine the requirements for computing resources;
- identify financial opportunities for investment in the development of BI platform. The choice of a BI system depends on the capabilities of the company.

Successful implementation of BI systems in any area is based on the following rules:

- correctness of data. If the data for the analysis are incorrect, then there is the possibility of a serious system error;
- full training for each user;
- quick implementation. It is necessary to focus on the correct formation of the necessary reports at all key places, and not on the ideal service of one user. You can always adjust the appearance of the report or add another section for convenience after implementation;
- be aware of the return on investment in the BI system. The effect depends on many factors and in some cases is visible only after a few months;
- equipment should be designed not only for the current situation, but also for the near future;
- be aware of why the implementation of the BI system was started and do not require the impossible from the software.

During the examination it is necessary:

- finding out the number of actual and potential users of the BI system;
- collection and analysis of requirements for a business analysis system;
- indicate the frequency of use of the formation of various requests and reports;
- identify data sources, related business applications, data formats (as they are and how they will be);
- agree on the requirements for synchronization, cleaning and granularity of data;
- analysis of the current infrastructure of the company;
- harmonization of functional requirements.

Based on the data obtained, the formation of customer requirements for the BI system is carried out. The result of the survey stage is the creation of a technical task, which defines the requirements, the procedure for creating a BI system. The terms of reference are used to establish requirements, clarify time costs and labor costs.

In accordance with the terms of reference, the design and development of the BI system is carried out, as well as the acceptance of the system at the time of commissioning.

Design phase:

After the development and approval of the terms of reference, the development of a technical project for the implementation of the BI system is carried out.

During the design phase, the following applies:

- study of the terms of reference;
- for each requirement of the technical specifications is determined:
  - specification for system modules;
  - a detailed implementation project for each requirement;
  - a list of improvements to the components of the BI system to implement the requirements of the technical specifications;
  - the ability to implement the requirements for the functionality of the finished system components.

- establishing interdependencies among the functional modules of the BI system;
- designing safety rules;
- creation of provisions on access to the BI system;
- architecture design:
  - analysis of information flows and data sources;
  - designing the interaction of information flows between systems;
  - definition of integration links;
  - development of regulations for interaction between systems;
  - designing data integration from existing systems;
  - definition of common data formats and schemes for converting source data into a single format.
- database design;
- designing interfaces of the BI system.

When working on a technical project, it is necessary to determine the architecture and develop in detail the configuration of the future BI system, including:

- designing the architecture of relationships with data from external sources, the rules for unloading and processing information;
- provision of data storage;
- development of data marts;
- development of reports and regulated applications;
- development of unregulated requests;
- architectural design for multidimensional analysis;
- design of control panels;
- organization of mobile access to information;
- organization of a notification system;
- BI system design interface;
- determination of hardware and software requirements for the future system.

The technical project defines the main methods used to develop the BI system for the final determination of the estimated cost of the system. The technical project identifies the most important methods for developing a BI system and determines the estimated costs.

In order to exclude the creation of isolated BI applications and create a single information structure that allows working with holistic and reliable information when building a distributed BI system, the solution architecture should rely on the use of common data and an object model, as well as a single security and management model.

According to statistics (the opinion of analysts at Technology Evaluation Centers (TEC)), only 30% of company executives are satisfied with the implementation of BI systems. Over the long years of the existence of business analysis software, key errors have been formulated that can reduce efficiency to a minimum:

- non-obviousness of the purpose of implementation for leadership. Often a project is created by the IT department without the close involvement of managers. In most cases, in the process of implementation and operation, questions arise regarding the goals and objectives of the BI system, the benefits and ease of use;
- lack of transparency in management, work of employees and decision-making. Managers may not know the work algorithms of field employees, and management decisions can be made not only on the basis of dry facts. This will lead to the inability to maintain the existing paradigm as a result of the implementation of the BI system. And it is often impossible to break the corporate governance culture that has developed over the years;
- insufficient data reliability. Getting false information into the business analysis system is unacceptable, otherwise employees will not be able to trust it and use it;
- wrong choice of a professional business intelligence system. Many examples in the history when the management hires a third-party organization to implement the BI system and does not take part in its selection speak for themselves. As a result, a system is introduced that does not allow obtaining the necessary report or with which it is impossible to integrate one of the existing software in the company;

- lack of a plan for the future. The peculiarity of BI systems is that it is not static software. It is impossible to complete the implementation project and not recall it. There are many requirements from users and management regarding improvements; management requirements;
- desire to save. In the business sphere, this is normal, but BI analytics only works if it takes into account all aspects of the company. That is why deep analytical systems with high cost are most effective. The desire to receive several reports on areas of interest leads to frequent data errors and a great dependence on the qualifications of IT specialists;
- different terminology in the company. It is important that all users understand the basic terms and their meaning. A simple misunderstanding can lead to an incorrect interpretation of reports and indicators of the BI system;
- lack of a unified business analysis strategy for the enterprise. Without a single course chosen for all employees, any BI-class system will be just a set of scattered reports that satisfy the requirements of individual managers.

From the programmer point of view, one of the main tasks of implementing an analytical information system is integration into an existing architectural solution of a company. Data integration involves combining data from different sources to provide the user with a unified form. During this process, a number of problems often arise, mainly related to ensuring high quality data to be analyzed. Difficulties arise at the stage of obtaining data. The difficulties include the lack of information sources, the need to "clean" the data, it is necessary to present them in the form required by the system. In addition, the quality of the information may not meet the requirements due to the inaccessibility of the future system infrastructure or IT architecture.

For this reason, at the time of data exchange between the systems, a violation of their integrity may occur, and this may be a critical factor in the incorrect operation of the enterprise information system. Also, the problem may not be the quality of information, but the state of the directories on the basis of which the analysis in BI takes place. In different information systems, the same objects of an institution may have different descriptions (if data exchange between them had not previously been ensured, and this information was not standardized within the same system).

However, these problems can be solved by first of all paying attention to the following tasks:

- implement the “cleaning” and “enrichment” of the data at the stage of their uploading in order to achieve the required quality;
- ensure the security of the transmitted data by automating the process of obtaining it from sources and, thus, preventing information leaks;
- establish a reliable data exchange process to ensure its integrity and completeness.

Implementation of BI systems is an important step that can help bring business to a new level. But this will require not only a sufficiently large infusion of finances, but also the time and effort of each employee of the company. Not every business is ready to competently complete the project of introducing a business analysis system.

4. Conclusion

To perform medical data analyzes, users, for example, in SQL, would require significantly more time than in BI systems. During the analysis of key performance indicators of hospitals, it was revealed that the main expenses of the organization are related to the patient's stay in the ward. Using visualized data in the analytical system, users can use this information for future focus on the strategy of reducing the amount of time spent by the patient in the ward. Such a solution will allow organizations to consider a new model of patient care at home, which will be cost-effective for the hospital. Using analytical systems, medical organizations can analyze and identify the relationships between various electronic patient records, clinical information systems and financial systems to improve the quality of patient care and reduce costs for certain items of expenditure.

Abstract

The crucial factor of the future sustainable industrial development in Russia is ability of workforce to cope with challenges of emerging Industry 4.0 presenting the new requirements for employees' digital skills. The goal of the study is identification of the digital skills in communication, study and research for Generation Y entering soon at the labor market of Russia when the Industry 4.0 will be a dominating concept. The target group of the study is students of Peter the Great St. Petersburg Polytechnic University. The target group belongs to the last wave of Generation Y cohort expected soon to enter labor force of Industry 4.0. The tool for data gathering was questionnaire consisting of 21 questions. The study was conducted in period of 2017-2019, and the total number of responses was 144. The study findings revealed the state of the art and dynamics in digital skills development and preferable ways of students to use digital technologies in communication, study and research.

Keywords: Digital skills; Industry 4.0, information and communication technology, Generation Y, university students.

Introduction

Sustainable development of every national economy is defined by various internal and external factors. The combination of these factors is specific for every country. Russian economy is too much dependent on prices at the volatile market of hydro carbonic resources. The mineral resources contain 53,4 % of the total Russian export in 2019 (Tsukerman V. et al, 2019). This dependence may be mitigated through strengthening of innovative industrial development (Dubgorn A. et al, 2019; Zharov V. and Tsukerman V., 2019). That means sustainable development and the growth of Russian economy depend on success of reindustrialization based on the modern concept of Industry 4.0 (Ilin, I.V. et al., (2017); Kozlov A. et al, 2019). However, there are a few barriers on Industry 4.0 introducing in Russia, connected with technical, juridical, bureaucratic and social limitations (Bagaeva, I. et al., 2018). The most crucial among these constraints is ability of workforce to cope with new challenges and requirements emerged by the

Industry 4.0. The new digital skills are needed to operate in modern working places. The basis for digital skills mastering is to be developed in universities. The current wave of the nearest year's university graduates coming soon into workforce of Industry 4.0 belongs to the Generation Y (Millennials). (Iapichino A., De Rosa A. and Liberace P., 2018; Kolnhofer-Derecskei A., Reicher, R.Z. and Szeghegyi, A., 2017). According to studies (Zemke R., Raines C. and Filipczak B., 1999; Ng E.S.W., Schweitzer L. and Lyons S.T., 2010) the representatives of Millennials are distinguishing from other generations by some specific features. They are seeking much more in return for their hard work than a paycheck. Millennials pay the greatest importance on individualistic aspects of a job. They had realistic expectations of their first job and salary but were seeking rapid advancement and the development of new skills, while also ensuring a meaningful and satisfying life outside of work (Ng E.S.W., Schweitzer L. and Lyons S.T., 2010) . Millenials are the first generation grown up during the digital era (Tapscott D., 1998; Terjesen S., Vinnicombe S. and Freeman C., 2007). They started to use computers, tablets, smartphones and other gadgets in primary or secondary school; to live in virtual reality of the global net is normal for them. However, their approaches, perceptions and preferences to digital tools of studying, investigating and communicating which is reasonable to extend on working are not researched properly and still unclear. Thus, the goal of the present investigation is identification of the digital skills and preferable ICT tools of communication, study and research for the last cohort of Generation Y entering soon at the labor market of Russia when the Industry 4.0 will be a dominating concept.

To achieve the goal, it is necessary to fulfill the following tasks:

- To adapt existing questionnaire for study purposes.
- To organize the interviewing process of representatives of the target group, students of Russian universities based on questionnaire.
- To handle the materials gathered during the interviewing process.
- To analyze and construe the results of handling and processing of materials gthered iden in.
- To reveal the state of the art and dynamics in approaches, perceptions and preferable ways of students to use digital technologies in communication, study and research.

Literature review

The fundamental values change during the time and depend on common global events (political, economic, social, and technological) and the principles of education (Howe N. and Strauss W, 1991; Ilin, I., Shirokova, S. and Lepekhin, A., 2018). The values formed in childhood may be implicit to the people while the difference in the values of generations creates difficulties in communication in society such as the organization of the learning process since there is one or two generations gap between students and teachers.

The difference in the preferred approaches to education process works for both Russia and other countries, which is described, for example, in the study (Hills C. M. et al, 2017). Studies by Turner T. L., Thammasitboon S., Ward M. A. (Turner T. L. et al., 2012) showed the difference in teaching styles for medical students of different generations. Differences in the learning styles of students of different generations are also noted in (Borges N.J. et al., 2006). The (Hills C. M. et al., 2017) notes a decrease in preference for reading and thinking among students of generation G. Thus, we see how the difference in the values of generations creates communication difficulties in organizing the learning process and reduces its effectiveness. It requires also the search for new comfortable for different generations' ways of interaction in the learning process.

Thus, the analysis of the introduction of the "flipped classroom" model (Gillispie V., 2016) allowed us to coordinate the tendency toward orderliness of generation X and the need for creative self-expression and solving collective problems of generation Y providing good results. However, the topicality of finding comfortable tools for the interaction of different generations in the learning process is not covered enough in the scientific literature. The new opportunities that the development of digital technologies also provides are not fully disclosed.

The studies are mainly devoted to the problem of organizing the labor process attracting and retaining employees of the new generation Y, taking into account their specific goals of motivation and behavior (Wong I.K.A., Wan Y.K.P. and Gao J.H. 2017). It is very different behavior for the generation Y from other generations, (Pînzaru F. et al., 2016; Naim MF et al., 2018), taking into consideration the specifics of generations in the management of corporate labor resources (Jiří B., 2016).

Another large group of articles is focused on the specifics of consumer behavior of generation Y (Valaei N. and Nikhashemi S.R. 2017; Soares R.R. et al., 2017), the difference from the behavior of buyers of previous generations (Lissitsa S. and Kol O., 2016.), their relation to the brands (Soh C.Q.Y. et al, 2017; Knittel Z., et al. 2016), an attempt to segment the online Generation Y shoppers by various characteristics (Ladhari R. et al, 2019).

Systematic research in Russia and the CIS countries starting in 2003 as part of "the RuGenerations - Generations Theory in Russia" project made it possible to adapt the generation theory to the country's specific development (Shamis E. and Antipov A., 2007; Miroshkina M.R, 2017; Nikonov E. and Shamis E., 2019). Russian research, mainly sociological, relies on this approach. We highlight some of the values of generations that are significant for the organization of the learning process taking into account Russian specifics (table 1).

Table 1 The difference in the values of generations in the learning process

Teachers	Students
The Baby Boomer Generation, 1943–1963 Values: optimism, high results achievement, interest in personal growth, collectivism and team spirit.	Generation Y 1983–2003. Values: responsibility, immediate reward, individualism and the importance of self-expression, indirect sociability, fashion, a wide range of interests, success, optimism
Generation X (unknown generation), 1963–1983. Values: readiness for change, opportunity to choose, global awareness, independence, informality of views, pragmatism, high level of material ambitions.	

According to (Khomyakova E. I., 2011), generation Y has developed social skills, a need for a high level of sociability, but they prefer to communicate using technical devices (telephone, social platforms and networks). It is so because of the possibility of access to digital technologies, which are an integral part of everyday life since childhood for generation Y, including social life. On the average, there is a relatively higher level of digital skills for generation Y in Russia than for previous generations. This problem was formulated by M. Prensky, (Prensky M., 2001; Prensky M.,2006), using the terms "digital native" and "digital immigrant". This generation Y trait is favorable for the use of digital technology in the learning process. At the same time, people whose

generation was not digital are engaged in the formation of digital competencies of "digital natives". For teachers - representatives of previous generations - the need to use digital technology in the learning process is not so simple and more labor-intensive.

They note that representatives of generation Y do not like to engage in one type of activity for a long time as prestigious work stopped being the main goal. Representatives of Y prefer not to plan events, careers, and learning process for a long time. Therefore, generation Y is aimed at gaining knowledge in various fields "horizontally" which will give them greater mobility in the future in the labor market. A significant part of generation Y does not plan to work long in one place and even in one profession. Many people prefer to work remotely.

The development of digital technology has contributed to the socialization of generation Y combining individuals with similar interests. Along with the importance of expressing their views the majority is also valuable that has led to the popularity of blogs and social networks. The generation X is characterized by the use of digital technologies to obtain information or new knowledge. Generation Y prefer personalized media with a high level of social service because of the desire for individualism, the high needs for self-realization, self-presentation and the seek for the comfort (Pazina L.O. and Zubareva S.S., 2015).

On the other hand, studies have shown that generation Y needs recommendations and approval from both its predecessors and contemporaries involved in cyberspace (Pazina L.O. and Zubareva S. S., 2015). Many authors argue that students in Generation Y have strong preferences in teaching and learning. However, studies have not confirmed this claim probably due to insufficient data.

Methodology

This study is the next step in chain of researches started in 2018 with students of Peter the Great St.Petersburg Polytechnic University as a target group. The first results were presented in the article (Kozlov et al, 2019) e. The next phase of the study conducted in 2019 has covered more students of the same university. All the studies are based on the classical interviewing techniques with survey developing and analysis of the results. The methodological basis for analysis was the general qualitative scientific methods, such as comparative, content, and systemic analysis, and quantitative ones typical for empirical data analysis.

Results

A comparison of the results of surveys conducted in 2017 and 2019 allows us to identify the dynamics of preferences in obtaining education and communication with teachers and students. The obtained results confirm some characteristics of generation Y.

Students were asked to evaluate ways of communicating with teachers on a scale of 0 – "not at all" to 4 "very often, almost always". Personal communication is most preferable (3.20 and 3.25, respectively). E-mail communication takes the second place but its attractiveness decreases from 2.63 in 2017 to 2.34 in 2019. Group communication in the social network in 2017 took the third place and had a score of 1.7 (very rare, sometimes) but in 2019 it sharply decreased its popularity (5th out of 6, estimated 1.32). The least popular is chatting in the electronic course chat (1.15 in 2017, 1.29 in 2019).

The generation of Millennials characterized by a higher level of common digital competencies is rather conservative in communication with teachers - half of the respondents consider its

importance to not only communicate at seminars and consultations on term papers but also at lectures (Table2).

Table 2. The need for personal communication with the teacher

Personal communication	% of the number of respondents in 2017	% of the number of respondents in 2019
a) necessary during lectures	42,77	49,82
b) necessary when performing practical tasks and term papers	79,19	80,92
c) necessary when performing practical tasks and term papers	2,89	4,95

Interviews with students showed that when answering a question about preferred ways of communicating with other students' young people hardly share educational and personal reasons. While the preferences in communication with teachers can be called traditional, the communication between students has changed significantly (Table 3). In 2019, communication in the social networks (chats) became most popular. Chats on electronic courses and e-mail are the least interesting for such communication. The results obtained allow us to conclude that the preferences in communication with other students change towards increasing the share of digital communication, however, personal communication still is very frequent. In digital communications, students prefer public social networks where their activity on educational issues is closely intertwined with the personal and public activity instead of specific educational channels.

Table 3. Preferences in communicating on academic occasions with other students

Not at all	Rarely	Sometimes	Often	Very often, almost always
0	1	2	3	4

Types of communications	2017	2019
A) in a group on a social network	2,67	2,35
B) in a conversation (chat) of a social network	3,19	3,12
C) in the messenger chat	1,89	1,98
D) in the chat / forum of the electronic course	0,69	1,04
E) by email	0,89	1,14
F) personally	3,24	2,99

Comparing distance and traditional education in 2019 students are more loyal to distance education (Table 4). The amount of people who consider it as a complement to traditional and find it more interesting is growing.

Table 4. Comparison of distance and traditional education

Distance education	2017	2019
A) more attractive than traditional	11,11	15,26
B) complements the traditional, expanding horizons and deepening knowledge in certain areas	37,43	45,13
C) forced to replace the traditional with low quality of the latter	9,94	6,17
D) cannot completely replace traditional education	42,11	31,17
E) other	3,51	2,27

Education requires the use of training materials. Students were asked to rate the attractiveness and comfort of use of the following types of training materials when working independently: a printed textbook, an electronic textbook and a video course on a scale of 1 (inconvenient) to 5 (most convenient). In 2017, priority was given to print media with a rating of 3.84, in 2019 - electronic publications with a rating of 3.77. By 2019, the attractiveness of video courses has grown - if in 2017 they were the least popular (3.29), then in 2019, their attractiveness was equal to the attractiveness of print media.

The study confirmed the high level of general digital competencies of students, their lack of significant barriers in using different gadgets and the contrast in relation to educational opportunities through various digital technologies. (Table 5). Comparing the preferences of 2017 and 2019, we note a decrease in interest in all types of digital applications, except for mobile educational platforms. Educational institutions stimulate the use of this type of digital educational resource; therefore, its share is naturally high. The share of those who do not use mobile educational applications at all is also growing (10.60% of all respondents in 2019).

Table 5. Types of mobile applications used for study (% of the number of respondents)

Types of mobile applications	2017	2019
Mobile educational platforms	33,33	40,64
Instant messengers	49,43	38,16
Event applications	11,49	5,65
Video Libraries	32,76	16,25
Textbook libraries	41,38	38,52
Ready-made libraries	24,14	12,37
Online tests	47,70	40,99
Not using	4,81	10,60

Our study confirmed the high level of ability and use by generation Y of general digital competencies for personal and social purposes, short-term interest in various new areas and forms of training. It also showed a high degree of conservatism in the development of the part of education that they consider fundamental.

Conclusion

Thus, the focus of the study was done at the representatives of the last wave of the Generation Y cohort, at discovering of their digital skills, perceptions, preferences and usage of on line learning

tools. Therefore, the target group was students of Peter the Great ST. Petersburg Polytechnic University who will join the ranks of Industry 4.0 in the nearest future. The study reveals some important facts regarding attitude and usage of ICT by students in educational process and distinctions between results of interviews done in 2017 and 2019. The results of the both studies confirmed the high level of general digital skills of students, the absence of significant barriers to the usage of various gadgets and on line tools. However, the last Millennials are quite conservative in their communication with teachers – half of the respondents consider it important and even necessary to communicate personally at seminars and consultations on term papers, and at lectures as well. It also shows a high degree of conservatism in the examination of the part of teaching materials that they consider fundamental. Nevertheless, there are some differences in students' perceptions and approaches in 2017 and 2019 highlighting important tendencies in moods of students in favour of on line educational tools. The study discovers that students in 2019 are more loyal to distance education and ICT in educational process, since the share of those who consider it as a supplement to traditional education has grown, as well as those for whom it is most attractive.

The limitations of the study are defined firstly, by not so wide samples of respondents in 2019, 67 interviews, secondly by focusing on the students of one university only.

The gathering of the data regarding the target group based on the same technique and survey in the current 2020 will be the important way of the future study. The other direction of the future investigation is spreading the study to other universities located in different parts of Russia and abroad.

Abstract

A practically proven and adjusted procedure of generating assignments related with product range analysis is suggested. The generated datasets can be used for ABC, XYZ analysis, BCG matrix and similar methods. In addition to generated datasets, analysis results of these variants are also generated. This can be used to create a flexible automated testing system. The results of this paper are suitable for mass distant learning courses of marketing orientation.

Keywords: distant learning, assignment generating, product range analysis, testing, assortment.

Introduction

In recent years, there has been a boom in online training courses. Students from almost any place of the Russian Federation and other countries can use them. The types of courses vary. One can find support for basic education, distance learning, and continuing education. The importance of this activity is emphasized in (Bril A.R., Kalinina O.V. and Ilin I.V., 2017), (Kozlov, A. and Teslya, A., 2017), (Ilin, I., Shirokova, S. and Lepekhin, A., 2018), (Kankovskaya, A., Kalinina, O. and Ilin, I., 2018), (Bagaeva, I., Iliashenko, O. and Borremans, A., 2018) and many others.

To improve the quality of training, courses must meet a number of requirements (Kurdi, G., Leo, J., Parsia, B. and Salam A., 2019), (Plevny, M. and Gladavsk'a, L., 2014), among which it is important to note the following:

● the ability to train a large number of participants, sometimes up to several thousand ● people; assignment checking in such courses cannot be performed manually;

● the proximity of training calculation examples to real situations;

● uniqueness of assignments; this requirement is due to the fact that, unfortunately, some students tend to copy each other's assignment results.

Thus, the problem arises of generating a variety of assignment variants that are close to reality and allow automated verification of the results of calculations performed by students.

This paper is devoted to the generator of sales volume data for assignments on product range analysis. This tool generates individual sets of initial data that are similar to real data, which will allow giving each student an individual task. The generated data can be used to perform ABC analysis, XYZ analysis, Boston consulting group matrix construction, and other similar methods of assortment analysis.

Similar approach of generating tasks can be found for the courses of mathematics (Gangur, Automatic generation of mathematic tasks, 2011), programming (Souza D.M., Felizardo K.R. and Barbosa E.F., 2016), and statistics (Gangur M. , 2018). In this work, we are talking about a complex: generating tasks, questions and correct answers. All the calculation formulae have been adjusted during practical usage. Thus, they are suitable for immediate implementation.

Methodology

In the version under consideration, data on annual sales volumes for **m=6** years are generated. Years are used to exclude seasonality. The model also contains **3** product lines of different depths, which expands the range of analysis. These limitations can be easy overcome, and the version under consideration is sufficient to demonstrate the specifics of the proposed procedure.
Signs of the formulae.
r is a random number evenly distributed from **0** to **1**. It is implemented with standard functions. In Excel, this is the **RAND ()** function.
R is a random number evenly distributed over a range of length **2**;

$$R=r*2-Kr.$$

If **Kr** is equal to **1**, **R** changes from **(-1)** to **1**, but by changing **Kr** between **0** and **2**, this range can be shifted to both higher and lower values.
n1, n2, n3 – the number of products in each product line. We highly recommend setting different values, such as **10**, **15**, and **20** items, respectively. This leads to the possibility of investigating the roles of product lines.
Generating of sales data is performed on Excel worksheet and consists of the following steps.
1. A table is made with the following columns: Product line number; Item number. Subsequent columns are formed as described below.
2. The role of the product line (its preliminary rank by sales: **1**, **2** or **3**) is defined. To do this, three random numbers (the **RAND()** function) are generated, and their ranks **Pi** are determined, **i** – is the product line number (Excel function **RANK(value, range)** is used). Thus, in various variants, each product line can play a different role.
3. Preliminary overall sales volumes of each product are determined:

$$Vj = \exp(r * Kv) * Pi,$$

where **j** is the number of product, **Pi** is the rank of the product line, **Kv** is selected empirically in order to set the cumulative sum of sales in ABC analysis close to the Pareto point (**20%** of the goods make up **80%** of sales). **Kv = 8** gives good results.
4. Slopes of sales volumes of each product are calculated.

$$Sj = R * Vj * Ks / m / 2.5,$$

Explanation:
● sales may undergo both growth and decline, so **R** is used. If **Kr = 1**, the numbers of products with an increasing and decreasing sales volumes are approximately equal. Decreasing **Kr** can enhance the role of commodities with increasing sales volumes and vice versa.
● there should not be negative value of sales, which is possible in the first or the last period due to the inclination sign, so **Ks** values should be less than **1**. In addition, large values of **Ks** gives little number of goods with **X** category, which has stable sales. Accordingly, the proposed value is **Ks = 0.5**.
● division by **m = 6** is performed to calculate the sales volume for one period from total value for all **6** periods;
● the change in sales volume for one period is determined. As long as the random component is not yet inserted and the growth is uniform, start and end points differ from the average one period value by **m / 2 – 0.5** (it should be recalled that in this version **m = 6**). Extreme values can be achieved either in the first or in the last period; that depends on the slope sign. The average value is in the middle of the considered time range, i.e. between the sales values of points **m / 2 = 3** and **m / 2 + 1 = 4**. The analysis is assumed to be short-term, that means that the stages of the product lifecycle do not change and it is possible to evaluate the sales volume dynamics with the help of linear trend.
5. The minimum sales volume in the presence of the slope, but without random variations is calculated:

$$Vj,min = Vj / 6-2.5 * abs (Sj).$$

6. Similarly, the maximum sales volume is calculated:

$$\mathbf{Vj,max = Vj / 6 + 2.5 * abs\ (Sj).}$$

7. The range of random fluctuations in sales is defined:

$$\mathbf{Dj = Vj,min * Kd.}$$

Since the sales volume cannot be less than zero, **Kd** cannot be greater than **1**. If it is close to **1**, a large oscillation occurs. In order to generate an assortment with some stable products of category **X**, **Kd** is set to **0.3**.
8. The random deviations from the ideal line with slope are calculated:

$$\mathbf{dij = Dj * R.}$$

9. The amount of each product sales for each period is set:

$$\mathbf{vij = Vj / 6 + Sj * Ai + dij.}$$

where **Ai (i = 1…m**; **m = 6)** is **{-2.5; -1.5; -0.5; 0.5; 1.5; 2.5}**.
The obtained values are rounded to two decimal places.
So, the resulting values sequentially appear by determining:
● total sales volumes;
● sloped sales volumes;
● random deviations of sales volumes.
This ensures data values for analysis being close to reality and admissible.
As a result, sales volumes are somewhat different from the initially defined, but deviations of **m** periods to some extent compensate each other, and the total amount of all goods is close to the original one.
10. Checks are performed. They are necessary to ensure the accuracy of the calculation formulas, proper selection of coefficients and for preparing desired (still somewhat simplified) data.
The importance of checks of automatically generated tasks is stated in (Abe, K., Cortez, R. and Vazhenin A., 2013).
10.1. The absence of equal sales volumes. If there are equal sales volumes, it can cause additional difficulties, which are unnecessary in case studies. This situation is possible even if all formulae are correct. In case this check fails, it is necessary to generate a new set of data.
10.2. The negativity of sales volumes is not possible. The situation can occur when coefficients are not correctly chosen.
10.3. The presence of all categories is necessary: **A**, **B**, **C** with standard boundaries of cumulative sales volumes of **80%** between categories **A** and **B**, and **95%** - between **B** and **C**. The lack of any category is undesirable for the analysis and this is practically impossible in real life situations.
10.4. The ratio of minimum to maximum sales among products should be less than **0.5**. Otherwise, analysis may appear useless.
10.5. The maximal absolute value of the slope of the linear trend should exceed **0.02**. Otherwise, there are no really growing and/or decreasing sales and analysis is also useless.
The training course developed by the authors uses the idea of building the BCG matrix, proposed in (I.V., 2000): the categorization is made within the internal secondary data of the product range. Products are divided into “dogs”, “cash cows”, “question marks” and “stars” by the average or median values of their sales volumes and sales volume growths. This provides analysis that is independent from external data. However, this analysis can become meaningless if it turns out that the sales volumes and the growth of these volumes are not significantly different.
10.6. The total number of A, B, C and the total number of X, Y, Z items should be equal to the total number of goods. This is the check of formulae correctness.
10.7. There should not be equal total sales volumes by product lines and equal average sales by product lines. This is not a requirement, but the violation of this condition makes the case study overcomplicated. The cause of this situation is sales rounding.

11. Further, each set of calculated sales volumes is saved in a separate Excel worksheet file, which is then given to the students for calculations in assignments. It is also possible to include some questions in this file. A wide range of test questions can be generated. They are aimed to check the students' calculations. For example:

- the number of items belonging to categories X, Y, Z, A, B, C, AX, BX, ..., CZ;
- recommendations for some randomly selected goods (withdraw from the market; develop);
- recommendations on product lines (expand, unify, not change);
- the category to which the product of some given number belongs.

In addition, a file version for the teacher or for automatic generation of test questions is also saved. It contains questions and correct answers obtained by proper calculations that students should do themselves.

Results

The suggested procedure fits the modern trend in IT called Synthetic data. Possible areas of its implementation are related with findings of (Iljashenko, O., Bagaeva, I. and Levina, A, 2019), (Zaychenko, I., Smirnova, A. and Kriukova, V., 2019), (Kalinina, O.V., Zaychenko, I.M. and Gutman, S.S., 2017), (Kozlov, A., Gutman, S., Rytova, E. and Zaychenko, I., 2017), (Zaychenko, I.M., Kalinina, O.V. and Gutman, S.S., 2016).

The process of files generating is performed by the simple Excel VBA macros, after passing all checks. This parallel generation of initial data, questions and answers allows easy automation of checking students' results.

This procedure has been implemented, adjusted and successfully tested in the course "Management of innovative products". Testing revealed additional recommendation: in order to avoid unnecessary complexity of report, the size of initial data table (i.e. the number of products) should fit one page of the report form.

Thus, the described system allows improving the studies of product range analysis, providing individual tasks with the parameters that are close to real data, as well as an automated check response of students. The adjusted formulae make it possible to use the suggested decisions directly.

Abstract

The relevance of the work is due to the development and widespread introduction of digital technologies in almost all socio-economic processes and the inevitable digital transformation of most enterprises. Which, as a result, leads to the need for business leaders implementing the digitalization process to study this process in depth, including understanding and analyzing terminology. Therefore, the goal was to identify approaches to the definition of the terms “digital business transformation” and “digital economy”.

The object of research is Russian enterprises and the economy in general.

The subject of the research is the concepts of “digital transformation of business” and “digital economy”.

In accordance with this goal, a number of terms “digital economy” and “digital transformation” were studied, the differences between them were identified and formulated. The evolution of the terminal process “digital business transformation” is characterized, the reasons causing changes in the interpretation of these concepts are identified, the main approaches to the development of the digitalization process are considered, and the industry specifics of the digital business transformation are studied.

As a result of the study, it was found that the terms “digital transformation” and “digital economy” are interpreted differently. The digital economy can be defined as part of the GDP obtained through the use of digital means; digital transformation, in the narrow sense, represents the transition from analog to digital data, and in the broad sense, it is a business transformation through the use of new digital technologies, which leads to new competitive advantages in the digital economy.
In conclusion, an author's interpretation of the concept of "digital business transformation" is proposed.

Keywords: digital business transformation, digitalization, digital economy, digital maturity.

Introduction

Each year, the level of computerization of various sectors of the economy is increasing and the idea of digital transformation is reaching the whole world. As a result, most developed countries, including Russia, pay great attention to such terms as digitalization, digital transformation, digital economy, digital maturity, digital strategy to study in depth a new area of scientific and technological process.
Although the terms “digital transformation of business” and “digital economy” have been firmly established in our usage, it is not clear whether there is a generally accepted definition of these terms, and if so, what the differences between them are.

Thus, the purpose of the paper is to study and analyze approaches to the concept of business digital transformation terms.

Materials and Methods

Nowadays, there are many definitions of digital transformation. It should be clarified that within the concept of “digital transformation” there are several terms [1] with different interpretations:
- digitization - is the transformation of information from physical to digital media, with no changes in the quality and content of information, it is simply converted into electronic form for further processing in digital format- digitalization) – is the initial creation of a new product in digital form.

Thus, the digital transformation is simultaneously aimed at improving the existing business processes and at creating competitive advantages by changing and creating new business processes within the enterprise.

Most Russian companies are now focused on the digital transformation of key business processes, and digitalization is perceived by them as a new round of automation and informatization. In this regard, it is necessary to distinguish between «digitalization» and "digital transformation of business" as compared to production automation.

Automation of production is a branch of scientific and technological progress that aims at freeing people from participation in the processes of obtaining, transforming, transferring and using energy, materials, products or information, in whole or in part, through the use of technical means and mathematical methods.

Digital transformation ensures that the fullest possible potential of digital technologies is unlocked through their use in all aspects of management - processes, products and services, decision making approaches. In the report "Russia 2025: From Human Resources to Talents" The Boston Consulting Group specialists emphasize [2] that digitalization is the use of online and innovative digital technologies by all participants of the economic system - from individuals to large companies and states. It is important to emphasize that digital transformation is not only about the availability of technology per se. In order for the process of digital transformation to be complete, clearly defined business objectives and data are needed.

In order to form an author's definition, this paper will analyze the terminological differences between the concepts of "digital economy", "digital transformation", and peculiarities of industry digital transformation.

It is proposed to consider the principles of business engineering and enterprise architecture as a methodological basis for the implementation of digital transformation at the level of national economy [8,9]. In accordance with these principles, it is necessary first to identify the main stakeholders of digital transformation, their expectations and requirements for the new format of activities, which determine the drivers of digital transformation, and then on the basis of these requirements to form the architecture of the new economic space.

At formation of conceptual model of architecture of digital space of Russian business approaches of disciplines "Enterprise architecture" and "Business engineering", in particular, were used:

- service orientation of the model being formed: elements of the system interact on the principle of providing services to each other;
- structuring by layers: business layer - business entities, business processes, business functions; IT layer - information and digital systems and technologies, IT services, IT functions; technological layer - IT and digital infrastructure that provides the deployment of information and digital systems and technologies, technological services.

Results

The eMarketer Subscription Market Research Company [3] defines digital transformation as the process whereby business leaders take advantage of the opportunities and benefits of new technologies to digitize their companies: their operations, products, marketing, culture and goals for future growth. Technology is a means of transformation, not an end in itself. The focus should be on setting a goal for the future and then building a strategy based on that vision.

Also, to study the chosen topic, the definition of digital transformation, presented by V. Mesropyan, the head of the project "Digital Economy of the Russian Federation", is of interest [4]: these are revolutionary changes in business models based on the use of digital platforms, which lead to radical growth in market volumes and competitiveness of companies.

Thus, the digital transformation of business can only be considered at the intersection of all three dimensions: the formulated business objective, data availability and technology. Thus, the digital transformation of business involves a fundamental rethinking of how the organization works and how it interacts with the external environment.

Evolution of the concept of "digital transformation of business" and its features

Obviously, there are many definitions of "digital transformation" in open sources. It is worth noting that the more the authors of these definitions try to link the concept in question with a set of technologies, the more cumbersome the list they get. As an example, let us consider the definition of the digital transformation of Detlef La Grande [5], in which he mentions social networks, crowdfunding, and crowdsourcing, and cloud technology, and mobile Internet, and big data technology, and intelligence, and 3D printers, and augmented reality, and carried devices, and open source products. It is clear that with this approach, as new technologies emerge, the concept of digital transformation will be refined and supplemented. Clearly, the meaning of the term "digital transformation" is also changing, transforming as information and communication technologies and business evolve.

The original meaning of the term "digital transformation" meant a shift towards digital data instead of analogue data. Today, this process is commonly referred to as digitalization. Data Relish [6] made a forecast of data growth on different media, which is shown in Figure 1.

Fig. 1: Prediction of data growth on different media [6].

If we rely on the data presented in Figure 1, we can conclude that in 2020 the share of analogue data should reach zero, which means that the process of digitalization should be completed. However, it is obvious that the digitalization process is on the contrary. This, in turn, indicates a broader meaning of the term in question.

It should be noted that the term "digitalization" has different accents for specialists in different fields. For instance, for engineers, the center of the digital transformation of business will be technology, while business consultants will focus on rethinking the company's strategy rather than on the technology on which the transformation of business is based. Recruiters will challenge themselves to find people with new thinking and qualifications. This raises two questions: what is the essence of the digital transformation of business and how to measure it?

There are three main characteristics of the digital transformation of business [7]:

1. Digital technologies are used to automate production and enterprise as a whole. If we stick to this hypothesis, we can fairly note that the process of digital transformation has been going on for decades, and the appearance of each new technology only adds new stages.

2. Digital transformation is directly linked to the development of information and communication technology (ICT). A turning point in this case can be considered the emergence of a third platform, which has contributed to the emergence of digital companies - a new business model operating with the help of new digital technologies ("big data", Internet of things, cloud storage, social technologies and mobility).

3. Digital transformation is relevant for both digital companies and traditional resource corporations. The latter, in turn, focus not so much on new technologies as on the new economic conditions in which the enterprise finds itself. This situation forces them to transform their business model of organization and look for the necessary information and communication technologies for further successful development.

It should also be emphasized that the meaning of the term "digital transformation of business" will differ significantly and will have its own specifics for certain countries, cities or even enterprises.

Unfortunately, at the moment there are no countries in which there would be companies that have fully completed the digital transformation of business. However, it should be noted that most countries are

striving for this, and the set of technologies that determine the digital transformation of enterprises will obviously differ for different sectors of the economy.

Industry Specifics of Digital Business Transformation

Above, the most general approaches to the interpretation of the concept of "digital transformation of business" were considered. However, it is obvious that within the framework of the implementation of the concept of digital transformation of business within a particular sector of the economy, the spectrum of transforming technologies and organizational methods should be clarified, since the specifics of the influence of many factors that determine the conduct of business in this sector are manifested.

For example, for the telecommunications industry [8], such technologies as software-configurable data transmission network SDN (software-defined network) or such an approach to the provision of network services as NFV (network functions virtualization), which implies the replacement of standard equipment with virtual machines running on conventional servers, will be of paramount importance.

Thus, for telecom operators, the digital business transformation represents a move beyond traditional business management models, with a focus on both B2C and B2B. The goal, in turn, is to provide mass access to various services, as well as to provide broadband Internet access for home users, which provides fast download of heavy video content, will be able to provide and maintain the services of "smart home".

An important direction for the transformation of this area is also the reconstruction of the network architecture with the help of SDN and NFV technologies [9], which implies the transition from the specialized machine implementation of network functions to their software implementation in standard server equipment.

An important point for the transformation of the telecommunications industry is also the "Internet of Things" (IoT) technology, which contributes to a change in the concept of "user" as more and more connected devices fall into this category.

In turn, if we consider the digital transformation within the framework of financial markets, the most relevant technologies are Internet banking and block-chain [10,11], for production enterprises - industrial Internet things [12], for retail - electronic commerce [13], for logistics - drones [14] and so on.

Thus, it can be concluded that, along with the general technological trends related to digital transformation, each industry has its own set of technologies, which comes into focus when trying to define the essence of such a phenomenon as digital transformation.

Digital Economy

For the first time, the concept of the “digital economy” appeared in 1995. This term was coined by Nicholas Negroponte, a fellow at the University of Massachusetts. There are many interpretations and definitions of the concept of “digital economy”, but so far, they all remain quite blurred.

Most of the presented definitions that can be found in the scientific literature include a list of services, technologies, and devices that are somehow related to the concept of “digital economy”, while they do not report which specific part of the economy can be attributed to the digital one.

The most common definition of the term “digital economy” sounds like [10]: it is a set of economic and social activities, that are provided by informational and communication technologies, such as the Internet, mobile and sensor networks, including communications, financial transactions, education, entertainment, and others a type of business, that based on the use of computers, telephones and other devices.

Fig. 2 [11] presents a detailed three-level ecosystem of the digital economy, according to which the first level is the hardware-network; the second level is the level of software infrastructure and related elements, and the third level is the application level, which is specific for various sectors of the economy.

Fig. 2: Ecosystem of the digital economy [11]

In the publication, OCED (Organization for Economic Cooperation and Development) [12], the "digital economy" is introduced as a term used to describe markets that focus on digital technologies and belong to the spectrum of economic, social and cultural events supported by the Internet and other ICT technologies. It is noted that the digital economy is associated with "trading information products and services through e-commerce". Emphasize that it is proposed that the digital economy not include the entire e-commerce market, but only that part, that is specifically related with the trading digital goods.

However, this approach is not supported by all market participants. For example, if we turn to the methodology for calculating the contribution of the digital economy to GDP, which was proposed by BCG [13], we can find a completely different approach to the definition of the concept under consideration. According to this document, the volume of the digital economy is online consumption plus the cost of building the infrastructure of this consumption. This method (on the example of the Russian Federation) is shown in Fig. 3. The volume of the digital economy, estimated at 1,580 billion rubles in 2015, is calculated as the sum of online consumption + access costs + expenses on access devices + investments + government spending + exports and - imports.

Figure 3: Assessment of the contribution to the digital economy by the BCG method [13]

Another study [14] emphasizes that the development of informational and communication technologies is ambiguous: on the one hand, this leads to an increase their value, and on the other hand, their mass promotion on the Internet leads to a decrease their value.

The authors of that work [14] propose to separate the “direct contribution to GDP” from the use of digital technologies: consumption of services from online companies, government agencies, export and import of online orders and services. "Indirect contribution to GDP," which is realized by providing more efficient search for information, by online services, by more efficient exchange of information on social networks, by being able to buy and sell goods more efficiently when using e-commerce and by optimizing costs when using cloud services. And also, the third category [15] — “contribution beyond the GDP” — the impact on the economy of using B2B e-commerce and online advertising platforms, benefits of using free services for the population, such as free search, communication in social networks, access to cultural values via on-line and others.

That makes clear, why the rates of the authors are so different. Thus, it can be concluded, that taking into account the size of the digital economy is impossible without taking into account the contribution to GDP.

An author 's definition of the term "digital business transformation" can be proposed.

The "digital transformation of business" is the transition from a traditional enterprise management system to an innovative one, that based on the introduction of relevant information and communication technologies into the enterprise’s activities, and aimed at conversion business and/or transforming it into a digital form to obtain and/or retain competitive advantages in modern society.

An architectural approach to the digital transformation of the national economy

The digital space of Russian business is proposed to be formed on the basis of the following principles:

- service orientation: one of the subjects sets the requirements for the services of the other. The latter provides the corresponding service in response to a request; [10]
- allocation of end-to-end technologies - for the state, market, industry;
- legal transparency and efficiency: the interaction of Russian business entities should take place in the legal field, in which the rules for conducting business activities and the rules for resolving disputes are established, brought to the attention of all entities, and equally take into

account the rights of all interacting parties and obligations arising during the implementation of business activities;

- symmetry of information: interacting entities should have equal access to sources of information about business entities, as well as business entities, to the extent that this is provided for by the rules for disclosing information about the activities of certain entities;
- information security: information provided by subjects of Russian business is correct, consistent, protected from unauthorized access, misuse; IT architecture and IT infrastructure of Russian business entities can provide information security requirements for Russian business entities;
- digital culture and human capital management: one of the subjects sets the requirements for the services of the other. The latter provides the corresponding service in response to a request;

The study revealed that the transition to a digital business basis has its own characteristics at different levels of the business ecosystem. From the above principles of the formation of the digital space of Russian business, the following principles of modeling its architecture were derived:

1. The multilevel architecture of Russian business (enterprise-level, industry level, region (state) level):
   1.1 Providing information interaction of subjects at each level;
   1.2 Providing a single information space within each level;
   1.3 Providing informative interaction between the different levels;
2. Assessment of the level of digital maturity of the object; [11]
3. Client-centricity: focus on and adapt to customer requirements;
4. The role of data in decision making and management;

The interaction of Russian business entities in accordance with the principle of service orientation provides that, entities (described in detail in [5]) provide each other the following services:

1. State:
   a. Rules for the implementation of business activities;
   b. Rules for resolving disputes and conflicts arising from the implementation of business activities;
   c. Ensuring compliance with the rules for the implementation of business activities;
2. Industry:
   a. Industry performance standards;
   b. Ensuring compliance with industry standards;
   c. Supporting industry professional community;
3. Market:
   a. Providing space for business activities;
   b. Support for business, regulatory mechanisms;
4. Legal entities and individual entrepreneurs:
   a. Business services in accordance with the agreements;
   b. Providing professional expertise and experience in the implementation of business activities;
   c. Charge for the opportunity to carry out activities.

Conclusion

The formation of an effective digital space of national business is a complex, multidimensional task, the implementation of which requires a systematic approach to the formation of a theoretical and methodological base for the transition to a new way of doing business. As a result of the work, approaches to the definition of "digital business transformation" were identified and studied. Important concepts such as “digital business transformation”, “digitalization” and “digital economy” were considered.

As a result of the study, it was revealed that the terms “digital business transformation” and “digital economy” are interpreted differently. It has been established that the digital economy can be expressed as part of the GDP obtained through the use of digital means. At the same time, there are a number of different methods for assessing the digital economy and, as a consequence, determining its essence. Estimating GDP is a prerequisite for assessing the level of the digital economy but calculating the indirect contribution to GDP can be difficult.

The term “digital business transformation” has evolved and will now include two important meanings: digital transformation, in the narrow sense, represents the transition from analog to digital data. And in the broad sense, it is a business transformation through the use of new digital technologies, which leads to an increase labor productivity in a particular period.

This work proposes to apply the architectural approach to the formation of the digital space of Russian business, based on the architectural approach to the design of socio-economic systems. The subjects described in the work, the principles of their interaction, the principles of forming a business space can become the basis for the formation of individual slices of the created business environment.

Acknowledgment

The study was carried out with a grant from the Russian Science Foundation (project No. 19-18-00452).

Abstract

In the modern world, in the conditions of the dynamic development of technologies, the focus of attention of enterprises is directed not only on technologies for the implementation of core activities, but also on management technologies. The leading ideological concepts, under the influence of which a modern healthcare system is being formed, are: value medicine, personalized medicine, Health 4.0 concept. This article analyzes the models of IT solutions for IT support of the medical organization, which implements the principles of value and personalized medicine and following the development trends of modern digital technologies. The analysis of the key characteristics and features of IT support for this type of medical organization.

Keywords: IT support, value-based medicine, IT solutions, technology.

Introduction

Today, a medical institution at any level needs modern management technologies. The culture of continuous improvement is one of the important factors for the successful growth of the institution.

In a world that is constantly evolving and facing strong competition, ensuring stability can no longer be a sufficient condition for the company to operate successfully for a long period of time. Continuous improvement with the use of modern technologies, the introduction of innovations and the encouragement of employee initiatives can be an impetus to advancement among competitors.

The main goal of healthcare management is to reduce social losses due to morbidity, disability and mortality. To achieve this goal, effective activity is required, both of the entire healthcare system, and of each medical organization, for which it is necessary to introduce other methods, principles, approaches and management models for absolutely all parts of the medical organization aimed at achieving the following interrelated goals:

- improving access to quality services and prompt medical care;
- improving the quality of life and public health;
- increase the profitability and profitability of the medical organization (Begkos et al., 2020).

However, not everyone understands and realizes the necessity and importance of economic efficiency and profitability for a public health organization. At the same time, practice shows that medical organizations that actively attract additional extra budgetary funds are the most effective.

Health management includes managing financial, labor and medical resources. In the healthcare sector, there is a tendency to increase the efficiency of healthcare institutions, therefore, it is necessary to introduce new modifications and ways to manage all elements of the organization (Siyam et al., 2019).

The leading concepts setting the development trend of the modern healthcare system are: value medicine, personalized medicine and the concept of healthcare digitalization Health 4.0 (Thuemmler and Bai, 2017).

Valuable medicine is a result-oriented approach to the organization of a medical care system, which involves the selection of a method of patient management, which at lower costs allows you to achieve better results.

The main goal of medicine within the framework of this approach is value from the point of view of the patient, and not just access to care, cost containment policy, convenience or service (Brown et al., 2003). With this approach, ideally, those who provide medical services are paid for actually helping the patient improve their health, reduce the incidence of chronic diseases and their complications, and also contribute to a better health of society as a whole. Of course, this approach should be used with extreme caution, since in medicine there is a huge share of uncertainty in the result, and often the most correct approaches and best techniques may be ineffective due to force majeure circumstances or unpredictability of the patient's reaction. Moreover, some experts believe that prioritizing some quality criteria will underestimate others and cause an imbalance in the provision of assistance. But, nevertheless, changing the wage system in medicine and avoiding increasing aid volumes today is considered a key point that can increase its effectiveness provided that resources are saved, the acute shortage of which worries health systems around the world.

In conditions of existing trends in the development of health care, the urgent task is to develop a model of the medical organization that implements the principles of value-based and personalized medicine, takes advantage of the technologies of the Health 4.0 concept, and allows for quick and flexible response to dynamically changing environmental conditions.

The requirements for compliance with the principles of value and personalized medicine should be reflected in the model of business processes of a medical organization. The possibilities for applying technologies of the Health 4.0 concept set requirements for the structure of IT support and the technological infrastructure that ensures the implementation of processes.

This makes it urgent to analyze models of IT solutions for IT support of a medical organization, which implements the principles of value and personalized medicine and follows the development trends of modern digital technologies.

Literature Review and Research Methodology

The concept of Health 4.0 implies the use of modern digital technologies (big data management, the Internet of things, blockchain, telemedicine, predictive analytics, etc.) to increase the economic and medical efficiency and accessibility of medical care. Modern medical organizations are not able to cope with the increasing flows of information, because the existing management architecture, including the architecture of information systems and applications, does not provide interfaces to interact with modern digital technologies. In addition, there is still patchwork automation of medical organizations, which absolutely does not imply an effective information exchange between the components of information technology architecture (Lee and Youn, 2015; Ilin et al., 2018; Borremans et al., 2019).

Ensuring accessibility requirements for medical care and compliance with the principles of value and personalized medicine are directly related to the possibility of increasing economic efficiency. The provision of medical care that is adequate, according to the patient, to a particular case, creates the prerequisites for the efficient use of the resources of medical organizations. Modern management technologies, including digital ones, have significant potential in solving a number of problems on the way to providing more affordable, cost-effective and high-quality medical care.

Health 4.0 is defined as a strategic concept for the healthcare industry based on the Industry 4.0 concept. The primary goal of Health 4.0 is to provide progressive virtualization to personalize patient health in real time. Personalization of healthcare will be achieved through the widespread use of cyber-physical systems, cloud computing, the Internet of things, predictive analytics, blockchain technology, streaming data from wearable devices, and various mobile systems (5G) (Cáceres et al., 2019). To understand the benefits of using the concept in the healthcare sector, it is necessary to precisely define the main advantages and goals of using the concept of the fourth industrial revolution as a whole (Mueschenich and Wamprecht, 2018). To date, the concept of "Industry 4.0" is one of the most significant organizational and technical systems. Such a solution provides for the end-to-end digitalization of all physical assets and their integration into the digital ecosystem, together with partners involved in the value chain (Hermann et al., 2016). The main strategy of the fourth industrial revolution is to expand the possibilities of relations between manufacturers and suppliers in various industries, which allows to increase the volume of individualization and personalization of customers.

The Industry 4.0 concept is defined by the following characteristics:

1. Digitalization and integration of vertical and horizontal value chains, from development and procurement to production, logistics and service. All existing data on the effectiveness of process control are available in real time in an integrated network. Horizontal integration allows you to reach suppliers, consumers and other key partners. Such integration uses a variety of technologies: from tracking and control devices to integrated planning integrated with real-time execution.

2. Digitalization of products and services, which includes the addition of existing products with various smart sensors or communication devices that are compatible with data analytics tools, as well as the creation of new digital products designed to provide comprehensive solutions. Due to the introduction of innovative methods of data collection and analysis, enterprises have the opportunity to obtain data on the use of products and modify these products in accordance with the new requirements of end users.

3. Digital business models and customer access, including comprehensive, personalized, data-driven services and integrated platforms. The main focus of new business models is to obtain additional profit from digital solutions, optimize interaction with the client and improve customer access (Kagermann et al., 2013).

This research paper will review technologies related to Health 4.0 from various global software and hardware vendors in order to analyze general trends in building the structure of IT support.

Results

The implementation of information systems and technologies at various types of enterprises, as a rule, is based on goals related to solving the most important business problems. An analysis of organizations in the healthcare sector showed that such tasks from the point of view of management include:

1. Improved diagnosis / treatment. The institution is not only a platform for the introduction of new technologies, but also achieves a significant improvement in the results of applying traditional approaches by using predictive modeling methods based on patients' medical data to select the optimal treatment depending on individual characteristics and organizational decisions.

2. Organization of “seamless” patient flows. Effective organization of patient flows means a reduction in waiting time and length of hospital stay, increasing the satisfaction of patients and doctors with the care process. The information system is configured to identify bottlenecks, analyze the causes and develop approaches to address them, which contributes to the optimal distribution of patient flows.

3. The active use of distance medical technologies and hospital to home technologies. One of the key tasks of remote monitoring methods is to expand the boundaries of the hospital with the possibility of further assistance to the patient at home. For these purposes, there are various medical devices - wearable, implantable, portable. But their main task is to provide information about certain vital functions of the patient (blood pressure level, electrical activity of the heart, oxygen saturation of the blood, glucose level, etc.) in real time to the clinic. Some devices are associated with additional therapeutic options, such as remote control of the dose of the drug. The most promising is the use of remote rehabilitation technologies, including during orthopedic operations, after a stroke, etc. This significantly reduces the need for patients to be hospitalized and, consequently, reduces the cost of providing care, along with an increase in patient satisfaction with the opportunity to receive the necessary help. at home. Data from wearable devices and applications originating from patients is medical information, a description of symptoms, biometric indicators, medical history, lifestyle indicators that are collected, recorded by the patient or his relatives. It is important to note that these data were collected outside the medical care process, because patients (not medical personnel) are responsible for collecting information and its quality, as well as maintaining its confidentiality (unless they are part of the services provided by the “smart clinic”) (Iljashenko et al., 2019). The advent of affordable wearable devices, sensors, and data transfer technologies, such as patient portals, provides a unique opportunity for long-term, continuous monitoring of daily activity and indicators of patients with chronic diseases. This promotes the involvement of patients and their relatives in the care process and the development of a continuously learning health system. Data from wearable devices can potentially fill many existing information gaps and provide a unique opportunity to track the patient’s condition and his adherence to treatment between visits to the clinic.

4. Improving patient safety. Improving the quality of care and the proper organization of patient flows leads to increased patient safety.

5. Reliability. A good reputation is a competitive advantage when choosing between different organizations. Reliability is also determined by the level of adherence to treatment and the creation of an integrative care system for patients, as this affects the results that a medical organization can achieve.

The world's largest software manufacturers, SAP, Microsoft, Oracle, etc., when developing IT solutions for the healthcare sector are guided, first of all, by the need to implement the ideas of value and personalized medicine. The main goal of modern IT solutions is to maintain a balance of medical and economic efficiency of the medical organization. The challenge is to provide cost-effective care, create a digital network for the new consumer-oriented healthcare ecosystem, and enable real-time information exchange between health care providers and patients. It is necessary to maintain a more personalized interaction between patients and a medical organization at all stages of the process, from prevention and diagnosis to treatment and postoperative care.

SAP IT-solutions

Digital technologies help the healthcare industry forecast the demand for medical services and provide real-time services, optimize the provision of preventive care and treatment, and give patients the opportunity to better control their health. Frequent changes in patient service quality standards require quick and constant adaptation by medical organizations, insurance companies, life sciences organizations, and software developers. There is a health ecosystem focused on the concept of Health 4.0, which goes beyond traditional management systems.

A modern consumer of medical services is informed, proactive, and is included in a single digital space for interaction with representatives of medical organizations. According to the CEO of SAP SE Healthcare Providers, SAP is developing digital solutions to bring patients and the healthcare industry closer together, using high technology to achieve more personalized care (SAP SE, 2020).

SAP's experience in digitally processing every aspect of the customer value chain is designed to help healthcare stakeholders improve their customer service delivery at an affordable price.

The SAP solution for the healthcare industry consists of 3 main modules:

1. patient care - the module for patient care is focused on solving many problems, such as organizing access to all patient data in real time, even on mobile devices; improving the overall health of patients while controlling costs.

2. Collaboration in the field of healthcare - ensuring collaboration between providers and consumers of health services contributes to the promotion of health and well-being and reduces the number of hospital visits. To ensure collaboration in the field of healthcare, this module helps to manage patient transitions from one healthcare provider to another when moving through the network, identify health problems before the patient needs to be in the hospital, and monitor patient redirection to maintain them within the network. This reduces the number of hospital visits, and collaboration between healthcare providers and consumers becomes more active. The healthcare collaboration module includes 2 submodules: patient involvement and patient relationship management.

3. health analytics and research - the main purpose of the application is to consolidate health data from various sources. The application includes 3 submodules: Healthcare Analytics, Medical Research Insights, Connected Health.

Thus, SAP IT solutions for healthcare include special solutions related to medical activities (Patient care, Care Collaboration, Healthcare Analytics and Research), and solutions supporting financial (Finance), human resources (Human Resources) and procurement (Procurement) activities. SAP provides IT architecture components with analytics solutions, application platform and infrastructure, information and database management, database and data management, IT management, and security software (Security Software), the Internet of Things and technology services (IoT Business and Technology Services).

Microsoft IT-solutions

Microsoft IT solutions implement the concept of Mental Health. The company provides Microsoft Digital Transformation for Health.

This solution allows you to improve patient care, allows them to receive medical care outside the home, anywhere in the world. With wearable sensors and service solutions, doctors can reduce the number of repeat visits and provide preventative care. Microsoft's solutions expand the power of the digital healthcare industry.

This is a single integrated platform that combines several solutions (Information Society, 2006):

• Health360 Care Coordination - coordination of patient care.

• Microsoft Dynamics 365 Sales and Field — A solution for field sales and service.

• Power BI - business intelligence.

• MS SharePoint - a platform for developing a corporate portal and managing corporate content.

• MS Azure - Microsoft's cloud platform.

The needs for the development of the health system are constantly growing with limited resources. In addressing issues of improving the quality of medical services, IT solutions in the field of e-health are an integral component of the digital transformation of a medical organization

Conclusions and Discussions

Thus, after analyzing the decisions of the world's largest software vendors, several key features of the structure of IT solutions were formed to support value-based and personalized medicine.

- Integration and connectivity to other products. Since the IT landscape of a medical organization consists of many different information systems, it is necessary to make sure that the selected systems will be able to use different databases (SQL, NoSQL), work with different standards for storing and transmitting data (XML, JSON) and have the ability to integrate with various software providers (SAP, IBM, Oracle);
- Performance. It is necessary to assess the amount of data that will be stored and transmitted in information systems, the number of users simultaneously using systems and peak loads on the entire IT landscape;
- Security. Since a huge amount of personal data is stored in the systems of a medical organization, protected by medical secrets and medical ethics, it is necessary in some parts of the landscape to use systems with clearly declared and customizable roles, as well as with the ability to isolate these systems from the "outside" world, without interrupting this interaction with other systems used in the landscape;
- Reporting. The doctor spends a large amount of working time on filling out and preparing reporting documents. Information systems of a medical organization should minimize this time in order to increase labor costs for direct duties of employees;
- Using cloud technology. The IT landscape of a medical organization should include systems that work fully or partially in the cloud, interacting with various equipment and sensors, for working with clients remotely, or for surgical treatment of inpatients, as well as for building telemedicine processes (Catarinucci et al., 2015; Meng et al., 2011; Piniewski et al., 2010).

Acknowledgments

The reported study was funded by RFBR according to the research project № 19-010-00579.

Abstract

The Nigerian experience of practicing entrepreneurs with the survival tactics is not new in occurrence coupled with its instability in the business environment. It is in line with this that the existence and patronization of the informal employment is believed in curbing the mitigating effects of unemployment. This study adopted a conceptual review of empirical literature of social motivation and sustainable competitive advantage. Articles were selected within the span of seven years from the Elsevier database. The selected articles were empirically written, thus being a selection for the review. The study reflects that increase application of sustainable competitive advantage continues to implore the informal activity while creating an influx into the different informal markets. The conduct of an empirical study is further suggested for further validation.

Keywords*:* Sustainable competitive advantage, Social motivation, Informal entrepreneur.

Introduction

The Nigerian experience of practising entrepreneurs with the use survival tactics of informal employment, with relations to insincere policy coupled with its instability in the business environment and the dynamic government regulations makes unemployment thrive. This assertion positively support International Labour Organisation (2014) conjecture on the patronization of the informal employment in curbing the mitigating effects of unemployment. Thus, making ways to avoid mitigating effects of non-practice of business informality. This effects ranges from, anxiety, psychosomatic symptoms, low subjective well-being amongst many others (Moses and Olokundun, 2014). With the provided data that shows the various percentage contribution in the emerging nation's economy stated as thus; Brazil: 39.8%, Russia: 46.1%, India: 23.1%, and Nigeria: 57.9% (Schneider, 2002).

This study adopts Webb et al. (2012) definition of informal entrepreneurship as economic activities that are outside of formal institutional boundaries (i.e., illegal but lawful) yet fall within informal institutional boundaries (i.e., legitimate) (Webb et al., 2009 cited in Webb et al, 2012). The informal sector is generally regarded as an avenue, in which practising entrepreneurs use to boycott

the due process that has been laid down by existing framework by the government in ensuring smooth running and monitoring of business activities. In place of this, the way forward is for the entrepreneur/business owners to find his or her niche (Jugdev, 2008; Samila & Sorenson, 2011; Timmons, 2011). Therefore, in connection with of Knight (1927, 2012) says on the line of economic prosperity in a nation, the transcending agent is the entrepreneur or in the informal setting, referred to as business operators. Knight (2012) propounds on the levels of risk encountered which produces the profit/loss result via the rendered service(s) of scientific research and thus reduces the ills that uncertainty would have brought with it. It is pertinent to note that risk is associated with uncertainty which produces profit or loss (Knight,(1921); Aven, 2012; Huang & Pearce, 2015; Low & MacMillan, 1988). This insights on the sources of profit have been instrumental in shaping modern economic theory and to the development of a useful understanding of probability. This is a characteristic that is tied to business activities which are ventured into. Therefore, one tends to pounder that the activities in the informal sector are legitimate by the majority of the populace, and thus, should there not be a structure in place to make them legally acceptable and income generators in the economy, with focus on Nigeria.

A business entity is a burden with the need to survive with rivalry as its stake holds amongst its contenders. Kwame & Colin (2012) made the findings via evaluating informal entrepreneurs 'motives in sub-Saharan Africa by reconciling the developed and developing economies by reflecting on the women informal entrepreneurs who are predominantly necessity-driven as against, men, known to be principally intentional participants in informal entrepreneurship.

Furthermore, Palmer (2007) earlier noted informal entrepreneurs in third world nations was necessity-driven and as a result, informal entrepreneurship has been widely depicted as conducted by marginalized populations out of necessity with the last resort in the absence of alternative sources of livelihood (Hanson, 2005; Altman & Morrison, 2015).

The perceived competition leads to the need to adopt strategies that will help the business to survive and attain retainership with the societal drive adopted from the cultural values embedded in the informal operators; this is common amongst the Igbo tribe (Ayeni, 2019).

Thus, this study intends to establish a possible link between social motivation and sustainable competitive advantage in the business operation of informal entrepreneurs using existing literature. The selected articles were within a decade range of been published with over a fifty citation achieved.

Reviews

The work of Rey-Martí, Ribeiro-Soriano, Palacios-Marqués (2015) assessed the level of attention given to social entrepreneurship-related research, which caused by social motivation. This further brought into limelight the areas with the greatest research output, countries and languages responsible for most social entrepreneurship research. The study was tied to the countries and the year conducted. In doing this, it provided an orientation to new researchers about parameters and authors in the social entrepreneurship that ought to be consulted when studying the social entrepreneurship phenomenon. The study employed a bibliometric analysis on the Web of Science online database on the related literature as its methodology. The conducted analysis of 2984 social entrepreneurship research documents revealed that 1851 are scientific articles in the English language in the business economics line of research for socially induced entrepreneurs. An extension of the study, being empirical would have been an input that could spawn new researchers into the line of study.

Amir, Sahar and Mohammad (2016) examined how to achieve sustainability through the Schumpeterian social entrepreneurship. This was viewed from the role of social enterprises. In their study, they decided to enhance social entrepreneurship with the Schumpeter's perspective developed in his magnum opus "Theorie der wirtschaftlichen Entwicklung". The methodology adopted for the study was theoretical analysis. The analysis made use of social enterprise, an effect of social motivation in transforming a business into an engine for sustainable development. The concept of corporate citizenship, social entrepreneurship, corporate social responsibility, social

enterprise, and sustainable development were employed in the study. From the concept generated, the socio-economic ecosystem was hypothesised to work in alignment with sustainable development but the evidence of empirical data was absence in the study.

Furthermore, Aquino, Lück and Schänzel (2018) provided a conceptual framework of tourism social entrepreneurship for sustainable community development, an offshoot utilising competitive advantage. This was designed to address this gap in knowledge of the conceptualisation of tourism social entrepreneurship as a more holistic strategy for sustainable community development. The study critically analysed related literature by creating a conceptual framework. The framework incorporates community development concepts, generic social entrepreneurship, tourism social entrepreneurship principles and community capitals perspectives. From the study, the emerging literature on tourism social entrepreneurship that assists the socially motivated entrepreneurs in the system was established. This was a view of projecting the established new community-centric social enterprises. The intent drivers into the tourism sector was a vital point missed alongside with no empirical data in the study.

While looking at the negativity of social entrepreneurship, birthed from social motivation, Lundmark and Westelius (2019) examined antisocial entrepreneurship conceptually. It was posited that studies were conducted from the viewpoint of social entrepreneurship while neglecting antisocial entrepreneurship. This brought about the provision of a conceptual foundation for antisocial entrepreneurship. Thus, making up the methodology of the research with illegal and destructive entrepreneurship serving as the constructs. The findings of the study brought to fore a suggestion for future research on antisocial entrepreneurship. These are entrepreneurs who are not socially motivated. The exclusion of empirical evidence limited the study strength.

Muñoz and Kimmittb (2019) explored the complex interactions between the strategic conditions of social entrepreneurs, birthed from drivers of social commitment. This was in relations to the development of market-oriented social missions. The qualitative method was qualitative comparative analysis (fsQCA) to analyse and explain the complex strategic conditions of social entrepreneurship. The findings from the study contributed to the already existing complex understanding between social and economic mission in social entrepreneurship. This further queried the postulation underlying the bindery of social entrepreneurs, who improve their social status and that of the people around them into the social mission. The exclusion of a quantitative method of analysis in the study relapsed the strength of the study.

Shedding more light on the motivational factors in social entrepreneurship, Dwivedia and Weerawardena (2018) saw the need to operationalise and conceptualise constructs by proposing a behavioural measure of social entrepreneurship orientation (SEO). These constructs were offered in five dimensions, namely; innovativeness, proactiveness, risk management, effectual orientation, and social mission orientation. With the use of descriptive statistics, chi-square and correlation, they were assessed methodologically to be fit. In the course of the study, an adoptable parameter for measurement was drafted to measure socially driven entrepreneurs, though with the marginalisation of a qualitative validation.

In creating an adaptable theory for social entrepreneurship-related research, entailing social entrepreneurship initiatives, development process and social value, Sekliuckiene and Kisielius (2015) developed a conceptual framework. The gap was filled using the analysis and synthesis of scientific literature. From the conducted research, a conceptual model was developed. It consisted of social entrepreneurship development initiatives; connecting contextual and entrepreneurial individual factors, social opportunities recognition factors and results gotten from nascent values from the social entrepreneurship development process. In relations to the social entrepreneurs' improvement of those around them and themselves, the findings birthed social entrepreneurship initiative, opportunity exploitation, opportunity identification and evaluation, opportunity formalization. Empirical evidence to the stated construct was missing in the study.

Douglas and Prentice (2019) explored innovation and profit motivations for social entrepreneurship by considering all three main pillars of social entrepreneurship. The pillars consisted of the role of prosocial, profit, and innovation motivations in the individual's decision to

become a social entrepreneur. Otherwise regarded as his intention of becoming an entrepreneur being motivated socially. With the adoption of qualitative comparative analysis (fsQCA) as the methodology in the study, configurations of motives, self-efficacies, and personal conditions were identified in the culmination of social entrepreneurial intention. Thus, revealing some asymmetric relationships between social entrepreneurial intention and prosocial attitude, innovation attitude, and entrepreneurial self-efficacy for socially motivated entrepreneurs with lapses of empirical qualitative analysis.

Establishing the diversity of social entrepreneurship, Langa and Finka (2018) developed a more nuanced and multilevel understanding of the social network arena in which the rural social entrepreneur operates. The study brought to fore the expansion of correlated social drivers in line with the causal effect and operations of social entrepreneurship in the rural setting. Qualitative content analysis was adopted as the methodology of the study. This was done by gathering materials in the narratives, alongside the semi-structured and expert interviews. The study informed future studies about the identification of the formation and configuration of the different types of social capital displayed in the proposed framework of social entrepreneurship and rural development as the lives of socially inept individuals were improved. The absence of quantitative information would have strengthened the finding from the research.

In instituting the importance of social entrepreneurship, which sprung from social motivation, Palacios-Marqués, García, Sánchez and Mari (2019) linked it with the organizational performance of a company. This was also aimed at showing a positive relationship between the extent to which social entrepreneurship is implemented via socially motivated scenarios while creating distinctive marketing competences. The stated competences served as the mediating role between social entrepreneurship and organizational performance. Descriptive statistics and chi-square were employed as the methodology in the study. The findings of the study reflected a positive relationship between the extent to which an organization introduces social entrepreneurship to socially motivated entrepreneurs and its organizational performance while the prove of qualitative evidence was omitted.

Cherrier, Goswami, and Ray (2018) examined the possibility of institutional complexity to provide opportunities for social entrepreneurship. Thus, providing the arising relationship from social motivation on entrepreneurial attainment to institutional complexity. The study employed a mixed-methods approach. The approach consisted of observations, in-depth, unstructured and semi-structured interviews and document analysis. From the findings, it was identified that the social venture's responses to institutional complexity in the forms of appropriation, integration, differentiation, and working-through have a valid interaction with the provided opportunities earned from social entrepreneurship. The use of quantitative measurement in the study would have strengthened the provided views of the researchers

Also from the study of Adele, Oyedokun, Adewoye and Afolabi (2015), factors motivating informal entrepreneurship in developing countries were examined. This was done to determine how peculiarities stimulate the choice to operate formally or informally by owners of businesses. The test was done to determine the socially related parameters that swing informal entrepreneurship into action. The study adopted the inferential statistical tool of multiple regression as the methodology to determine the conformity of informal entrepreneurship to socially related motivation parameters. These parameters include traditional culture, norms and values. The study revealed that informal entrepreneurship, who are socially motivated, adapts to the traditional culture, norms and values with the perception of the imposition of formal rules/principles. The researchers' position on the premise defined in the study was undermined with the lack of qualitative evidence.

Anetor (2015) made an investigation into the value of street vending, a common scene of an informal trade practised in Nigeria. Though commonly assumed as a result of socially related motives, the study considered the value of the street vending activity in Nigeria. This was done to stop the belief of the assumed negativity of street vending. In postulating this, the study adopted a descriptive analysis to test the collated responses to the study. The findings of the study revealed that the existence of street vending aids government and business communities capsuled on the

realisable benefits. It also immensely contributed to the economic, social, and economic life of Nigerians. The oversight of utilising qualitative analysis weakened the provided revelation from the study.

The usage of competitive advantage as a tool of product differentiation was understudied by Dirisu, Iyiola, and Ibidunni, (2013). It was researched to attain evidence of optimal performance relationship in businesses organisation. Business organisation are the products of an entrepreneur's business establishment. The researchers postulated that competitive advantage influences the performance of the organization. To test the stated assumption, simple linear regression and correlation analysis were adopted for the research's methodology. The findings revealed a positive significant relationship between new product innovation and customer satisfaction of an entrepreneurial organization. The study was limited to the quantitative method adopted.

Sołoducho-Pelc (2014) examined the relationships between competitive advantage and courage when formulating objectives for the business organisation. The study made use of correlation for the methodology. This was based on the analysed assumptions regarding sources and evaluation of a business competitive advantage concerning the courage in formulating key objectives. The study adopted a correlation methodology. The findings from the study sort to building and developing the advantage over competitors, as it is required to implement offensive strategies, in which the risk level is much higher and difficult to assess unambiguously. It further posited the importance of the implementation of risky strategies, a reflection of success in the domination over competitors. The non-qualitative assessment of the risky strategies was the gap of the literature.

The work of Block, Kohn, Miller and Ullrich (2014) expressed the relationship between the compulsorily engaged type of entrepreneurship and competitive strategy, also regarded as a competitive advantage. In their opinion, it was posited that entrepreneurial start-ups chose to contend with existing entrepreneurial firms using a particular generic strategy; the cost leadership or differentiation strategy. With the objective of the study was the assessment of how the choice made was depended on necessity. A dataset of 4,568 German start-ups was qualitatively collected and descriptively analysed alongside Blinder-Oaxaca-type decompositions adapted to the non-linear were adopted for the study's methodology. The study showed necessity entrepreneurs are more likely to pursue a cost leadership strategy than a differentiation strategy. This was correlated and attributed to distinct endowments of human capital, socioeconomic attributes (a reflection of social motivational features exhibited by social entrepreneurs), and start-up project characteristics. The omission empirical qualitative analysis was needed to buttress the posited view of the researchers.

Studies on competitive advantage being related to entrepreneurship were further undertaken by Badenhorst-Weiss and Cilliers (2014). The study explored the various sources of competitive advantage with focus placed on differentiation and a unique value packaging. This was engaged as a market strategy to ensure competitiveness and sustainability for formal independent small businesses in Soweto. The study made use of descriptive and inferential statistical methods to analyse the data. Parametric (Anova being utilized) and nonparametric tests statistically certified significant differences between mean scores of the different business. The study reported that sustainable formal independent small businesses, who were socially motivated into the business activities, retained their competitive nature via the respective differentiation made on the elements of the unique value package they offer to customers. They also posited that sustainable businesses regard price, shopping hours, personal attention and close relationships as important differentiating elements. The excluding of informal entrepreneurs limited the study.

Greenidge (2015) conducted a study on competitive advantage, entrepreneurship and strategy using Trinidad and Tobago's steelpan Industry as a case study. The study investigated the causes of this decline, and to outline possible strategies for addressing the loss of competitive advantage in one of the country's first indigenous industries. It also explored the structure and trajectory of the global steelpan industry. The method adopted for the research was an interview, which was analysed. The findings revealed that the current trajectory of the industry continues over the next 7-10 years, Trinidad and Tobago will not possess a significantly greater degree of access to the

main sources of its competitive advantage, i.e. human capital and technological know-how, than its nearest competitors. The study was not substantiated with empirical qualitative evidence.

Table 1: Summary Table of Literature on Social Motivations and Sustainable Competitive Advantage

S/N	Author/Year	Topics	The objective of the study	Methodology	Findings	Gaps
1	Rey-Martí, Ribeiro-Soriano and Palacios-Marqués (2015)	A bibliometric analysis of social entrepreneurship	The study accessed the level of attention given to social entrepreneurship-related research	Bibliometric analysis of literature from World of science (W.O.S)	It was revealed that 1851 are scientific articles in the English language in the business economics line of research for socially induced entrepreneurs	There was no empirical analysis conducted not all the motivations were considered.

Descriptive analysis alongside Blinder-Oaxaca-type decompositions	The study showed necessity entrepreneurs are more likely to pursue a cost leadership strategy than a differentiation strategy. This was correlated and attributed to distinct endowments of human capital, socioeconomic attributes (a reflection of social motivational features exhibited by social entrepreneurs), and start-up project characteristics	The omission empirical qualitative analysis
17	Badenhorst-Weiss, J.A. and Cilliers, J.O. (2014)	The competitive advantage of independent small businesses in Soweto	The study explored the various sources of competitive advantage with the focus placed on differentiation and a unique value packaging	The study made use of descriptive and inferential statistical methods to analyse the data.	The study reported that sustainable formal independent small businesses, who were socially motivated into the business activities, retained their competitive nature via the respective	It did not consider the informal sector of the market and not all the motivations were examined

					differentiation made on the elements of the unique value package they offer to customers.	
18	Greenidge, C.O. (2015)	Competitive advantage, entrepreneurship and strategy in the global south: A case study of Trinidad and Tobago's steelpan industry	The study went on to investigate the causes of this decline and to outline possible strategies for addressing the loss of competitive advantage in one of the country's first indigenous industries.	Analysed Interview	The findings revealed that the current trajectory of the industry continues over the next 7-10 years, Trinidad and Tobago will not possess a significantly greater degree of access to the main sources of its competitive advantage, i.e. human capital and technological know-how, than its nearest competitors	There was an absence of an empirical quantitative assessment and partial consideration of the motivation into informal business activities.

Conclusion

The incongruous findings across different scholarly works make social motivation and sustainable competitive advantage concepts intellectually thought-provoking but demands hypothetical fusions' towards critiquing existing works.

The motivation was earned via the need to meet the social demands of entrepreneurs. However, the actions poised by informal entrepreneurs, regarded as social entrepreneurs because of their drive to improve their social status and that of the people around them in relations to the engaging activities has not been understudied.

Therefore, the study establishes the need for an empirical study to fill the void of social motivation linked with the usability of sustainable competitive advantage in the informal market for its business operation continuity. The understudied research which attempts to validate the existence of such linkage was with the omission of empirical stance. This comes as a result of a literature absence to that fully link the two parameters with the required evidence. The increasing application of sustainable competitive advantage continues to implore the informal activity while creating an influx into different informal markets. The conduct of an empirical study is further suggested to attest a concrete validation.

Abstract

Basic infrastructure consists of the fundamental physical and organizational structures and services required for the operation of a society. Some infrastructure are however deemed to be "critical" in nature due to their nature and their significance to the maintenance of normalcy in daily life within a country. Critical infrastructure has therefore received special attention in most countries in recent years due also to the changing dynamics in the international system necessitating the formulation and implementation of strategies in this regard. This paper assessed the importance and significance of critical infrastructure to national development in Nigeria and underscores the apparent neglect of this very important issue by Nigerian government. The paper employs the use of a theoretical framework to empirically explain and justify this study. Having studied critical infrastructure policies of some selected countries, the study concludes that the Nigerian government has continued to neglect this very significant aspect necessary for its socio-economic development.

Keywords: Infrastructure, Critical Infrastructure, Strategic, National Development, Socio-economic development

Introduction and Background of Study

Infrastructure as a concept is not new, it is very broad and has assumed changing connotations and definitions over the years (Oyedele, 2012). Fulmer (2009) opines that infrastructure consists of all physical assets that are deemed fundamental facilities and systems serving the country, city, or area. It typically refers to the technical structures that support a society, such as roads, water, electrical national grid, telecommunications and so forth (Na & Raksakulthai, 2006). Infrastructure can also be seen as "the physical components of interrelated systems providing commodities and services essential to enable sustain, or enhance societal living conditions" (Fulmer, 2009.30-32).

Furthermore, Nedozi, Obasanmi & Ighata (2014) considers Infrastructure as indeed intricately linked to development. Infrastructure therefore remains very critical to broad-based socio-economic development of any country as lack of adequate infrastructure remains one of the major constraints to

the economic growth of many African states, Nigeria inclusive. To quote renowned economist Dr. V.K.R.V. Rao, "infrastructure and development is a continuous process and progress in development, if we are to fulfill our declared objectives of a self-accelerating process of economic development" (Islahi, 1997). This perspective was also echoed by Ihembe, (2011: 504) when he opined that "Infrastructure as a critical form of development plays an important role in any country or region or state as it seriously constitutes the hub upon which socio-economic aspects of society revolve. The term "critical infrastructure" is however used in a more strategic sense to underscore those structures whose importance underpin the overall existence of a country.

The Federal Republic of Nigeria is often referred to as the "Giant of Africa", owing to its large population and economy (Holmes, 1987) with an estimated population of 206 million inhabitants, Nigeria is the most populous country in Africa and the seventh most populous country in the world (Bloomberg, 2020). Nigeria has the third-largest youth population in the world, after India and China, with more than 90 million of its population under the age of eighteen (Library of Congress Country Profile, 2018). Nigeria is also the world's 20th largest economy as of 2015, worth more than $500 billion and $1 trillion in terms of nominal GDP and purchasing power parity, respectively (The World Fact Book, 2018). Since Nigeria's return to Democracy in 1999, the country has continued to battle with severe shortfall in provision of modern infrastructure required to fast-track economic growth and development. The country's infrastructure challenge has become even more pathetic due to the increased demand and limited resources (Olanipekun, 2014; Oyedele, 2012). Considering the staggering volume of funds required for infrastructural development and the meagre annual budgetary allocations for infrastructure, the Nigerian infrastructure deficit is indeed a cause for alarm. Critical infrastructure in Nigeria include communications; emergency services; energy sector; dams; food; public services; industry; health; transport; gas; public communications, radio and television; and commercial facilities (Adigun, 2018).

Statement of the Problem

In spite of Nigeria's economic potentials and regional power, the country has serially suffered from absence or neglect of critical infrastructure, a very disturbing trend as infrastructure is the mainstay of Nigeria's economy, security, and health. In simple terms, the critical infrastructure that should provide the essential services that underpin Nigerian society are lacking and where they exist, these critical systems and structures are often taken for granted. While existing literature on Nigeria's critical infrastructure such as Iwendi and Allen (2011), Badiora and Obadiora (2011), Ofoegbu (2014) and Adigun (2018) all advocated for the protection of the existing critical infrastructure in Nigeria, there exist a lacuna as to the area of assessment of the strategic importance of critical infrastructure to the socio-economic development of the country.

The aforementioned therefore makes it pertinent to investigate how the availability of critical infrastructure can fast track socio-economic growth and development of Nigeria.

Objective of the Study

The main objective of the study is to make a case for the availability of sufficient critical infrastructure required to engender socio-economic growth and development of Nigeria.

Conceptualizing Critical Infrastructure

Even though there seem not to be a generally acceptable global definition of the term "Critical Infrastructure", existing literature have in several ways explained the concept. According to the Department of Homeland Security (DHS) Critical infrastructure includes the vast network of highways, connecting bridges and tunnels, railways, utilities and buildings necessary to maintain normalcy in daily life. Transportation, commerce, clean water and electricity all rely on these vital systems (DHS Critical Infrastructure Protection Report, 2019). Also, the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 (USA

PATRIOT Act) refers to systems and assets so vital to the United States that their incapacity or destruction would have a debilitating impact on security, national economic security, national public health or safety, or any combination of these matters. This means that it is the backbone of a country's economy, security, and health. In simple terms, it provides the essential services that underpin society.

In addition, the term has also been widely adopted to distinguish those infrastructure elements that, if significantly damaged or destroyed, would cause serious disruption of the dependent system or organization (American Heritage Dictionary, 2009). In other words, governments use the term to describe assets that are essential for the functioning of a society and economy. According to Meier (1995), Critical Infrastructure are such assets are identified as basic facilities, services and installations critical to the socio economic well-being of any state. The way and manner these physical assets function and upon which these services are delivered are considered critical infrastructure.

In strategic terms, Critical infrastructure refers to the body of systems, networks and assets that are so essential that their continued operation is required to ensure the security of a given nation, its economy, and the public's health and/or safety.

Critical Infrastructure divergence across the world

Although critical infrastructure is similar in all nations due to the basic requirements of life, the infrastructure deemed critical can vary according to a nation's needs, resources and development level. Sectors that are considered as "critical infrastructure" differ among different countries, but most would comprise: energy, water, food, transport, telecommunications, healthcare, as well as banking and finance. Since there is no universally agreed definition of the term "critical infrastructure", each country defines it based on national priorities, self-interest and power capabilities.

Globally however, the severity of critical infrastructures necessitates that deliberate policies be formulated and implemented to operationalize the strategic importance to national security and well-being. Many countries have national plans or strategies and these strategies generally define what nature of infrastructure are "critical". The table below indicates some selected states, the definitions given to the subject matter and the varying sectors that are deemed critical to the countries.

TABLE 1: Variations in Sectors and Number of Sectors of Critical Infrastructure in Selected Countries

Country	Definition of Critical Infrastructure	No of Sectors	Critical Infrastructure Sectors
CANADA	According to the Department of Public Safety-Canada, Critical infrastructure refers to processes, systems, facilities, technologies, networks, assets and services essential to the health, safety, security or economic well-being of Canadians and the effective functioning of government	**10 Sectors**	Health, Food, Finance, Water, Information and Communication Technology, Safety, Energy and Utilities, Manufacturing, Government and Transportation
USA	The Department of Homeland Security **(DHS)** defines Critical infrastructure to include the vast network of highways, connecting bridges and tunnels, railways, utilities and buildings necessary to maintain normalcy in daily life. Transportation, commerce, clean water and electricity all rely on these vital systems. Also, the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 (USA PATRIOT Act) refers to systems and assets so vital to the United States that their incapacity or destruction would have a debilitating impact on security, national economic security, national public health or safety, or any combination of these matters	**16 Sectors**	Chemical, Commercial Facilities, Communications, Critical Manufacturing, Dams, Defense Industrial Base, Emergency Services, Energy, Financial Services, Food and Agriculture, Government Facilities, Health Care and Public Health, Information Technology, Nuclear Reactors, Materials and Waste, Transportation Systems, Water and Waste Water Systems
UNITED KINGDOM	According to the Centre for the Protection of National Infrastructure, Critical Infrastructure are those facilities, systems, sites, information, people, networks and processes, necessary for a country to function and upon which daily life depends. It also includes some functions, sites and organisations which are not critical to the maintenance of essential services, but which need protection due to the potential danger to the public	**13 Sectors**	Chemicals, Civil Nuclear Communications, Defence, Emergency Services, Energy, Finance, Food, Government, Health, Space, Transport and Water
EUROPEAN UNION	The European Programme for Critical Infrastructure Protection (EPCIP) defines Critical infrastructure to mean an asset, system or part thereof located in Member States which is essential for the maintenance of vital societal functions, health, safety, security, economic or social well-being of people, and the disruption or destruction of which would have a significant impact in a Member State as a result of the failure to maintain those functions.	**8 Sectors**	Electricity, Oil, Gas, Road transport, Rail transport, Air transport, Inland waterways transport, Ocean and short-sea shipping and ports
SOUTH AFRICA	Critical Infrastructure Protection Act, 2019 ("the **CIP Act**") recognises that certain infrastructure is critical for public safety, national security and the continuous provision of basic public services.	**11 Sectors**	Government Facilities, Defence industry, Critical manufacturing, Energy, Water supply, Food and agriculture, Healthcare & Emergency, Information & communication technology, Transportation, Financial, Chemical, Atomic energy

Theoretical Framework

The Structural Functional Analysis theory by Gabriel Almond is engaged in this work to empirically explain and justify this study. In his theory, Almond's mode of analysis is fundamentally concerned with the phenomenon of system maintenance and regulation. The basic theoretical proposition is that in all social systems, certain basic functions have to be performed. Almond provided a model for structural functional analysis, which identified the functional requirements of the political system and explained the contribution of these functions toward the maintenance of stability of the system. In this study, we are more concerned about how the maintenance and stability of our critical infrastructure can enhance sustainable development in Nigeria. He further noted that every political system has some structures and these structures perform certain functions meant for it. These structures in this study represent critical infrastructures and their functions in society.

The Nigerian Scenario

In Nigeria, critical national infrastructure includes transport, emergency services, water and telecommunications and other critical assets, systems and functions that are integral to a her capacity to function as a sovereign nation. According to Ihembe (2011: 504) critical infrastructure plays a significant role in the development of any country or region or state as it constitutes the hub upon which socio-economic aspects of society revolve. Despite this foregoing, the government of Nigeria is yet to underscore the significance of critical infrastructure to National development as Nigeria remains one of the countries yet to formulate and implement a deliberate strategy for the development and eventual protection of critical infrastructure across the country. While most developed countries are far ahead of the developing economies in formulating and implementing policies regarding to the critical infrastructure so that they can deliver both economic and social benefits for individuals and for the society as a whole (Case, 2010), Nigeria and most developing states still lag behind (Gabriel, 2014).

The services and systems provided by critical infrastructures are so intertwined into the fabric of our everyday life that a small failure or down time can cause far reaching effects. Persistent downtime of any critical service can grind a country to halt, stopping economic activities, coordinated security and emergency services and many every day services whose importance in our lives we underestimate. This

has been the Nigerian experience over time as several challenges beset the country's critical infrastructure in diverse ways first of which is the issue of gross underfunding of infrastructure. In a December 2nd interview in The PUNCH Newspapers, the Federal Roads Maintenance Agency (FERMA) Managing Director/CEO Engr. Nurudeen Rafindadi blamed the bad state of Nigeria roads to poor funding, hindering the agency's capacity in proper road maintenance nationwide (Punch news, 2019). This statement further confirms the big issue of infrastructure funding in Nigeria, for new infrastructure and maintenance of existing ones. It is bad enough that the amount budgeted for capital projects is inadequate (averagely 27% over the last 12 years), the amount that finally gets into actual project implementation equally faces huge challenges. These includes delay in fund release or outright insufficient release, fund diversion, loopholes in the procurement processes, failure of citizens to involve themselves in project execution process, etc. In the end, the actual spending on capital projects is barely 17-20% of budgeted amount (Ausick, 2019; NBS, 2019). Corruption is also a very visible factor that has affected critical infrastructure in Nigeria. The case of corruption is visible in the prevalence of inflated government contracts for capital projects which end up poorly executed and funds allocated for human capital development diverted (Hope, 2019).

Conclusions and Recommendations

The Role of critical infrastructure in the socio-economic development of Nigeria cannot be over-emphasized as it is intricately linked to development. Nigeria's broad-based socio-economic development is obviously being hampered as lack of adequate critical infrastructure. The study revealed that poor funding, corruption, lack of maintenance and absence of a deliberate strategic policy on infrastructure as the main challenges of critical infrastructure in Nigeria.

To forestall this trend and put the country back on the path of socio-economic growth, the study hereby recommends that Nigeria as a matter of urgency, sign into law the Critical Infrastructure Protection Bill already passed by the 7th National Assembly but yet to be assented to by the President. This will ensure the proper protection and maintenance of critical and essential facilities that affects daily living in the country. Furthermore, anti-corruption efforts should be intensified by the government to forestall the diversion of public funds meant for critical infrastructure. Also, more funding opportunities should be explored by the government in order to have additional infrastructure funding required to enhance the socio-economic development of the country.

Introduction

Every created State has a major responsibility to satisfy and improve her populace socio-economic wellbeing (Shuaib, 2018). These responsibilities are largely seen in wage policies with the improvement of citizen lifestyle. Furthermore, a clear documentation in respect to this, is reflected in the Constitution of Nigeria having security and welfare at heart. Olatunji (2014) opines that salaries and wages are great motivating factors as it is a reward for labour or work. Hence reasonable wages must be fixed and paid on time.

Wages deals basically with all forms of remunerations, allowances, earnings paid to employees as a form of reward to labour or hours put in work. The International Labour Organization (ILO) (1996, 2008 and 2009) explained that the major purpose of Minimum wage is to protect against low pay for workers. Thus, it does by ensuring the protection of workers right to a fair and substantial wage. Eme (2009) defined minimum wage as the payment made to an employee to provide for himself and his family and to get the essentials, carter for the children and to save for the future. At no point was reference made to the inclusion of a possible transition of his standard of living. This therefore insinuate that the wage paid is targeted at a survival stipend to keep the employee in use for the designated labour.

According to Nwude (2013), In 1894 by the government of New Zealand the minimum wage legislation came to be, the minimum wage law in 1896 of Victoria State of Australia was next. The amendment led to the creation of a wage. The wages board was deficient in some ways as it did not set a commonly acceptable minimum wage standard that is universal rather it brought about low wages because of the basic wages for six industries that was set up. In the history of the USA industrial relations system, in 1912 the Massachusetts enacted its minimum wage law. The practice of wage fixation is very old but its nature and practice varies from country to country (Eme, 2009).

The Nigerian history of minimum wage dates back to the colonization. Though, there were past undocumented payment of when workers are paid their dues after being engaged in labour before the arrival of the colonizers. The constant agitations for better working conditions for workers have always been a matter of concern to governments. Eme (2010) stated that, the Nigeria's independence era both

before and after, experienced situations where, workers have always taken the hit of the policy enacted as they are paid lower wages and benefits. Actions have been taken by various regimes which led to the setting up of several panels, commissions or tribunals and series of reforms since 1934 to address wage challenges.

This has always been the trend, with state government claiming to not have the capacity needed to pay the required sum. Uncoincidentally, it was noted that an increase in wage negotiated on is usually met by an increase of price commodities in the market. This vis-à-vis leads to a general rise in cost of living rendering such newly agreed wage increases a little worth after being enacted (Okeke, Nwele and Achilike, 2017).

For the increase in wage, the role of demand and supply cannot be undermined. The forces of demand and supply analyzes how the government and labor unions interact to determine wage levels as well as see that these wages reflect the value of work put in any area. Understanding these interactions will help us understand the foundations of demand and supply and how they determine wage levels. In the course of this study, Demand, refers to the clamor of labor unions for the increase of wages so as to meet the increasing cost and standard of living. The willingness and the ability for labor unions to take up this responsibility is the vital reason it was established.

The supply therefore relates to the requirements that needs to be in place to meet the unrelating demands. This cannot be shorted as it will lead to tension neither must it be relaxed as waste will occur. Therefore, the negotiated wage increase needs to consider the impact of the demand and supply paradigm. The process by which the forces of demand and supply play a great role is in collective bargaining.

The collective bargaining process deals with negotiations between parties. This parties refers to the employees under the umbrella of the labor unions and the Government. This is done in other for employees to put into higher consideration the set of demands for their employer or government. In the case of the wage increase scenario, the bargaining committee comprises of Union representatives and the government at the "bargaining table,". The involved parties present various intended outcome which is in document form that should explain the intent behind them which should be clear and concise. Agreements are to be reached on such proposals and counter offers over the upcoming unresolved issues. The duration of such deliberations varies depending on the strength of the bargaining proposals. (Johasson, 2016). To this end, wage determination needs to be conceptualized. it is the outcome of interactions between the tripartite partners in industrial relations, namely, the government, employers and workers represented by their unions (Armstrong, 2009).

A developing nation such as Nigeria, has the federal government of Nigeria responsible for wage determination, making sure that its decisions are implemented both by the state and local government. Akinwale and Elegbede (2017), said that some states lack the financial strength and capacity to implement the federal government wage policy, this accounts to wage differential in the sectors as both federal and state government workers do not earn the same.

The recently negotiated and yet to be fully implemented N30,000 minimum wage on April 18 2019 has been the joy of workers but the implemtnation of this new wage by the state government is yet to be indetified. This stalling reflexs a negative impoulse in thew Nigerian state as federal government workers have started enjoying the this new wage. In same vien, states like Lagos state has commenced payment. The argument by those in denial hjas been the non consultation before the implementation, leading to the unawareness of the template used for the payment (PM News, 2019).

To this end, the research calls for need to understand the paragdym for having a minimum wage reflecting the standard of living at all level of governemt with reduced or emiminated conflits of going back to the bargaining board within a short span of years.

Minimum Wage Laws in Nigeria

The first well established National minimum Wage Act prescribed a minimum wage of N125 per month (FGN Official Gazette 1981) which was in 1981. Then it became N250 in 1991 and N5, 500 in 2000 through the Minimum wage Act of 2000. The effect of this was that the lowest paid worker in the

formal sector and state governments employment pay was N5, 500 monthly while the federal workers were N7500 per month (Aminu, 2008).

Generally, it has been observed that poor pay has been in prevalence in the public sector, becoming a stigma leading to the pay structure of the public sector being inferior as opposed to the private sector, leading to further agitations and an upward revision of the wage to N18, 000 through a well negotiated tripate structure under President Goodluck Johnathan, exclusive of all deductions. This was with exception of the specification laid out in the law that issues such as pension, income tax and all other contributions. Notably, when prescribed by the law, in kind payments can be considered. To this end, it was signed into law by the National Assembly with a clear provision that there will be constant review of the National Minimum Wage every five years. It was also clarified in the document that the agreement reached is that it would be declared null and void if the wages agreed upon is less than what is stipulated (Fagbemi, 2018).

These recommendations were fully documented in the bill submitted by Justice Alfa Belgore Committee. It stated that the new minimum wage for both public and private sector with fifty workers and above will be meted with punishments or imprisonment or fines not more than a stipulated amount in the case where this offence still persist the fine N10, 000 per day during which the offence continues (Irughe, 2013). March 15, 2011 saw the bill being passed, it was also negotiated and signed August 16, 2011 which revised the wage to N18,900, which has recently been revised to 30,000.

The National Minimum wage bill (2019) main objective was to provide for a well detailed legal structure for an effortless review of the minimum wage within the period stated. It also stated that every worker except stated otherwise, be paid nothing less than the agreed barest monthly Minimum Wage of N30, 000. This amendment was affected throughout the Federal Republic of Nigeria without due consideration of the state capabilities the capabilities was in reference to the state revenue as well as expenses. It is in line with this that the federal government was noted to always be the dominant player in wage determination. This affirmation was in line with Abimbola (2014).

For issues that could arise in Nigeria, the Minimum Wage compliance is regulated by the Labour Inspectorate is saddled with the responsibility of making sure the agreed upon wage is complied with. This structure was put in place to forcibly bring about compliance but once again with the omission of the capabilities of the involved parties. With reference to the National Minimum Wage Act (1981) exempts were given to the following organizations from the obligation to pay the national minimum wage. They include;

i. A firm with less than 50 workers;
ii. A firm with part time workers working for less than an average of 40 hours a week.
iii. an establishment at which workers are paid on commission or on piece rate basis;
iv. occasional employment workers and
v. aircraft crew members.

(Official Gazette, 1981; Official Gazette, 2000; National Minimum Wage Act amendment of 2011; Wages Boards and Industrial Council Act, 1974)

The duration of wage payment is between a day to one month, depending on what is stated in the contract at the point or time of employment. The Labour Act,(2009) stipulates that the employer must provide every worker a statement clearly written to specify the following, among other things;

i. wage rates,
ii. the strategy for wage calculation,
iii. period and manner of wage payment.

The payment period should under no circumstance exceed a month except the written consent from the state authority has been obtained specifically for this purpose. The Labour Act states that wages are payable at the end of the duration as expressed in the contract provided that where it is more than a month, the wages become due and payable not exceeding a month

Furthermore, the designated places of wages were provided. If the worker is employed on the premises of the sale of liquor or goods then it is not subject that it should be paid. Wage advance can be taken with a three-month period of paying back. The Nigeria Labour Act (2009) is against the unnecessary deductions of employee's salary except when specified

An employer within the ambit of the law is allowed to deduct income tax and pension contribution from the wage with the full consent of the worker. Also, union contribution which can be deducted from workers' wages, such workers can decide to opt put of it with no form of penalty or punishments attached (Labour Act, 1990). In spite of these laws wage increase protest between workers and government, its final destination is far from being attained in Nigeria.

Agitations for The Review of Minimum Wage

According to Salawu et al. (2013), wage agitation history in Nigeria dates back 1941 COLA agitation. The nation had also experienced other protest before this, because of the economic difficulties created by the British government during their involvement in the second world war, which affected mostly the working class than any other class.

Thus, this led to the economic class demanding a substantial cost-of-living award in 1941 (Salawu et al., 2013). The request was not hidden to which led to full blown crises, the government had to create a committee, with this in place the government then provided for a cost – of - living allowance (COLA) to all its workers (Salawu et al., 2013). When this was done a host of other trade unions sprang up agitate for and get the COLA allowance.

Another prominent wage agitation that looked Nigeria in the face was the 1945 general strike which resulted in a huge wage movement. The issue that led to the strike was the poor economic conditions of the post war era, economic depressions, the unions took a strategic stand to capitalize on the prevailing success which was recorded in the earlier strike or agitation. To demand for a cost-of-living increase over the awards made by the government in 1942. The government also refused to their demands like it was done before during the 1941 COLA agitation, the railway unions also engineered the general strike of 1945.

In all the strike was successful in its approach. Uzoh (2016) forth-five days strike, was successful due to the fact that all economics activities were paralyzed and the government was forced to appoint the Tudor Davies commission. Government equally awarded substantial increases. As a result of this in 2000, there was the Campaign for living wage. Which lead to the June 2000-2007 the nationwide strikes against increases in fuel prices. These strikes or agitations has led to creation of committees or commissions to oversee wage increase and implementations.

Moyosore, (2018) made it clear that it is important to understand how the current agitation for a new national minimum wage came about. He posited the occurrence was during the 2016 May Day celebration with the NLC President calling for a press conference to inform the press-corps on the need for an upward review of the national minimum wage (Moyosore, 2018). This was with the reference with the last one been the 2011 minimum wage act. The NLC President called for a tripartite committee to the review the minimum wage, with the negotiation process at a roundtable.

According to Eme and Ogbochie (2017), these demands came up at a time where most states are unable pay workers' salaries as when due, been the major reason for the consistent visitation by the governors to President Muhammadu Buhari in Abuja for another lifeline bailout. This was the second within ten months.

Barely two months after the bailout was given, the governors, through their Chairman, Alhaji Abdulaziz Yari of Zamfara State, stated that the states could no longer pay the N18, 000 minimum wage because 24 out of the 36 states were unable pay workers' salaries (reference). The Federal Government and the Nigeria Labour Congress in their attempts to reach a common ground and as a prelude to maintaining industrial peace decided to set up a 15-man committee to work out palliative measures with the intent of fashioning out a new minimum wage in the public sector. This occurrence therefore insinuates the need for a difference in wage payment structure by the different levels of government.

Challenges to The National Minimum Wage

Fapohunda (2004) identified one major challenge as the Market Situation of labour. It was noted that in a seemingly competitive labour market, the relationship between supply and demand is the most important determinant of benefits. This was further to elucidated on about the function of the price mechanism being minimal especially in a developing country like Nigeria.

It was also stated that unemployment does not really mean that it is as a result of high pays, as employers can attract high caliber employees without necessarily giving the legal minimum wage which may be considered too much (Fapohunda, 2004). The labor market scarcity of skill will definitely witness high movements of wages as it provides market forces the allowance to sufficiently allocate wages and employment.

The Nigerian labour market situation is with the perception of many skilled labour pursing few jobs. With the presence of the wage system, which has some influence in the Nigeria industrial employment indicator. This was said that the presence of a determined wage unequivocally stated the worth of the employee. Therefore, better paying job are sorted after while meagre offers are overlooked, thus increasing unemployment. A conclusion was reached that increase in federal minimum wage causes unemployment.

Of a note,when it comes to payments is often not enforceable or implemented properly, thus calling for the legal framework. This is believed to enable the design of the minimum wage accomplishment. The enforcement capacity of the federal government agencies experiences various challenges as the presence of insufficient qualified personnel for the purpose of ensuring that the provisions of the labour laws is the norm in the society. International Labour Organisation (2008) observed that many countries labour inspections services are understaffed and penalties for non-compliance with minimum wage regulations are too weak and should be worked on if the situation is to handled properly or have any significant change. For example, a close examination of the number of officers working in the Federal Ministry of Labour and Productivity vis-à-vis the level of industrial activities tend to support this line of thinking.

Incessantly, Fapohunda (2004) highlighted other challenges to the implementation of minimum wage as economic factors constituting challenge to employers' capacity to pay a specified minimum wage. A quantitative assessment of this capacity may be difficult but would include measuring the level of wage payments relative to other payments.

Politics in Minimum Wage Issues

It is generally acknowledged that the reference of politics is assumed to be in line with the underlying issues of any phenomenon. Such that it acts as an interest achieve amidst all odds while maneuvering the required expectation. This is not far from the minimum wage occurrence in Nigeria coupled with the variation in state revenue. The problem of how resources are shared has generated a lot of heat. The federal government and its component unit has always been at longer heads due to the allocation formula.

The allocation formula design is such that all involved party states gets funds for being opart of the Nigerian state from the federal purse, vis-à-vis their contribution into the purse. To this end, it must be noted that the revenue shared between federal and state government are never the same. Federal government gets the chunk of the revenue leaving the rest to be shared between the state and local government. The federal government is entitled to 52 percent of the revenue while the state and local government grapple with the remaining 48 percent (Okeke, 2015). With this, the federal government does not find it difficult to pay its workers and in the case of a minimum wage increase it is easily implemented (Aniche, 2015).

There are states despite these allocations still have the capability to pay the proposed national minimum wage. Oil producing states such as Bayelsa, Delta receive allocations from the federal account due to the derivation principle which allows for 13 percent to be paid to states where natural resources are derived on the basis of the amount exploited. Oil producing States get different percentages depending on the volume of oil gotten (Oko, 2011). It was on this basis that Okeke (2015) stated that the

expenditure assignment and revenue sharing have been generally inadequate in addressing the needs and resource gaps in the nation.

Arowolo (2011) states that so long as states in Nigeria depend on the federal government economically, the controversy surrounding the issue of minimum wage will remain a recurring problem in Nigeria. This was on the basis that Labour does not buy into the idea of state variation in revenue. Thus, creating an argument of wage discrimination between workers at federal, state and local on the same grade levels and steps in the federation. In the real sense labour is requesting for a unified salary structure and equal pay for equal work.

Incessant and Differential Call for Wage Review:

Inflationary shocks associated with salaries increase include sudden increase in the general price of commodities and services, and reductions in the number of jobs availability. There is also the problem of various government agencies calling for differential wage benefits justified under the pretext of the nature of their job. There may be some justification in this call, it would also prompt other security agencies to make similar calls.

A parameter that is significantly the basis of the need for the increase is wage is the cost of living. Cost of living deals basically with the amount of money needed to sustain a certain standard of living. This amount should in no small way afford the populace to provide for basic expenses such as housing, medical, healthcare and others. In Nigeria, cost of living varies, as states such as Lagos, Abuja, Portharcourt have an increased cost of living when compared to Oyo, Kwara, Ekiti and others (Aniche, 2015).

Ogunna, (1999) stated that location determines how high or low the cost of living is. He further explained that the continuous rise in cost of living should meet with a continuous rise in wage rates. Wage Indicator (2019) estimated living wage for a single adult at N23,100 to N32,900 and a family at N74,200 to N104,200. Thus, making the minimum wage far below the living wage. Many believe that living wage should be adopted as living wage which is based on the idea that work should provide an adequate income to cover necessary living cost of a family.

A Possible Framework on Minimum Wage Interface

The continuous agitation for a new review of minimum wage coupled with the inability to pay as at when due calls for a new design. This structure is expected to meet the survival needs of the employees in the respective organization. This therefore calls for a union in the deliberation of what should be done to fix the incessant wage increment. The wage increment policy could be tailored to follow each state perceived standard of living minimum requirement. This will reduce its usage as a political tool as it will be engaged by technocrat in its conceptualization. The chosen of technocrat will be of immense usage based on experience and qualification. With the omission of political office holders in this determination, a swindling usage of minimum wage alongside its delay will be avoided. The provision of a qualitative study will be of immense quality to the stated view.

Abstract

The study examines the impacts of business entrepreneurship venture on Nigerian University Internally Generated Revenue with reference to Landmark University Omu – Aran, Kwara State, Nigeria. The study adopts descriptive statistics to analyze the data and the use of Regression analysis to test the significant impact by ordinary least square analysis and vector auto-regression estimates. The study reveals that the impact of business entrepreneurship venture in University is positive for three business ventures of the four ventures undertaken by the university. Also, the findings show that the difference in guest house were caused by their seasoned patronage therefore, still have impact on the University revenue. The study revealed that Cafeteria, Shopping Mall, Commercial farm and Guest House proceeds had huge impact on the internally generated revenue of the University. There is no doubt that the above named business ventures contributed tremendously to the financial base of the University. It is also revealed that from the study that the source of revenue generated by the University can be maintained through improvement and new marketing strategies to attract the public to buy into its commercial and other revenue generation activities. Therefore, the study recommends that other Universities' Management are to look inward and emulate Landmark University Experience in generating funds and manage them effectively.

Keywords: Business entrepreneurship venture, Internally generated revenue, Landmark University, Financial base

Introduction

The global financial crisis which ravaged the various sectors of the country's economy has made it difficult for government to solely undertake essential services. Therefore, Public-Private partnership has been encouraged by the government and has extended to the educational sector of the economy. Having realized the reality of tertiary education in the country, the Nigerian government on May 10, 1999 issued certificate of registration to three private universities in Nigeria (Ajadi 2010). The universities include Babcock university, Igbinedion university, and Madonna university (Ajadi 2010). In Nigeria, private universities have been established to render services side by side the public universities. Private universities are set up to provide high-level manpower for the development of the country (Olawore 2013). The major challenge that faced private universities at creation was inadequate fund (Olawore 2013). Ajadi (2010) observes that the supply of education in Nigeria is limited by the amount of funds. One of the measures adopted by private universities to improve their internal revenue generation base was the setting up of Business Entrepreneurship Ventures (BEV). BEV creates high level of job satisfaction to the teeming youths and enhances life status (Martin 2006).

Higher levels of BEV accomplishments lead to higher income earnings which reduce the rate of unemployment within the society. Apart from generating revenue to the institution, it builds the mindsets

of students to environment, which nurture them for entrepreneurial skills. The impacts of the BEV are that it serves as a basis of producing young generation of Nigerians entrepreneurial oriented who could be employers of labour in the nearest future (Daniel 2010; Badariah, Abdul and Mariana 2016). According to Alexander (2014), BEV are equally crucial and very essential in any bad economy or recession situation. It could be the only alternative in changing the economic situation from the worst to a stable economy, by injecting new business ideas and innovation that turns to job opportunities as a means to reduce unemployment (Zalinaim, Firdaus and Azman 2016). The paper therefore seeks to unveil the impact BEV has on private universities development with particular reference to Landmark university. Also, it aims at ascertaining whether there is a relationship between their LMU ventures and the University revenue over the period of 5 years after operation.

Conceptual framework

The concepts that are central to this study are internally generated revenue and entrepreneurship.

Internally Generated Revenue: Internally generated revenue is the revenue that is generated within an organization. Within the university system, it is used to supplement their funding stream through the establishment of revenue yielding ventures or projects (Abosede and Akintola 2014). Such projects or ventures like bookshops, hotel and catering services, printing press, consultancy service, pure water factory and so on, are veritable means of raising funds needed to enhance their service delivery.

Adams (2002) is of different opinions, that government is to increase the universities subvention to 100% as the major source of funds to the institution. Governments are to safeguard the poor economy by means of increasing the tax rate and partner with non-governmental organizations (Bruno 2014). Revenue generated may not safeguard the university performance if the resources of revenue are not well protected from corrupt leaders, non-politicized and avoidance of misappropriation (Stella 2015). Generating revenue also requires adequate access to capital for potential investment which is the biggest hurdles to growing a business venture (William and Ramana 2009). An insufficient fund is a threat to an efficient innovator (William and Ramana 2009).

Therefore, Adeyemi (2011) posits that Universities are confronting many competitive challenges accompanied with poor funding and the only solution is to actively engage in entrepreneurship through the establishment of new funding stream and research investment.

Entrepreneurship: This is the practice of starting business from the scrap to meet customer needs to satisfy the entrepreneur either in profit maximization or status attained which can go in a long way to improve the economy strength of the nation by generating massive returns to the organization at all levels (IGR) (Vera 2012; Ilesanmi 2012). The word entrepreneurial came from entrepreneur. Entrepreneurial is therefore described as a person that makes money by starting business which involves identifying opportunity and able to take risk, an ability and willingness to take risks and focus on maximize profit (Vera 2012). The practice of starting business from the scrap to meet customer needs to satisfy the entrepreneur either in profit maximization or status attained which can go in a long way to improve the economy strength of the nation by generating massive returns to the organization at all levels (IGR) (Vera 2012; Ilesanmi 2012). The enterprises that are involved in the identification of business opportunities in Nigeria and undertaking the risks involved in bringing together all the factors of production to establish and run an enterprises for profit or non-profit intention (David 1995).

Literature Review

Entrepreneurship is the process of initiating, organizing and innovating business, with the sole aim of creating new market ideas and for making profit. It has been the driving force of internal generated revenue (IGR) mobilization for institutional growth. Onuoha (2013) observes that there should be alternative means or non - traditional way of sourcing for fund in the tertiary institution. Extant literature

presents the impact of business entrepreneurship programme on IGR at the level of university (Tax Payer Guide, 2015).

In the year 2016, it was declared by the National Bureau of Statistics (NBS) that the Nigerian economic growth dropped drastically into recession, which resulted to poor funding of the government owns institutions (National Bureau of Statistics 2016). Nigerian Government confirmed that the recent economic recession was responsible for the poor funding of educational public institutions in the Country (Vanguard Newspaper 26 September 2016).
Many universities workers have been agitating for their salary to be paid in full and workers in state like Bayelsa also clamoring for payment of their seven months' salary and related arrears which led to the closure of government owned tertiary institutions (News Agency of Nigeria, October 3 2016); while some State governors has openly made a commitment to restore the lost dignity of education in their State (News Agency of Nigeria, June 21 2016). These contributed to the battered educational system in the country with the poor funding. This therefore calls for urgent sustainable IGR source for the universities as supplement to the traditional means of allocation.

Entrepreneurship is considered to be the channel of economic growth in Nigeria due to its innovativeness, rebranding, product development and minimizing unemployment rate in the country (Adeoye 2015; Amir and Mohammad 2016). Alexander (2014) asserted that Entrepreneurship is very crucial in sustaining organization. The impact of entrepreneurship is to generate revenue to the organization (Carree and Thurik 2002). The undergraduate students are valuable assets that can contribute to the business development programme within the university context (Huub, Dugassa, and Alemfrie 2015).

Ajaero (2016) stipulated that standard BEV is the bedrock to national development. BEV is one way by which institutions generate the desired revenue to provide solution to funding crises and thereby reduce the rate of poverty in a community (Eze 2016; Ogueze and Orji 2015).

Internally generated revenue (IGR) is becoming essential in solidifying financing, and running education system in Nigeria. According to David, Yung-Chi, Benjamin and Chiyan (2015), successful IGR is a feasible means to improve funding of institution by enterprising, and to make the institution entrepreneurial become financial autonomous. With the recent trend of economic challenges in Nigeria, there is need for the University Management to look inward in funding the institution as a means of alternative channels (Ibeogu and Ulo 2015; Felicia and Hezekiah (2016). Famade, Omiyale, Grace and Adebola (2015) stated that to improve the financial stand in education, another approach of generating funds for institutions is required and institution management can supplement their funding stream by establishing business ventures or consultancy services to raise funds highly needed for the smooth running of the university. IGR is associated with many activities as means of generating alternate sources of revenue to enhance the financial condition for university education system (Gregory, Dave, Timothy, Robert, and Cora 2006),

Landmark University (LMU) has adopted revenue generated strategy as a private institution by running business ventures in order to generate revenue (Sani 2015). The BEV of Landmark includes LMU commercial farms, LMU Health Centre, Centre for System and Information Services (CSIS), Mechanical Workshops, LMU Bakery, LMU Pure Water Factory, LMU Guest House, Car Wash, Boutique, Shopping Mall, Bookshop and Unisex Saloon all a subsidiary of Landmark University Development Venture (LMDV) which has greatly boosted the University IGR.

Ogbogu (2011) stated that other means of generating funds in financing institutions can only be preferred through the universities business entrepreneurship activities like ventures and consultancy services. Although, conventional universities are directly funded by the State, as they are owned by government. However, many institutions have reformed themselves from being mainly for learning and research purposes to entrepreneurial universities with robust tie to business activities (Barbara and Bostjan 2014).

Entrepreneurial and Business Entrepreneurship Venture

The word entrepreneur refers to the prior taking initiatives, ideas to start a new business to bring new ideas and innovation to carry out business activities and act as a catalytic agent for a new project to maximize profit (Edwsaurd and Martin 2007). It is the creation of new venture and providing better ways of running the business (Jahangir and Zhiping 2016) providing innovations that confront the current market orders (Hamilton and Harper 1994). Schumpeter 1912, 1934, 1942 in his theory of Business Enterprise, stated that the entrepreneur is a promoter to an organization, endowed with characteristic of being a venture capitalist and profit driving (Alvaro and Salvador 2014). This is also an innovation as the commercialization of an invention (Alvaro and Salvador 2014). However, Kirzner (1973) stated that entrepreneur is person that is able to discover strength and opportunities to transform their competitive domain by engaging themselves in enterprises with intention of achieving large market share, cited in (Florian, Dominic, Mathew and Janic 2017).

According to Metcalfe and Ramlogan (2005), Hezelkorin (2013), and Didier and Fernadez (2016) stated entrepreneur education is the way of training and educating youths to be self-reliance to the reducing high rate unemployment in the labour market (Filippo et al., 2015). Societal transformation requires foundational learning (Mathias and Marco 2012); implementation of redesigned curriculum related to be self-reliance through academic teaching to increase productive capacity. Better development depends on institutional programme to meet demand for capacity building within a global knowledge economy (Maria, Joanne, Moria, Natalie and Roy 2016). The quality education services require reliability empathy responsiveness and assurance (Zhang et al., 2016). Providing a conceptual integration of the literature on business venture (Jonathan, Janice, Alain and Phillip, 2010), Joseph Tixier and Barbara Barone (2010):, Maria and Soumodip (2017) stated that strong impact (i.e. the activities that generate new ideas) could only be spawned by creating opportunities outside the organization.

Thus, Entrepreneurship Venture (EV) is a construct that has gained importance in the field of business and management by the extent to which managers are tending to engage in entrepreneurial related risks and active pursuit of new opportunities to sustain the organization (Florian 2017). Entrepreneurship Venture (EV) helps to increase the understanding of the youths towards the essence of the entrepreneurial experience (Florian Dominic, Mathew and Janice 2017) that educate the youths on why, when, and of how opportunity creation, recognition, and utilization emerged which help to access new technologies in accelerating economic growth (Adam and Micheline 2013).

Entrepreneurship Venture (EV) is much more than curriculum to university and skill tool (Dominic, Chang, and Dirk 2016). It has become a major hub as part of the mechanisms towards attaining poverty alleviation (Adebowale 2011). Judging from this approach, it can be added that EV is a required skill in engaging the teeming youths towards entrepreneurial ambition (Agu and Ayogu 2015; Wim 2013) .

Funding Universities from the Internally Generated Revenue (IGR) Perspective

The private owned universities in Nigeria are solely funded from their internally generated funds and serve as the reason for smooth running of private institutions. For this reason, government-owned-institutions in Nigeria should therefore wake-up and inculcate this attitude of alternative funding as another means of funding the university without depending on the Federal or State governments' subventions which is now facing challenges on meeting the funding of public universities (Ezekwesili 2016). Universities are founded on research purpose and non-funding pose threat on adequate research. Hence, money generated from other means can be used as a supplement in good time for research purpose. No doubt, policies such as business acquired policy, business theory on entrepreneurial programmes, Market and consumer theory, the demand and supply theory, PESTEL analysis and American and Japanese Keiretsu theory are many approaches to boost the revenue for tertiary institutions.

According to David (2015), institutions are graciously urged to sort for another means of educational funding like total commercialization of the university technology has been practiced in Taiwan to form better relieve to the government in other to address all the economic issues confronting the nation.

It is becoming progressively clearer that IGR has become a tradition and alternative means of funding in Landmark university. This is because the University is adequately engaging in business practices like University Medical Centre, Landmark University Development venture, and Commercial Farm outside of the regular tuition fee, students' subscription and other administrative charges which forms part of their innovative ideas. Considering the challenges confronting education in Nigeria, it is imperative to drive the revenue mobilization for the government owned institution not to endanger the future of our teeming youths by supporting revenue generation, (Adeyemi 2011).

Discussion and Results

The study used descriptive economic analytical tools in studying four business unit of the private university with 57 observations for the period of 2013 – 2017. Basically to examine the trend of revenue of these selected business ventures to the University. This was done by examining each venture using CMF, CFT, SHM and GTH as the independent and the dependent variable is represented by internally generated revenue (IGR). This ultimately led to the accomplishment of an important aim of the study which is to ascertain whether there is a relationship between their ventures and the University revenue over the period of 5 years after operation.

The Descriptive technique shows the summary of the information for a number of variables in a single table and computed the systemized values. Table 4.1 below shows the descriptive statistics. The Descriptive results disclose representation of data exists between dependent variable and each of the independent variables.

Hypothesis 1

$H_{0:}$ There is no significant relationship between LMU Cafeteria and the University IGR.

$H_{1:}$ There is significant relationship between LMU Cafeteria and the University IGR.

Table 4.1 Descriptive Statistics and Correlations

Descriptive Statistics

	Mean	Std. Deviation	N
CAFETERIA	18500078.09	6819224.753	57
INTERNAL GENERATED REVENUE	90599189.77	35714605.070	57

Correlations

			INTERNAL GENERATED REVENUE	CAFETERIA
Spearman's rho	INTERNAL GENERATED REVENUE	Correlation Coefficient	1.000	.468
		Sig. (2-tailed)	.	.000
		N	57	57
	CAFETERIA	Correlation Coefficient	.468	1.000
		Sig. (2-tailed)	.000	.
		N	57	57

Spearman's rho correlation of university IGR and LMU Cafeteria = 0.468

P-Value = 0.000

INTERPRETATION

The correlation coefficient of the university IGR and LMU Cafeteria is 0.468 which implies that the strength of relationship between the University IGR and the LMU Cafeteria is a moderate positive relationship.

The P-value is 0.000 (< 0.05) which implies that we will reject the null hypothesis and conclude that there is significant relationship between LMU Cafeteria and the University IGR.

We can also say that 23% (0.468^2) of the variation in the University IGR is explained by the LMU Cafeteria revenue.

Hypothesis 2
$H_{0:}$ There is no significant relationship between LMU Shopping mall and the University IGR.

Table 4.2: Descriptive Statistics showing dependent and independent variables
Correlations

			INTERNAL GENERATED REVENUE	SHOPPING MAIL
Spearman's rho	INTERNAL GENERATED REVENUE	Correlation Coefficient	1.000	.918
		Sig. (2-tailed)	.	.000
		N	57	57
	SHOPPING MALL	Correlation Coefficient	.918	1.000
		Sig. (2-tailed)	.000	.
		N	57	57

$H_{1:}$ There is significant relationship between LMU Shopping mall and the University IGR.

Table 4.2 below shows the descriptive statistics. The Descriptive results disclose representation of data exists between dependent variable and each of the independent variables.

Descriptive Statistics

	Mean	Std. Deviation	N
INTERNAL GENERATED REVENUE	90599189.77	35714605.070	57
SHOPPING MAIL	39091606.32	16558211.699	57

Spearman's rho correlation of university IGR and LMU shopping mall = 0.918

P-Value = 0.000

INTERPRETATION

The correlation coefficient of the University IGR and LMU shopping mall is 0.918 which implies that the strength of relationship between the university IGR and the LMU Shopping mall is a perfect positive relationship.

The P-value is 0.000 (< 0.05) which implies that we will reject the null hypothesis and conclude that there is significant relationship between LMU shopping mall and the University IGR.

We can also say that 84% (0.918^2) of the variation in the University IGR is explained by the LMU Shopping mall.

Hypothesis 3

$H_{0:}$ There is no significant relationship between LMU Commercial farm and the University IGR.

$H_{1:}$ There is significant relationship between LMU Commercial farm and the University IGR.

Table 4.3 below shows the descriptive statistics results that disclose representation of data exists between dependent variable and each of the independent variable.

Table 4.3: Descriptive Statistics showing dependent and independent variables

Descriptive Statistics

	Mean	Std. Deviation	N
INTERNAL GENERATED REVENUE	90599189.77	35714605.070	57
COMMERCIAL FARM	32406500.05	19303346.898	57

Correlations

			INTERNAL GENERATED REVENUE	COMMERCIAL FARM
Spearman's rho	INTERNAL GENERATED REVENUE	Correlation Coefficient	1.000	.881
		Sig. (2-tailed)	.	.000
		N	57	57
	COMMERCIAL FARM	Correlation Coefficient	.881	1.000
		Sig. (2-tailed)	.000	.
		N	57	57

Spearman's rho correlation of University IGR and LMU Commercial farm = 0.881

P-Value = 0.000.

INTERPRETATION

The correlation coefficient of the University IGR and LMU Commercial farm is 0.881 which implies that the strength of relationship between the University IGR and the LMU shopping mall is a strong positive relationship.

The P-value is 0.000 (< 0.05) which implies that we will reject the null hypothesis and conclude that there is significant relationship between LMU Commercial farm and the University IGR.

We can also say that 78% (0.881^2) of the variation in the University IGR is explained by the LMU Commercial farm.

Hypothesis 4

$H_{0:}$ There is no significant relationship between LMU Guest house and the University IGR.

$H_{1:}$ There is significant relationship between LMU Guest house and the University IGR.

Table 4.1 below shows the descriptive statistics which the results disclose representation of data exists between dependent variable and each of the independent variable.

Table 4.4: Descriptive Statistics showing dependent and independent variables

	Sig. (2-tailed)		.848
	N	57	57
GUEST HOUSE	Pearson Correlation	.026	1
	Sig. (2-tailed)	.848	
	N	57	57

Pearson correlation of university IGR and LMU Guest house = 0.026

Table 4.5: Descriptive Statistics showing dependent and independent variables

	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
					Lower Bound	Upper Bound		
CMF	57	18500078.09	6819224.753	903228.383	16690694.21	20309461.96	9658446	52721907
SHM	57	39091606.32	16558211.699	2193188.717	34698121.37	43485091.26	5221000	68730863
CFT	57	32406500.05	19303346.898	2556790.757	27284632.70	37528367.41	7089975	67782226
GTH	57	601005.32	212500.725	28146.409	544621.28	657389.35	101999	982156
Total	228	22649797.44	19728791.981	1306571.167	20075238.79	25224356.09	101999	68730863

P-Value = 0.848

INTERPRETATION

The correlation coefficient of the University IGR and LMU Guest house is 0.026 which implies that the strength of relationship between the University IGR and the LMU Guest house is a weak positive relationship.

The P-value is 0.848(> 0.05) which implies that we do not reject the null hypothesis and conclude that there is no significant relationship between LMU Guest house and the University IGR.

We can also say that 0.068% (0.026^2) of the variation in the University IGR is explained by the LMU Guest house.

TEST 2

HYPOTHESIS 1

$H_{0:}$ $\mu_1 = \mu_2 = \mu_3 = \mu_4$

$H_{1:}$ The means are not equal (for at least one mean)

Table 4.6: The ANOVA table shows the hypotheses

ANOVA

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	49527056599663776.000	3	16509018866554590.000	95.243	.000
Within Groups	38827071299894696.000	224	173335139731672.780		
Total	88354127899558480.000	227			

INTERPRETATION

The ANOVA table above shows that P-Value = 0.000 which implies that we will reject the null hypothesis because P-value (0.000) is less than 0.05 and we then conclude that there is statistically significant difference between the means of LMU Cafeteria, LMU Shopping mall, LMU Commercial farm and LMU Guest house at 5% Level of significant.

GRAPHICAL REPRESENTATION

Fig. 4.1: Bar chart showing the mean effect in percentage of LMU Cafeteria, LMU Shopping Mall, LMU Commercial Farm and LMU Guest House on the University Internally Generated Revenue

INTERPRETATION

The bar chart above shows the mean effect of LMU Cafeteria, LMU Shopping mall, LMU Commercial farm and LMU Guest house on the University IGR in percentage. It further shows that LMU cafeteria contributes 20.4% on the University IGR, LMU Shopping mall contributes 43.1% on the University IGR, LMU Commercial farm contributes 35.8% on the University IGR while LMU Guest house contributes 0.7% on the University IGR respectively.

Fig 4.2: Piechart showing the mean effect in percentage of LMU Cafeteria, LMU Shopping Mall, LMU Commercial Farm and LMU Guest House on the University Internally Generated Revenue

INTERPRETATION

The pie chart above shows the mean effect of LMU Cafeteria, LMU Shopping mall, LMU Commercial farm and LMU Guest house on the University IGR in percentage. It further shows that LMU Cafeteria contributes 20.4% on the University IGR, LMU Shopping mall contributes 43.1% on the University IGR, LMU Commercial farm contributes 35.8% on the University IGR while LMU Guest house contributes 0.7% on the University IGR respectively.

Conclusion

Based on the findings from this research, the following conclusions are drawn:
Revenue sources like Sales of farm produce from the Commercial farm, establishing of the shopping mall for both students and staff for shopping, provision of hygienic cafeteria on the campus and accommodation facilities for the users contribute huge amount to the internally generated revenue of this young growing University.
Since the price of major resource in the country has been falling in the global market, and the universities are facing serious challenges of funding from the government and order for the universities to increase revenue, the university can come out with new marketing strategies to attract the public to buy into its commercial and other revenue generation activities.

RECOMMENDATIONS

Based on the findings earlier stated in this research work, the following recommendations are suggested:

i. The Management of University is to put in place effective measures that would ensure that those IGR sources that contributed huge amount of revenue on the activities of the University like Commercial farm, Cafeteria, and Shopping are much more improved upon and efficiently managed to ensure long-term sustainability.

ii. The findings also showed that the difference in guest house were caused by their seasonal patronage therefore, still have impact on the University revenue and therefore recommends for marketing strategies to attract more customers.
iii. By inference other Universities in Nigeria that are not yet involved in the IGR should buy into the strategy for additional funding.

Acknowledgment

This is to acknowledge Landmark University for the provision of fund for the publication of the research work.

The Evolution of Women's Military Service in The Subsequent Decades of the 21st Century

Damian Matysiak

marcingornikiewicz2014@gmail.com (**Corresponding author**)

Abstract:

This article is dedicated to the evolution of the military service of women in the era of social and civilization changes. The status of women in the armed forces has changed with technological development and the shaping of the information society. Nowadays, the suitability of soldiers for military service depends on psychophysical features and intellectual competences. The gender differences between the soldiers are irrelevant. In the future, the ratio of men and women serving in the military will be equal, and the suitability of military structures will be determined by inborn abilities and previously acquired competences.

Keywords: military security, military service, woman soldiers

Introduction

The aim of this article is to predict the evolution of the military service of women in state defence systems in the 21st century. The forecast concerned mainly the period of the first three decades, from the 3rd to the 6th decade of this century. This perspective results from the 20-30 year cycle of replacing most of the equipment, weapons and personnel systems adopted in many armies of the world.

Methodology and research area

In the forecast, the author used an empirical method to collect initial data in the form of a literature query (mainly based on scientific studies with high reliability) and expert interviews conducted in the period 2019-2020 with people with specialist knowledge. Subsequently, the author used theoretical methods such as analysis and synthesis to develop a forecast. Thus, the paper adopts the following problem question: How will the military service of women evolve in the next decades of the 21st century? The aim of the study is to present the vision of this evolution, and above all the impact of this evolution on the change of the personnel process in the armies of developed countries in the 21st century.

Literature review & Discussion

Historically, nations have vied for control of strategically important geographic areas. These areas were characterized by a suitably favorable location and the topography ensuring safety and easier

access to resources. This guaranteed not only security, but also conditions ensuring that a given community could develop its own power. In a world where social groups competed with each other for attractive territory and resources, security was guaranteed in those communities that were the strongest. During the ancient and early medieval period, women often served shoulder to shoulder with men on the battlefield. This was due to numerically limited societies, so it also had an impact on the number of warriors. It is therefore not surprising that physically fit women who were willing to fight were welcome in the ranks of the fighting troops.[1] T. Szczurek – the author of the above considerations, introducing the reader to the considerations undertaken, referred to the achievements of many outstanding academics, among which it is worth mentioning, for example, Alvin Toffler, the author of the wavelength concept, which allows a better understanding of the wider context of the ongoing civilization changes affecting the nature of women's military service.

Alvin Toffler categorized these civilization changes and linked them to specific stages in the history of mankind. He referred to these stages as waves, which was to allow a better understanding of their fluid character manifested in the continuously successive social and civilization processes. These processes, at the time of their initiation, were no longer possible to stop. Along with the development of social structures and the increase in the number of members of the social group, the level of advancement of civilization increased. It was influenced by the growing number of group members, and therefore also the growing percentage of people with a higher intelligence quotient, who contributed to the faster and faster civilization development.

The first wave was called agrarian by Alvin Toffler. It began nearly ten thousand years ago with humanity mastering the skill of farming the land. This particular skill completely reorganized the hitherto functioning mode of human tribes. From the hunter-gatherer mode, a transition was made to the sedentary mode, which in turn allowed for a gradual increase in the number of people. The increasing number of people, influenced the higher professionalization of individuals, and later social groups. In small communities, any person, regardless of gender, could be involved in defense matters. With the increase in the number, only people with the best predispositions to fight were involved in the defense of the community, while the remaining residents were engaged in activities enabling the entire community to function and develop efficiently. Therefore, apart from social and economic life, also culture, art and intellectual life began to develop. It was possible thanks to free time for activities other than the struggle for survival. With the development of the intellectual level, military thought also began to develop, which led to the further professionalization of the group responsible for defending against assault or carrying out attacks on other communities.

The development of land cultivation techniques meant that communities began to settle permanently in areas with favorable geographic and spatial conditions. Therefore, it was necessary to defend this area, as opposed to a situation where a given community led an itinerant lifestyle and could always relatively easily change its current place of residence. Previously, all men were hunters, so from childhood they trained in tracking, masking and hunting. These skills proved useful in battles with other nomadic tribes for access to resources such as water and food. Caves offering a good shelter from weather conditions and wild animals, with a limited number of entrances, could also be temporarily attractive, allowing some of the tribe to sleep and recharge their batteries. A sedentary lifestyle eliminated the need for constant hunting to survive, but it also created new types of threats. The excess of food and the possibility of collecting it for the winter, in turn, influenced the dynamic increase in the number of people. This increased the importance of larger tribes among others with a worse demographic condition. Therefore, the aforementioned specializations appeared within a given, more and more numerous society.[2]

Humanity, along with the increase in population and the acceleration of civilization development, more and more quickly passed through the stages of technological advancement. In an industrial era characterized by the massive use of steam engines supported by the ever-broader electrification of industry and everyday life, the division into male and female roles in society began to blur.[3] Of course, in the nineteenth century women still occupied a lower social position than men, but nevertheless there were more and more educated women and taking up various jobs, even typically

[2] *United Nations*, 2011, World Population Prospects, 2010 Revision, t. 1, New York, p. 24.

male. At that time, ladies often resorted to deception pretending to be men. At the same time, there were events with dramatic social overtones, such as uprisings in which women fought on an equal footing with men. An example is the famous Polish patriot and fighter for the freedom of the Polish nation, Emilia Plater. Of course, it was by no means a mass phenomenon, but women tried to emphasize their own value and equality towards men favored by social norms more and more at various levels of life. The 20th century brought the birth of democracy, which started back in the 19th century with the growing awareness of European societies, the speed of spreading information about the world, and the growing group of educated members of society not coming from the privileged classes.[4] It should be added that the ideological foundations of the later democratic, communist and national socialist movements were most often created by representatives of the impoverished aristocracy who received a good education and at the same time were characterized by an outstanding intellect. It can therefore be assumed that from the seventh decade of the eighteenth century to the twentieth century, there were gradual changes in the mentality of European societies, which were accelerated by the industrial revolution, the increasingly widely available press and thus the wide spread of printed and oral information. The situation of women also changed, because in the newly created democratic countries in the interwar period, the formal and legal position of women was almost equal to that of men, and the barriers that still existed at that time resulted from the system of social beliefs shaped for millennia, mainly among men. The explosion of National Socialism and Communism rapidly began to equalize even these social limitations in dealing with women and men, making women appear in the armed forces, something unthinkable a few decades earlier. Of course, most often female positions functioned in administration, logistics and military special services. In the case of, for example, the Soviet Union, women even appeared in special units, including taking sniper positions. After the end of World War II in democratic countries there were no doubts about the equal position of women and men, and all other manifestations of thinking resulted from still deeply rooted prejudices, and often from complexes. At the same time, no one had any doubts about the value of women in many "typically male" occupations of everyday life, as well as in uniformed services, including the armed forces. In practice, in many countries, despite the absence of official obstacles, women were still rarely seen, but the picture was gradually changing. At the end of the second decade of the 21st century, in the armed forces of European countries, women were still in the minority compared to men, but no one created artificial barriers anymore, and on the contrary, the armies of many European countries actively encouraged and encouraged women to enter the path of a military career.

Thus, from the agrarian wave, through the industrial wave, along with the development of civilization, the attitude to the internal differentiation of society members also changed through the use of various criteria of division, including gender. A. Toffler predicted that the changes would result, among others, in[5]:

[4] Hanley W. (2005). The Genesis of Napoleonic Propaganda 1796–1799, Columbia University Press, Nowy Jork, pp. 141–158.
[5] Toffler A. (2006). Trzecia fala, Wydawnictwo Kurpisz, Poznań, pp. 7–22.

- a completely new lifestyle resulting from the widespread use of energy sources currently considered alternative (for example, nowadays there is a trend of more and more installation of solar panels by owners of single-family houses);
- the widespread use in everyday life of more and more modern technological solutions that improve the quality of life (it can be seen on the example of both communication technologies using the Internet and the dynamically developing sector of the so-called smart home services, in the near future the AI technology in the form of home robots will probably become more popular);
- introducing new production methods;
- the new family model, which can be associated with universal mobility, now needs to be seen in an international dimension (you can work in one country and live in another) and the developing trend of working remotely from anywhere on the planet;
- a new way of organizing and functioning of the education system, taking into account differences between students and with greater emphasis on the development of not only intelligence, but also the social dimension resulting from properly developed interpersonal relations;
- the increase in the importance of individual people in social organizations, and thus a gradual abandonment of "mass" in favor of valuable individuals massively contributing to the general social development and welfare, and as a result, a completely new model of corporation functioning;
- valuing the different point of view of individuals who bring added value to numerous social groups functioning in the global society, special appreciation of creativity and individual (subjective) approach to the surrounding reality.

Conclusions

To sum up, the ongoing civilization evolution will be much more humanitarian, and its consequence will be the assessment of human value through the prism of contribution to the further development of civilization. Therefore, people endowed with the appropriate intellect, charisma and abilities (mental, manual), which through their daily activity will influence the higher potential of the social structure in which they will function, will be appreciated.[6] Taking the example of the armed forces, this means that it will not matter whether the soldier is male or female. It will be important what added value it brings by strengthening the potential of the unit in which it serves, and thus indirectly strengthening the potential of the entire armed forces. It can be presumed that the tedious and repetitive exercises will be increasingly carried out by machines, and therefore the value of a physically fit soldier

[6] Masuda Y. (1984). The information society as post-industrial society, Editorial Fundesco, Madrid, p. 171.

deprived of additional values will be lower over time, until it disappears completely, eliminating such a candidate as redundant in the tasks carried out by more and more automated armed forces.[7]

Therefore, when attempting to answer the problem question formulated at the beginning, it can be assumed that the number of women in uniform will increase, and with time the difference in the numbers of female and male servants will be leveled out. Recruited will be people with appropriate psychophysical and intellectual qualities, who at the time of recruitment will already have certain skills or abilities, and will be able to quickly learn new content and skills. It can therefore be presumed that the number of soldiers (men and women) with cybernetic, command-management, psychological, engineering and administrative-staff predispositions will systematically grow. Most of the tasks related to direct combat operations, the functioning of the logistics and reconnaissance and information facilities will be performed by autonomous systems, and therefore the demand for people with predispositions to perform such tasks will gradually decrease. On the other hand, scientific teams responsible for developing the existing technological solutions as well as creating innovations and implementing them for the needs of the armed forces may be developed[8]. Due to the growing demand for people with a high level of creativity, there will also be a growing demand for the creation of internally psychophysically and intellectually diverse teams, which will support the development of creativity, and therefore may translate into the creation of new solutions to old and only evolving problems. At the end of the 21st century, the armed forces of technologically advanced countries will probably consist of men and women with a high level of individualism, special psychophysical and intellectual predispositions. With the end of the industrial era and the advent of the information and post-industrial era, the mass character of the army of the past Second Wave will give way to the highly individualized, internally differentiated (also gender-specific) and expert military characteristic of the Third Wave.

An Insight into The Key Resources in Business Models. What We Can Learn from High-Growth Enterprises.

Iwona OTOLA
Faculty of Management, Czestochowa University of Technology, Czestochowa, Poland,
email: iwona.otola@wz.pcz.pl

Abstract

The article covers important issues related to the business model and resources. The main scientific aim of this paper is to analyze the resource base, in a business model of high-growth enterprises. For this purpose, the theory of systems was used to visualize the resources at the input and output in the business model. The empirical research was carried out among managerial personnel of 150 high-growth enterprises in Poland. The research proves that human capital, organizational capital and intellectual property are crucial for a business model of those enterprises. Moreover, knowledge a resource purchased on the resource market.

Keywords: resources, business model, system approach, high-growth enterprises,

Introduction

High growth enterprises are an interesting challenge for researchers. Why some enterprises go bankrupt, others do well and others grow fast has always interested researchers. So far, research on high-growth enterprises (HGE) has focused on factors such as human capital (Holzl, 2009; Coad et al., 2014; Senderovitz et al., 2016), strategy (O'Regan et al., 2006; Parker et al., 2010) and innovation (Coad and Rao, 2008; Koski and Pajarinen, 2013). There are two reasons of interesting this topic: these companies create most jobs in the world economy and can maintain high growth rates for long periods of time (Barbero et al., 2011). One of the concepts describing the company's growth is resource based view. According to this theory, having strategic resources, properly configured and integrated should generate value for both the customer and the company. In the resource based view, an enterprise is treated as a set of assets (resources) and skills, whose configuration into key competences becomes a source of its success and competitive advantage (Obłój, 2007). Currently, in addition to the important role of strategy with business management, significant attention is paid to the business model. The proper configuration of individual elements of the business model contributes to market success. Therefore, since fast-growing enterprises are "business gazelles", according to the assumptions of the business model concept and resource based view, their resource base and business model should be configured carefully. The motivation for conducting this study is a closer look at what resources in creating business models use high-growth enterprises. This paper contributes to increasing knowledge of the resources in business model from the high-growth enterprises perspective. A look at the resources in business models has been based on systems theory, exposing resources at the input, transformation and output. The main objective of this study is to carry out an analysis of the whole process of transformation of resources in business models of high-growth enterprises.

Literature review

The Concept of Business Models

The concept of business models (BM) is known in the literature on the subject and is much more frequently presented from its practical side rather than focusing on the theoretical concepts. The development of BM began with the conceptualisation of this term and most publications present its definitions, classifications and components. The business model, initially perceived as an operative plan for creating a suitable information system, later developed into an integrated presentation of the company organisation the goal of which is such management in the decision-making process that the company is successful on the market (Writz et al., 2016). This paper, instead of reviewing the numerous definitions presented in the literature (see i.e. Zott et al., 2011; Nisa and Ravichandran, 2013; Writz et al., 2016; Foss and Saebi, 2017, Peric et al., 2017), focuses on the essence of the model, the purpose of its creation and its selected components. However, it is necessary to present the definition that is the most relevant to the scholarly deliberations in this paper. The author agrees with Afuah (2004, p.10) that the business model is a set of activities implemented by an enterprise by means of specific methods and in a specific timeframe, using resources in such a way as to create the benefits that a customer expects, while at the same time ensuring value for the enterprise. This broad definition makes it possible to observe the BM as a holistic and at the same time complex conceptualisation created for the purpose of designing and implementing a specific business activity. Accordingly, it is a specific logic of action of an enterprise (Casadesus-Masanell and Ricart, 2010; Zott et al., 2011). Meanwhile, the point of creating the business model of an enterprise is to generate profit, which today is frequently seen through the prism of the value, which in turn is the indicator of market success over competitors. Thus, it can be stated that the idea of the BM is to show the road of development for an enterprise. A fit business model should be a unique concept that will enable to maintain lasting competitive advantage. Thus, the question is how to create such a model. J. Magretta (2002) refers to the questions posed by P. Drucker (2011), which should be answered when telling the story of the enterprise. They are four basic questions: Who is the customer? What does the customer value? How does an enterprise earn money from its activity? How the value is delivered to the customer, taking into account its cost?

The literature on the subject presents many ways to construct business models, each of which is based on the components that the author of a given idea considers to be crucial. It may be noted that researchers present different structural elements of the BM, which, however, have some things in common. The research conducted by Falencikowski (2013), concerning both the definition and components of business models, leads to the following conclusions: An analysis of the definitions of the business model suggests that most of those definitions mention the creation/delivery of values and products and combination/configuration of resources. Meanwhile, the popular element of BM components is the value proposition. Other common elements are: the sources of income, the customer, the value chain, key resources, key activities, relationships. The most frequent terms used both in definitions and in components of the BM are the value and resources. Insofar as the value is the end effect of business models, resources are the initial element of their construction.

The most popular and the most often quoted BM is the 9-block construct, the Business Model Canvas, developed by Osterwalder. This model focuses on factors that are directly controlled by an enterprise and does not include factors linked to the environment (Fritscher and Pigneur, 2015). The components of the model may be grouped into four main pillars: product innovation (value proposition), customer management

(customer segments, distribution channel, customer relationship), infrastructure management (key resources, key activities, key partners), financials (revenue streams, cost structure).

The coherence of the respective elements is of key importance for the development of the BM. The respective components of the business model form a complete system, which means that its efficiency depends not only on the individual elements but also on the relationships between them (Leszczewska, 2016). It is also worth noting the method of designing the BM. Zott and Amit (2010) state that BM designing may be based on the activity system perspective, which includes such elements as: novelty, lock-in, complementarities and efficiency. The idea of developing the BM by means of the novelty-oriented activity system perspective is to depart from the established model and implement innovative content and/or means of action as well as modern management methods. Using the lock-in element is associated with creating a strong bond between an enterprise and a selected group of stakeholders who are treated as participants of the BM. Business model design based on complementarities is associated with the synergy effect, where mutual interaction and cooperation leads to greater effects than would be achieved by the individual BM components. Meanwhile, efficiency-oriented design concerns the method of increasing input in order to achieve the expected effects.

Resources in business models

Resources are in the centre of interest of numerous contemporary economic theories and management sciences that describe increasingly complex processes taking place within an enterprise and in its environment (Otola, 2018). The multiplicity of studies on resources, conducted from different perspectives, makes it impossible to construct a single, generally accepted definition of the term. In general, an enterprise, in order to create products and services, needs resources and, more specifically, a resource base (de Witt and Meyer, 2010).

The most classical division of resources identifies the tangible group and the non-tangible group (Grant, 1991; Barney, 1991). Although most researchers agree that tangible resources are all the assets of physical nature (Carmeli, 2004; de Wit and Meyer, 2010), the problem is how to define precisely what intangible resources are. There are many different classifications of intangible resources, but they include all the intangible assets whose value is hard to determine, such as, for example, culture, organisation, intellectual property, human capital, relationships, positioning resources, core competencies. Not all researchers agree that intangible resources should be understood so broadly. For example, human capital is not always identified as an intangible resource. Also, core competencies, which are often referred to as capabilities, are excluded from resources and identified as a separate category (Teece et al., 1997; Makadok, 2001). Leaving aside further polemics on the classification of resources, it is relevant in the context of this article to focus on their importance for an enterprise. The main role of resources is to achieve the goals of an enterprise. Each enterprise should have an own resource base, configured in such a way as to bring as many benefits as possible, this way ensuring a certain market position. Not all resources involved in the value creation process contribute equally to that value. The importance of resources in the development of an enterprise is particularly emphasised by the resource-based view, according to which they are seen as a strategic potential for an enterprise (Sopińska and Mierzejewska, 2017) with the specific attributes defined by the VRIN/VRIO acronym (valuable, rare, inimitable, non-substitutable, organised) (Barney, 1991; Barney, 2008). Thus, it is not important how many resources an enterprise has or controls, instead, what matters is how the resource base defined by the VRIN/VRIO framework is configured (Otola et al., 2018). The unique nature of

resources and their proper configuration make it possible to achieve the effect of synergy. Such effect may be achieved thanks to applying a business model to the operationalisation of activities in an enterprise.

Conceptualisaton

The business model may be analysed in a systemic approach: input – transformation – output. The theory of systems shows that the operation of every element of a whole affects the operation of all the other elements (von Bertalanffy, 1956). The systemic approach to the business model makes it possible to analyse every element of the system separately and to analyse the mutual couplings between those elements and their relationships with the environment. As previously highlighted, key resources and key activities are an essential component of the business model.

Fig 1. Systemic approach to resources in business model

Input resources may be created independently by an organisation, or they may be purchased in the resource market, e.g. from key suppliers. Not every enterprise is able to create products based on its own resource-base. Some enterprises will acquire resources in the form of raw materials, semi-finished products, components or infrastructure. There are also enterprises that use intellectual property, i.e. trademarks, licenses, copyright, databases. Finally, the most valuable resources as knowledge should be at the disposal of the enterprise. However, it may happen that none of the employees of an enterprise has the required knowledge and it is reasonable to use the knowledge resources of other enterprises. At the input stage, it is important to determine what resources an enterprise owns and what resources and how many of them it needs to buy in the resource market.

The process of transforming input elements into output elements is associated with management areas, such as: finance management, HR management, marketing, innovation and production processes as well as strategy and planning. The processes taking place during transformation are aimed at achieve the tasks implemented by an organisation and they are identified as output elements. However, it is possible to look at the transformation process in a different way. In this approach, the transformation process consists in the

way products/services are produced. Accordingly, it disregards the processes associated with enterprise management. Looking at the transformation process as a way of generating products/services makes it possible to identify several approaches to the activity of an enterprise. It can be distinguished the proprietary concept of generating a product/service or a contrary, license-based concept. Not all enterprises want to use licenses, even if they are not able to independently develop solutions to generate products/services. In such case, they decide to cooperate with other enterprises or scientific and research institutions. Such cooperation makes it possible to create a bond of social, economic, service-provision and technical nature with the aim of reducing total costs and increasing the value of enterprises, to mutual benefit of the parties involved (Lefaix-Durand et al., 2005). Another possible procedure in the transformation process is to take actions according to the customer's wishes. An idea, plan or design is fully developed by the customer and discussed with the manufacturer, and on its basis, a product/service is generated. It should be noted that most enterprises will not focus on a single possible method of generating products/services, but rather, they will offer several options.

Output resources are products/services that an enterprise delivers to its customers. On the one hand, resources are regarded in the context of the end products but, on the other hand, there are key activities for the customer. In this context, it may be examined how an enterprise satisfies the needs of its customers. Is the activity of an enterprise limited to generating and selling a product or does it also offer a number of other activities, beginning with consulting through designing, manufacture, sales and implementation, or even service? Output activities show how a value is delivered to the customer and how an enterprise differs from its competitors.

Methodology and research design

Data sample and method

The empirical research concerning the business models of high-growth enterprises was conducted by means of a survey among managerial personnel in early 2019. 150 Polish enterprises participated in the research. According to the OECD definition, high-growth enterprises are the enterprises where revenues from sales or employment are expected to grow by more than 20% on average annually over the next three years. Enterprises that satisfied one of these two conditions were qualified for the survey. The research focused only on the issue of resources in business models. The research results were analysed in the context of the entire research sample and broken down into the categories of the size of an enterprise (small, medium, large), based on the number of employees (see Fig 2).

Fig 2. Basic statistics on the examined enterprises

Input resources

The respondents were asked what resources they acquired from their key and/or permanent suppliers. The possible responses included: i) knowledge and experience, ii) raw materials, semi-finished products, components, goods, iii) access to infrastructure, real property, iv) licensees, trademarks, copyright, v) data bases. All the enterprises acquired resources from key and/or permanent suppliers. Almost 63% of the examined enterprises acquired two types of resources, while 17% of the respondents stated they used one type of resources available on the market, or three types of resources, respectively. No enterprise reported acquiring resources from all of the above groups. Considering the volume of acquired resources with respect to the size of the enterprise, it should be noted that in every group, enterprises most frequently used two types of external resources. Also, small and medium-sized enterprises more frequently acquired one type of resources, while large enterprises used 3 types of resources (Table 1).

Table 1: The number of resources group acquired from key and/or permanent suppliers

Number of resources groups	Small	Medium	Large	Total
5	0,0%	0,0%	0,0%	0,0%
4	3,3%	7,7%	0,0%	2,7%
3	17,3%	9,6%	16,4%	29,7%
2	62,7%	67,3%	60,7%	59,5%
1	16,7%	15,4%	23,0%	8,1%

Almost all enterprises procured raw materials, semi-finished products, components and goods. It is surprising, however, that as many as 70% of the examined enterprises acquired knowledge as a necessary resource to operate, and the size of the enterprise was not relevant here. The other types of resources were not so frequently acquired. No more than 20% of the examined enterprises declared that they purchased on the market the following resources: iii) access to infrastructure, real property, iv) licensees, trademarks, copyright, v) databases (Table 2).

Table 2: Resources acquired from key and/or permanent suppliers

Type of resources	Small	Medium	Large	Total
Knowledge and experience	70,0%	73,1%	65,6%	73,0%
Raw materials, semi-finished products, components, goods	99,3%	98,1%	100,0%	100,0%
Access to infrastructure, real property	10,0%	13,5%	4,9%	13,5%
Licensees, trademarks, copyright	16,7%	19,2%	13,1%	18,9%
Databases	11,3%	5,8%	9,8%	21,6%

The next question addressed to the respondents concerned the percentage importance of selected four groups of resources (i.e. i. technological resources, ii. human resources, iii. other intangible resources, iv. financial resources) for generating key products/services (Fig 3). More than 40% of the respondents declared that, to generate key products, they needed approx. 31-40% of technological resources, while for 30% of the respondents, this ranged between 21 and 30%. Similar responses were given concerning the group of human resources. 31-40% of human resources were crucial do generate a product for 42% of the respondent, while 33% of them selected a lower range from 21 to 31%. Interestingly, 30% of the examined enterprises did not need any other intangible resources (this concerns only the group of small enterprises), while for 37%, their relevance was below 10%. Most (nearly 50%) respondents declared that their need for financial resources to generate key products ranged between 11 and 20%. An analysis of this issue regarding the size of the enterprise led to similar conclusions. The only differences are visible in the human resources group, which is more important in large enterprises. 40% of the respondents from the group of enterprises with more than 250 employees consider they need between 31 and 40% of human resources, while 38% of them chose the range from 41 to 50%. Financial resources are also important for large enterprises: for 43% of them, the need for those resources ranges from 31 to 40%.

Fig 3. The share of resource groups in generating products/services

The respondents were asked to identify essential groups of intangible resources in their enterprises according to the typology presented in Table 3.

Table 3: Typology of intangible resources

Group of intangible resources	Components
Human capital	Employee skills; employee experience; employee intellectual potential; managerial skills of the managerial personnel; creativity
Organisational capital	Organisational structure, organisational culture, management methods, relationships within the enterprise
Intellectual property	Patents, licenses, trademarks, copyright, contacts, data bases
Core competencies	Know–how, knowledge, specialist knowledge, experience, skills and behaviours
Relationships	Formal, informal, with the environment, inside the organisation, with customers, with suppliers
Employee attitudes and behaviours	Loyalty, availability, motivation and commitment to work
Positioning resources	Commercial brand, customer loyalty, reputation, company image, knowledge about competitors

The least relevant groups of resources, according to the respondents, are employee attitudes and behaviours, positioning resources and relationships (Fig 4). For 33% of high-growth enterprises, the most valuable group of intangible resources are human resources. Another highly valued group is organisational capital,

considered to be the most valuable resource by 22% of the respondents and the second most valuable resource by 24% of the respondents. Intellectual value is perceived as very valuable by 10% of the respondents and as valuable by nearly 21% of them. The results for the core competencies category is surprising. Only above 3% of the respondents think it to be a very valuable resource, while more than 5% – to be valuable. This is unexpected, because the literature on the subject emphasises the great significance of core competencies in building the competitive advantage of an enterprise on the market (Hamel and Prahalad, 1990).

Fig 4. Significant groups of intangible resources

Resources in the transformation process

In the transformation process, the resources put into the system are transformed into output products. The transformation process is mainly linked with how the business model works, but in the context of resources, it is possible to focus on the way of the generation of products/services. The respondents were asked to declare how they generated their products/services, whether: i) they were their proprietary solution, ii) were made on the basis of a license; iii) were made on the basis of cooperation, iv) were made according to the customer's plans or projects, v) were associated with supply logistics.

Table 4: Methods of generating products/services

	Small	Medium	Large	Total
Proprietary solution	57,7%	63,9%	70,3%	63,3%
License	15,4%	24,6%	29,7%	22,7%
Cooperation	67,3%	60,7%	59,5%	62,7%
According to the customer's plans or projects	76,9%	54,1%	45,9%	60,0%
Supply logistics	30,8%	21,3%	16,2%	23,3%

An analysis of the responses shows that proprietary solutions, cooperation and generating products according to the customer's suggestions are crucial for more than 60% of the respondents (see Table 4). Meanwhile, more than 23% of the respondents declared that their products were associated with supply logistics and more than 22% – that they were generated on the basis of licenses. In the case of small enterprises, products are most often generated on the basis of plans (77%) and cooperation (67%), followed by proprietary solutions (58%). In medium-sized enterprises, proprietary solutions were selected by 64% of the respondents and cooperation – by 60% of the respondents. Products based on the customer's idea are generated by more than half of those enterprises. Similar is the case with large enterprises. Here, the dominant method of generating products are proprietary solutions (70%). 60% of the large entrepreneurs base their activity on cooperation, while 46% generate products/services according to the conditions determined by the customer. A quantitative analysis of this question shows that the respondents most often choose two methods of generating a product (36%), while 32% of the responding enterprises use three methods. Less than 1/4 of the respondents focus on one of the listed methods of product generation. Medium-sized and large enterprises are not different in this respect. Small enterprises most frequently selected three methods of product generation (38.5%), followed by two methods (28.5%).

Output resources

An analysis of the output resources is based on the respondents' declarations concerning what exactly they offered to their customers (Table 5). The respondents could choose several from the suggested options, i.e. i) consulting, ii) product/service designing, iii) product/service generation, iv) product/service sales, v) product/service implementation, vi) product/service training, vii) service. The examined enterprises focused especially on the production (99%) and sales (98%) of goods. More than half of them offered designing (56%), service (55%) and implementation, and 40% provide consulting. An analysis of the output resources through the prism of the size of the enterprise led to identical conclusions. It is also worth noting how many types of activities an enterprise performs for its customers. Not many, because only 3.3% of the responding enterprises perform one activity and less than 10% – two activities. 28% of the respondents declared that their enterprises performed three activities for their customers. More than 3 activities are performed in total by almost 50% of the examined enterprises. The same as in the case of the types of activities, an analysis taking into account the size of an enterprise led to the same conclusions.

Table 5: Activities for customers

	Small	Medium	Large	Total
Consulting	40,4%	41,0%	37,8%	40,0%
Product/service designing	42,3%	60,7%	67,6%	56,0%
Product/service generation	96,2%	100,0%	100,0%	98,7%
Product/service sales	90,4%	100,0%	91,9%	94,7%
Product/service implementation	55,8%	50,8%	45,9%	51,3%
Product/service training	32,7%	26,2%	16,2%	26,0%
Service	53,8%	59,0%	48,6%	54,7%

Conclusion

An important observation concerning the resource base in the business models of high-growth enterprises is the lack of significant differences depending on the size of the enterprise. This means that these enterprises construct and configure their resource base in a similar way. Currently, a lot is said in the literature about core competencies and their importance for enterprises. Competence determines how people should behave and what they should know to do their job properly. Nevertheless, the studies do not confirm that this is a key resource for high-growth enterprises. The components of core competencies are know-how, knowledge, specialist knowledge, experience, skills and behaviours. Taking into account that 70% of respondents indicate that they are acquiring knowledge on the resources market, the result of core competencies should not be surprising. So which resources are important in creating a business model of HGEs? The two most recognised groups of intangible resources are human capital and organisational capital. It is worth noting which components are in each group. The human capital includes employee skills, employee experience and intellectual potential, managerial skills. The components of organizational capital are organisational culture, management methods, relationships within the enterprise. From the conducted research it can be concluded that creating a fit business model is based on people who are provided with an appropriate system of standards, patterns, values in the enterprise. The combination of human capital with organizational capital and intellectual property makes that the business model will bring market success. The ways in which the products are manufactured are hardly dependent on the size of the enterprise. The activities for clients, the proprietary solution and cooperation are visible. Licensed activities do not contribute to the rapid growth of the enterprise. This is natural, since the purchase of a licence on the market can be made by any enterprise and therefore does not confer a competitive advantage in the form of generating resources characterised by the acronym VRIN/VRIO. Moreover, while constructing their business model, these enterprises focus on performing usually three activities for the clients. One or two key activities is not a solution that allows for a competitive business model of HGEs.

Abstract

This paper studies the efficiency of investment strategies created by the machine learning algorithm for the 50 largest US companies. The Random Forest, as a representative of the algorithms based on decision trees, has many advantageous features for the time series analysis, in particular, for problems of regression and classification. The Random Forest was applied in the study to detect a signal whether to buy, sell, or hold a specific stock for one month. The decisions are based on the classification and consider multiple macro-economic and market variables. The case was analyzed for three classes that comply with investors' expectations regarding the forecast of price changes. It is desired to focus on the accuracy measure to verify how the presented algorithm will work, namely, how many times it may correctly predict a specific result among three investment decisions – to buy, hold or sell shares. The effectiveness of strategies' signals was translated into the verification of the hypothesis about market efficiency. The Matthews correlation coefficient was used as a synthetic measure of the forecasts quality. It is based on the concept of the confusion matrix. As it was expected, the results support the thesis that the market is becoming more and more efficient. Moreover, contrary to the imposed concepts, even utilizing a large data set and sophisticated deep machine learning tools does not lead to a satisfactory result in practice.

Keywords: Investment Strategies, Random Forest, Deep Learning, Forecasts, Confusion Matrix

Introduction

The aim of this study is to test the ability of the Random Forest algorithm to determine the signal for investment strategies for the most significant American listed companies. Such an approach may provide a beneficial tool for market participants, namely, for investors, economists, or policymakers. They also account for a good source for understanding the drivers of stock movements and may enhance the understanding of global capital markets relationships. The primary assumption for the creation of these strategies is the possible market dependencies and non-linear relationships, which may influence future price movements. In this paper, one month period for a stock is considered, which means that the strategy rebalancing is performed every month.

The importance of market relationships integration between stock markets across countries and global or regional economies might be justified by the rich body of evidence. Firstly, investors and funds benefit from the integrated market by fairly priced assets, which grants them a lower risk premium required to invest in the specific markets. Secondly, it also concerns the aspect of the market efficiency hypothesis since the integrated markets support the flows of information. Finally, the integration of the

markets enables economists and scientists to analyze and understand more deeply the global economic environment and its dependencies.

The most fundamental factors of stock prices' movements are supply and demand. The law of supply states that an increase in price results in an increase in quantity supplied, whereas the law of demand displays the inverse relationship. If the price rises, the quantity demanded decreases. According to these laws, the price is determined by supply and demand at the point of the equilibrium. It is the most common approach to determine the asset price on stock markets. However, both demand and supply are affected by many factors like the company's, industry's and country's performance, government policies, international economic situation, and many others. In such a case, factors like earnings, dividends, or volume of sales and costs are classified as microeconomic variables and remain specific to a particular asset or group of assets. Thus, the macro-economic factors are common for all kinds of assets and include such variables as inflation, commodity prices, economic indicators, exchange rates, or bond yields.

In this paper, the application of the Random Forest, a machine learning algorithm, is tackled differently to look into the macro- and micro-economic relationships among stock prices. Under this research, fifty currently largest American stocks were chosen from the S&P 500 aggregate. The additional criterion for the choice of stocks was the availability of quotations for at least twenty years. This assumption implies that the entire data set includes the data from the period between January 2000 and January 2020. Therefore, the total number of monthly observations amounted to 240.

The further part of this paper is divided into five sections. Section 2 depicts the general idea of investment strategy. The next section presents some characteristics of the Random Forest algorithm and how it can be used for the decision-making process. Section 4 describes the steps needed for correct data preparation for processing them with the algorithm, the methodology of model training with the data set, and the evaluation methods. The next section focuses on the Matthews correlation coefficient used to evaluate the quality of the forecasts. Finally, section 5 presents and summarizes the results of the research.

Quantitative approach in investment strategy

An investment strategy for any investor is a collection of principles or rules determining the time of investment and the financial instrument, which is the subject of investment (Basile 2016). Before the establishment of the rules, it is required to identify a purpose, a time horizon, and the risk aversion of an investor. Ferrari (2016) lists the general steps needed to be performed to create an investment strategy:

1. Identification of objectives and constraints,
2. Formalization of the investment strategy,
3. Implementation of the financial plan,
4. Periodic rebalancing of the portfolio,
5. Performance assessment and risk control

The author states that the level of detail and structure of each point may be different for various investor types, size of the portfolio, the complexity of management, and relevant regulations. The collection of principles allows the portfolio manager to detect a signal whether to buy an asset, hold it, or sell it in an appropriate time – the formalization step. The implementation becomes the next step. However, Pederson (2015) suggests that it should be preceded by the backtesting phase in which an assessment is made to determine if the chosen strategy achieved a specific outcome in the past. Followingly, periodic rebalancing should be performed. If the portfolio does not change over time, the active strategy is not needed as it would be equal for the buy-strategy and the passive hold-strategy. The last step is performance assessment and risk control, in which the appropriate measure is chosen to determine the efficiency and to keep the risk in bounds.

The paper is focused on the formalization of investment strategies. Nevertheless, the next steps are also tackled but not in such a detailed manner. In this research the signals are based on the outcomes of the Random Forest classification problem: if the next month price return is higher than four percent, the signal (class) is to buy (1), if the return is smaller than four percent – sell (-1), otherwise the signal is to hold, and the class is '0'.

The idea of using the machine learning algorithm was prompted by the main characteristic of the big data approach and the choice of variables for the model. The Random Forest algorithm enables it to use an extensive data set of features and may not be limited to the factors chosen by the economic logic. The most important conclusion from the literature review is that the scientists firstly investigate potential logical reasoning and then test this relationship, similar to internal and external factors (ex. Heins and Allison 1966, Garefalkis et al. 2013, Hartono 2004). Although such an approach is generally accepted, it does not concentrate on finding the determinants, but only on justifying the choice of the factors. The comparison of two approaches is presented by Breiman (2001) who states that the statistical modeling could be divided between the Data Modeling culture, where the inputs and outputs are known, and the model is the one to be chosen and tested, and the Algorithmic Modeling culture, where the model is left as 'black box' and is concentrated only on the relationship between inputs and outputs. According to Breiman, the Data Modeling Culture is used by 98% of all statisticians, whereas the Algorithmic Modeling Culture is applied only by 2%. This study is directed towards the algorithmic approach, which allows it to utilize a highly complex model, so-called 'black box,' in which the inputs are selected to fit the output variables most appropriately. The chosen 'black box' algorithm is the Random Forest.

Random Forest algorithm

The Random Forest is classified in the ensemble classification and regression algorithms of the Machine Learning and was first described by Breiman (2001). The name originated from the structure and fundamental elements of the algorithm. The basic elements are decision trees that serve as predictors. All the trees are structured with some extent of randomness, which means that each created tree should be unique in comparison to the other. In common decision trees, each tree is split in such a manner that all variables are considered. In the Random Forest, the trees are split differently; it applies only the random subset of input variables. There are two possible approaches to how the algorithm might be used. Firstly, it may be employed to solve a classification problem in which the majority of voting is conducted among all trees to derive the outcome class. Secondly, it may be utilized in the regression problem in which the result is obtained as an average value of all trees' results. Because of the random construction of all decision trees, the Random Forest is designed for large data sets where the relationships between inputs and output are not linear and obvious. It provides for the explanation why the Random Forest might serve as a 'black box' model in the Algorithmic Culture of statistical modeling, and thus the determinants of the stock prices do not need to be chosen before implementing the algorithm which may also enhance the possibilities to create an efficient investment strategy.

As an algorithm, the Radom Forest accounts for several advantages. This collection of decision trees may solve not only the classification problems but also the ones regarding regression. Both categorical and continuous inputs could be applied to the model. While working with empirical data, a common issue is to spot the outliers. The algorithm easily handles it as randomness ensures an outcome that always entails some trees not considering such values as needed. The same advantages tackle the problem of incomplete data sets and missing data points. Therefore, their impact is most likely to be diminished. It also implies that the algorithm is invulnerable to the minor changes in input data. The Random Forest could be classified as the 'black box' algorithm since deriving an impact of one variable may be very problematic. This characteristic could be treated as an advantage if the relationships between input and output variables are not significant. Still, it also might prove to be a disadvantage as these relationships could not be reasonably justified. Another advantage of the algorithm is it's insensitivity to the multi-collinearity issue since the variables are chosen randomly for each tree. This issue might have an impact on the interpretability of the importance, but it does not affect the accuracy of the model.

The most important feature of the Random Forest is its ability to hold non-linear relationships in decision trees. The reasoning behind the decision process is not evident and it may be much more complex in comparison to human reasoning, which, on the contrary, tends to capture often only linear dependencies.

The structure of the algorithm allows it to limit the number of external variables and to assess their importance. The importance of variables is used mainly in the process of variable selection, and the Random Forest provides the taxonomy of such calculations. The first calculation mode uses a metric called "Gini importance" or "mean decrease in impurity." The Gini importance score affords a relative order of the input variables and is also used in the process of splitting the nodes in decision trees. The score is determined by measuring how efficient the input variable remains in the attempt to reduce variance or uncertainty. The Gini importance, however, is criticized by Strobl (2007), who declares that this measure is not adequate for variables when they vary in the scale and the number of categories. The second calculation, which is also recommended, occurs while utilizing permutation. According to Gregorutti (2017), the permutation importance is measured as follows:

1. Fit the model and record the first score, ex. accuracy (for classifiers) or R^2 (for regression),
2. Permute all values of a single input variable,
3. Pass the whole dataset with permuted variable to the model,
4. Fit and evaluate the model,
5. The difference between the two scores is the permutation importance.

The permutation importance is characterized by its simplicity. It may be used not only with the 'black box' models but even with a simple OLS. A practical application of the methodology mentioned above is displayed in the further parts of the paper.

Data preparation

The monthly data from January 2000 to January 2020 were collected for the constituents of S&P500 from February 2020. The data set entails 240 observations of the single company. Since calculations and training process is very time-consuming, it has been decided to limit the number of stocks to fifty largest companies with a track record of at least twenty years – see Table 1A in the Appendix (with the list of the chosen companies). The input data includes the most popular global equity indices like MSCI World, Stoxx 600. It also captures prices of commodities such as oil or gold, some macro-economic variables, for instance, inflation, interest rates, unemployment rates, sovereign bond yields, and exchange rates. All of them have been gathered as a whole set of 224 macro-economic variables. These variables are listed in Table 2A in the Appendix.

According to Specht (1991), the input variables, which are derived from various scales, should be preliminarily normalized to keep similar variances among the chosen features. The normalization causes the model training to be more efficient over time and also may improve the results (Jayalakshmi 2011). There are numerous methods to deliver the normalization process, among which the most popular ones are to be found, namely, the Min-Max method or the Z-Score method.
The normalization of the observations concluded the data preparation step. All variables were normalized into 1-month changes – percentage or absolute depending on the data characteristics. Additionally, 5-year rolling z-scores were implemented. For every stock which has been chosen out of fifty above mentioned stocks, all input variables were taken into the training process, which is described in the following section.

Training the algorithm

The training is based on forecasting the next month's price movement of the stock. A classification problem is being investigated. Class '1' stands for next month raise in the price above 4%, '-1' stands for a decrease of more than 4%, and '0' otherwise. This training method of the algorithm is called supervised learning, and it requires an additional supervised time series. It is treated as a teacher in a

learning process. A common approach to validate a model is to split it between training and testing subsets, for example, 60% to 40%, respectively. However, such an approach does not explore the full information available in the data set. It also loses the ability of the algorithm to learn over time. Hart (1994) proposed a time series cross-validation, which enables the model to benefit from the time aspect of the data. Similarly to the rolling approach in the normalization process by z-scores, the time series cross-validation uses a rolling window over the data set. There are two ways of conducting it. The first approach imposes the starting point of the window to be fixed, and with a new observation, a new window is added. The second approach, however, uses a fixed horizon of the rolling window. Thus, it is more suitable for economic data as the influence of the inputs may vary over time. In the conducted empirical research, the rolling period includes 60 observations, and it implies that the window covers a collection of the data gathered within five years. Each time the window moves forward, the forecast is conducted solely for the following observation, which is not included in the window. Therefore, for a 5-year-long window with 60 observations, the forecast is performed only in the 61st observation. The rolling window moves forward and includes data from the second to the 61st observation. This methodology allows it to apply properties of analyzed time manners of the data. It also leads to a situation in which only the first 60 observations may be considered as a training set or an in-sample period.

The next step in the training process is the optimization of the hyperparameters, which are the parameters set before the training begins. Actual model parameters are optimized in the learning process. Multiple ways of adjusting the hyperparameters are available, for example, the manual search, grid search, or random search (Bergstra and Bengio 2012). The Random Forest algorithm is characterized by the following hyperparameters, namely, by the number of trees, the number of variables in each split inside a tree, or the maximum depth of a tree. There is no verified approach determining which set of hyperparameters is optimal to solve the specific problem. Therefore, the methods mentioned above depend on testing possible combinations bounded by previously established limits. In this research, the hyperparameters were determined by the grid search method.

When the hyperparameters are optimized, the variable selection process starts. As has been described in the previous parts of the paper, the Random Forest enables the permutation importance to be calculated, which allows it to rank the input variables (Genuer et al. 2010). And so, the process called Recursive Feature Elimination is applied. When the variables are ranked according to their importance, the last variable is removed from the series. Then the process repeats. The final variables could be chosen either by selecting the data set with the highest evaluation score or when the quantity of input variables is limited to a specific number. Reducing the number of variables is aimed at a potential decrease in overfitting and is likely to increase the model's effectiveness. In this empirical research, the chosen number of input variables is constant and equals 10 to limit the number of variables taken for each stock.

As the rolling approach is accepted, the steps are reiterated every time the rolling window moves forward. It means that all hyperparameters are optimized, the Recursive Feature Elimination is conducted each time. Thus, it results in more than one model utilized in the learning process in the entire data set, which means that repeated use of the Random Forest creates the outcome. Once the mechanism, as mentioned above, is determined, the predictions are collected and evaluated for each company.

The process was performed with the application of the Python language with the PyCharm environment. The main packages were 'pandas', 'numpy', and 'sklearn'.

Quality of the classifiers – evaluation of forecasts

The concept of the confusion matrix has been used to assess the quality of the forecasts. It analyses the number of compliant and non-compliant states for forecasts of price changes on the market (-1 for forecasts of decreases in the next period above the assumed level, 1 for forecasts of increases above the assumed level and 0 for other cases) with the states identified for actual price changes. It is the preferred

and widely used approach (Troiano, L., Bhandari, A., Villa E. (2020)) for evaluating deep learning techniques. Thus, for the three-state case, the confusion matrix took the form, which is presented in Table1.

Table 1: Confusion Matrix idea

	Confusion Matrix C	Actual states		
		-1	0	1
Predicted states	-1	$\mathbf{c_{(-1,-1)}}$	$c_{(-1,0)}$	$c_{(-1,1)}$
	0	$c_{(0,-1)}$	$\mathbf{c_{(0,0)}}$	$c_{(0,1)}$
	1	$c_{(1,-1)}$	$c_{(1,0)}$	$\mathbf{c_{(-1,-1)}}$

Source: own preparation.

The higher values of c(i,i) for i={-1,0,1} and the lower values of c(i,j) for i≠j and i,j= {-1,0,1}, the better investment signals generated by the investment algorithm and the better random forest classifiers. For example, the confusion matrix result [13,11,25;11,14,30;13,16,47] means that the price decrease (state -1) was correctly predicted in 13 cases and that the algorithm predicted a decrease (state -1) in 11 cases when in fact the prices did not change (state 0). There were 180 forecasts in total. The Matthews correlation coefficient was employed as a synthetic measure of the forecasts quality. It displays several advantages over other approaches (Chicco D, Jurman G. (2020)). The measure takes the value of 1 for the perfect classification (perfect forecast). The lower value, the worse the evaluation of the prognostic method. For K x K confusion matrix C, the value is estimated from the formula:

$$MCC = \frac{\sum_k \sum_l \sum_m (c_{kk} c_{lm} - c_{kl} c_{mk})}{\sqrt{\sum_k (\sum_l c_{kl})(\sum_{k' \vee k' \neq k} \sum_{l'} c_{k'l'})} \sqrt{\sum_k (\sum_l c_{lk})(\sum_{k' \vee k' \neq k} \sum_{l'} c_{l'k'})}}.$$

The quality of the algorithm throughout the entire available data history was examined, and the hypothesis of the financial market efficiency change was verified for the two sub-periods.

Therefore, the MCC(1:180) value has been estimated for the full range of historical data (180 months) and the first and second half of the sample – MCC(1:90) and MCC(91:180). The hypothesis MCC(1:90)>MCC(91:180) was verified with the application of the bootstrap method, in which two samples were drawn up with outcomes of 90 observations from the original 180 periods (sampling with replacement). On such a basis, the distribution of test statistics was estimated under H0, and the p-value was determined.

Empirical results conclusions

Table 2 presents the Confusion Matrix results for each company for the entire period (180 months) and two subperiods (both 90 months long).

The obtained results do not indicate the usefulness of a given method for building an investment strategy in practice, despite the use of large variables set and a quite flexible tool, i.e., random forests. A large number of non-zero values that lie out of the diagonal of confusion matrices account for a high forecasting error.

Table 2: Confusion Matrix results for companies

Company	Conf. Matrix (1:180)	Conf. Matrix (1:90)	Conf. Matrix (91:180)

The summary results of the adopted synthetic forecast quality measure are presented in Table 3. In most cases, correlation values are statistically significant but too low to achieve satisfactory strategy results from a financial point of view. What is worth emphasizing, the compliance values of forecasts are lower in the second analyzed sub-period. The column "sign" presents the information if the MCC measure was higher for the first subperiod. The last column presents the p-value for testing the hypothesis that the MCC measure was higher for the first subperiods. It might be interpreted accordingly – the market efficiency was lower in the first subperiod, and the forecast tools worked better.

The empirical proof of the increasing market efficiency confirmed the intuitive assumptions delivered by the authors.

In 30 out of 50 cases, a higher MCC was obtained in the first sub-period. Still, the analysis with the bootstrap techniques leads to the conclusion that the difference was statistically significant at the level of 10% in only seven cases. It allows deductions to be made that throughout the period under the analysis, no lack of information efficiency of the market to achieve satisfactory financial results was detected while employing a given strategy. Additionally, according to the current research, there is an increase in the efficiency of financial markets (Troiano, L., Bhandari, A., Villa E. (2020).

Conclusion

The values of the MCC correlation obtained by the authors (close to zero) indicate low compliance of forecasts with the actual changes in share prices. The proposed strategy with the use of the analyzed data set does not lead to satisfactory financial results. Thus, there are no grounds to reject the hypothesis that the market is efficient.

The results are in line with the authors' expectations that the markets, in particular, the American market, are information efficient, and the level of efficiency increases over time. The empirical proof of the increasing efficiency of markets confirmed the intuitive assumptions of the authors. The use of sophisticated machine learning algorithms and a broad set of input data does not guarantee satisfactory results of investment strategies. It does not preclude the need to construct and verify subsequent innovation strategies based on other data sets and algorithms (Troiano, L., Bhandari, A., Villa E. (2020)), particularly, for data with a different (higher) frequency which will be an area of the authors' further analysis.

Abstract

Digitalization of production environment, also called Industry 4.0, the term invented by Prof. Wahlster in Germany, is now one of the hottest topics in the software/hardware engineering departments at universities and companies. It splits to many subtopics and technologies. One of the most interesting concerns Augmented Reality glasses – giving a very natural human-machine interface – possibility to present the needed information right in front of user's eyes and ability to communicate with the system by simple gestures and voice. To show the long-lasting need of convenient presentation of information, authors show different examples in different markets, but then, concentrate on one example around the production maintenance team. The point of this paper is the AR system usability evaluation – as noted by scientists around the world note, in-depth studies about the effects of AR applications are sparse. In the first part of this paper, authors recall the concept presented in 2018 about the new method of monitoring the production line with the AR glasses. In the second part, there is a description of conducted study for this concept, carried out in the real production environment on the real production process. Finally, authors deliberate about conclusions, technology imperfections, limitations and future development.

Keywords: Augmented Reality, industry, maintenance, AR glasses.

Introduction

From the research conducted by Digital Technology Poland and University of Zielona Gora team comes, that convenient presentation of the right information in the right place is now one of the biggest problems is many areas of our (information overloaded) lives. We often have the right information, but advanced optimization that is observed nowadays, requires to match it with other factors – like eg. the right place. Additionally, preferably, searched and displayed automatically.

In the researched health and beauty retailer and pharmacy chain the staff knows that the certain product gets low on the store's shelf, but where exactly is this shelf? In the researched food market chain, the staff have the list of products with the expired date. But the same problem – where are these products? How to quickly track the expired sausage, when there are 40 different ones one next to another. And there are 40 other product on the expired date list… Additionally, products rotate around the whole shop, cased by the strategy of the marketing department, to make people walk around the whole shop. This however make the life of the staff much harder when talking about normal, everyday duties. In the researched shoe and sportswear retail chain, one of the biggest problems is warehouse conveyor stops. The right information is written on the control cabinet, so the worker must go to this location,

read the information and go to the right place to fix the issue with the conveyor. This takes too much time. Could be reduced when matching the known, right information, with the right place.

Many more examples were observed and identified, and the result was that products were not refilled on time and part of the shelf was empty, although these products were at the shop warehouse. Or, the products with the expired date are not collected on time and the customers are able to buy them (if not perceptive enough, which is in most cases).

The same problem touches the production environment. Especially the traffic management and maintenance team, which is one of the most important, since it fights for smooth production without stops and downtimes. Where exactly is the machine, that is reported with the predictive maintenance system as the problematic one that could stop shortly? In such cases, the reaction time is crucial. Will the staff fix the problem on time or will the machine stop and make the whole production line stop, causing delays and painful losses.

In the above mention examples, one can see that each business has its own requirements. The better business, the more procedures and more sophisticated system of work. The more optimization, the better profits. However, there is a performance line which cannot be exceeded without extra help. The answer could be hiring more people, but this may mean that the whole profit from the optimization is used, or even surpassed by the extra worker. The staff work optimization is often state of the art now, so there is not much room for improvements. The only answer nowadays in technology.

Perfect Information

What means perfect information? Is it the information itself? From the mentioned examples we can conclude that the right information is not enough. The perfect information is needed. This means the right information + the right place + the right time. Preferably automatically shown. Staff provided with such perfect information is able to perform much better than today. Not only faster performance is the advantage. The perfect information makes the work easier and less annoying. The worker is actually more happy and relaxed, with better performance in the same time. Up till now, new, additional duties were causing more stress, so the perfect information seems to be a winner for everybody – the boss and the worker. A comparison to the navigation system comes to mind. Remember going to an unknown, big city with a paper map? How better is going to the certain location with the navi? How better than the regular, hard coded navi is the newest navi that shows the actual, real-time traffic, and is choosing the fastest route for the user? This is exactly the evolvement of the information towards the perfect information, that serves the best, gives the best performance and makes users actually more relaxed.

The following sections describe Augmented Reality (AR) technology as a tool that provides the user with the right information in the right place at the right time. The concept solution was widely described in 2018, together with a broad description of Augmented Reality technology by Szajna et al. (2018). The presented in this paper research is a form of continuation of the above mentioned one, enriched with the study of comparison and results of carrying out the production line inspection by the maintenance team with and without the AR glasses, giving clear usability evaluation for this specific application. As noted by scientists from the University of Oxford and Graz University of Technology presented by Vorraber et al. (2019)., in-depth studies about the effects of AR applications on key performance process indicators are sparse.

Providing the traffic maintenance team with the perfect information through Augmented Reality glasses – 2018 concept overview

Monitoring a production line is a daily and necessary task in every factory. In modern, “Industry 4.0” factories described by Gorecky et al. (2014), this is done with the use of advanced systems for automatic monitoring and warning, and more and more often, also intelligent response. Usually, however, daily inspection is performed by a human being - a qualified factory worker. In this case, it is necessary to provide him/her with IT systems providing the best possible support, perfect information with

transparent human/machine interfaces. Tablet devices are a great improvement for the employee performing the review, however they are still sub-optimal and cumbersome.

One of the most interesting and flexible for the user options of the natural human-machine interface are Augmented Reality projection glasses - in simplified terms, two miniaturized projectors mounted over each glass in a casing thus allowing them to be worn in front of the eyes in a manner analogous to traditional, eyeglasses or sunglasses as Cakmakci at al. (2006) notes.

The Augmented Reality technology is known from 1960's when firstly introduced in military segment as Helmet-Mounted Display described by Haller et al. (2006) and from 1990's when firstly named "Augmented Reality" by scientists working for Boeing on the system supporting identification of the beams and individual electric wires in the aircraft they were constructing recalled by Reifur (2010). The AR revolution, that spreads and is strongly seen in the last 3 years, when new glasses were introduced by world's biggest companies, opened new flexible and natural possibilities of the human-machine communication and interaction. The leading industry companies show increasing research in this topic with real life applications that can be observed during the biggest trade fairs, like CES or Hannover Messe.

Digital Technology Poland, together with the University of Zielona Gora are researching the Augmented Reality possibilities for production purposes. Many places were visited in our region in Poland and in selected German factories, that cooperate with our scientific or business partners. Surprisingly, although we live in the XXI century, at many visited older production lines, even the right information is often the problem. Manual, handheld meters or sensors, like for measuring vibrations, is often the reality. Real-time measurements, analytics and predictive maintenance is on a wish list, with no real action plan behind. In a research study by Saniuk et al (2019), Sąsiadek et al (2018), Nowicki et al (2019), many factories are far from the Industry 4.0 concept. At the newest factories, this is not the case, but providing the right information in the right place for the traffic maintenance team is not really covered.

Here the Augmented Reality glasses seem to be the right answer to natural human-machine interaction need. Advanced DTPoland-UZ works show that AR with installed sensors, proprietary software and connection to the cloud provides a very useful and ergonomic tool for maintenance team. Issues of uninterrupted production process, proper functioning and effective diagnostics are now supported with intuitive and user friendly system. The pre-defined, step by step maintenance instructions, connected to the flexible virtual advisor, based on real-time data from sensors and meters that analyze the current situation of eg. machine behavior, enhanced with hints and alerts based on historic behavior, potentially allow a user to do the job faster (first research results are the topic of this paper and will be presented in the following chapters), when talking about regular maintenance procedures. Additionally, reports are created instantly, visible to managers in real-time. All the data is gathered in the cloud, processed and directed to obtain noticeable trends and future valuable hints. This helps to constantly improve the system and even better support the operator. Based on carried maintenance inspection, the operator can add new comments to the machine's maintenance history by clicking virtual buttons, writing text notes or dictating a note with voice. All the necessary data are displayed to the user in front of his/her eyes, while all the control, making of notes and writing of reports are done using simple gestures and speech. Solutions of this type allow the life-span of individual parts to be utilized to their fullest extent by optimizing their replacement dates and controlling their operating processes; this, then translates into measurable financial savings and impacts, ultimately, on the financial condition of an enterprise.

The structure and operating principles of a support system using Augmented Reality technology

The developed system consists of edge computing devices connected to each of the machines or group of machines, sensors and meters (including energy meters), cloud resources for different data tasks (inc. analytics) and preparation of visualization, AR glasses, proprietary DTPoland-UZ image processing and analysis software and, optionally, a keypad. In a research study by Schmalstieg et al.

(2002), the AR glasses, depending on the requirements of the system operator, may be exchanged with a tablet or improved by physical manipulators, to develop the most user friendly supported system.
The system works in real time. The needed information is displayed on virtual screens (dashboards) or as other virtual elements and 3D models in front of user's eyes, notes Dugelay et al. (2008). The right info is automatically pulled out from the Cloud by proprietary DTPoland-UZ software and shown in the right place – where the user is standing, based on recognition of special physical (or virtual) markers (Sun et al., 2011; Uchiyama and Marchand, 2012), placed right next to the inspected machine. The navigation may be additionally influenced by the operator with the help of virtual menu and buttons or voice commands. The operator may see the exact service instructions, step by step, if pre-defined, or get to desired documentation of checked equipment, to see eg. normal working or edge parameters. In case when the machine is equipped with additional sensors (eg. measuring vibrations), is connected to the network and gathers historical operational logs, the technician can go through it to look for potential internal or external issues and potential sources of problems. The system is very intuitive and user friendly.

An important element of the system is the proprietary algorithm for enriching the real image with virtual objects. The challenge was to create a real-time module for calculating the delta from its original position when the user moves, so that virtual objects are displayed in the right place. In this case, the fault location can be highlighted using the virtual arrow, and then it is important for the arrow to stand still in the right place when the user is moving.

The system with the most important elements is shown below (Fig 1).

Fig. 1: Virtual objects, such as, displays, dashboards, buttons or suggested path to follow (symbolized with the pink line) and virtual arrows and pointers, embedded on the actual observed scene – a production line, with physical objects, eg. machines. Source: Own materials based on the DTPoland project.

The methodology also assumes application of the system in such areas as:

- repairs with the possibility of online video-call to the call center with qualified experts recommended by Baumann et al. (2016),

- support of assembly recommended by Wójcicki (2013) or conducting flexible, customized assembly recommended by Łunarski (2000),
- training of technical staff.

The use of an AR maintenance support system in the production line inspection process - case study

The authors state the following thesis: Automatic access to the right information, in the right place (3D space) at the right time, will shorten the time of performing activities at selected work stations. The subject of the conducted research are: information availability, information transfer method, time needed to perform selected activities, limitation of employee functionality. The research included the process of inspecting the production line by maintenance workers. Based on the definition by Apanowicz (2002), in the study, the authors used two leading research methods: experimental and statistical method. The results obtained so far have allowed to formulate the first research hypotheses and conclusions, although the entire scope of research has not yet been fully done at the time of writing this paper.

The same process of inspection of the production line was compared with and without the AR support system - the time needed to perform the same work in a traditional way was compared to work with the proposed AR support system. As Levitt (2004) notes, the case presented only involved regular inspections (checking of measured values, alarms and data stored; no issues; no additional documentation was searched, etc.).

Current production line control procedures were analyzed for three technological solutions that differed in time of putting into use:
for an older production line:

- Approach the machine
- Take the first manual meter (eg. for vibrations) from the bag
- Measure the value
- Look for the right page on the notepad corresponding to this machine or look for the machine on the list on the tablet
- Note
- Take the second meter (eg. for temperature)
- Measure the value
- Note
- Repeat at the next machine

for a newer production line:

- Approach the machine
- See the values on the info screen of the machine (values are stored locally for the period of 7-90 days depending on measuring frequency)
- Look for the right page on the notepad corresponding to this machine or look for the machine on the list on the tablet
- Note (values at the machine are overwritten after 7-90 day period)
- Repeat at the next machine

for the newest production line:

- Approach the machine
- See the values on the info screen of the machine (values are stored in the cloud, but one must approach the machine to see it)
- Repeat at the next machine.

Inspection procedure with the new AR system:

- Look at the machine without approaching
- See the values measured in real time that are automatically stored in the cloud (without approaching)
- Repeat at the next machine

The course of the study is shown below in Figure 2. The left side shows the inspection method currently used, without the AR support system. The right side presents an inspection with the system. In the first case, the maintenance worker is forced to physically approach each machine M and conduct a test with a manual meter or, if available, read information values on a given screen of the machine. In the second case, the employee does not have to approach the machines. When you look at a given machine, the software automatically recognizes the machine you are looking at and displays the desired values in front of your eyes.

The current control procedures were examined in older and newest facilities, without and using the AR support system. The times of inspections carried out using the method currently used, without AR, were calculated according to formula:

$$T = t_1 + t_2 + t_3(x,y,z) \qquad \text{(formula 1)}$$

where:

T - measured inspection time by the method currently used; t_1 – time to walk; t_2 - time to obtain information; t_3 – time to perform the selected process measurements (x, y, z - process parameters, e.g. vibration, temperature, noise).

and using the AR support system according to formula:

$$T' = t_1' + t_2' + t_3'(x,y,z) \qquad \text{(formula 2)}$$

where:

T'- measured inspection time using the AR support system. Other parameters are analogous to those defined in accordance with formula 1.

Fig. 2: The time study required to conduct the production line inspection process, between machines M, without and with the AR support system. Source: Own materials based on the DTPoland project.

Summary, conclusions, Directions of Total Practice

The right information is often available. However, to optimize the work, this information should be provided to the user in the most convenient way with the possibility of natural communication. Such possibility is given by Augmented Reality glasses. They display all the needed information right in front of the user's eyes and allow for gesture and voice communication. This creates a completely new, hands-free tool that supports the user with the perfect information – the right info in the right place at the right time. AR opens new way of working that can be significantly more efficient. Unfortunately, there are no ready glasses that can be used on a large scale in industry.

Based on the hypotheses and the first results obtained, preliminary conclusions were developed. Full results presented in the form of summary tables and further conclusions will be published and discussed when the entire scope of research will be finished.

Conclusion 1: it is possible to reduce the duration of specific inspection tasks by 10-30%. The first value applies to newest plants with machines equipped with sensors and status screens; time was saved mostly only on walking distance saved. The second, much higher value of 30% was observable in older plants, where the machines were not equipped with automatic measurement systems. Middle savings of around 20% were observed in plants where the machines were equipped with measuring systems, but the entire plant was not integrated into one network and one place aggregating data, so that the inspection employee was forced to physically approach the machine and search the needed information. In this case, he did not have to make manual measurements, but the time to obtain information saved on the machine screen was noticeable.

Conclusion 2: based on conclusion 1, the sensors installed (or not) on the machine give one factor of the optimization process, however, the way to pass the information and display it in the most convenient way is the other important factor. In other words, the information itself coming from the sensors is crucial but even when the sensors are available, the way to ergonomically (automatically) show the readings it is also very important.

Conclusion 3: Additional benefits from the use of the AR support system have been observed. Created reports are immediately visible in real time for managers of selected areas of production plant. All data is collected in the cloud, which allows you to easily view history. This feature, however, is not a differentiator in relation to other methods and market-available solutions.

Conclusion 4: AR technology makes users seem more relaxed, although thanks to time savings, they can be given more responsibilities at the same time. This is due to the automatic display of the desired information in the right place at the right time, and significant savings in searching and obtaining information. These observations require more research.

The quality of the support system is an important aspect. When creating proprietary software, great attention was put to the quality of information presentation on the glasses, so that it was legible and did not interfere with current human work activities. Stability and display quality has a significant impact on human feelings - prolonged use without a stabilizing module has allowed to observe eye fatigue and deterioration. The proprietary stabilization module eliminated negative feelings. However, visual feelings were not the goal of the study, so it is too early to draw final conclusions in this regard. It was an element noticed, but not very important. This is definitely an area for further research.

Among the tested AR: Meta, Epson and HoloLens glasses, the latter seem to be technologically most advanced and suitable for the proposed AR system due to the largest area of display of virtual image elements. After all, their design and technology does not yet meet industrial requirements. This is due to the delicate structure, weight, battery life, and still too small area of displaying virtual information compared to the area covered by the eyesight. It is planned to repeat the research on the latest HoloLens 2, which, according to manufacturer will have much better performance parameters. They should be available in the first half of 2020.

In the future, it is planned to replace markers (needed for AR glasses to recognize a particular machine) with advanced image recognition techniques that use the latest approach of artificial intelligence recommended by Hinton et al. (2006), Bengio et al. (2007), Le et al. (2012) i.e. deep neural networks currently under development by the research team. The second planned area of development of the AR support system, related to artificial intelligence, is advanced data analysis, thanks to which the virtual advisor will be even more effective and more flexible through the possibility of providing accurate guidance. Solutions of this type can allow maximum utilization of the life span of individual parts of the production line by optimizing their replacement dates and controlling operational processes; this approach translates into measurable financial savings and ultimately affects the financial situation of the enterprise.

Further research activities are planned to evaluate the AR support system in such areas as: repairs with the option of online video connection with a call center and qualified experts, assembly support or flexible, custom assembly, training of technical staff.

Abstract

This article presents the possibility of applying a strategy for the construction of the diagnostic systems used, among other things, in order to increase the stability of the manufacturing processes. The experimental and statistical method was used for the research process. This means that the selection of the number of signals and the location of the measurement points responsible for the product's compliance with construction assumptions, was adopted on the basis of experience in the implementation of similar solutions in the past

Keywords: Diagnostic Systems, Manufacturing Process Stability, Hybrid Drives, SCADA, Machining Defects

Introduction

The term diagnostics comes from the Greek language, where *diagnosis* means recognising, distinguishing, judging and where *'diagnostike techne'* means the art of distinguishing and making a diagnosis, according in the interpretation Cempel (1898). In turn according Zółtowski (1996), technical diagnostics includes assessment of the technical condition of a disassembled machine by testing the properties of its working processes and testing the properties of machine products.

A common feature of diagnostic methods is the way information is obtained and processed. The process implemented by various methods comes down to:

- selecting a measurable physical quantity containing potential information about the state of the object;
- verification of the correlation between the selected quantity and events at which the condition of the object changes;
- processing signals to remove possible interference;
- the classification of signals;
- continuous monitoring of symptoms and the generating of diagnostic decisions.

The use of diagnostics in manufacturing processes, whose primary goal is to maintain continuity of production, applies to many technologies, starting with chemical processes and ending with machining technology which is still of significant use, in such as the automotive industry, where he conducted research Lipski (2013).

The Use of Diagnostic Signals to Maintain the Stability of the Manufacturing Process

Variability of production system parameters, caused by wear or random factors, may become a threat to the stability of manufacturing processes, as implemented. Loss of stability here is understood to mean exceeding the significant measurable parameters of acceptable limits. These limits are set by both the designer of the product manufactured by machining methods and the technologist. Lipski 2013 mentioned, that exceeding these limits causes an avalanche of unfavourable changes resulting in the production of deficiencies or a catastrophic event. Violation of the stability of machining processes can have significant effects on the economy and on the security of these processes. In this situation, the designer of manufacturing processes may adopt one of two strategies.

The first strategy is to significantly lower the process parameters used and increase the supervision of the machine operator. This means an increase in manufacturing costs due to reduced performance and the cancellation of the multi-user service, usually associated with the automated machining process. It is a strategy to reduce the risk of the instability of the cutting process, while assuming that human supervision over an automated process will be fast enough to eliminate catastrophic, random events, which unfortunately is not always possible.

The second strategy is the construction of diagnostic systems for manufacturing processes. If the overriding goal of the process is to produce a product having the features recorded in the construction documentation, with the help of production resources declared in technology, the efficiency of these resources can be continuously or discreetly confirmed by diagnostic systems. The correct implementation of diagnostic processes should significantly affect such production parameters as performance, costs and quality.

Information is collected from the diagnostic devices installed in selected places of the technological process and should be used to:

- permit the commencement or the continuation of the technological process at the diagnosed position;
- indicate the source of the malfunction of the position;
- indicate the reasons for not achieving the parameters of the product manufactured at the diagnosed position;
- predict future states of the diagnosed object.

The addressee of information on the basis of which actions may be taken to improve individual stages of the manufacturing process may be a human or an IT system. In the first case, the human *rôle* is to implement the procedures assigned to the results of the diagnosis. Legutko (2009) mentioned, that they must be formulated so that the man operating the machine easily identifies their content and method of implementation. Usually these are control lamps, codes or inscriptions on alpha-numeric displays. Such a system, called the ***Andon System***, can be found in Toyota factories around the world, Figure 1, previously published by Nawrocki (2019).

Figure 1: Table of the *Andon System* in Toyota factories in Poland Source: Own study based on [*Nawrocki 2019*]

The indication of the source of the malfunction makes it easier for the operator to detect the cause of the alarm and remove it. In order to use information from the diagnostic system to indicate the reasons for not achieving the set product parameters, the operator must confront two pieces of information, namely, the results of the measuring of given product features and the results of the diagnosis of the manufacturing system. In this case, specialist knowledge and experience are needed to draw conclusions. In the option of using diagnostic information, it is the human operator who undertakes the *rôles* both of regulator and executor of the control decisions made.

When diagnostic information is used by an IT system, this information complements other information related to automatic production control processes. Most automated technological processes take place in constant repetitive cycles. If the diagnostic system detects a collision or incorrect condition of the machine sub-assembly, it sends a signal to the machine control system with a request to interrupt the cycle. In most simple diagnostic systems, this ends their *rôle.* The control system should have built-in procedures for handling such an event, depending on the current state of the machine. These procedures may require additional diagnostic information to locate the cause, in order to check the possibilities for eliminating it. If the diagnosed reason is on the repair procedure list, then the control system attempts to execute the repair programme.

The correct or incorrect operation of some diagnostic systems may depend on the results of parameter control, which is significantly affected by the diagnosed machine, tool or instrumentation features. Cutting tools diagnostics can be a classic example of this relationship. In a research study by Akgerman and Frisch (1991)*, w*hen constructing diagnostic systems in this group, special attention is paid to the correlations between the selected signal measure, such as the values of the components of the cutting force and the measurable features of blade wear. However, in order to tune such a diagnostic system to make it useful, the practical relationship between the measured, diagnostic signal and the effects of the procedures carried out, in a given process, should be known. The tool, which, due to the state of the geometrical parameters (*estimated with the help of symptoms*), is recognised by the diagnostic system as sufficiently functional, can shape the incorrect roughness of some surfaces or exceed dimensional tolerance. This condition, without taking into account the support of additional diagnostic system information, generates a number of deficiencies. Since control systems-do not have the knowledge and experience of the operators, attempts are made to construct and apply expert systems. Such systems, after analysing the results of the implementation of technology and information on process parameters (*those set and those obtained from diagnostic systems)* are able to make correct decisions, controlling both the replacement of tools and undertaking corrective actions in order to stabilise the production process.

Corrective actions can also be taken at the level of the technological machine using the results of the periodic diagnosis of the differences in parameters from the nominal condition. An example of the above is the automatic introduction of the correction of control programmes based on the laser diagnosis of the geometry of the machine tool. Differences in temperature levels of various components of the machine tool may cause changes in its geometry, which may result in product faults. The measurement and compensation of deformations improve the stability of the parameters of the machined part. The space for the parameters, determining the condition of the product is very large, some of them are controllable while some can only be changed by replacing the entire instrument or tool. In addition, functional relationships between product parameters and process parameters are, to a large extent, non-linear. Therefore, according to Lipski (2013), any improvement in production parameters including diagnostic results, requires the use of learning systems.

This article presents the possibility of applying a strategy for the construction of the diagnostic systems used, among other things, in order to increase the stability of the manufacturing processes. The experimental and statistical method was used for the research process. This means that the selection of the number of signals and the location of the measurement points responsible for the product's compliance with construction assumptions, was adopted on the basis of experience in the implementation of similar solutions in the past; the correctness and accuracy of the solution, in terms of process, were verified using W.E. Deming's model, published by Deming (2012) and used by Woźniak (2017).

Case study - Signal Diagnostics in the Manufacturing Process of the e-CVT Hybrid Transmission

Research on the analysis and possibilities of using diagnostic signals to improve the stability of the manufacturing process are carried out at the Toyota factory in Poland, located in Lower Silesia. The main products of the factory are components for the passenger car drive system, such as:

- 1,0-litre, three-cylinder internal combustion engine;
- 5-speed and 6-speed manual gearbox;
- e-CVT 1.8 hybrid electric transmission (Continuously Variable Transmission), According to the operating principle presented by Korzeniowski (2020);
- hybrid engine on the TNGA platform (Toyota New Global Architecture) with a capacity of 2,0 L, according to the concept Toyota (2019-1).

Currently, along with the growing demand for hybrid vehicles (*cars with internal combustion and electric engines that can do their work at the same time or alternately, presented by Ockerblom (2015)),* an investment is underway that will allow the production of two new components:

- e-CVT 1,5 hybrid electric transmission;
- TNGA 1,5 L three-cylinder hybrid engine developed by Toyota (2019).

Considering the growing importance of alternative drives and the need to improve their production, in the first step the tests covered one of the production lines located in the area of the hybrid e-CVT 1.8 transmission. Aluminium housings for this gear are produced on this line. The e-CVT 1.8 transmission housing consists of two main components:

- electrical components housings;
- mechanical transmission housings, Figure 2.

Figure 2: View of hybrid transmission construction: A - electrical components housing, B - mechanical transmission housing Source: Own work

The gearing is machined on four-axis, vertical CNC machining centres, manufactured by the Japanese company NTC Ltd. (*Nippei Toyama Corporation LTD.*), Figure 3.

Figure 3: Part of the processing line for e-CVT 1.8 transmission housings Source: Own work

In order to develop, diagnose and enable testing, the lines of the e-CVT 1.8 hybrid transmission housings are equipped with the proprietary SCADA diagnostic system (Supervisory Control and Data Acquisition), called TIS (Total Information System). The basic tasks of the system comprise:

- production management;
- collecting information on the current availability of the production line;
- reporting.

An additional functionality which is currently being studied and developed is the collection of diagnostic signals from numerical machine tools, such as:

- the position of the drive axes relative to the machine spindle;
- the temperature of the main components: propulsion engines, driving axles;
- the current loads on engines and driving axles;
- spindle vibration.

As a result of collecting and analysing the above signals, the TIS system becomes a tool, enabling the introduction of rules to improve the production process in terms of reducing interference thereto.

In order to select the appropriate diagnostic signals that can be correlated with occurring machining defects, an analysis was carried out of the percentage and quantitative share of deficiencies in the production of the e-CVT 1.8 transmission casing, Figure 4, Figure 5. The research covered the three-shift production period from February to November 2019.

Figure 4: Quantitative share of deficiencies in the production of e-CVT 1.8 transmission housings Source: Own work

Figure 5: Quantitative share of deficiencies in the production of e-CVT 1.8 transmission housings Source: Own work

As can be seen, the assumed level of deficiencies set at X% was only achieved in June 2019. The remaining months showed the situation where the target was exceeded while showing an upward trend. In the next stage of the analysis, deficiencies resulting from errors occurring during the casting process were separated from deficiencies occurring in the machining process; these deficiencies included such as casing leaks due to porosity. In this case, the quantitative assessment of the defectiveness is shown in Figure 6. At the same time, the type of defect appearing is marked.

Figure 6: Deficiencies in the machining process of the e-CVT 1.8 transmission housings by type of defect Source: Own work

As can be seen in the chart, a significant number of deficiencies (approximately 40%) arises in the machining process, of which 55% is mechanical damage, such as broken threads, broken assembly holes, etc; they happen, among other things, as a result of fractures or by being chipped by cutting tools. One of the quality defects arising as a result of machining is the lack of the required

coaxiality of the diameters A and B (Figure 7) of the mounting holes for the rolling bearings of the drive shafts called MG1 and MG2 (Motor/Generator). The rollers connect the mechanical part to the electric gear. Shaft bearing holes must be made with a high precision of mutual axiality in order not to make the gearing dysfunctional.

Figure 7: Schematic drawing showing the dimensional dependence of the diameters A and B of the MG1 and MG2 holes, and their location in the eCVT 1.8 transmission housing Source: Own work

An additional technological difficulty is the fact that the holes are made on two adjacent machine tools; moreover, diameter B is made after the gear housing turns some 180º. In order to avoid a potential quality error, a diagnostic system was used. The basis of the system is a diagnostic signal indicating the current location of the diameters A of the MG1 and MG2 holes relative to the set machine base point. The main tasks of the system are:

- to measure the position of the diameters A of the holes MG1 and MG2 made in the previous process, relative to the machine tool base point

- to send information with the measurement result for registration in the TIS system (Figure 8.)
- to correct the machining position of the diameters B (Figure 7) automatically, if the measurement of the position of the diameters A is within the range of +/- 0.04 mm relative to the machine base point
- to stop the process with the error display on the **Andon** array [*Nawrocki 2019*] in the case when the measurement of the diameter position A exceeds the limit of +/- 0.04 mm relative to the machine base point
- to register measurements of the position of the diameters A of the MG1 and MG2 boreholes to observe the pattern of deterioration quality in the manufacturing process (Figure 9).

Figure 8: Screenshot from the TIS system screen with the recorded result of the measuring of the position of the diameters A of the holes MG1 and MG2 Source: Own work

Figure 9: Trend in position measurements of the diameters A of MG1 and MG2 holes Source: Own work

The diagnostic system used has two recipients, depending on the value of the diagnostic signal. If the diagnostic signal does not exceed the warning threshold (+/- 0.04 mm), the addressee of the information is the machine tool control system, which automatically corrects the position of making the B diameters.

When the warning threshold has been exceeded, the addressee is the machine tool, which follows established procedures, in order to diagnose the occurrence of irregularities.

Summary

The article has shown that even the latest manufacturing processes used for production in the automotive industry are not free from interference, in the form of defective products, for example. There is still room for improvement and stabilisation. Currently the progress of automation in the computerisation of manufacturing processes creates a great opportunity to use selected diagnostic signals to improve the stability of these processes. Available signals include the temperature of machine components, spindle and bearing vibrations, current load and location of drive systems, etc. The example described shows how a diagnostic system, based on a selected signal, can independently control and correct the stability of the manufacturing process. It carries out its task by automatically checking and correcting the position of the holes made, or in extreme cases, by stopping the manufacturing process altogether, when it detects that the permissible dimensional deviation has been exceeded. By using an IT system (TIS), all data recorded by the diagnostic system is collected and analysed to further improve the manufacturing process. It is based on observing the trends of transmitted data and predicting the future potential behaviour of the process, which is to enable appropriate corrective measures to be taken before the process destabilises itself. Research into the correlation of selected diagnostic signals and disturbances, occurring in the production process to improve these processes, will be continued at Toyota factories in Poland.

The Potential Harnessing of Globalization on the Example of The Trade War Between the United States and China

Alicja SZYSZKO

Jagiellonian University, Faculty of Management and Social Communication, Kraków, Poland
alicja.szyszko@uj.edu.pl

Abstract

The global financial crisis of 2007-2009, which affected the most developed countries, revealed the negative consequences of globalisation. As a result of the crisis, discontent with the process began to grow and visions of stopping it appeared. The society's dissatisfaction was aroused, among others, by the relocation of production to developing countries, migrations that caused the loss of jobs for the middle class. These factors have resulted in the growth of international flows, which have benefited transnational corporations and the richest class. Examples of the retreat from globalisation are Brexit in the UK or the election of President Donald Trump in the United States and his protectionist actions. The aim of the article is to analyze theoretical knowledge about the trade war between the United States and China. The study uses an inductive approach. On the basis of the conducted observations, conclusions were drawn concerning the possibility of stopping the process of globalization and verification of the research hypothesis: the current stage of the globalization process is unstoppable, it can only be slowed down or modified.

Keywords: Trade War - Harnessing Globalisation - Delocalisation Of Production

Introduction

We can talk about the process of globalization from the very beginning of ancient civilizations, whose economic flows were based primarily on trade. Historical analysis of this process has made it possible to list three main stages of globalisation. The first one is related to geographical discoveries in the 14th century. The next phase is related to the industrial revolution in the 19th century. At the beginning of the 20th century, the process of globalisation was more advanced in some aspects than it is today. An example is the free passage of people. This process was stopped with the beginning of the First and then the Second World War. The consequence of these events was a bipolar world division: the Western world - capitalist and the Eastern socialist world. With the political slump in the block of states dependent on the Soviet Union in the 1980s, followed by the fall of the Iron Curtain, the current phase of globalisation has begun. We consider the turn of the 1980s and 1990s as its beginning.

In the literature exists a wide range of opportunities to defining globalisation, very often identified with internationalisation, westernisation or Americanisation depending on the dimension: economic, social or political (Scholte, 2005). For the analysis of the economic dimension, a definition that describes the globalisation as a process of acceleration, broadening and deepening of interconnections and interdependencies between regions, countries, corporations, companies or societies as a result of growing economic flows (trade, capital, investment, technology or labour) seems to be the most appropriate (Liberska, 2001). A number of definitions in the literature emphasize the increasing interdependence in the world economy (Kaldor, 1999), where the territory becomes irrelevant (Stiglitz, 2002).

The current stage of globalisation is much more intense than previous. As a result, more and more critics of this process have started to appear. They argued that globalisation is increasing inequality (Stiglitz, 2015). Over the past four decades, scientific interests have focused on the division of the world into developed countries known as the "wealthy North" and developing countries identified with the "poor South". These disparities in development have been presented as a negative effect of

the globalisation. Antiglobalists have argued that developing countries depend on developed economies. Transnational corporations from the "rich North" exploiting e.g. fuels, natural resources, and the established industrial plants maximise profits by not respecting labour rights or ecological norms and standards (Stiglitz, 2011).

Since the global financial crisis of 2007-2009 there have been shifts in the global economy. A group of emerging markets and the BRICS group (Brazil, Russia, India, China, South Africa) have emerged among developing countries. These countries are no longer economically dependent on the developed country, but rather are increasingly taking advantage of and indeed shaping the globalisation. This is reflected, for example, in the emergence of trade between developing countries (south-south trade), the implementation of the New Silk Road project, the establishment of the Asian Infrastructure Investment Bank or an increase in investment flows.

The benefits of globalisation are unequally distributed, not only between countries, but also within countries. In developed economies, globalisation has mainly benefited transnational corporations and the wealthiest class, while the middle class working in industry has lost. Migration also causes great social dissatisfaction with the loss of jobs. These changes have resulted in increased dissatisfaction with the process in developed countries. A sign of objection to globalisation is the election of President Trump in the United States and the exit of Great Britain from the European Union.

These issues are analysed in both national and English language literature. Considerations on the retreat from globalisation in the context of the global financial crisis 2007-2009 have been undertaken (A G van Bergeijk, 2018) and global challenges. A comprehensive view of the globalisation process and its possible containment includes, e.g. analysis of trade and investment flows and activities of transnational corporations (James, 2017). This problem is also widely discussed in the context of the global economy (Steenbergen, Siczek, 2017) in relation to individual countries such as China (Witt, 2019), the United States.

The aim of the paper is to discuss the problem of stopping globalisation on the example of the trade war between the United States and China. The following research questions have been posed for the purpose of this study:

1. What are the winners and losers of globalisation?
2. Why is the process of globalisation causing a growing discontent?
3. What are the dimensions of the trade war announced by President Trump?
3. Is it possible to stop the globalisation?

The research hypothesis, formulated on the basis of literature studies and research questions posed, is as follows: The current stage of globalization is impossible to stop, it can only be slowed down or adjusted.

Literature and theoretical background of research. General overview of globalization effect

At the turn of the 1980s and 1990s, developed countries (including the United States, Great Britain and other Western European countries) have began to enter the post-industrial stage. This was associated with the transition from manufacturing to services and high technologies. The consequence of these changes was the delocalisation of low-tech production, including footwear, clothing, textiles or toys, to developing countries with large resources of cheap, unskilled labour.

Using global resources, transnational corporations have also gradually increased the scale of global production. Thanks to new opportunities associated with the ICT revolution or the reduction of transport costs, they have completely eliminated warehousing by moving to a just-in-time production model. This involved creating a global supply chain, dividing the production of individual parts and components and then assembling them in countries that have comparative advantages (including cost or technology).

The greatest beneficiaries of globalization are transnational corporations, which have sought to increase the efficiency of their operations through relocation and fragmentation of production. The shifting of low-tech production to countries with large labour resources has made it possible to reduce labour costs. On the other hand, the creation of lean production based on the global supply chain has enabled final production with the lowest possible share of inventories, saving time and improving the quality of manufactured products (Łasak, 2013).

The consequence of these changes is ndustrialization and the integration of developing countries, in particular Asia with China, into global production and trade. Chart 1 shows the share of individual countries in global industrial output between 1990 and 2016. In 1990, developed countries of Europe and North America represented about 65% of global industrial output, while China and Asian developing countries contributed about 25%. In 2013, these disparities decreased as these developed economies decreased their share in global production to about 45%, while China increased its share to about 25%, and the other developing countries in Asia maintained a share of about 25% . China now accounts for about 28% of global industrial output.

Chart 1. Share in industrial output in 1990 and 2016.

* Rest of Asia: developing and emerging industrial economies (excl. China) + Japan + South Korea.
** developing and emerging industrial economies: Afghanistan, Armenia, Azerbaijan, Bangladesh, Bhutan, Brunei, Cambodia, Cook Islands, South Korea, Fiji, India, Indonesia, Iran, Iraq, Jordan, Kazakhstan, Kiribati, Kirgizstan, Laos, Lebanon, Maladies, Marshall Islands, Burma, Mongolia, Nepal, Oman, Pakistan, Palau, Papua New Guinea, Philippines, Samoa, Saudi Arabia, Solomon Islands, Sir Lanka, Palestine, Syria, Tajikistan, Thailand, East Timor, Tonga, Turkmenistan, Tuvalu, Uzbekistan, Vanuatu, Vietnam, Yemen.
Source: *own work based on UNIDO database*.

Shifts in industrial output are also reflected in shifts in world trade. Chart 2 shows the share of individual countries and regions in world exports in 1990 and 2018. Over the analysed years, the share of developed countries represented by the European Union and North America decreased from about 60% in 1990 to about 45% in 2018. At the same time, the significance of Asian countries in world exports increased. This was due to an almost 7-fold increase in China's share of world exports, to 12.8% in 2018. Considering the role of other Asian countries, we can see a stable, about 20% share in global exports. It should be emphasized that in 1990 it was caused mainly by the high importance of Japan, which was responsible for over 8% of world exports, while in 2018 its share declined to less than 4%. The position of the other Asian countries was maintained thanks to the increase in exports

in India (1.7%), South Korea (3.1%), Malaysia (1.2%), Saudi Arabia (1.5%), Singapore (2.1%), Thailand (1.3%), the United Arab Emirates (1.6%) and Vietnam (1.2%).

As a consequence of ongoing globalisation, developing countries have experienced dynamic economic development. On the basis of the data presented in Table 1, it can be seen that over the period 1990-2018 the differences in nominal GDP between developing and developed countries have decreased. In 1990 the volume of GDP of developed countries was 4.5 times higher than that of developing countries (18 trillion dollars to 4 trillion), while in 2018 these disparities are 1,5 times higher (49 trillion dollars to 33 trillion). The high nominal GDP growth of developing countries is mainly associated with the developing countries in Asia, led by China. These countries account for 77% of the nominal GDP of developing countries, while China represents as much as 40% of this value.

Nominal GDP shows the process of catching up with developed countries by developing economies. This may lead to wrong conclusions, therefore GDP per capita should also be analysed. On the basis of the data presented in Table 1, it can be seen that these differences are very large. The gross domestic product per capita in developed countries is about 46 thousand dollars, while in developing countries it is 8,5 times lower and is only about 5,4 thousand dollars. It is important to mention that over the last 28 years developing countries have increased their GDP per capita by 5,5 times, Asian countries by 8 times and China by 28 times.

The delocalisation of production to developing countries has created new industrial jobs there. As a result, the middle class in these countries has also benefited from globalisation. In 2009, Europe and North America together accounted for 54% of the world's middle class, and Asia 28%. The centre of gravity of the world economy is shifting to the East (Pan, Xu, Wu, 2014). It is estimated that by 2020 these ratios will reverse and Asia will represent 54% of the world's middle class and Europe and North America 32%. These disparities will be continued to grow over the next decades. Projections indicate that by 2030 these proportions will be 66% to 21% (Kharas, 2010).

In China, as a consequence of economic reforms since 1978, more than 300 million citizens have been dragged out of poverty and moved from the countryside to the city, supplying a large resource of cheap labour force (Louçã, Ash, 2018). By 2020, it is estimated that the number of people living in cities will be 800 million, and will increase by another 300 million over the next three decades (China Development Research, 2014). According to McKinsey Institute calculations, in 2012 the middle class in China represented 68% of the population living in urban areas. It was classified into two groups. The first is the mass middle class, accounting for 54% of the urban population, and the second is the upper middle class, accounting for only 14% of the urban population. The projections for 2022 estimate that the middle class will account for 76% of the urban population, while the ratio between the first and second groups will reverse. It is expected that by 2022 the middle class with a higher statute will constitute 54% of the urban population, while the one with a lower statute will only 22%. The same calculations show that over the last decade the number of poor people living in cities will decrease from 29% in 2012 to 16% in 2022 (Barton, Chen, Jin, 2013).

It should be noted that globalisation also has the effect of increasing inequality within a country. Data presenting the growth of the middle class in China highlights that in 2012 87% of the middle class lived in the eastern, the most industrialised part of China, and only 13% of them lived inland. China's approach and management of globalisation begins with an increasing inequality. The reforms undertaken in 1978 were based on a Confucian philosophy. One of the key idea was given the opportunity to "enrichment themselves" and primarily made the inequalities deeper. However, estimates indicate that the imbalance in regional development is being reduced, by the year 2022 as much as 39% of the middle class will have been lived in inland areas (Barton, Chen, Jin, 2013).

Discussed changes represent the negative impact of globalisation on developed countries. There has been growing dissatisfaction with globalisation among those who have lost industrial jobs to developing countries. A consequence of deindustrialisation is the declining employment in industrial production over the last two decades. A negative phenomenon occurring in developed economies is

also a drop in real wage growth, despite the increase in labour productivity. In the United States, in the years 200-2007, the increase in labour productivity was 2,2%, while the rate of growth of the median hourly wage rate reached -0,1%. In 2006, the real hourly wage rate in the private sector (outside agriculture) was the same as in 1967. This resulted in the reduction of middle and working class income. The share of wages in GDP fell from 53% in 1970 to 46% in 2005 (Foster, McChesney, 2014). However, there was a concentration of household income among the richest class. The 1% of the richest households purchased about 21% of total income in 2014. Following the increase in inequality from the 1% of the richest households in recent years, the richest 0,01% emerged, which was as much as 5% (Seaz, 2015).

At the turn of the 20th and 21st century, these adjustments were desirable as highly developed countries moved to the service sector and high technology. Nowadays, over 60% of GDP in these countries is created in services. Figure 3 shows the volume of employment in industry, non-agricultural sector and services in the years 1990-2019. During this period, over 85% of employment in the non-agricultural sector was generated by services. The share of employment in services increased by about 65%, from about 86 thousand in 1990 to 130 thousand in 2019. The negative consequences of the transformation of the employment structure in the United States were exposed by the global financial crisis of 2007-2009. The burst of the speculative bubble in the real estate market resulted in the economic collapse and a drop in employment in the non-agricultural sector and in services in 2009-2012. Only from 2014 has there been a progressive increase in employment in these categories.

Chart 3. Employment in industrial production, non-agricultural sector and services in the United States in 1990-2019 (in thousands).

Source: own work based on U. S. Bureau of Labor Statistics database (www.bls.gov, 25.01.2020).

The main driver of economic growth in highly developed countries is no more manufacturing, but services, especially financial services. The lost workplaces in industry were created in a wide range of services, e.g. transport, hotels, catering, finance, insurance related to financial markets, e.g. real estate agency. Chart 3 shows the volume of employment in financial services and individual categories. In the years 1990-2019 the employment in financial services increased from about 6.5 million to about 8.5 million. It is important to note that as a result of the crisis, there was a decrease in employment, and the level of 2008 was achieved only in 2016. The bursting of the speculative bubble, the raising of the Federal Reserve System's interest rates and the limitation of lending have affected the credit intermediary sector the most. A detailed analysis of the individual service categories shows that their level has not returned during the last 10 years to the pre-crisis period.

Chart. 4: Employment in particular service categories in the United States between 1990-2019.
Source: own worked based on Bureau of Labor Statistics database (www.bls.gov, 25.01.2020).

Chart 4 illustrates that the most significant fall in employment in the non-deposit category of credit intermediation was the fall in employment. This category consists of public (government sponsored) and private entities, which are involved in, e.g. issuing credit cards, granting consumer loans or mortgages. This decrease is visible in the first years of the collapse, i.e. 2006-2010, which reached as much as 33%, while in the whole period 2006-2010 it amounted to 20%. In the years 2014-2019, there was a slow increase in employment in this category, which currently reached the level of 1999. Another category is the activities related to financial intermediation undertaken by para-banks. This category also shows a decrease in employment over the last decade, and the level of employment is equal to the pre-crisis period, i.e. 2003.

Research approach and methods

The first stage of the research process was the assumption that globalization is a dynamic, multidimensional, cross-border process, with a global scope. In comparison with previous periods, the intensity of this phenomenon is stronger due to the increased links and interdependencies between countries, regions, markets, companies, societies as a result of growing economic flows (trade, investment, capital, technology, labour). Therefore, the contemporary stage of globalisation is becoming a challenge for nation states due to the gradual disappearance of borders, the growing importance of transnational corporations, the internationalisation of the production process, the dissemination of, for instance, patterns of organisation, the production system, data processing, legal norms and the harmonisation of norms and standards.

The research approach includes the inductive procedure. The methodology of academic research indicates that induction consists in moving from empirical observations to theoretical generalizations, however, conducting observations is closely related to understanding and analyzing theoretical knowledge (Lindström, 1998).

The research hypothesis of the possibility of halting globalisation is verified on the basis of a case study such as the trade war launched by the United States. The application of the case study enables a better understanding of the causes of the trade war and its successive stages. It will permit a comprehensive understanding of the process of globalization, the links and interdependencies that have arisen and the possible ways to stop it. This is particularly important in view of the political, economic and social dimensions of the demands to move away from globalisation.

The achievement of the aim of the study and the verification of the research hypothesis required conducting literature studies and collecting statistical data such as trade, production, economic

growth and balance of payments. The analysis of literature enabled to characterize the process of globalization, indicate its effects and develop a case study on trade war. The accumulation of empirical data was used to compare the impact of globalization on individual countries and groups of countries and to indicate the winners and losers of the process. On the grounds of expanded issues, collected statistical data and the case study, the answer was given to the question whether the globalisation process can be stopped.

US-China trade war: example of retreat from globalization

Over the past decades, globalisation has extended to all countries of the world. Since the 1980s, this process has mainly benefited developed countries, referred to as the "rich North". The dynamic nature of the globalisation process caused changes in the economic system. The developed countries began to take the place of developing countries. The countries referred to as the "poor South" have not only been included in this process in recent years, but have also started to benefit from it, and over the last decade they have also begun to shape globalisation. The shift in the position of countries in the structure of the world economy has resulted in increased dissatisfaction with globalisation. The election of President Donald Trump in the United States is a sign of this opposition. In his election campaign, he pointed out that the economic problems of the United States are a consequence of, for example, trade liberalisation, which caused a trade deficit.

Chart. 5: United States trade balance and United States - China trade balance (million US dollars).

Source: own source based on UNCTAD database.

Chart 5 shows the US trade balance and the US and China trade balance. According to the data, the trade deficit was growing with the intensification of globalisation. Since the turn of the twentieth and twenty-first century, transnational corporations started to use global resources and relocate production to, for instance, developing countries in Asia, including China. In 2007-2009, the US trade deficit amounted to 900 billion USD. Analysis of US-China trade shows that China's exports to the United States began to boost after China acceded to the World Trade Organization in 2001. From 2015, the trade deficit with China is about 400 billion USD, which is 40%. These facts and accusations of protectionist practices against China have become the basis of the election campaign and the key to Trump's success in the presidential election.

At first the vision of a trade war, in the context of US participation in the World Trade Organisation (WTO), seemed impossible. With the assumption of the office of the President of the United States, D. Trump went on to implement his proposals for a trade war. This can be seen as the beginning of an investigation initiated by The US Trada Representative (USTR) in August 2017 into the Chinese government's practices of technology transfer, innovation and intellectual property that violate U.S.

interests (Office of the United States Trade Representative. Executive Office of the President, 18.08.2017). The investigation was concluded by an announcement on March 22, 2018. The USTR, citing Section 301 of the Trade Act of 1974, found that China is engaging in unfair practices of technology transfer, innovation, forcing the disclosure of sensitive information and violating respect for intellectual property. These practices threaten U.S. companies, deprive them of a fair remuneration for their innovations, inhibit exports, contribute to the trade deficit, weaken U.S. manufacturing, services and innovation (Office of the United States Trade Representative. Executive Office of the President, 22.03.2018).

The trade war initiated by President Trump can be divided into three main dimensions. The first dimension of the trade dispute concerns imports of solar panels and washing machines. The USTR considered that imports hurt US industries and recommended that the President impose trade restrictions (Office of the United States Trade Representative. Executive Office of the President, 22.01.2018). The final settlement was made on 22 February 2018, when D. Trump imposed global safeguard tariffs of $8,5 billion on imports of solar panels and $1,8 billion on imports of washing machines (Office of the United States Trade Representative. Executive Office of the President, 22.01.2018) .

This decision was not unavoidable for trade partners to react. On April 17, 2018 the Chinese government announced preliminary anti-dumping duties of 178.6% on imports of sorghum from the United States (The State Council The People's Republic of China, 17.04.2018). The next step taken by the Chinese government was to file a formal application at the WTO on 14 August 2018. The China's Commerce Ministry has justified this by stating that US tariffs on solar panels have harmed China's commercial interests (World Trade Organization, 2018).

The second dimension of the trade war concerns the impact of steel and aluminium imports on US national security. The Trade Secretary presented his opinion in February 2018, and on March 1, 2018 the United States announced the introduction of duties of 25% on steel and 10% on aluminum to all trading partners. The largest part of these imports include goods originating from Canada, the EU, Mexico and South Korea. Finally, the tariff barriers became effective on March 23, 2018 and covered steel products worth about 10 billion dollars and aluminum products worth about 8 billion dollars. In the beginning, tariff exemptions were granted to Canada, Mexico, the EU and Korea, and a permanent exemption or a specific quota was granted to Australia, Argentina and Brazil respectively. China was not included in the temporary tariff exemption period. In retaliation, on April 2, 2018, China imposed duties on American products, exported in 2017 to the amount of 2,4 billion dollars. The 25% tariffs were imposed on, e.g. aluminium waste and scrap, pork, fruit, nuts and 15% on other goods (Kerrigan, 2019). On April 2, 2018 China identified 128 American product categories which are subject to 15% and 25% tariffs (World Trade Organization, 29.03.2018).

The third dimension of the trade war concerns technology transfer and intellectual property. The main charges against China are technology theft through regulation of foreign direct investment. Foreign companies operating in China are required to enter into joint ventures with a domestic producer. The increase in the degree of innovation in China is achieved through the exchange of academic staff. China welcomes the most talented academic and specialist, mainly in the sciences, and sends the best students to foreign universities thereafter to expand their knowledge at home. These activities have resulted in an increasing level of technology in China. A third issue threatening the US technological hegemony is mergers and acquisitions of US technology enterprises by Chinese companies (White House, 14.08.2017) .

On March 22, 2018, Donald Trump's administration announced the introduction of tariff barriers for Chinese goods in the amount of 60 billion dollars and indicated the need to adjust the law on investments. On April 3, 2018 the administration published a list of 1333 Chinese products worth 50 billion dollars, which are subject to a 25% tariffs. The sectors most affected are machinery, mechanical appliances and electrical equipment. Approximately 85% of imports covered by tariffs concern intermediate products and capital goods, which would increase costs in the supply chains of American companies. In revange, China publishes a list of 106 products covered by future 25%

tariffs one day later, including 50 billion dollars of Chinese imports from the US. These are predominantly vehicles, aircraft, floating vehicles and plant products (soyabean) (Office of the United States Trade Representative. Executive Office of the President, 15.06.2018).

On June 15, 2018 China and the USA announced the introduction of the first phase of the tariffs effective as of 6th July. Both countries are announcing the introduction of 25% of the tariffs on goods worth 50 billion dollars respectively. The USA is updating the list of goods, which is extended even more parts and components imported by American companies from China. China, however, is extended to include mineral fuels, consumer goods and medical equipment and is removing planes from the list. Additionally, they announce that the introduction of tariffs is divided into two stages. As of July 6, duties on goods (including soyabean and vehicles) worth 34 billion dollars will start to apply (Ibidem) whereas the next stage will include the other goods worth 16 billion dollars. Finally, these duties were introduced on August 23, 2018 (Organization for Economic Cooperation and Development, 2018).

On July 10, 2018, the US Trade Administrative announced a list of goods imported from China to the amount of 200 billion dollars, which will be covered by 10% of the tariffs. This list includes intermediate goods such as computer and car components (47% of the list) and specified consumer goods such as telephones, computers, furniture, laptops, suitcases. Finally, on September 24, 2018, 10% tariffs on Chinese goods were introduced and it was announced that from January 1, 2019, they will increase to 25% (Office of the United States Trade Representative. Executive Office of the President, 18.09.2018).

The American side's efforts were not without the reaction of China. In response to the U.S. threats of July 2018, China has announced the establishment of tariffs from 5 to 25% on intermediate products, capital goods and consumer goods worth 60 billion dollars. These announcements were finalised on September 24, 2018, by the introduction of tariffs from 5% to 10% and then by raising the tariff to 25% on June 1, 2019 (International Monetary Fund, 2019).

Until now, the United States has announced two lists of 50 billion dollars worth of goods and 200 billion dollars worth of goods include about 50% of US imports from China, worth 563 billion dollars in 2017 (www 1). On July 20, 2018, D. Trump is jeopardising further tariffs on the rest of consumer and capital goods (mobile phones, laptops and clothing) worth 262 billion dollars. Following the G-20 meeting in Buenos Aires on December 1, 2018, Presidents Trump and Xi announced an agreement to end the escalation of tariffs. After several months of action on May 10, 2019, customs tariffs raised from 10 to 25% (Pauken II, 2020).

Due to the lack of agreement and successive tariffs introduced by China, on May 5, 2019, D. Trump announced the adoption of 25% tariffs on the rest of Chinese goods. These are mainly consumer products such as toys, footwear and electronics. On August 13, 2019, 10% duty became effective on imports from China worth 112 billion dollars, from September 1, 2019, on clothing and footwear products and from December 15, 2019, on toys and electronics worth 160 billion dollars. The escalation of the conflict intensified on August 23, 2019, when China announced the imposition of duties on American exports worth 74 billion dollars as of September 1 and December 15 (Office of the United States Trade Representative. Executive Office of the President, 13.08.2019).

In September, China announced the exemption of 16 products from tariffs imposed in 2018 on certain animal feed, chemicals, petroleum products. President Trump, meanwhile, announced a delay in the increase in customs duties on Chinese imports scheduled for October 1 and December 15 (Swanson, 2019). On January 15, 2020, the leaders sign an agreement according to which China agrees to purchase additional US exports worth 200 billion dollars. This agreement entered into force on February 14, 2020 (Bisio, Horne, Listerud, 2020). As a consequence of the trade war, U.S. tariffs on imports from China are more than 6 times higher than in early 2018. As a result of the agreement signed, Chinese customs tariffs have dropped marginally.

Research Results and Discussion

The introduction of the trade war by President Trump became the subject of a discussion on how to stop globalisation. Considering only the process of trade globalisation, this solution can be considered as one of the possibilities. This would have to be linked to the collapse of the World Trade Organization or its marginal importance in the liberalisation of flows of goods and services. Countries would reduce trade and increasingly reoffshoring would take place. This would lead to increases in production, employment and GDP. At first glance, it may seem that such a solution would be a remedy for the economic problems of developed countries.

Analysing the global economic conditions, it seems that the trade war between the US and China has resulted in reduced trade flows and slowed down economic growth. On the basis of the data presented in the graph, it can be seen that the slowdown in the growth of global exports has occurred since the beginning of the global financial crisis. The crisis was caused by a cyclical factor, according to which there was a dependence of global export growth and global GDP. During this period, the growth rate of global exports was at least double the GDP growth rate (World Trade Organisation, 2016). After the global financial crisis, this correlation has disappeared. Since 2012, the growth rate of global export and GDP is similar, and in 2015 the export rate is negative. Analysing the cyclical factors affecting international trade, it can be observed that the growth of international trade is less dependent on the GDP growth rate, and increasingly important are protectionist tendencies, leading to a reduction in trade dependence in response to the crisis.

Chart 6. World merchandise trade growth and GDP growth, 1990-2018 (annual percentage change).

Source: own work based on UNCTAD database.

The slowdown in post-crisis trade flows is also caused to a large extent by structural factors, i.e. low commodity prices, currency depreciation to increase export competitiveness, the economic slowdown in China, fluctuations in demand in developing countries and changes in the global supply chain, where some of the previously imported components are produced by the countries where the final product is assembled (Constantinescu, Mattoo, Ruta,2015).

The way data is calculated is also important in measuring trade flows. Trade data include the value of goods leaving the port. Currently the data methodology does not cover the actual supply chain. Consequently, final products consist of parts and components from other countries, which in turn consist of materials or parts from other countries. The constant changes in global resources have

made it challenging to measure real trade relations and the added value must be taken into account (Organization for Economic Cooperation and Development, 2012).

An additional argument that the reasons for a trade war presented by President Trump are incorrect is the lack of incorporation of digital technologies into exports. The statistical data also do not reflect products that are not related to the flow of goods between countries, such as software installed on electronic equipment. The analyses show that including such data would reduce the trade deficit between the USA and China (McKinsey Global Institute, 2019) [1].

The trade war led by President Trump has highlighted even more the global expansion of transnational corporations. These entities are associated with specific countries, while their owners are investors from all over the world. International expansion is also the main source of income for these companies. Transnational corporations, because of the growing middle class and the increase in number of millionaires, perceive the Chinese market as the major market.

Conclusions

The analysis of shifts in the global economy and the trade war between the United States and China shows that it is impossible to stop the current stage of globalisation. Its consequence is an increase in interconnections and interdependencies between regions, countries, corporations or societies, which as a result of the digital revolution have taken on an extraordinary scale. These two major superpowers are characterised by the greatest global interdependencies.

Harnessing globalisation through tariffs is only an inept attempt. It should be stressed that the slowdown in trade growth occurred after the global financial crisis of 2007-2009. Raising tariffs is counterproductive, as other countries are integrating even more. China, in response to the Trump's administration, is reducing tariffs for other partners, which further exacerbates the problems of US companies. Assessing the phenomenon of globalisation through the perspective of the US-China trade war, it should be emphasised that globalisation is not slowing down, but evolving and changing its character.

Russia And Russian-Speaking Separatism in Estonia: Economic, National and Social aspects

Marek ŻYŁA – Akademia Sztuki Wojennej
Jarosław GRABOWSKI – Departament Szkolnictwa Wojskowego
marcingornikiewicz2014@gmail.com **(Correspond Author)**

Abstract

The aim of the article is to present a potential opportunity to involve the Russian and Russian-speaking diaspora, living permanently in Estonia, in separatist activities. Estonian statehood has relatively modest historical traditions. Its centuries-long subordination to its more powerful neighbours has led to drastic changes in its ethnic structure. The ethnic and ethno-linguistic structure is one of the most important elements of Estonia's national security policy. The restoration of independence has put the Estonian elite before the problem of addressing the Russian and Russian-speaking minorities. The process of change was initiated in 1987 by the so-called "Singing Revolution". During this period, Estonia made attempts to create, or rather recreate, its own ethnic policy based on pre-war patterns.

Currently, a potential source of threats is the significant Russian and Russian-speaking diaspora. Ethnic affiliation and the national identity that goes with it shape cohesion and at the same time, in certain cases, disintegrate modern states. This is an extremely important factor in the state's security policy, especially given the threat of the rebuilding of Russian neo-imperialism. Despite controversy over human rights, for example, Estonia's integration policy is producing the expected results, and the success of the integration policy will raise the security level of both Estonia itself and the subregion.

Keywords: Russia, Estonia, Separatism, Baltic States

Introduction

National identity and the nationalism that follows seems to be one of the most rooted elements in human consciousness today. Therefore, the thesis that the bloodiest and most dangerous conflicts take place between people belonging to different ethnic groups is not surprising. The ethnic factor remains one of the basic sources of conflicts. The reasons for this state of affairs can be found, among other things, in the increase in the sense of national consciousness of individual ethnic groups and the universality of the idea proclaiming the right of nations to self-determination. The ethnic and ethno-linguistic structure is one of the most important elements in the area of national security in Estonia. The regaining of independence put the Estonian elite before the problem of addressing the Russian-speaking minority.

Estonia has tried to create, or rather recreate, its own ethnic policy immediately after regaining independence. The restitution of Estonian legislation from before the period of "Soviet occupation", i.e. before 17 June 1940, was called for. The Citizenship Act of 1 July 1938 was restored by the Supreme Council of the ESRR on 26 February 1992. As a result of these changes, as many as 500,000 people (32% of the population) permanently residing in Estonia were deprived of Estonian citizenship, creating a sizeable group of apatrides. The Estonian

authorities, thus limiting the influence of the Russian population on the functioning of the country, aimed to create an ethnically uniform state as possible.

In connection with the large Russian-speaking and Russian-speaking minority in Estonia, tensions arise, inter alia, in the context of World War II. An example is the so-called "war of monuments" from 2004-2007. The impulse for the conflict were attempts to honour Estonian volunteers fighting in German troops. As a result, the state authorities did not grant this category of veterans the status of fighters for state freedom. Nevertheless, this problem was an impulse for discussion on the unequal treatment of Estonian veterans fighting on the German or Soviet sides.

A significant Russian and Russian-speaking diaspora remains a potential source of threats. Ethnic affiliation and the resulting national identity shape cohesion and, in certain cases, disintegrate modern states. For most local societies, national identity is of paramount importance. A very important element in this context is the subjective self-identification of individual individuals of a given community. Internally consolidated ethnic groups, such as the Russian and Russian-speaking population, are characterised by a strong sense of community. In order to maintain their individuality, they often enter into conflicts with the authorities of the countries in which they live, and Estonia in particular. This poses a direct threat to the security and cohesion of the country, and over time may also become a serious threat to the international order.

The aim of the article is to present a potential opportunity to involve the Russian and Russian-speaking diaspora, living permanently in Estonia, in separatist activities. The main research problem, in the light of this objective, has been formulated in the form of a question: What is the significance of Russian ethnic and linguistic separateness in the context of the security and integrity of Estonia? For further consideration, a hypothesis was adopted in connection with the research problem, which assumes that the Russian and Russian-speaking diasporas provide a convenient background and, at the same time, a basis for initiating and taking separatist actions against Estonia, at least in a propaganda and international dimension. The significant proportion of ethnic Russians, multiplied by the Russian-speaking population living permanently in Estonia, is particularly important in this respect. The article is of a study nature. To a large extent, it is an analysis of Estonian and Russian source materials and expert studies dealing with the issues defined in its title. The attempt to present the presented problem was connected with the necessity of a comprehensive reference to the Russian and Russian-speaking minority in the indicated area. Verification of the adopted working hypothesis required the examination of the ethnic and linguistic structure of Estonia and its position in the functional arrangement of the Estonian state.

Russian and Russian-speaking centrifugal tendencies

Since the beginning of its independence, Estonia has faced a problem of ethnic unity. It stems from the historical legacy of the Soviet Union. It is symbolised by the political and cultural divisions of society and the constantly present centrifugal tendencies. After independence, national minorities made up more than 38.5% of the total population of Estonia[1]. The most numerous were respectively: Russians - 474.8 thousand (30.2%), Ukrainians - 48.3 thousand (3.1%) and Belarusians - 27.7 thousand (1.8%). The total number of national minorities was over 602.4 thousand people. After twenty years of independence, at the beginning of the second decade of the XXI century, according to official data, 105.6 thousand permanent residents of Estonia had a different citizenship

[1] *Всесоюзная перепись населения 1989 года. Национальный состав населения по республикам СССР*, http://www.demoscope.ru/weekly/ssp/sng_nac_89.php?reg=15, (Accessed: 16 July 2020).

than Estonian[2]. The most numerous group - 90.5 thousand people - were citizens of the Russian Federation (including 79.4 thousand indigenous Russians). Persons who do not have Estonian citizenship are a serious problem. According to official data, this group comprises 86 thousand people. In total, persons with other than Estonian citizenship and stateless persons constitute 191.1 thousand residents of the state. Of these, ethnic Russians are 148.2 thousand people, i.e. 11.4% of the total population of Estonia.

The process of massive Russian colonization of the Estonian territory has particularly affected large urban centres such as Tallinn, Tartu and Narva[3]. In these cities, the Estonian/Russian ratio in 2011 was as follows (in thousands): Tallinn - 217.6/144.7 (53.3%/36.8%), Tartu - 79.7/14.3 (81.6%/14.6%) and Narva - 3/51.4 (5.1%/87.6). The overall ethnic ratio in urbanized areas is 523.1/299.6 (59.5%/34.1%) and rural areas 379.4/26.6 (91.3%/6.4%). The Russian population inhabits mainly four regions: Harjumaa, Ida-Viru, Tartumaa and Jagevâmaa. Outside the capital region, the largest percentage lives in the north-eastern part of the country, including the largest cities in the region: Narew, Kohtla-Jarve and Sillamäe. The post-war industrial development in the 1950s and 1960s changed the character of Estonia from agricultural to industrial-agricultural. This created a premise for a mass influx of Russian and Russian-speaking people into the emerging industrial centres.

The large Russian-speaking and Russian-speaking minority has a significant impact on Estonia's security. It provides a natural basis for the development of separatist and centrifugal trends. The majority of the Russian and Russian-speaking population is concentrated in industrial, more densely populated districts of Estonia. They live mainly in the northeast and in the capital (Fig. 2). In Estonia's third largest city, Narva, the Russian-speaking population, mainly indigenous Russians, accounts for about 97% of the total population, and in Tallinn about half of its population. Until the break-up of the Soviet Union, the higher living standards in the Estonian SSR were conducive to economic migration and, to a lesser extent through marriage, family ties. The significant influx of Russians and the Russian-speaking population was associated with the dislocation of the Soviet armed forces, whose professional staff consisted mostly of indigenous Russians, and with the filling of political-administrative posts, for which Russians or Russian-speaking citizens of the Soviet Union were usually appointed. The passive attitude or declared reluctance of Russian-speaking Estonian citizens to the naturalisation process has a negative impact on its security. It also creates, certainly in propaganda and media terms, the basis for the development of separatist movements of a centrifugal nature. These, in turn, are, or may soon become, a tool of the security policy of the Russian Federation.

Figure 1: Russian-speaking residents of Estonia by administrative division

The ethnic problem in the context of separatist movements is primarily related to the indigenous Russian and Russian-speaking population. The indigenous inhabitants of Estonia distinguish and at the same time divide almost everything from the Russians, a completely different language, non-Slavic ethnicity, Western cultural background, history, religion, mentality, customs, etc. The Russian-speaking population identifies poorly, or even at all, with the Estonian state. As a rule, they are pro-Russian-speaking, to which Estonian naturalisation policy makes a significant contribution. Those who have acquired citizenship declare loyalty to their new homeland in most cases. Such attitudes are fostered primarily by the difference in socio-economic standards between Russia and Estonia. The level of loyalty of the people who have not yet obtained citizenship is difficult to assess reliably. The postponement or boycott of naturalisation does not always result directly from disloyalty. The source of such attitudes is the expectation that this procedure will be simplified or that it will be convenient. It should be stressed that a certain group of Russian-speaking people do not fully identify with the Estonian state, focusing primarily on improving their own living conditions.

Despite the political and organisational fragmentation, the Russians and the Russian-speaking population are an important political pressure group, which the Kremlin supports in certain cases. Russian-language parties, associations and media focus their activities on two areas: citizenship and status of the Russian language. In the cultural sphere, the Russian minority has relatively greater rights than in political life and access to citizenship. As a result, Russians develop their own culture, education, press and religious and association activities. Furthermore, the Russian-speaking press is an important integrating element. There are fundamental restrictions in the economic

sphere. Only a person with Estonian citizenship can open up activity in certain sectors (e.g. media, banks). Despite these restrictions Russian citizens dominate the ownership structure of private companies[4].

The attitude of the authorities of the Russian Federation and Estonian-Russian bilateral relations are important for Estonia's internal situation. Since the break-up of the USSR, Estonia has sought to formally dissociate itself from the legacy of the former USSR and has been heading for a western European area of prosperity and security[5]. Russia has repeatedly protested against this course of policy in the international arena. Officially, it did so on behalf of the Russian-speaking and Russian-speaking minority, whose rights were being restricted or sought to be restricted. Moscow often inspired the protests of the Russian and Russian-speaking minorities in Estonia and influenced the negative message of international organisations' reports on respect for the rights of national minorities in the Baltic republics. Russian objections to national policy also served to oppose plans to expand the North Atlantic Alliance and the European Union to the east.

The Russians, also the Russian-speaking population, who consider themselves Russians, maintain ties with the Russian Federation. These are primarily cultural and business ties. Much stronger ties with the mother ties are maintained by a group of Russians living in Estonia, who have assumed Russian citizenship. They manifest themselves in participating in the Russian elections. This often concerns Russian politicians who are reluctant or even hostile towards Estonia. For economic reasons, these people do not think about re-emigration. Their main forms of contact with Russia are activities in organisations that maintain links with the matrix and widely available Russian-speaking television and radio programmes. The basic element of cultural ties with Russia is Russian-speaking education in Estonia and the fight to maintain it.

In general terms, it should be stressed that Russian culture continues to dominate the Russian-speaking population in Estonia. However, political, and social consciousness distinguishes the Estonian Russian-speaking population from Russians in the Russian Federation. Estonian Russians and the Russian-speaking population are a group that is fully aware of democracy and its civil rights. This is evidenced, among other things, by their approach to the issue of naturalisation, including their focus on personal interests rather than sentiment towards Russia. The practical ability to exercise citizens' rights is evidenced by numerous complaints against the Estonian state at the Court of Human Rights in Strasbourg and the raising of human rights violations in Estonia at international level. The main demands made by the representatives of the Russian-speaking minority include abolishing, or at least liberalising, the naturalisation procedure and granting citizenship to persons residing in Estonia. Another expectation is to maintain education in the Russian language and to grant those who do not have Estonian citizenship but who permanently reside there the right to participate in municipal elections. Other demands include: granting the right to use Russian in official matters in the areas inhabited by the Russian-speaking population, access to Russian-speaking information in state and local government institutions (including bilingual signs and inscriptions), and limiting the number of professions (posts) in which people who do not speak the state language cannot work.

Migration movements in the area of the former USSR have led to changes in the ethnic structure of local communities. A typical example of this is the contemporary ethnic structure of the Narew River, where Russians constitute the overwhelming majority of its inhabitants. Often seen in the streets of this city are symbols of past

[4] Sozański, J. (1998) Prawa mniejszości narodowych w niepodległej Litwie, Łotwie i Estonii (międzynarodowo-prawny zarys porównawczy sytuacji w latach 1918–1940 oraz 1990–1996. Warsaw, pp. 85–94.
[5] Webber, M. (1996) The International Politics of Russia and the Successor States, Manchester-New York, pp. 111.

belonging, such as monuments to the heroes of the Red Army. Due to the immediate vicinity of Russia and the local predominance of the Russian population, the northeastern part of Estonia should be regarded as an area of particular risk on an ethnic-Russian background. Another ethnically inflammable place is the capital city of Tallinn, where Russians and the Russian-speaking population make up a significant proportion of the overall population. The remaining national and ethnic minorities have little impact on state security, compared to indigenous Russians and the Russian-speaking population. In a single view, they constitute very small communities dissolving in the total population of the state.

Conclusions

Estonian statehood has relatively modest historical traditions. Its centuries-long subordination to its more powerful neighbours has led to drastic changes in its ethnic structure. The ethnic and cultural situation of Estonian society deteriorated with the occupation of Estonian lands by Moscow. The centuries-long subordination to tsarist and soviet Russia, which coincided with the awakening of the Estonian national consciousness, led to fundamental social changes. The tsarist authorities launched an intensive process of Russification. The next stage of the process was Sovietization, which was in principle only an ideologized form of the former, which lasted, with small interruptions, until the break-up of the Soviet Union. The Soviet authorities annihilated a large part of the nationally conscious intelligentsia and the Estonian bourgeoisie, thus depriving Estonian society of a large part of the elite.

Both Russification and the ethnic cleansing of the Soviet Union were accompanied by an influx of ethnic Russians into Estonia. It first took on a massive character at the turn of the 19th and 20th century, connected with the process of industrialisation of the Estonian lands. Its next stage was the period of the October Revolution, when its territory became a refuge for "white" Russians and other fugitives who feared the new Soviet power. Another large wave of Russian-speaking people appeared in Estonia after the end of World War II, supplementing the biological losses of war. The deliberate Russian-Soviet ethnic policy led to the national degeneration of ethnic Estonians and a significant decrease in the percentage of their population in the total population of the republic. The population of Russians and the Russian-speaking population (Russians not Russians) has increased rapidly, which is now mainly a serious problem and a source of potential internal conflicts. The problem of intra-state unity is closely related to the historical heritage, deep political and cultural divisions of society. It fosters centrifugal tendencies, which are reinforced by the Kremlin's neo-imperial policies. Stopping, and ultimately eliminating, ethnic disintegration processes and ensuring political unity is an important challenge for state stability. This factor is and will continue to be used by the Russian Federation. From Moscow's perspective, the large Russian-speaking and Russian-speaking minority in Estonia is one of the main tools to put pressure on Tallinn.

The national situation in Estonia is complex. This is due to the intensity of the depopulation processes that have affected the area twice in the last hundred years. The first one took place during the Soviet Union. As a result, the percentage share of the Estonian population in the total population of Estonia (Estonian SSR) decreased significantly. The effect of the second one is a reduction in the size of the Russian population, and more broadly the Russian-speaking population, which began after independence. However, the Russian-speaking population is still significant in size and as such has a significant impact on the functioning of the state. The second depopulation trend is clearly shaped and leads to a systematic decline in the share of Russians and the Russian-speaking population (mainly Belarusians and Ukrainians) in the overall population of the state. From the point of view of part of this population, loyalty to the local statehood is a guarantee of a conflict-free stay in a country belonging

to the European Union. This attitude is supported by economic issues and living standards that are significantly higher than in Russia. However, in several urban centres, the persistently high percentage of the Russian-speaking and Russian-speaking population still poses a certain threat. This may be a conflicting ground in relations between the state authorities and residents who cultivate the memory of Russia and the Soviet past. Current trends of changes in the ethnic structure are leading to the strengthening of the Estonian element. However, the issue of the Russian-speaking minority will continue to be a difficult one. From time to time, this will lead to confrontations that can be internationalised in certain circumstances. Until now, these have usually been rhetorical in nature and have created an atmosphere of mutual distrust. It should be stressed, however, that they may be a premise for more radical actions in the future.

Modern Estonia gained its independence within the borders of the Estonian Soviet Socialist Republic in December 1991 after the break-up of the Union of Soviet Socialist Republics. The centuries-old dependence on foreign political entities negatively affected the cohesion of society. It generates problems with the self-determination of national identity by a large part of the local population, which is commonly referred to as the Russian-speaking population. The movements of the population in the last century in the area of present-day Estonia have radically changed its ethnic structure. Modern Estonian society is largely immigrant in character, with strongly obliterated features of national identity. This fact deepens internal divisions, becoming a source of potential ethnic conflicts. Moreover, ethnic Russians and Russian-speaking Estonians are the largest minority in Estonia. The effects of long-term dependence make it difficult for the authorities in Tallinn to pursue a coherent prostate policy.

Estonia has been an area with a bilingual social structure for several decades. A significant part of its inhabitants, including those officially declaring their Estonian nationality, speak and write exclusively or usually Russian. Many, not being ethnic Russians, consider Russian as their mother tongue. Others, although they feel Estonian national-linguistic consciousness or belonging to another nation, treat Russian as their primary means of communication. When considering the language issues that fundamentally affect the sense of national and national belonging, it must be recognised that bilingualism is a serious problem in contemporary Estonia. Language is very important for the intellectual elite and nationalist circles, especially Russian. For them, language is an essential tool for expansion and ideological rule. Being a carrier of Russian culture and tradition, Russian has a negative impact on social - state consolidation. The Russian Federation treats language as a tool for far-reaching reintegration both in the spiritual (cultural-symbolical) and political sphere. This is particularly important in the context of pro-Russian separatist movements.

The ethnic and ethno-linguistic structure has its direct impact on the political life of the state. Districts with a significant percentage of ethnic Russians and the Russian language as a common tool for communication are the mother treasure troops for pro-Russian groups. Internal divisions are in no way mitigated by the religious factor. There are several churches and religious groups of different territorial scope in the country. Among the largest are the Orthodox Church of the Moscow Patriarchate, which is largely dependent on the Kremlin. The ethnic problem is exacerbated by the issue of stateless people, which continues to have negative social consequences. These are manifested in persistent ethnic divisions and the feeling of exclusion of the Russian-speaking part of society. They have negative political consequences, and above all divisions within the political elite, as well as pressure from Russia and stigmatisation of the policy towards stateless persons. To sum up, it must therefore be assumed that the

Russian-speaking and Russian-speaking minority living permanently in Estonia continues to be a potential source of separatist threats, at least in terms of propaganda and internationalism.

Low-Cost Carrier's Domestic Flights and The Tourism Market: The Case of Selected Routes in Poland

Lukasz OLIPRA

Wroclaw University of Economics and Business, Wroclaw, Poland
lukasz.olipra@ue.wroc.pl

Abstract

The aim of the paper is to verify whether low-cost domestic flights in Poland offered by Ryanair contribute to the growth of tourism market and if yes – how they influence the tourism market and to what extent. Main research method used in this study is a questionnaire survey carried out at airports in the form of CAPI – Computer Assisted Personal Interview. Survey is complemented by desk research, statistical analysis and elements of counterfactual analysis.
Survey results allowed to conclude, that low-cost domestic flights in Poland offered by Ryanair contribute to the growth of tourism markets to a significant degree and in different ways. When it comes to the structure according to the purpose of the trip, the highest percentage belong to leisure tourists. In the case of Gdańsk they constitute vast majority of passengers incoming to the city by Ryanair flights (86%) while results for Wroclaw showed more balanced structure (34,5% - leisure, 29,5% - business, 27% - VFR; results for winter 2015 survey). 20% respondents in the case of Gdańsk and between 15% and 18% in the case of Wroclaw declared that they are travelling on a particular route for the first time (by any means of transport). Moreover 25% (Gdańsk) and between 15% and 19% (Wroclaw) of passengers visiting Gdańsk or Wroclaw (accordingly) declared that would not come to this city if there were no Ryanair flights.

Keywords: low-cost carriers, domestic flights, tourism market, relation between air transport and tourism, Poland

Introduction: interrelation between air transport and tourism

Tourism is a global phenomenon of one of the highest economic importance (Papatheodoru and Lei 2006, p. 1). According to the glossary of the World Tourism Organisation, 'tourism is a social, cultural and economic phenomenon which entails the movement of people to countries or places outside their *usual environment* for *personal* or *business/professional purposes*. These people are called *visitors* (which may be either *tourists* or *excursionists*; residents or non-residents) and tourism has to do with their activities, some of which involve *tourism expenditure'* (UNWTO, 2014). The movement to another countries or places outside the place of residence causes the need to use transport connections, what makes transport and particularly air transport indispensable element of the tourism market.

The interrelation between tourism and air transport is mutual. On one hand the desire to visit interesting places, spend holidays in a beautiful surrounding, visit friends or relatives living sometimes in another country or to do business with partners remote from our company generates demand for transport services and particularly air transport services (especially at long distance travel). On the other hand accessibility of the city, region or tourist attraction, determined by transport connections, facilitates the development of the tourism market in these places. The better accessibility, the higher potential number of tourists and excursionists (Graham, Papatheodorou and Forsyth, 2008, p. 1.).

Tourism, together with the impact on investment location decisions and economic activity, is considered to be one of the main areas of air transport catalytic impact on the regional economy. The impact of tourism on the regional economy is measured mainly through the estimation of expenditure made by tourists arriving to the region (Button and Taylor, 2000; Francis, Fidato and Humphreys, 2003). In the next step tourism multipliers are used to indicate the total increase in output, labour

earnings, and employment through inter-industry linkages in a region. The expenditure of visitors generates additional demand for goods and services in the region, influencing the growth of GDP (Eugenio-Martin and Inchausti-Sintes 2016).

There are many studies in the literature of the relationship between aviation, tourism and regional economies. Taking into consideration the topic of this paper, special emphasis should be given here to those research analyzing the significance of low cost carriers for the tourism market. Donzelli (2010) for example, using evidence from southern Italy, analyses the effect of low cost air transport on the local Italian economies through the tourist market. Other research focuses on Malta and the impact of low cost airline operations on the development of cultural heritage tourism and the tourism market in general (Graham and Dennis, 2010; Smith, 2009), the impact of low cost carriers on Korean Island tourism (Chung and Whang, 2011), the effect of low-cost airlines on tourism in Spain (Rey et al., 2011) and booming leisure air travel to Norway (Lian and Denstadli, 2010). Another paper devoted to Spanish market (Castillo-Manzano, López-Valpuesta and González-Laxe, 2011) analyzes results of the survey of almost 500 tourist establishment managers. It showed, that most of the tourism sector considers LCCs to be perfect substitutes for network carriers and even improvements on these in many cases. After literature review it seemed however, that there were not many research taking Poland and Polish regions as case studies and analyzing the relation between low-cost flights and tourism market in Poland. Empirical studies were missing particularly. Thus, the author became convinced that it cannot allow to consider this area as well described neither in English nor in Polish literature. It additionally encouraged the author to conduct this study.

Although there are relatively many research in the literature on the relation between LCCs and tourism market, they analyze only international connections or all LCCs routes without division into categories. It seems that none of studies focuses particularly on the significance of domestic flights of low-cost airlines on the tourism market and its development, thus the author believe, that this analysis fulfills important gap is the literature.

The aim of the paper is to verify whether low-cost domestic flights in Poland offered by Ryanair contribute to the growth of tourism market and if yes – how they influence the tourism market. Main research method used in this study is a questionnaire survey carried out at airports in the form of CAPI – Computer Assisted Personal Interview. Survey is complemented by literature review, desk research, elements of statistical analysis and elements of counterfactual analysis.

The article, along with some general and theoretical information which help to understand the relation between LCCs and tourism market, includes primarily original empirical data gathered through the survey and complemented by an analysis. Thus, the study gains also practical character and conclusions can be useful for regional policy makers as well as city and regional authorities. Very often low-cost carriers require financial support from public authorities when opening new routes claiming, that local and regional economies will benefit from growth of tourism and other economic activities resulting from higher number of incoming passengers and better accessibility of the region. Sometimes this support is unofficially a condition for opening a new routes and transfer of money has a form of so called 'marketing fees' paid to the airline for an advertising on the carriers' websites and in their magazines. Data obtained in the survey show real and just declared effects generated by these routes and can help to verify and analyze rationality of the decision on financial support for new LCCs domestic routes.

Development of Low-Cost Carriers in Europe and its domestic connections

Low-cost airlines grew fastest in Great Britain and on routes between the United Kingdom and Ireland due to lower labor costs, a huge London market and a relatively liberal regulatory environment (Doganis 2006, p. 88). Since 1999, after the expansion on the British and Irish markets, cheap airlines began the conquest of the whole of the European continent, increasing its market share each year. Market share of LCCs in Europe from increased 4,9% in 2001 to 36,3% of European seats in 2018 (European Commission, 2011, p. 97; ANNA, 2018). There were also nine markets in Europe (countries) where LCCs account for over 50% of seats (ANNA, 2018).

At initial stage of the development of LCCs European network their growth was focused on the Western European market, where they represented the most determining factor in the evolution of airline networks. They were offering point-to-point (mainly North-South) connections complementing those of full service network carriers (FSNCs) as well as charter routes. On some routes they were also directly competing with charters. The use of air freedoms beyond the fourth was limited, but exclusive routes were a frequent phenomenon linked to the option for secondary (urban or regional) airports and/or niches (Doruszkes, 2006). After European Union's enlargements in 2004 and 2007 and thus liberalization of the new member states aviation markets, the opportunity to open routes to/in these countries encouraged low-cost airlines to develop new routes in Central-East European countries. Although LCCs business has expanded to Central-East Europe, Marocco and a few remote areas, it remains mainly focused on the intra-Western market the share of which amounted in 2012 82% of 'low-cost seats' (Dobruszkes, 2009 and 2013; Pijet-Migoń, 2017).

Simultaneously cheap airlines have significantly entered many of the main European domestic routes and represent a significant part of the nationwide domestic air services. The share of domestic air service operated by LCCs in January 2012 in the UK, Italy, Norway and Spain amounted 37, 35, 34 and 29 per cent respectively and between 10 and 20 percent in 6 other European countries (Dobruszkes, 2013). Considerable part of these routes are a 'full cabotage' type of service, what means, that they are offered by carriers from another country (Pijet-Migoń, 2016). Pijet-Migoń (2016) notices also, that 'full cabotage' connections in Europe are operated mainly by low-cost airlines.

Low-cost domestic connections in Poland

It can be considered, that first attempt of the development of domestic LCCs network in Poland took place in April 2012. The airline OLT Express started operations in Poland offering charter and several international services as well as domestic connections between regional airports and Warsaw-Chopin Airport as well as directly between several regional airports. The experimental and brave concept of the expansion of domestic network and also the whole business concept of the OLT Express airlines was a total fiasco and resulted in bankruptcy already in July 2012, but brought a lot of knowledge about the potential of this market, mainly for those who are interested in its development (Serafin 2012 and 2013). Two years after OLT-experiment, in April 2014 Ryanair decided to open two domestic routes: Gdańsk-Warsaw-Modlin (GDN-WMI) and Wroclaw-Warsaw-Modlin (WRO-WMI) and in July 2014 another two from Kraków to Gdańsk and from Wrocław to Gdańsk. Details of new Ryanair domestic routes opened in 2014 are presented in the table 1 and on the figure 1. Research presented in this paper was carried out for the WRO-WMI and GDN-WMI routes and are marked on the figure.

Table 1: Ryanair domestic routes in Poland opened in 2014

Route	Date of the beginning of flights	Frequency
Wrocław – Warsaw-Modlin	2nd April 2014	1 flight per day, since the Autumn schedule – 2 flights per day
Gdańsk – Warsaw-Modlin	2nd April 2014	1 flight per day, since the Autumn schedule – 2 flights per day
Kraków – Gdańsk	1st July 2014	3 flights per week (only during summer)
Wrocław – Gdańsk	1st July 2014	3 flights per week (only during summer)

The network of Ryanair domestic flights was constantly evolving. The airline was changing frequency of flights, cancelling some routes and opening new ones. One of the most important change was the move of connections from Wroclaw and Gdańsk to Warsaw-Chopin Airport from secondary Modlin what took place in October 2016. However already 1,5 year later Ryanair withdrew this routes from its schedule giving as a reason too high airport fees and discriminatory decisions of Chopin Airport authorities. The evolution of Ryanair domestic network in Poland has been presented in tables 2-3 and on the figures 2-3.

Table 2: Ryanair domestic routes in Poland since October 2016

Route	Date of the beginning of flights	Frequency
Wrocław – Warsaw-Chopin	1st October 2016	3 flights everyday
Gdańsk – Warsaw- Chopin	1st October 2016	3 flights everyday
Kraków – Gdańsk	1st July 2016	3 flights per week

Classification of tourists and air transport passengers

The definition of tourism has been written above in the introduction. It is however also important to know categories of tourism. A tourism trip can be classified by the visitor's socio-economic characteristics or by specific features of the trip. One of attributes characterising tourism trips is the 'main purpose' of a trip, defined as the purpose in the absence of which the trip would not have taken place (UNWTO, 2010). The main purpose of a trip helps to determine whether it qualifies as a tourism trip and the traveller qualifies as a visitor. The classification of a trip according to its main purpose should be related to the main activities undertaken during the traveller's stay. In case of travel, during which individuals may have more than one purpose, the main purpose of the trip should be the one that is central to the decision to take the trip (UNWTO, 2010).

Classification of tourism trips according to the main purpose distinguish two main categories as well as eight sub-categories (UNWTO, 2010):

- Personal
    - Holidays, leisure and recreation
    - Visiting friends and relatives
    - Education and training
    - Health and medical care
    - Religion/pilgrimages
    - Shopping
    - Transit
    - Other
- Business and professional

Classification of tourists according to the purpose of the tourism trip overlaps with classification of air transport passengers. Three main categories of air transport passengers are: business passengers, leisure tourism passengers and VFR passengers (visiting friends and relatives). This three categories and groups of passengers appear also further in the study and are carefully analyzed for routes under consideration.

Methodology

The basic method of the research was a survey carried out among passengers departing from Wrocław Airport (WRO) and Gdańsk Airport (GDN) to Warsaw-Modlin Airport (WMI), which is the secondary airport for Warsaw – the capital of Poland. The survey was undertaken in four rounds in the period from May 2014 until September 2016. Three of them were carried out at Wroclaw Airport and one at Gdańsk Airport. Every survey was undertaken in different circumstances, namely: different seasons of the year and with different frequency of flights per day. Particular rounds with dates and circumstances are presented in the table below (table 4).

Table 4: Basic information about rounds of survey

No	Date of the survey	Place of the survey	Route	Frequency of flights and other information
1.	May – June 2014	Wrocław Airport (WRO)	WRO-WMI	1 flight per day: in the afternoon, about 6pm
2.	July – August 2014	Wrocław Airport (WRO)	WRO-WMI	1 flight per day: in the afternoon, about 6pm
3.	February – March 2015	Wrocław Airport (WRO)	WRO-WMI	2 flights per day, morning (about 7am) and afternoon, (about 6pm)
4.	September 2016	Gdańsk Airport (GDN)	GDN-WMI	2 flights per day, morning (about 7am) and afternoon, (about 6pm)

Source: own work.

The sample amounted from slightly less than 400 to 588 respondents and the percentage of passengers surveyed from 17 to 22 per cent. Statistical error amounted not more than 4% in each survey. Detailed information regarding surveys are presented in the table 5.

Table 5: The number and percentage of surveyed passengers

Source: own work.

Table 6 includes basic information about respondents taking part in the survey. Vast majority of respondents are Poles living in Poland (more than 90% in each survey and in each category). For almost all respondents Warsaw-Modlin was final destination. However it should be noted, that after adding second flight per day to the schedule at both of these routes the percentage of passengers declaring transfer at Modlin Airport increased by ca. 10% at both connections.

Survey Results

At the initial stage of the analysis it is important to outline the structure of passengers according to the type of the trip, i.e. whether the passenger is at the beginning or start of their trip, whether they are returning to their place of residence, whether they are transferring at Wroclaw Airport or Gdańsk Airport, or maybe staying in the region as part of a longer trip. Taking into consideration the development of the tourism in Wroclaw and in Gdańsk a particular interest should be given to passengers declaring that they are going back home because they are coming to these cities for certain purpose and sometimes stay two or more days. The analysis below in some places focus only on this group of passengers. As it is presented in the table below (table 7), the share of this group of passengers varies depending on the location and season of the survey, but amounts not more than 53% and in the case of the survey carried out in Wroclaw in the winter time it falls to even 34%. We have to note also a relatively high percentage of travellers declaring other type of journey in the case survey in Gdańsk (8,2%). The reason for this can be the fact, that Gdańsk Airport has a very well developed network of connections with Scandinavia and for some group of passengers is used as a transfer airport during flights to Norway, Sweden or Finland.

Data in the above tables show a considerable difference between the structure of passengers in Gdańsk and in Wrocław. Vast majority of passengers departing from Gdańsk to Warsaw-Modlin declare themselves as leisure tourists. Leisure tourism as a purpose of the trip has been indicated by 73,8% of all passengers and 86,2% of those who were returning home. Other options has been indicated rarely. While in the case of Wroclaw the structure is more balanced. Most important group is also leisure tourists (from 33% to 38,6% of 'going back home' respondents) but they are followed by only a little smaller VFR group (from 26,8% to 32,4% respectively). In the case of Wroclaw the relative high share of business passengers, amounted over 25% (except the summer time), should also be noted.

When it comes to the length of stay (Table 10) over 85% of passengers in every of 4 surveys spend in their destination not more than 5 days and from 42% to 55% travelers even not more than 2 days (one night). After adding a second flight per day to the schedule by Ryanair we can also observe a considerable increase of passengers indicating one-day trip (same-day visitors or excursionists).

Analysing the significance of LCCs domestic flights in Poland for the growth of tourism it seems very important to consider also data regarding frequency of travelling. They has been presented in the Table 11. Data reveal, that passengers using Ryanair domestic flights cannot be consider 'frequent travellers'. Again the difference between passengers in Gdańsk and those surveyed in Wroclaw is noticeable. While 46% respondents travel on the Gdańsk-Warsaw route (by any means of transport) once per year

or less frequently, this group in Wroclaw fluctuate only around 20%. We should focus more, however on the last possible option in the survey, namely "I travel on this route for the first time". The percentage of passengers who were travelling between Wroclaw and Warsaw for the first time amounted 15,1% in the winter 2015 survey, 18,9% in the spring 2014 survey and in the case of Gdańsk-Warsaw route even 20,1%.

Source: own work.

The main aim of this study is to investigate the role of Ryanair domestic flights for tourism market. So, it would be desirable to distinguish between tourists (and other visitors) who would not have travelled to the region if there were no airport and those who would not have come anyway by some other form of transportation Butler and Kiernan (1992). Mainly the former are relevant for the assessment of the role of LCCs flights for the development and growth of tourism market. In order to identify these passengers and estimate the size of this group the elements of counterfactual analysis has been used and one of the questions in the survey has been formulated as follows: Would you come to Wrocław/Gdańsk if there were no Ryanair flight? The structure of answers for this question hase been presented in the Table 12.

Table 12: Answer for the question: "Would you come to Wrocław/Gdańsk if there were no Ryanair flight?" ('go back home' passengers only)

Round of the survey	1.		2.		3.		4.	
	WRO-WMI May-June 2014		WRO-WMI July-August 2014		WRO-WMI Feb.-March 2015		GDN-WMI September 2016

Based on data presented in the Table 12 we can conclude, that the role of Ryanair flights in the growth of tourism market in Gdańsk and in Wroclaw is considerable. One forth of respondents answered that if there were no Ryanair flights from Warsaw-Modlin to Gdańsk they would not come to Gdańsk at all. These shares for Wroclaw amounted 15,6%, 18,6% and 19% in the 1st, 2nd and 3rd rounds respectively. This question has been asked only to passengers declaring return to the place of residents, so we can draw conclusions precisely for these two cities and tourist markets.

Conclusions

Based on the results of the survey and analysis presented above we can conclude, that low-cost domestic flights in Poland contribute to the growth of tourism markets to a significant degree.

In the case of GDN-WMI route Ryanair domestic flights contribute mainly to the growth of leisure tourist traffic. Significance for VFR passengers is not so high and for business travelers is even very modest. In the case of WRO-WMI route significance of Ryanair domestic flights for business travels and VFR is at higher level than in the case of Gdańsk, the structure of passengers according to the purpose of the trip is more balanced, however still the biggest share of demand comes from leisure tourists.

Opportunity of fast and cheap travels by airplane encourage people to fly and to travel at all. Ryanair low-cost domestic flights attract new tourists who are visiting particular place for the first time and moreover declare, that in case that there were no Ryanair flights they would not visit Wrocław or Gdańsk at all. Adding second flight per day (in the morning) on these routes increased also the share of excursionists (same-day visitors), who can make one-day trip thanks to short travel time by air transport. New tourists attracted by cheap flights facilitate increase of demand for local products and services and thus contribute to the growth and development of tourism market at these destinations.
