Abstract

Such factors as a significant size of the territory, low population density, and regional inequality, set before the Russian state one of the urgent tasks to develop single-industry towns (monotowns) under the conditions of a coordinated and progressive update of the infrastructure. Currently, a number of priority projects and programs in the field of construction and reconstruction of infrastructure facilities in single-industry towns are provided for at the federal level. Their implementation requires a significant amount of capital investment and is being carried out mainly at the expense of public funds. Given the limited budget funding, there is a need for private investment that can be raised under municipal-private partnerships (MPPs). In the authors' opinion, in the scientific and specialized literature to date, the question of the MPP model implementation in resource single-industry towns has not been sufficiently studied. In this regard, the purpose of this article is to study the conditions and prerequisites for the implementation of the MPP mechanism as a growth factor for single-industry towns in Russia. In the study, the tendencies for improving the legal and regulatory framework of the development of Russian single-industry towns are identified; a model for the interaction of MPP participants and a methodology for assessing the effectiveness of implementing MPP projects are developed based on the analysis of the existing methods; and the social and economic effects of implementing the MPP mechanism in single-industry towns of the Sverdlovsk Region are assessed.It is concluded that the formation of the Russian legal and regulatory framework for the establishment and functioning of MPP allows for the suggestion that this institution may become one of the promising tools for the development of the urban economy. The results obtained can be useful for scholars, government bodies, and analytical organizations that carry out research in the field of the development of MPP models at the regional level.

Keywords: public-private partnership, municipal-private partnership, development of single-industry towns (monotowns), infrastructure projects, construction, effectiveness

Introduction

Urgency. Russia currently faces one of the strategic tasks, which is to diversify the economy of single-industry towns and to search for ways to increase their economic stability and development that will allow raising investment, creating conditions and prerequisites for the development of private initiative and business, as well as creating new workplaces. Russian President V.V. Putin

Cite this Article as: Natalia V. GORODNOVA, Elena G. SHABLOVA, Dmitry L. SKIPIN, Anastasiya A. PESHKOVA and Ivan S. ROZHENTSOV "Analysis of The Municipal-Private Partnership Model as a Growth Driver for Single-Industry Towns (Monotowns)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

notes the special traditional complexity of solving this problem, which is associated primarily with the specifics of the economic condition of municipal and urban entities (hereinafter referred to as m.e./u.e.), in particular, with the almost complete lack of land plots for constructing socially significant objects that would be prepared to attract investors or prepared in terms of infrastructure. In this regard, the topic of the study devoted to the incorporation of municipal-private partnership models as one of the main growth drivers for single-industry towns in the conditions of economic instability, external challenges and threats, is becoming even more urgent**.**

Ensuring sustainable social and economic development of single-industry municipal entities (single-industry towns) is one of the priority tasks of the Russian state policy; the quality of life of the people in these settlements depends on its implementation.

The current versions of the regulations contain no definition of a single-industry town as such. In its efforts to highlight the qualifying features of a single-industry town, the Government of the Russian Federation in its resolution of July 29, 2014, approved a list of criteria for classifying municipal entities as "single-industry":

a) the status of an urban district or a municipal settlement;

b) the resident population is not less than 3 thousand people;

c) employment in one of the organizations operating within the territory of the municipality is at least 20 % of the total employed population;

d) the organization is engaged in mineral extraction (except oil and gas) and/or the production (processing) of industrial products;

e) the municipal entity is included in the list of single-industry towns determined by the Government of the Russian Federation.

The compliance with these criteria is essential for towns since obtaining the status of "single-industry" allows receiving significant government support, including financing the construction and reconstruction of infrastructure facilities.

The purpose of the study. The formation by the Russian state of the legal and regulatory framework for the establishment and functioning of MPP allows for the suggestion that this institution may become one of the promising tools for the development of the urban economy. However, to what extent is it possible to use this tool in resource single-industry towns? In the authors' opinion, this issue has not been studied sufficiently in the scientific literature to date. In this regard**, the purpose of this article** is to study the conditions and prerequisites for the implementation of the MPP mechanism as a growth factor for single-industry towns in the Russian Federation.

Methods and methodology. The methodological framework of the study includes general scientific methods of cognition, in particular, synthesis, comparative analytical and logical analysis, a systemic method, and simulation modelling. A system of factors of interaction between the state and the municipality, as well as the results of the analysis of existing methods for assessing the factors of interaction between subjects of public-private (municipal-private) partnerships, are adopted as the basis of the author's municipal-private partnership model.

Testing the author's model of municipal-private partnerships in single-industry towns has allowed obtaining the following main results:

1) the PPP mechanism is mainly used for infrastructure development in such areas as transport, water supply, energy, and solid waste disposal and recycling (Su, Ang, 2012);

2) the development of the legal regulation of PPP activities is confirmed by the adoption of new legislation in a number of countries with emerging markets, including the Russian Federation;

3) the quality of the legal and regulatory framework and the institutional environment is an important (but not a key) factor affecting the implementation of PPP (MPP) projects;

4) key factors of the PPP (MPP) development are the level of state support, many years of technical experience and potential, as well as the availability of investment;

5) the deficit of financial resources (including private resources) significantly restrains the development of the PPP market.

The conducted study allows developing the following recommendations to improve the effectiveness of PPPs (MPPs) in emerging markets:

a) ensuring cooperation and coordination regarding the PPP issues among various ministries, departments, and specialized structures;

b) ensuring transparency at all stages of the PPP project implementation, including holding open tenders, publishing contract terms, assessing the effectiveness and social significance of projects, and creating accessible public registers;

c) taking into account the concept of “sustainable economic development” in the selection and implementation of PPP projects.

In the authors' opinion, the above recommendations are relevant for the Russian emerging market of PPP (MPP).

Main Part of the Study

The stated objective, tasks, and expected results of testing have determined the logic and structure of the study. The general logic of the study is presented in the fig. 1 below.

Fig. 1: Modules of the Study

The topic of the study - the problem of the development of Russian single-industry towns in modern economic conditions - is recognized by the expert community as relevant and rather urgent.

Module 1. The state strategy of supporting single-industry town

As of July 2019, the government distinguishes three categories with 319 single-industry towns, depending on the risk of their social and economic situation worsening. Since July 2016, the "Integrated Development of Single-Industry Towns" program that defines a set of measures for the period up to 2025 has been underway. The main objectives of this program are as follows:

- to create new opportunities and niches for business in single-industry towns;
- to ensure coordination of support measures, including for projects in the field of healthcare, education, road quality, housing and communal services and the urban environment, small and medium-sized enterprises, and industrial development;
- to create managerial competencies in single-industry towns.

A special aspect of the above program is its comprehensive nature, as it integrates activities from various priority projects and programs and includes support measures for federal and regional government bodies, development institutions, and other organizations. In particular, among the main measures the following should be highlighted:

1) The activity of the non-profit organization "Single-Industry Towns Development Foundation" to establish the necessary conditions for creating new jobs, attracting investments in single-industry towns, as well as developing the urban environment. This goal can be achieved by co-financing the expenses of constituent entities of the Russian Federation and municipalities on constructing and reconstructing infrastructure facilities required to launch new investment projects, as well by forming teams to manage single-industry town development projects, including the organization of their training.

In order to fulfil the tasks assigned to the Foundation, the budget allocations from federal funds in the amount of RUB 6.5 billion were made in 2017, RUB 4.7 billion - in 2018, and RUB 4.7 billion - in 2019.

As of year-end 2017, the Foundation achieved the following results in the construction and (or) reconstruction of infrastructure facilities:

- financial obligations under 12 agreements on co-financing of expenses of constituent entities of the Russian Federation for the construction of infrastructure facilities in the amount of RUB 4.96 billion were fulfilled;
- 30 infrastructure facilities worth RUB 6.3 billion were commissioned in 13 single-industry towns;
- 17 agreements on infrastructure in the amount of RUB 7.34 billion are financed.

2) Establishing Priority Social and Economic Development Areas (PSEDA) in order to diversify the economy of single-industry towns and reduce dependence on dominant local employers (town-supporting enterprises). PSEDA residents in single-industry towns receive a wide range of preferences: income tax, corporate property tax and land tax benefits, as well as benefits on insurance contributions to state extra-budgetary funds.

As of year-end 2017, PSEDA were established in 36 single-industry towns, where 93 residents are registered, which should contribute to the creation of more than 5,100 jobs and attract RUB 1.5 billion by 2026.

3) Implementing the "Safe and High-Quality Roads" project, through which the program for the comprehensive development of transport infrastructure in 38 urban agglomerations, including 42 single-industry towns, is also being implemented. As of year-end 2017, the share of the road network that meets the regulatory state in these single-industry towns increased on average from 45 % (in 2016) to 52 % (in 2017).

4) Implementing the "Five Steps of Improvement" concept aimed at creating comfortable public spaces in single-industry towns of Russia. The concept includes the following steps:

- improving vibrant public space;
- creating modern spaces for the young;
- revitalizing the city attractions;
- updating or creating an object of social infrastructure;
- activating abandoned or inefficiently used buildings and territories. According to the data (InfraONE, 2018) as of year-end 2017, 1,149 projects were implemented in single-industry towns.

5) Implementing the "Forming a Comfortable Urban Environment" project where monotowns received financing in the amount of RUB 5.8 billion, including RUB 3.9 billion from the federal budget and RUB 1.9 billion from regional budgets.

Thus, the above data indicate the interest of the state in developing the infrastructure of single-industry towns, which, in turn, requires a significant amount of capital investment. On average, public investment accounts for about 65-70 %, while private investment accounts for 30-35 %. The state has no opportunity to finance a larger share of funds due to the state budget deficit and high debt burden to Western countries (Reynaers, Grimmelikhuijsen, 2015).

Today, in Russia as a whole, the minimum yearly need for investments in infrastructure projects is RUB 2.3 trillion. Additional RUB 3.3 trillion (InfraONE, 2018) is required to ensure the development of infrastructure According to experts, the average underfunding of infrastructure is 20-40 %. In this regard, there is *a tendency to strengthen the role of private investment in infrastructure projects, various instruments of interaction between the state and private sector entities are being developed and implemented*, including municipal-private partnerships (MPPs).

Module 2. The objective of the study

In the authors' opinion, the issue of taking into account the specifics of the development of Russian single-industry towns in the context of implementing municipal-private partnership projects in the construction of capital construction and land development projects has not been studied sufficiently. In this regard, **the purpose of this article** is to study the conditions and prerequisites for the implementation of the MPP mechanism as a growth factor for single-industry towns in the Russian Federation.

Module 3. Methods and methodology of the study

The authors' model of assessing the effectiveness of implementing the PPP (MPP) projects

The methodological basis of the study included general scientific methods of cognition, in particular, synthesis, comparative analytical and logical analysis, and the system method. The method of simulation modelling is used as the basis of the author's model for implementing municipal-private partnerships (MPPs) in Russian single-industry towns and the mechanism of interaction between subjects of MPPs.

In this regard, the authors of the study analysed the experience of implementing MPP projects in the Urals region assessed by an integral indicator of the effectiveness of implementing partnership projects, which includes an assessment of six qualitative characteristics of each specific PPP (MPP) project, in particular:

1) belonging to two or more related industries;

2) compliance with the features of PPP (MPP) defined by the Russian legal and regulatory framework;

3) the duration of implementing the MPP project in Russian single-industry towns;

4) the complexity and specificity of the MPP project implemented in single-industry towns;

5) the stage of the project;

6) the amount of private investment.

The integral indicator of the effectiveness of implementing the MPP projects is calculated according to the following formula:

$R_i = k_1 L_i + k_2 N_i + k_3 E_i$, where (1)

R_i – the integral indicator for the *i*-region;

k_1, k_2, k_3 – coefficients that define the significance (weight) of sub-indicators,

where $k_1 = 0.03$, $k_2 = 0.03$, $k_3 = 0.04$;

L_i – the level of a sub-indicator evaluating the development of the region's institutional environment;

N_i – the level of a sub-indicator evaluating the region's legal and regulatory framework in the field of PPP (MPP);

E_i – the level of a sub-indicator evaluating the experience of implementing PPP (MPP) projects in the region.

The key factor in making the region one of the leaders is the experience in implementing projects, the presence of which determines the attraction of the desired infrastructure investor. The authors calculated the integral indicator for the *i*-region R_i and compiled a rating of the regions in terms of the effectiveness of PPP projects (table 1).

Table 1: Ranking of Russian regions by the level of PPP mechanism development

Ranking	Economic entity	Value of the complex indicator (R_i)
1	City of Moscow	90.0
2	City of Saint Petersburg	90.0
3	The Moscow region	90.0
4	The Republic of Tatarstan	84.5
5	The Republic of Bashkortostan	83.2
6	The Perm Krai	80.6
7	The Sverdlovsk region	76.9

According to the results of the study, it can be concluded that the Sverdlovsk region is in the top 10 regions with the most developed mechanism of public-private partnership.

Analyzing the existing methods for assessing factors of interaction between the subjects of public-private (municipal-private) partnerships

Among the foreign instruments that allow assessing the prevailing conditions on a national scale, the *methodology of The Economist Intelligence Unit analytical company* should be singled out (The Economist Intelligence Unit, 2017). The Integral Index (the Infrascope index) includes 23 indicators grouped into five groups and consisting of 78 qualitative and quantitative sub-indicators.

Based on the results of testing the methodology using the example of 13 countries with an emerging PPP market (Albania, Belarus, Bulgaria, Egypt, Georgia, Jordan, Kazakhstan, Morocco, Romania, Serbia, Slovakia, Turkey, Ukraine), the analysts of The Economist Intelligence Unit obtained the following results:

1) the PPP mechanism is mainly used for infrastructure development in such areas as transport, water supply, energy, and solid waste disposal and recycling;

2) the development of the legal regulation of PPP operation is confirmed by the adoption of new legislation in a number of countries, including Belarus (2016), Jordan (2014), Kazakhstan (2015), Morocco (2014), and Romania (2016);

3) The quality of the legal and regulatory framework and the institutional environment is an important (but not a key) factor affecting the implementation of PPP projects. Thus, Turkey and Morocco, distinguished by their extensive experience in implementing projects, are at the stage of formation of the legal regulation of the relevant activities. On the other hand, in Belarus and Kazakhstan, where the legal and regulatory framework is well-developed, there are practically no examples of completed projects (at the time of the study);

4) key factors of the PPP development are the level of state support, many years of technical experience and potential, as well as the availability of investment;

5) the deficit of financial resources (including private resources) significantly restrains the development of the PPP market. The latter is due to the long payback period of investments and the large volume of capital investments. Active attraction of funds of institutional investors was noted only in Jordan and Turkey, despite the fact that this source is one of the main ones in Western countries. Two countries, Morocco and Turkey, used the so-called “green bonds” (Choi, 2015), an innovative financing tool that is not used to a sufficient degree in the emerging markets around the world.

Analyzing the data of The Economist Intelligence Unit allows developing the following recommendations to improve the efficiency of PPPs in emerging markets:

a) ensuring cooperation and coordination regarding the PPP issues among various ministries, departments, and specialized structures. This is confirmed by the fact that most countries with the highest level of integral index were highly rated by the sub-index in the corresponding area (Kazakhstan, Slovakia, and Jordan). The country's legal and regulatory framework should clearly define roles and responsibilities, while the public-private partnership development program should be consistent with the national infrastructure development plan;

b) ensuring transparency at all stages of the PPP project implementation, including holding open tenders, publishing contract terms, assessing the effectiveness and social significance of projects, and creating accessible public registers. The following statistical data regarding this are available as part of a study by The Economist Intelligence Unit:

- in all these countries, one of the mandatory requirements is the publication of tender documentation;
- two countries (Albania and Slovakia) stipulate the need for full publication of contracts;
- three countries (Bulgaria, Egypt, and Serbia) have a publicly accessible online PPP registry. The lack of a registry significantly limits the knowledge available on the scale and area of PPP application;
- two countries (Georgia and Morocco) publish the results of public consultations on the PPP implementation;
- none of the countries reviewed publishes the results of evaluating the effectiveness of PPP projects, which, according to the company analysts, is a serious omission in terms of accountability;

c) taking into account the concept of “sustainable economic development” in the selection and implementation of PPP projects. Most of the reviewed countries require environmental impact assessments as part of the feasibility study for projects. However, none of them provides a system for managing natural disaster risks, changing climatic conditions or adapting to them. Natural disaster risk is partially accounted for in three countries (Bulgaria, Turkey, and Kazakhstan) using the project insurance requirement.

In the authors' opinion, the above recommendations are relevant for the Russian emerging PPP market as well.

In the Russian scientific literature, the interaction factors are analysed at the regional level *according to the methodology of the National Center for PPP*. Each year, a ranking of the Russian regions is formed according to the level of public-private partnership development. The regions are ranked using the integral index, which includes 22 assessment indicators combined in three groups (Association “The PPP Development Center”, 2016):

1) *The development of the region’s institutional environment* in the field of public-private partnerships (10 indicators used to assess the availability and quality of specialized PPP bodies, information resources, PPP specialists, taking into account PPP mechanisms in strategic and program documents of the region, the effectiveness of various measures to support private partners);

2) *The region's legal and regulatory framework in the field of PPPs* (5 indicators used to assess the availability and quality of the procedure for inter-agency cooperation at all stages of the PPP project implementation cycle, as well as compliance with federal law);

Upon the analysis of methods for assessing the effectiveness of PPP (MPP) projects, the following conclusions can be made:

1) the existing index systems differ in calculation methodology, structure, as well as a set of indicators and are focused on assessing the environmental factors, including the regulatory support of the PPP (MPP) sphere, the development of the institutional environment, experience in project implementation, and the availability of financing;

2) most of the indicators used do not allow for the analysis of factors affecting the effectiveness of implementing digital projects;

3) the indicators that allow assessing the level of project support by the population, as well as the degree of willingness of private partners to participate in implementing large investment and construction projects based on the use of digital technologies are not taken into account.

In the authors' opinion, the last factors are the main ones due to the high social significance of large investment and construction projects. *Awareness of the population about projects, the possibility to express their opinions on issues of adopting or implementing decisions are some of the key conditions for the development of the PPP (MPP) mechanism*. In addition, the effectiveness of project implementation depends on the quality of the internal institutional environment, the level of development of the economic, technical, digital, and other potentials of private partners. Therefore, these indicators should also be taken into account when assessing the factors of interaction between PPP entities.

In this regard, in addition to the existing analytical tools, the authors have developed a methodology for assessing the interaction among the subjects of public-private partnerships, taking into account the above groups of indicators, as well as the specifics of digital projects.

Module 4. The mechanism of municipal-private partnership as a growth factor for single-industry towns

The creation and progressive improvement of the legal and regulatory framework for the formation and functioning of public-private (municipal-private) partnership in Russia confirms the relevance of the use of this mechanism in the field of urban development.

Initially, this mechanism could be applied to the following objects and facilities: roads, bridges, road service facilities; public transport; railway and pipeline transport facilities; sea and river ports, ships; airports; facilities for the production, transmission, and distribution of electrical energy; hydraulic engineering structures, platforms, artificial islands; health care, education, culture, sports, recreation and tourism facilities, etc.

Later, creating information technologies and technologically related property was included in the list of objects. Considering that the changes have come into effect relatively recently (since 2018), currently this mechanism is not widely tested on the example of implementing projects for the single-industry town development.

It should be noted that, upon the adoption of Federal Law “On Public-Private Partnership (PPP), Municipal Private Partnership in the Russian Federation and Amending Certain Legislative Acts of the Russian Federation” of July 13, 2015, the number of PPP projects in Russia increased sharply from 873 in 2015 to 2,183 in 2016. According to Dealogic Projectware, from 2000 to 2015, the total

number of partnerships in the European Union amounted to 1,184; the total cost of PPP projects is EUR 270 billion.

When Russia adopted the agenda of improving social and economic conditions of society, infrastructure development and the implementation of socially significant innovative projects, it has led to the development of the legal and regulatory framework for establishing structures integrated with the state and their functioning. In particular, on January 1, 2016, special Federal Law No. 224-FZ "On Public-Private Partnerships" entered into force. This gave a new impetus to the development of such institution as PPP in the construction industry, in healthcare, and in the provision of educational services. Legal conflicts and the lack of experience in implementing social and infrastructure projects for the development of single-industry towns in PPP conditions dictate the need for research in this area.

The concept of PPP is often used as "cooperation between a public (state) entity and a private (commercial) entity to achieve a specific goal or set of goals" (Busch, Givens, 2013). PPP is a special type of management network that can be defined as "*more or less stable models of social relations between interdependent entities that are formed as part of a state program and/or cluster, are supported and transformed through a series of business contracts*" (Koppenjan, de Jong, 2018, Schaeffer, Loveridge, 2002). The management network covers all relevant stakeholders regarding the development and/or implementation of a government project or program (Steijn, Klijn, Edelenbos, 2011). An analysis of international experience shows that *the pace of development of individual industries largely depends on the directions of national economic policy*, which is the basis for the effective functioning of the national economy. The following impact methods can be used to control economic processes (Kovaleva, Chernov, 2017).

1. Direct impact: introducing new rules of behaviour by establishing them as legal norms, for example, establishing algorithms for financial support of individual business entities. State control in the economy should correspond to market opportunities and be applied within the appropriate legal and regulatory framework, the degree of elaboration of which is one of the problems discussed in modern science.

2. Indirect impact: the impact that the actions of the government carried out within the framework of the established rules of conduct have on the economic behaviour of entities. For example, a government agency may provide financial support to individual business entities that supply essential goods to the public procurement system.

The methods of direct and indirect impact are mutually complementary and are based on the principle of economic efficiency. In addition, the application of any method should maintain equilibrium in the economic system. Strengthening a number of administrative methods of direct impact (for example, legislative restrictions) can reduce the initiatives of economic entities, while the abuse of indirect methods (for example, unjustified financial support of some entities) weakens market mechanisms (Istiak, Serletis, 2018).

In addition to the above-listed methods of state control, another special form is state enterprise, where the state acts as a direct participant in social and economic processes (Ingham, Doig, Hargrove, 1988, Kingdon, 2011). The aim of the state entrepreneurship is to solve social and economic problems, but not to make a profit: achieving economic growth, increasing employment, protecting the environment and supporting vital knowledge and capital-intensive industries (Millward, 2011). PPP differs from traditional and innovative forms (design and construction contracts) of a public-private contract in that private players must make a financial contribution to the PPP mission. PPP productivity depends on the social context, institutional environment, and political struggle, which determines their form and functioning (Sørensen, Torfing, 2009).

The advantages of market competition and the practice of contract execution are recognized, however, the scientific literature analyses the experience of legal conflicts and failures in the

development and signing of contracts. In scientific works, the practice of legal regulation of PPPs, the strengths and limitations of applying the contract system, the classification of contracts, and the analysis of the development of the contract system were studied. The study (Marx, Jadir, 2016) developed a model for the participation of a private partner in the implementation of PPP (MPP) projects (BOOT or BOT contracts). In addition, they pay special attention to the process of managing and sharing risks among project participants in the framework of PPPs, including identifying and grouping the main risks of private contracts, as well as monitoring the implementation of contracts. The authors emphasize the priority of contracted PPPs alongside institutional PPPs.

The authors of another study (Kivleniece, Quelin, 2012) emphasize the importance of the governance structure and improving efficiency through the development of the theoretical basis of two conceptual public-private structural alternatives: autonomous mode and an integrative PPP management model, each of which is associated with different capabilities of creating values, considerations and conclusions

This study (Mahoney, Mcgahan, Pitelis, 2009) focuses on private or public institutions without constantly considering their interdependencies. Attention to private or public interests increased with a deepening of professional knowledge: for example, academic managers tend to consider a corporation as a unit of analysis (Gorodnova, Khaykin, 2009), while scientists in the field of public policy analyze the government and multilateral, public and non-profit organizations. The authors advocate a partial combination of these research programs because private and public interests cannot be fully taken into account if they are conceived independently.

In studies of foreign authors, limitations of the national budget are noted (Barlow, Roehrich, Wright, 2013): European and American governments are more likely to cooperate with the private sector in order to obtain guarantees that the costs of the construction and operation of socially significant capital construction projects will be borne by the private partner, the state -private partnerships help the government avoid initial investments, while private sector partners receive a return on investment (Marx, 2017).

As a rule, state-owned enterprises operate in areas related to the function of the state, including the creation and maintenance of socially significant infrastructure facilities, and significant and capital investments from the state are necessary for their prompt and proper maintenance (Wang, Zhao, 2014).

In Russia, the smallest amount required for investments intended for the development of transport, energy, social, and public utility infrastructure is about 3.5 % of GDP. In order to achieve this level, over the next 5-7 years investment in Russia should increase by 6-10 % per year. This is practically consistent with world estimates (an average of 3.8 % of global GDP per year (The Economist Intelligence Unit, 2019)). The current volume of research is focused on assessing the cash flows of future PPP projects, and there are significant opportunities for studying the factors that form the operating environment for PPPs (Yang, Shieh et al., 2018).

According to (Kivleniece, Quelin, 2012), the existing body of a research body has three main limitations. Public-private cooperation requires further theoretical conceptualization. Greater efforts may be required to understand the exact mechanism for creating value in public-private relations, again about alternative forms of economic organization and border elections between sectors. Existing studies of the mechanisms for distributing cash and creating value in relations between the public and private sectors, as a rule, are aimed at obtaining significant economic benefits that private actors derive from relations with the public sector, bypassing the wider organizational and managerial dilemmas inherent in such cooperation, and any potential adverse effects on the private sector.

Cruz and Marques emphasize that PPP mechanisms are particularly vulnerable to the uncertainties and risks posed by several factors (Cruz, Marques, 2013). A variety of risks contributed to the possibility of revision (Engel, Fischer, Galetovic, 2006). Barlow and Roehrich reveal that the

innovative ability of PPP projects in social sectors was not encouraged under the Private Financial Initiatives Program (Barlow, Roehrich, Wright, 2013). When Russia adopted new national projects for the development of the digital economy, and given the urgent need to develop breakthrough technologies in all areas of society and to implement the concept of information and intellectual technologies, the emphasis is on studying the effectiveness of innovative projects. within the framework of PPP mechanisms it becomes even more relevant (Choi, 2015).

In essence, the mechanism of public-private partnership allows a public partner (local governments) to involve private law entities in performing functions related to the sphere of activity of the state, in particular the creation and reconstruction of socially significant objects.

Social and economic effects of implementing the MPP mechanism

The studies often emphasize that MPP is one of the promising tools for the development of urban economy (Roumboutsos, 2016).

In 2017, in the wings of the round table "Development of Public-Private And Municipal-Private Partnerships", it was noted that public-private partnerships are becoming an increasingly visible form of cooperation between the state and private business in Russia and one of the promising tools for developing public infrastructure in the long term . Also, based on the example of the housing and public utility services sector, the heterogeneity of the development of partnerships in large and small cities was noted; the reason of this is that the private sector is not particularly interested in participating in such projects due to increased depreciation of fixed assets, low incomes of the population, long payback on investments, and insufficient profitability.

According to the analysis of scientific literature (Mostafavi, Abraham, Sinfield, 2014), the authors concluded that the social and economic effects of implementing the mechanism of municipal-private partnership is the following positive results for the state, society, and private investors:

- increasing the investment attractiveness of municipalities as a result of improving the infrastructure network;

- improving the living conditions of the population of municipalities through the development of transport and social infrastructure;

- improving the availability and quality of services provided by the public sector, in connection with the full (or partial) transfer to the private partner of the risks associated with the cost and quality of construction work and maintenance that determine the level of economic benefits received by the private partner during the operation phase of the facility;

- reducing the budget load with regard to the obligation of a private partner to finance the creation of an infrastructure facility;

- increasing the financial stability and economic efficiency of the construction industry and business entities, taking into account private partners receiving guarantees, subsidies, benefits that are secured in legislation, for example, guarantees for the completion of construction within a reasonable time due to government participation, guarantees for the lowest prices on the market due to cost optimization for payment of taxes, acquisition of land, construction of facilities;

- introducing state-owned land plots into the economy as a result of the expansion of large cities and the construction of a local road and infrastructure network.

Despite the significant number of the above listed positive effects, there are also a number of difficulties in implementing MPP projects.

The authors' model of interaction between the subjects of public-private (municipal-private) partnerships

The legal basis for forming and implementing an agreement on public-private (municipal-private) partnership (hereinafter "PPP" and "MPP") was fixed at the federal level in 2016. Initially, this mechanism could be applied to the following objects and facilities: roads, bridges, road service facilities; public transport; railway and pipeline transport facilities; sea and river ports, ships; airports; facilities for the production, transmission, and distribution of electrical energy; hydraulic engineering structures, platforms, artificial islands; health care, education, culture, sports, recreation and tourism facilities, etc.

Later, creating information technologies and technologically related property was included in the list of objects. Considering that the changes have come into effect relatively recently (since 2018), currently this mechanism is not widely tested on the example of implementing projects for creating "smart cities". Lack of project implementation practices is one of the obstacles to attracting private investors, as this leads to difficulties in assessing potential risks and uncertainties. For this reason, standard models for implementing digital projects must be developed, which, in the authors' opinion, allows identifying the main relationships and principles of interaction between the subjects of the partnership and simplifies understanding and analysis of the mechanism for participants in the process.

The results of analysing the Russian literature show that the existing model presentation options outlined by the National Center for PPP are based on the concession agreement mechanism and do not take into account the specifics of the alternative form of implementing digital projects - municipal-private partnership agreements. Taking into account the latest changes in the legislation, the authors developed a structure for implementing investment projects for the construction of capital construction projects as part of an agreement on public-private partnership.

In order to build "smart city" facilities, the municipality provides to a private partner a land plot for rent without bidding, which reduces administrative barriers and reduces costs due to lower transaction costs.

Creating an object (a facility) under an MPP agreement is financed through investments from a private partner. Under the agreement, the project may be co-financed by the municipality, whose share must not exceed 50 %. As a rule, due to the budget deficit of municipalities, funds are allocated from the regional budget in the form of intergovernmental subsidies.

In the process of project implementation, a private partner may raise credit resources, so a facility under construction may be pledged to a credit institution (Shelepov, Andronova, 2018). In the case of foreclosure on the subject of pledge, the municipality has the pre-emptive right to purchase the pledged property.

As a general rule, a private partner is obliged to fulfil obligations under an MPP agreement at its own expense. If necessary, it may engage third parties (subcontractors), if permitted by the terms of the agreement. In this case, the private partner is responsible for the actions of the subcontractors as for its own.

If, when creating an object (a facility), the results of intellectual activity or technical means that belong to third parties (copyright holders) are applied, then the public partner must provide the private partner with the opportunity to use these rights. For this, the public partner and the copyright holders enter into a license agreement. Then, based on the written consent of the copyright holder,

public and private partners enter into a sublicensing agreement. If the corresponding rights are not granted by the public partner, the private partner may acquire such rights from third parties (copyright holders) at its own expense.

As a result of the project, a private partner acquires ownership of the object of the agreement. If the amount of project financing by a municipality in total exceeds the amount invested by a private partner, then the object of the agreement and exclusive rights to the results of intellectual activity are transferred to the municipality no later than on the day the agreement is terminated.

The agreement may provide for a fee paid by a private partner to the municipality during the operation of the object of the agreement. The size of the fee, the form, the procedure, and the timing of the payment shall be established by the MPP agreement. Private partners may pay the fees as follows:

- payments (in a fixed amount) made periodically or one-time to the budget of the municipal entity;
- the established share of products or the share of income received by a private partner as a result of implementing activities provided for by the agreement;
- transfer of the ownership of property owned by a private partner to a municipal entity.

In order to increase the effectiveness of interaction between subjects of public-private (municipal-private) partnerships, analytical tools that allow assessing the conditions that affect the effectiveness of activities, as well as identifying functional areas that require further development and should be taken into account when planning interaction must be developed. The application of methods for assessing factors is a kind of indicator of the level of methodological readiness of modern managers and specialists to develop partnership activities.

Module 5. Testing the model of public-private partnership in Russian single-industry towns

In order to study the conditions and prerequisites for implementing the mechanism of municipal-private partnership in Russian single-industry towns, the authors conducted a study using the example of the metallurgical urban district of Krasnouralsk.

Currently, the creation and reconstruction of construction projects in the urban entity Krasnouralsk is funded mainly at the expense of budgetary funds.

In the authors' opinion, the private sector is not particularly interested in participating in MPP projects mainly due to the following factors:

1) a long payback period of capital investments (10-15 years) with a non-obvious guarantee of demand for an object, taking into account negative demographic trends;
2) the lack of standard infrastructure projects with a streamlined implementation mechanism (Schaeffer, Loveridge, 2002);
3) the complexity of contractual relations for MPP projects in comparison with the state order or other types of legal relations between the public and private parties. This leads to a higher cost of preparatory and pre-project works and takes much more time at the stage of coordination between the municipality and private sector entities.

In the authors' opinion, the existing norms of federal legislation do not take into account the specifics of municipal entities; a too long procedure for entering into MPP agreements is in place. Therefore, in case of a private initiative, the period from submitting a proposal for the implementation of a PPP project to the moment a public partner makes a decision on the implementation of the project may take up to 330 days, which is equivalent to the period for PPP projects implemented at the federal or regional level. It is necessary to consider the possibility of establishing a more simplified and accelerated procedure for reviewing, negotiating, and entering into agreements for MPP projects. In this case, the dynamics of the number of agreements on municipal-private partnerships could increase.

Conclusion and Discussion

Thus, according to the results of the study, the authors came to the conclusion that currently in Russia there is a tendency to develop mechanisms and models of public-private partnerships (PPPs), which are becoming the preferred form of cooperation between the state and private business and one of the promising tools for developing public infrastructure in long term. At the same time, the role of private investment in infrastructure projects and in the development of territories of single-industry towns is also growing.

Creating and implementing various mechanisms to develop the town and increase its investment attractiveness, including through creating new and reconstructing existing construction projects, is an issue of survival for Russian single-industry towns in the face of a negative demographic trend (population decline and population aging). Lack of investment and financial resources for the development of the economy and urban improvement aggravates the need to attract private investment for implementing infrastructure projects using the mechanism of municipal-private partnership. According to representatives of the scientific community and a number of large domestic companies, MPP is *a promising mechanism for the development of urban economy*.

Ensuring sustainable social and economic development of single-industry municipal entities (monotowns) is one of the priority tasks of Russian state policy. However, the effective application of this mechanism in Russian single-industry towns is impeded by a number of conditions and factors that prevent increasing the participation rate of private investors.

Abstract

In a competitive environment and in the context of accelerating the globalisation process, organisations are forced to develop new strategies to stay competitive on short term, but especially on long term. The organisations are aware and encouraged to integrate and involve themselves in social responsibility issues. Climate change, environmental degradation, social troubles, etc. are addressed in reporting non-financial information. In order to effectively respond these global issues and the requests of the interested parties, the reporting of non-financial information must be harmonised and interconnected with the financial reporting, Ienciu, I.A., et al., (2014). The result of these harmonisations and interconnections is materialised in what we call the integrated reporting of organisations. In this paper one presents a study on how the OMV Petrom Group has identified the aspects of corporate social responsibility, prioritised them and integrated them into the business strategy and integrated reporting. At the same time, the study sets to identify the challenges that the OMV Petrom Group dealt with during the implementation of integrated reporting according to international integrated reporting standards. Once these challenges have been identified, we suggest some best practice recommendations that should be addressed in providing non-financial information through integrated reporting.

Keywords: corporate social responsibility, non-financial information, integrated reporting.

JEL classification: M41, M14, G43

Introduction

By adopting a socially responsible conduct, organisations obtain many advantages, differentiate themselves from competitors and bring their contribution to the sustainable development. Different categories of stakeholders are exerting increasing pressures for the responsible performance of economic activities, James, M.L., (2015). These tendencies are manifesting more and more strongly in Romania, especially after the moment of integration into the European Union. Thus, those organisations that will understand the importance of the new requirements and will act in due time regarding the development of a corporate social responsibility are in advantage (CSR -Corporate Social Responsibility).

Organisations of all types and sizes are called to become socially responsible, ecologically sustainable and economically competitive, Orlitzky M. et al., (2011). Managers could try to maximise the benefits and value of their business, satisfying the expectations of interested parties. However, this maximisation of value cannot be measured only from a financial perspective, but also from a broader approach.

The objective of the paper is to identify the challenges in disclosing aspects of corporate social responsibility in integrated reporting. Once these aspects are identified, we analyze the extent to which OMV Petrom has complied with the five essential principles of the organization's ability to create long-term value.

Research Methodology

Case Study

The research carried out supposed taking the following steps:

- Step one consisted of a documentation regarding the evolution of the process of integration of the corporate social responsibility aspects into the integrated reporting model within the OMV Petrom Group. In this regard, we studied the integrated reporting for the period 2014 - 2018 provided by Omv Petrom (available at https://www.omvpetrom.com).
- Step two: in this stage, based on the documentation made in step one, one proceeded to the performance of a research that consisted of following the way in which the OMV Petrom Group captured the social responsibility aspects in the integrated reporting. At the same time, one also analysed how the integrated reporting models were adopted by OMV Petrom Group and the extent to which it respected the five essential principles of the capacity to create value, namely: connectivity of non-financial information; materiality, the concise character; reliability and completeness; consistency and comparability. In looking for the way to fulfil the application of the five principles we identified the challenges of OMV Petrom Group in disclosing the social responsibility aspects, its approaches, identifying some recommendations.

The management of corporate social responsibility aspects by the OMV Petrom Group is done by integrating them in the structure of the general governance of the organisation. These aspects are treated with the same importance as the economic aspects of the OMV Petrom Group, establishing an organisation scheme that corresponds to the key indicators of social performance. The employed experts of OMV Petrom Group maintain a continuous communication of the progress made in the field of social and environmental aspects, according to the strategy and the objectives of corporate social responsibility by disclosing them in the integrated reports.

The Social Responsibility Department has been developing and communicating for almost a decade the Social Responsibility Platform of the Group, entitled " Țara lui Andrei (Andrei's Country)", contributing with their efforts and ideas to the fulfilment of the sustainability projects for the development of the community. The specificity of the activity sector of the OMV Petrom Group makes it address special precaution measures to support the protection of its employees, its assets, the environment and also the community where it operates. That is why, a first aspect of corporate social responsibility addressed by OMV Petrom Group in the integrated reports is health, safety, security and environment (HSSE).

The commitment of the organisation to lead a responsible activity led to the implementation of a vision called "No injuries-no loss". This vision was implemented with the help of the HSSE2021+ strategy, in which the OMV Petrom Group tried to reduce the risk of employees' illnesses. The HSSE2021+ strategy involved carrying out several campaigns: "Passport for health", "Earn health: now!", as well as over 36,000 screenings, which involved employees in creating a work environment that is beneficial to physical and mental health. During 2014-2018, the rate of preventive consultations increased, leading to a decrease in the risks of illness of employees (figure no.1).

Figure 1: Rate of preventive consultations

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

Another aspect of social responsibility is workplace safety. In 2018, the program "Be smart, Be safe", "Champion in the field of safety", "Take safety home with you" was initiated, through which the organisation identified the risks in the field of safety, and internally certified over 1000 employees at training courses. Workplace safety represents an important goal for the organisation, which is why a series of modernisation and improvement projects have been initiated.

OMV Petrom Group has collaborated with various institutions (European Process Safety Centre, Center for Chemical Process Safety BEACON) for the elaboration of some studies for the application and improvement. OMV Petrom Group complies with the recommendations of the International Association of Oil and Gas Producers regarding the key performance indicators for process safety. These indicators support learning from past events in order to make improvements in the future. In the integrated reporting from 2016-2018 the OMV Petrom Group shows a constant decrease of the TIER1 incidents and the maintenance of the TIER2 type incidents regarding the process safety, figure no.2.

Figure 2: Process safety events

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

Another important corporate social responsibility aspect that is an integral part of the OMV Petrom group objective is environmental management. The organisation aims to minimise the impact of its activity on the environment over the entire life of its products. In order to achieve this objective, the organisation carried out a series of activities: they reviewed the environmental risk assessment registers and implemented measures to reduce it; they elaborated water and waste management reports; they implemented measures to reduce water use; they conducted studies on biodiversity

assessment in the most important locations; they developed the Program "Modelling environmental values through performance" and evaluated its compliance with OMV/ISO14001 Standard.

As for the greenhouse gases (GHG), the OMV Petrom group initiated a project that resulted in the use of solar energy at points that distribute fuel. The results of this project showed a decrease of the impact of greenhouse gas emissions on the environment, resulting in substantial cost reductions, thus increasing social performance: GHG Goal 1 "Direct emissions from operations that are owned or controlled by the organisation" (figure no.3.) and GHG Purpose 2 "Indirect energy emissions resulting from generation of electric energy, heating, cooling or steam purchased" (figure no.4).

OMV Petrom Group shows in the integrated report of the year 2018 a tendency of decrease in the evolution of the impact of the activity on the environment at the level of 2017 compared to 2016 regarding direct GHG emissions. For the year 2018, the organisation explains the reached level of 4.5 million CO2 eq, slightly increased as being caused by the increase of electricity production.

The impact of GHG indirect emissions (emissions related to the production of energy purchased by the organisation for the activity performance) generally had a slight increase tendency generated by the increase of the quantity of electricity purchased, in total consumption by the organisation. The organisation also claims that the purchased energy had higher green CO2 compared to 2017.

Figure 3: GHG direct emissions

The social responsibility aspects captured in the integrated reporting of the OMV Petrom Group during 2014-2018 are synthetized in five main areas: business principles and social responsibility;

safety, health, security, environment; efficient carbon management, employees and innovation. OMV Petrom Group will continue with these areas of interest for which it proposes commitments and objectives for the 2025 horizon (table no.1).

Table 1: OMV 2025 Areas of interest and objectives of social responsibility

Areas of interest	Commitments	Objectives	Sustained durable development objectives
Health, Safety, Security, Environment (HSSE)	HSSE have the highest priority in all actions carried out by OMV Petrom Group. Proactive risk management is key to achieving the HSSE vision of "No injury - no loss"	One of the most important objectives is *to obtain zero accidents at the place of work*. Other equally important goals are also to maintain as leader for the event rate for process safety and stabilising the injury rate at the workplace.	ODD3- Health and well-being ODD8- Decent work and economic growth ODD6-Clean water
Carbon efficient management	OMV Petrom Group focuses on increasing the efficiency of carbon emissions in its operations, as well as the responsible management of waste produced by OMV Petrom Group	Decreased intensity of carbon dioxide emissions by 19% compared to 2010 at OMV1 and up to 4% at OMV2. Reaching the level of zero routine gas flaring.	ODD13- Climate action ODD7- Clean energy at affordable prices
Innovation	Increasing innovation through investments, research and development. Production optimisation and development of innovative energy solutions.	Increasing the share of sustainable raw materials co-processed in refineries at approx. 200,000 tons per year. Increasing the recovery factor in the ECE region in the selected fields by 5% to 15% adopting innovative solutions of assisted oil recovery. ReOil development on an industrial scale approx. 200,000 tons/year.	ODD13- Climate action ODD12- Responsible consumption and production ODD9- Industry, innovation and infrastructure ODD8- Decent work and economic growth
Employees	Creation and maintenance of competent employees. OMV Petrom Group is dedicated to the vision of diversity and gender equality.	Increasing the percentage of women in the management compartments from 3% to 25%. Maintaining the percentage of 75% of managers who have internal experience	ODD10- Reducing inequality ODD5- Gender equality
Business principles and social responsibility	OMV Petrom Group makes efforts to maintain high quality ethical standards. OMV Petrom Group is a	Promoting awareness of ethical principles and values through access to training courses and training sessions on	ODD16- Peace, justice and efficient institutions ODD4- Education and quality

	signatory to the United Nations Global Compact (UN) and is committed to respecting the UN guiding principles on human rights.	human rights for all OMV Petrom Group employees.	ODD8- Decent work and economic growth

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

In its integrated reporting OMV Petrom Group supports responsible behaviour towards all interested parties as a priority and not just an option in carrying out its activity. The integration of the corporate social responsibility aspects represents a journey of the organisation towards the promotion of the leadership test in sustainability. Integrated reporting represents such a good tool - in an era where organisations gain so much reputation for being transparent - that it is a pity to invest so much money, work and energy in a tool just to inform investors. Therefore, OMV Petrom Group considers larger target groups when identifying integrated reporting content. At the same time, the OMV Petrom Group believes that Web-based technology (a tool with all the features that make it simple and easy to use for information searching) can be used to meet the non-financial information needs of all interested parties.

Following the analysis of the integrated reports for the period 2014-2018, we tried to identify the manner of fulfilment of the application of the five essential principles when disclosing the social responsibility aspects. Thus, we identified what challenges the OMV Petrom Group deals with, what approaches it adopts and we identified some recommendations (table no.2).

Table 2 : Non-financial information connectivity - identified challenges, approaches and recommendations

Non-financial information connectivity		
Challenges identified	**Practical approaches**	**Recommendations**
• OMV Petrom Group initially made separate financial and corporate social responsibility reports, that it now integrates into one. This integration is likely to lead to better reporting, which should meet the needs of stakeholders. For example, financial reporting standards require reporting of employee related costs (for example, pensions and salaries). At the same time, the quality of the employees, their involvement and motivation are some of the strongest aspects of corporate social responsibility and, at the same time, indicators of success for any organisation. The information regarding the costs of the employees would be found in the financial reporting, while information on the report of the employees etc. would be found in the non-financial reporting. Achieving connectivity of the two types of information would be a reached goal. • Another challenge of connectivity would be to improve the link between risks and the strategy adopted by OMV Petrom Group.	• One aspect of the connectivity principle is how OMV Petrom Group helps readers navigate between different parts of the integrated report, including the use of cross-references. • OMV Petrom Group uses for its Annual Integrated Report and Consolidated Financial Statements a help page, entitled *About the report*, which presents the symbols used for cross-references on the Internet, from other sections of the report or other group reports. The page also graphically explains how sections of the integrated annual report refer to content elements within the Integrated Report (IR). Then, in a Note to the	• OMV Petrom Group must continue to use technology to help readers navigate between relevant and connected sections of their reports. For example, certain social responsibility aspects, such as health and safety, should be included in a separate section when we talk about the safety and security of the employees or when the OMV Petrom Group refers to the health and safety of external interested parties (mainly the clients of the organisation). • Approaching the integrated report as a general and concise

Connecting the strategy with the determined risks, with the resources held and the moment when these resources are turned into financial resources, would be a reached objective. • Improving the understanding of how the value of resources translates into financial value (building an innovation team, at one point, translates into financial value). • Other challenges in achieving connectivity would be between the social responsibility indicators and the financial results, because a change of the social responsibility indicator will have an impact on the financial indicator which is not immediate, does not appear in the same year, having a certain gap. • Connecting the notions of past, present and future. In order to achieve this connectivity, the OMV Petrom Group must address this by defining several "impact indicators". For example, instead of focusing on "outcome" indicators such as the number of employees participating in volunteer initiatives, an impact indicator would refer to people in the community who have improved their lives as a result of such initiatives.	Management Report, it is usually explained how they approached the principle of connectivity. As part of this explanation, the OMV Petrom Group also publishes an interactive version of the financial statements integrated on their website as another tool to highlight the connectivity of the information. • OMV Petrom Group aims to use technology to help readers navigate between relevant and connected sections of their reports. For example, the report "*Our Energy for a Sustainable Future*" for 2018 includes cross-references and links to sites.	document, connecting other more detailed regulatory reports and information. • Using clear indicators directing readers to connected information from the integrated report and other parts, including online reports. • Making connections between management information, boardroom discussions and priority topics relevant to investors and other interested parties.

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

In an attempt to align with the guidelines of the European Union Directive 95/2014, the OMV Petrom group has developed a vast consultation process with all the stakeholders of the organisation in order to manage in identifying the material issues in the disclosure of the integrated reports. The result of these consultations was the identification of thirteen material aspects that show the major interest of the stakeholders for the impact that is generated by the activity of the OMV Petrom group (table no.3).

Table 3: Materiality - identified challenges, approaches and recommendations

Materiality		
Identified challenges	**Practical approaches**	**Recommendations**
• Reconciling the needs of different interested parties when determining materiality; • Applying materiality filters that focus on identifying the key factors of the organisation. • Identifying material risks in a way that meets the needs of different investors.	• OMV Petrom Group has developed and supported an entire consultation process with the interested parties, both inside and outside the group in order to determine the material aspects for the Integrated Report. The organisation identified thirteen material issues (energy efficiency; local communities; human rights; health, safety and security; innovation and	• Identifying the main user of the integrated report and determining the materiality (therefore - this will be essential to determine what to be

• OMV Petrom Group tends to present in its corporate reports strategic risks such as the volatility of the oil and gas market, climate change, political risks, regulatory risk, risk related to human capital, risk related to technology and innovation. Among these there are risks that are extremely unlikely to materialize. • According to the Framework, the materiality of a risk depends on the size of its impact, if materialised, and on the probability that it will materialise. The probability of natural disasters is low, but the magnitude of their impact could be huge; on the other hand, focusing on such risks might mean that other, more immediate risks are overlooked. One solution might be to include only the material risks in the main body of the report, but offering a more extensive list of risks in an appendix. This could meet the needs of different types of investors (for example, long-term and short-term investors), who may have different expectations from the reporting of OMV Petrom Group.	technologies; environment; greenhouse gases GHG and other emissions; occupancy degree and employees' skills development; supply chain management; ; risk management, water management; business ethics and anti-corruption; hydrocarbon spills) which it has classified into five areas of interest (Health, safety, security, environment; efficient carbon management; innovation; employees; business principles and social responsibility). • Beside these material aspects, the OMV Petrom Group also refers to other additional topics just as important to the organisation and interested parties (product responsibility, biodiversity and waste management). • OMV Petrom Group discloses in the integrated reports explanations about how risks and opportunities must be considered in terms of value creation. These reports include a comprehensive explanation of the risks that the OMV Petrom Group is facing and the measures it takes. • OMV Petrom Group presents a management system for both gross and net risks (risks that exist after taking countermeasures into account), which shows the financial liability against the probability of occurrence or frequency.	included and what to be excluded from the report). • Clear explanation of the process of materiality assessment, including how OMV Petrom Group evaluated and prioritised material problems. • Including a comprehensive explanation of the risks they face and the measures taken.

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

The challenges identified by OMV Petrom Group in revealing the aspects of social responsibility, practical approaches as well as recommendations for best practices for concision are identified in table no.4.

Table 4 : Concise character - identified challenges, approaches and recommendations

Concise character		
Identified challenges	**Practical approaches**	**Recommendations**
• The framework of the report regarding the disclosure of aspects of social responsibility is quite detailed and this can make it difficult for the OMV Petrom Group to produce concise reports that investors can read and understand. • The concise nature is also	• The reporting includes informative diagrams that explain the functioning of the activity of OMV Petrom Group, visually presenting how the product	• Use of cross-references in the OMV Petrom Group report (internal and external to other reports) and the efficient use of several graphical elements, tables, and diagrams. • Identifying problems to be reported by implementing solid materiality determination

a challenge when the OMV Petrom Group wishes to include new aspects of social responsibility addressed, either to meet the regulatory requirements or because the additional content could be useful to the readers. • OMV Petrom Group is also concerned about the risk of losing valuable non-financial information for some stakeholders by focusing too much on the concise character. • Sometimes, the importance of concision can be outweighed so that some primary data accessible on the Internet do not present risks, for instance when non-financial information is used outside the context by the media. • Part of the impulse for greater concision comes from users' feedback. Thus, beside fewer pages, readers may request that financial content be easier to understand for people who are not financial analysts.	supply chain works on the market. • OMV Petrom Group embraced the challenge of concision, applying a mantra of *rethinking, reuse, reduction*. By rethinking the interim reporting approach, the quarterly reports were reduced. sometimes this reduction is impossible to achieve having more specific regulatory requirements and certain detailed notes must be provided.	processes - this would also contribute to improving reliability and completeness. • Applying a robust materiality determination process to filter out the things that must be excluded (i.e. those that are not important for value creation) when assessing their relative importance. • Consider how digital technology could help satisfying the broader information needs of the interested parties. • Online reporting could help to reconcile the need for concision with the desire to provide a detailed social responsibility aspect that some stakeholders may appreciate.

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

The probability that the integrated reporting of the OMV Petrom Group will fulfil its intended function, under set conditions of use, for a specified period of time can be determined by its wish to include as much and as exhaustively as possible the aspects of corporate social responsibility (table no.5).

Table 5: Reliability and completeness - identified challenges, approaches and recommendations

Reliability and completeness		
Identified challenges	**Practical approaches**	**Recommendations**
• OMV Petrom Group is aware that the corporate social responsibility information included in an integrated report should be submitted to similar levels of rigor, if investors consider them useful. However, non-financial reporting is not yet mature. There is a lack of coherence between the many existing non-financial reporting frameworks and standards, and the widely recognised mechanisms that provide corporate social responsibility information have not yet appeared in non-financial reporting. • OMV Petrom Group considers that internal systems and processes hold the key.	• Establishing a firm line for reporting the data from year to year to contribute to the assurance of a more balanced reporting of good and bad news. • OMV Petrom Group attempts to disclose consistent corporate social responsibility aspects from year to	• OMV Petrom Group must make sure that the supervision of the reporting content is exercised by the Board of Directors. • Establishing clear internal control processes for non-financial information that will be included in the integrated reports. • Identifying relevant standards and

The process of obtaining data to an insufficient standard may lead to failure of reporting. For instance, as a main indicator or representative of social impact, the OMV Petrom Group uses to measure the number of professionals it has trained, but it was possible for one person to participate in several training sessions. Thus, the price they pay for reporting social responsibility aspects is, at least in some individuals' opinion, that there is less information about sustainability. • Lack of any *guideline or template* that insurance providers could use when providing insurance for social responsibility information. OMV Petrom Group addressed this issue by creating an annex that shows how the main content areas of the framework were covered and sought external assurance in this regard (establishing an audit process for this). • Looking from a broader perspective, a key issue is that in which the reporting of social responsibility issues cannot be done in a common language to assess whether it is a good report or not.	year, even for those years in which they do not do so well. Explanations regarding the measures taken to solve any issues are presented. • Changes in strategy are explained by the OMV Petrom Group, so that readers are confident that the adjustments are not designed to hide poor results.	frameworks used and disclosing them in the report. • Reporting non-financial information used by management in business management. • Clearly explaining why certain key corporate social responsibility indicators are used and the reason for some changes in the reported indicators. • Disclosure of negative aspects of social performance, as well as positive aspects and explanation of what management will do to meet the challenges.

Source: Adaptation and processing after OMV Petrom, Sustainability Reports https://www.omvpetrom.com/services/downloads/00/omvpetrom.com/1522170967456/OMVPetrom-Raport%20Sustenabilitate%202018

A consistent and comparable integrated report is the expected result by all interested parties of OMV Petrom Group (www.omvpetrom.com). In order to obtain such a report, the organisation took a step forward with each disclosed reporting, adapting to the rigour of the requirements of the stakeholders. However, OMV Petrom Group has encountered many challenges in reporting corporate social responsibility aspects (table no.6).

Table 6: Consistency and comparability - identified challenges, approaches and recommendations

Consistency and comparability		
Identified challenges	**Practical approaches**	**Recommendations**
• Providing significant non-financial information over such a long period can be difficult. While acknowledging the importance of consistency, the OMV Petrom Group considers that it is appropriate to change the measures reported if the organisation has good reasons for doing so and clearly explains this. For example, the indicator showing customer satisfaction can be changed with the indicator showing customer experience, which for the OMV Petrom Group is a better measure, because it uses it for internal management processes. OMV Petrom Group will explain the reason for the change and will include a comparative figure for the previous year. OMV Petrom Group is currently more	• OMV Petrom Group presents its economic and corporate social responsibility aspects through figures and tables for a better consistency and comparability from one year to another. • If the OMV Petrom Group will want to start using new key indicators of corporate social responsibility, procedures and a rigorous internal control are established first.	• Including specific social responsibility indicators for comparability for several periods of time when they are available. • The keeping by OMV Petrom Group of the same specific indicators of social responsibility from year to year, if it does not have to change them to

concerned about internal consistency and reporting consistent measures over time than with reporting information comparable to those of other organisations. • There are certain convergences in the sectors. For example, for human capital, staff employment measures become a common practice. Another convergence - the comparison between market participants that is not a short-term target. Market participants need time to adapt and find the right balance. They do not see player comparison as a priority. The priority here is to disclose the way of creating values in an authentic, concrete, and substantial way. • Challenges regarding the production of non-financial information that can be compared between the OMV Petrom Group and other organisations who are concerned that the interested parties will compare pears with apples because of differences in how organisations calculate and present specific indicators of social performance. • We are many light years from comparability on certain topics. This is partly due to different legal regimes around the world, which may require or prohibit the reporting or collection of certain information (for instance, information about the ethnic origin of employees).	• When developing new indicators for the environment or social performance, they undergo a review before being presented in the integrated report. Then, comparable data are presented for two previous years, in order not to produce the opportunity to be taken out of context. • The corporate social responsibility indicators must be consistent data, and therefore OMV Petrom Group does not introduce a new corporate social responsibility indicator until it has three years of data disclosed by the report.	improve the utility and relevance of the comparability of non-financial information for the interested parties. • Explanation by OMV Petrom Group of any modification of the selection or calculation of specific indicators of social responsibility from year to year. • The adoption by the OMV Petrom Group of a robust review process for any new specific social responsibility indicator to ensure the significant character from one year to another.

Conclusions and Discussions

Reporting information on sustainable development helps organisations define goals, measure performance, and adopt changes for the performance of more sustainable operations. A sustainability report provides information regarding the positive or negative impact of the actions of the organisation on the environment, society and the strategy of the organisation, Velte, P.; Stawinoga, M. (2017). The integrated reporting of any sustainable organisation must include the following elements: an overview of the performed activity and the external context, the risks, and opportunities of the activity, as well as the strategy and governance, IIRC (2013a.). All these content elements represent the business model that shapes the performance of the sustainable organisation.

Integrated reporting allows organisations to identify more clearly and fully what really drives them forward. This leads to a greater clarity regarding business management, determining the challenges and finding the opportunities. The next steps of integrated reporting are represented by the way technology can be used to help the interested parties to access more effectively the data they need. The organisations are aware that there are a lot of possibilities to display information, so it would be easier for the interested parties, especially the investors, to gather all the data they need and analyse it, Dura, C., Baron, O.D. (2015).

Following the documentation made on the integrated reporting of the OMV Petrom Group, we conducted a research on how the corporate social responsibility aspects were captured in the

integrated reports. Upon this research, it was outlined that the OMV Petrom Group has made sustained efforts to reduce pollution, being also concerned about the involvement in various corporate social responsibility actions. The case study revealed a significant presence of the term sustainability in the integrated reports published in the period 2014-2018. Moreover, the study carried out on the integrated reporting of the OMV Petrom Group highlighted a superior use of the corporate social responsibility aspects.

The annual integrated reports of OMV Petrom Group for 2014-2018 include information on the financial, social, and environmental performances. They also include long-term social and environmental goals. Each integrated report also provides a brief explanation of the performance against the goals related to water and energy consumption, also providing the context necessary to assess the social performance of the organisation. In this manner, the OMV Petrom Group has demonstrated its responsibility regarding its performance.

In its 2014 Annual Report, the OMV Petrom Group included for the first time a statement of the Board of Directors and of the executive management, according to which the report was prepared in compliance with the GRI international standards. One defines in the report the principles and content for filling in sustainability reports and they are submitted to the GRI context indexing standard. The sustainable development goals approved by the General Assembly of the United Nations, which OMV Petrom Group integrates in its strategy, are presented in the annex Areas of interest and the objectives of social responsibility OMV 2025.

OMV Petrom Group states that they have approached a continuous process to improve quality and control over environmental and social data. The audit committee requested that all non-financial data have the same validity as the financial data. The chapters on human capital management and environmental management include indicators whose sphere includes information about group affiliates due to the impact of the problems shown by the report. This applies to biodiversity indicators and labour force indicators. Once this process was finalised, the Audit Committee accepted that all data is of equivalent quality. For the integrated reports of OMV Petrom Group to make specific reference to the compliance with the international integrated reporting framework, a separate process has been conducted. In this way, the report offers a complete and balanced overview of the group's position and performance, while also demonstrating responsibility, concision, materiality, and reliability.

OMV Petrom Group has understood that it must develop its understanding and capacity to integrate corporate social responsibility practices into its business strategies, because such activities can lead to long-term profits, competitive advantage, and consolidation of the product position on the market. The result of all social responsibility activities is the creation of long-term value of the organisation.
We consider the relevance of the research o represents knowledge of how OMV Petrom has approached the best practices of corporate social responsibility in integrated reporting. These approaches could serve as examples for other organizations to change their paradigm and make the CSR strategy part contribute to their business.

A future way of research that we intend to explore is the possibility of developing a theoretical model to establish the thematic representation of the best aspects of corporate social responsibility in integrated reporting that can be followed by other organizations operating in similar branches or in affiliated sectors.

Abstract

Work intensification has risen the working time for employees and challenges the balance of time allocation in their life. Using dispositional theory, we examine how employees perceived working time and its implication to their work satisfaction. The working time perception variable is elaborate into four dimensions, including discipline, incentive, knowledge, and commitment. Based on a survey of 320 employees, we conclude that working time perception have a linear influence to work satisfaction with a fair intensity. We conclude that employees who are bounded by their work setting would have a fairly work satisfaction when they perceived their working hours positively.

Keyword: Working Time, Work Satisfaction, Individual Trait, Dispositional Theory

Introduction

Work intensification is turning into a mainstream management approach amid the liberal economy. The approach promotes employees high-performance to achieve organization efficiency (Green, 2001). Organization management arrange workloads that takes longer working time and require higher skills to complete (Burchielli, Bartram, & Thanacoody, 2008; Peetz, 2019). Employers can ask for more effort to their employees by giving them a relative degree of discretion to do their job and remunerate their endavour based on performance (Bartling, Fehr, and Schmidt, 2013). In this sense, employees are divided into two groups, one that is able to arrange the work setting and one that only follows (Clark et al, 2014).

Work setting arrangement modify working environment for employees to adapt when they are living their organization's life (Goodarzi, Nurmi, & Rantanen, 2015). One of the objective factors in the work setting arrangement is working time. Working time shapes workers experience and influence their productivity (O'Carroll, 2015; KÜnn-Nelen. De Grip. And Fourarge, 2013; Azwir dan Satriawan, 2018). There are two groups of interest regarding to the working time arrangement in organization. The employer arranges work hours in their favor to generate maximum production output, which makes them prefer longer working hours. On the other hand, the employees prefer shorter working time so that they can have more time to arrange their personal life and wellbeings (Vielers, Münderlein, and Koster 2013; Garnero, Kampelmann, and Rycx, 2014; Leuze and Strauß, 2016). These two opposite

Cite this Article as: Umar BAIHAQKI, Meila Riskia FITRI And Wulan A.KHAIRUNISA "Vigor at Work, How Employees' Perception of Working Time Influence Their Work Satisfaction" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

interest is not symmetrical, whereas the employer has a better bargaining position and the employee is in the position to comply (O'Carroll, 2015; Watson, 2008 : 246).

However, the employer should not unilaterally determine working time. Several studies on working time concludes that working time have a nonlinear correlation on productivity (Beherens, 2013; Bannai and Tamakoshi, 2014). Employees' working time only support productivity rate until a certain turning point where adding more working time would reduce their productivity. Excessive working time are hazardous to employees' health and also become one of the occupational stress factor that cause anxiety. Long working hours could generate health issue whereas employees do not have enough time to rest, which increase the possibility to fall sick and force them to absence from their work (Nätti, Oinas, & Anttila, 2015). This issue could harm organizational productivity due to employees' absence because of health reasons. Prolonged work hours and excessive workload also raised the psychological risk of employees (Boschetto, De Rosa, & Marini, 2016). Long work hours increase the work-family conflict which reduces the ability of the employees to focus on what they are doing in the organization (O'Carroll, 2015; Burchielli, Bartram, & Thanacoody, 2008). Therefor work hour is not a one-dimensional concept, and it is more useful to understand work hours from the employees' perspective (O'Carroll, 2015).

Employees responses to work time arrangements vary according to the context they are experiencing. Part-time employee and the full-time employee has a different way to perceived working time in this sense. For part-time employees, especially those who are paid based on their working time, they tend to work extra hours to get more income (Vielers, Wanrooy and Wilson, 2006; KÜnn-Nelen. De Grip. And Fourarge, 2013; Münderlein, and Koster, 2013; Garnero, Kampelmann, & rycx, 2014; Baihaqki & Jahja, 2019). Meanwhile, full-time employees with a fixed income from their employer prefers shorter working time. They perceived working time as a part of their workload, and would prefer to outsmart their work setting to reduce the workload by taking leave, absence from the office, or even quit their job (Surachman, 2016; Nätti, Oinas, & Anttila, 2015; Ruppanner & Maume, 2016). These two-argument depict the subjectivity of employees' perception on work time arrangement. Therefore it is useful to use the dispositional theory that covers individual perceived work setting, and how that perception influences their work satisfaction (Peng & Mao, 2015; Judge, Bono, & Locke, 2000; Cropanzano, James, & Konovsky, 1993).

Dispositional theory see individual behavior influence worker behavior. This research describe individual as worker who perceive his/her working time. This view leads them to the strategy to finish the job within a certain time. Regarding working over time, employee consider that they will receive rewards, namely incentives and more knowledge. The reward then affects their work satisfaction because it is obtained from the success of managing self-esteem, being confident in their skill and being able to control the situation in the form of pressure from supervisors (Mitchell, Smyser, & Weed, 1975; Ford & Collinson, 2011), team members (Frazier, et al, 2015; Zhai, Lindorff & Cooper, 2013), as well as the working time (Okulicz-Kozaryn & Golden, 2018).

Thus it becomes important to discuss the effect of working time on job satisfaction. Ideally, the ideal working time is 8 hours a day (Bannai and Tamakoshi, 2014), but in fact employee often spend longer than the office. The working arrangement may also encourages employee to complete the work on time by providing incentives. Accordingly the goals or targets of the organization could be achieved effectively and efficiently. Therefor this article continues to elaborate the impact of employees' working time on their satisfaction.

Personal Trait and Work Satisfaction

Social environments nurture personality traits through social relations. Work setting creates a certain environment that is intended to influence employees' behavior (Goodarzi, et al, 2015). The Worker

adaptation to the dynamic of their work setting in the organization are varies according to their personal traits. Dispositional theory explain the importance of personality trait to regulate the mood of an individual toward his/her environment. Several studies have used this theory to explain the relationship between employees personality as a factor of their work satisfaction. The first group of study focus on self determination as an internal drive of individual action that support his or her approach to adapt to organizational change. (Shogren, et al, 2015). Self determination is an outonomous desire to actualize his/her interest that is driven by personal disposition. The next group of study put more attantion to the organization as a dynamic environment that influence workers wellbeing (Frazier, et al, 2015). Workers consciousely evaluate their attachment to the organization, including their trust and confidence of the fulfillment of their personal interest through organization (Frazier, et al, 2015; Samnani & Singh, 2016; Peng & Mao, 2015). The worker use self efficacy to evaluate his/her position in the organization through in response to organizational trietment.Worker who is personally fit to his/her organizational environment has higher job satisfaction than the one who continously struggle to adopt with the work setting (Peng & Mao, 2015). Judge et al (2000) have elaborated self core evaluation of individual employee as a variable that influence employees work satisfaction into four dimensions: self-esteem, self-efficacy, locus of control, and neuroticism (Judge, Bono & Locke, 2000: 237).

Working life build self-esteem to the worker by giving a sense of identity according to their role in society (Grint & Nixon, 2015; Baihaqki & Jahja, 2019). However, the meaning of work for an individual also depends on how they perceived their role in the job they are working on. Employee evaluates their role in an organization, whereas they would be motivated when they are involve in the achievment of organizational goals (Nencini, Romaioli, & Meneghini, 2016), and the social relationship with their colleagues (Zhai, Lindorff & Cooper, 2013).

Self Efficacy also plays an important role to job satisfaction. Employees are actualizing themselves through their work, therefor person job-fit would improve their commitment to the job and cope with other demands from outside of their organization life (Peng & Mao, 2015). The high-performance working system stated that a certain amount of discretion would benefit employees and increase their performance, and thus their satisfaction (Bartling, Fehr, & Schmidt, 2013; Okulicz-Kozaryn & Golden, 2018). Employees perceive that they have an acceptable locus of control which makes them able to control what is important in their working live (Mitchell, Smyser, & Weed, 1975).

Working Time Arrangement

Modern organizational management aims to create a competitive production process. Organization management use flexible work arrangements to coopt with the liberal competition. These flexible arrangements could be classified into functional flexibility and numerical flexibility (Peetz, 2019). Functional flexibility refers to managerial settings that treat employees as an active resource that are able to develop themselves. Employers start to intensify the workload of their employees. They manages human resources so that their employees are ready to adapt to variety of workloads. Numerical flexibility puts the number of workers or the hours they work according to the needs of the organization. Employers arrange the remuneration system for their employees to pursue efficiency. Hourly wages and overtime wages are replaced by periodic full-paid incentives. This system benefits employers because they do not need to pay employees who have to worked overtime to finish their tasks. Since employee also has received benefits, their productivity expectations have also increased. Thus, employees perceive working time as part of the worload because it relates to the incentives they receive.

Working time perception is not a one-dimensional concept, such as the amount of time spent working. This notion is perceived differently by the employer and the employee. For employers, working hours are a variable of productivity, whereas increasing or reducing work hours would influence the production output. Employers may give incentives for their employees to work extra time. The high-performance management system suggests discretion for employees in completing an extensive workload (Bartling, Fehr & Schmidt, 2013). To maintain employees' motivation, management also

provides a relatively huge benefit for employees who can achieve their given target. This work arrangement is aimed to nurture self-motivation from the employee to be responsible for their achievement, as employees may need more time to finish their task. Therefore they voluntarily work overtime so that they would get the full benefit from completing their task.

Employees perciefed working time as part of their workload, thus the amount of work hours also influences their work satisfaction (Boschetto, De Rosa, & Marini 2016; O'Carroll, 2015). They realized that their labor are paid from their productivity, and the number of hours they spend working are one of the basis to value their performance. They perceive that having more working hours could generate more income for them (Vielers, Münderlein, & Koster, 2013; Wanroy & Wilson, 2006). However, allocating their time for work would reduce the time for their other needs, namely for their family life and recreation. Thus spending more time for work is considered as a determinant factor that generate work to family conflict, since work has taken most of the time to maintain employee's family live (Yeh, 2015; Clark, et al, 2014; Voydanoff, 2014; Kelly, et al, 2014). To reduce the risk of work to family conflict, one should compartementualize their organizational life and family life strictly.

Spending more time to work also increase employees' fatigue which increase the risk for employee's health and their psychological distress. Overwork and being unable to refresh their physiq and psychology also known factors for depression and physical illness, that force employees to take absence for health reason (Nätti, Oinas, & Anttila, 2015; Bannai & Tamakoshi, 2014). Another reason work hours become a stressor factor is because it generates work-family conflict for the worker (Yeh, 2015; King, et al, 2014; Voydanoff, 2014). However, it not always be the case that shorter work hours would be guaranteed less work-family conflict as concluded by Ruppanner & Maume which stresses the presence of an individualistic cultural ideology that interfere how worker balance their time for organization and family (Ruppanner & Maume, 2016). Long work hours make workers seek for an adaptive strategy for balancing their organization life and family life (Hill, Märtinson, & Ferris 2004).

Method

The literatur review concludes work hours is a multidimensional concepts that also useful to explain employee's work satisfaction. This article presents a model for the influence of the working time perception to employee's work satisfaction. Respondents are given questions with four responses categories coded in number 1 through 5 which are refers as follow: 1= very low, 2 = low, 3 = fair, 4 = high, 5 = very high. Our hypothesis is working time perception influences work satisfaction. To test this hypothesis, we survey 320 employees from various formal organizations. Form their responses, we built a linear relationship model between the two variables.

The working time perception variable is measured from employees' perception of the work hours at their workplace. Dispositional theory suggests that every individual is driven by their personality trait. Employees who are fit with the workting time arrangement as part of the work setting in their organization perceived the official work hours positively. The worktime perception variable value composed of the four dimensions, which include: Work time discipline (Xd1), Work time incentive (Xd2), Work time knowledge (Xd3), and Work time commitment (Xd4). The work time perception index is obtained with the following equation:

$$X = (\Sigma Xd1i) + (\Sigma Xd2i) + (\Sigma Xd3i) + (\Sigma Xd4i)$$

The respondents were given questions as follows:

The dependent variable in this study is job satisfaction. We follow the work of Timothy Judge in describing employee work satisfaction perception into four dimensions of personal trait, including self-esteem, self-efficacy, locus of control, and neuroticism. The measurement elaborated into four dimension variables, which include: Self Esteem, (Yd1), Self-efficacy (Yd2), Locus of control (Yd3) and neuroticism (Yd4). The job satisfaction index obtained by the following equation:

$$Y = (\Sigma Yd1i) + (\Sigma Yd2i) + (\Sigma Yd3i) + (\Sigma Yd4i)$$

*p < .01; * p < 0.05; ***

Product moment correlation is used to test the validity of each question to measure both of test variables. The validity test result show that all items are valid and included in the idex variables equation. A regression test is used to verify the relationship model between the two test variabel, that employees working time perceptions influence their work satisfaction. The regression test includes three satistical assumption, including normality test to ensure the varians of collected data is distributed normally; liniearity test of the two test variables to verivy the best model to depict the relationship between work time perceptions and work satisfaction.

Participants

The respondent involved in this survey are those who has work more than 12 months. They are employees who work in government or privat institution with a formal working agreement. Therefore, all the respondent has sallary above the official minimum paymant in the city and considered as a middle income. Respondents were recruited using snowball sampling technique. The were given the questionnaire link via through their social media accounts.

Finding and Discussion

Workers have a low perception of their work time. However, the elaboration in the perception of work time variables shows the variation of values in its four dimensions. Measurement of the perception of work time divided into four dimensions. Workers who have a good work time discipline are punctual in starting work and returning from work. Their knowledge of the detailed regulations regarding their working time is also high. However, they tend to take for granted in responding to work time. They do not question the details of working time regulations in their respective institutions. However, workers are aware of the incentives provided by their offices concerning work time. They also realize that the remuneration system in their office no longer provides an incentive for working extra time. Thus, their commitment to completing work outside office hours is low. This particular finding supports the conclusion from the previous study that suggests workers prefer shorter work hours.

Table 4: Test Variable Dimensions Index Values

Work Time Perception Dimension Variables	**Mean**	**St.dev**	**Meaning**
Work time discipline	3.63	1.03	High
Work time incentive	3.57	1.12	High
Work time knowledge	3.94	1.08	High
Work time commitment	3.05	1.16	Fair
Work Satisfaction Dimension Variables	**Mean**	**St.dev**	
Self-esteem	4.39	0.80	High
Self-efficacy	4.31	0.73	High
Locus of control	4.15	0.765	High
Neuroticism	3.69	0.88	High
N = 320			

Most respondents have a high perception of work satisfaction. Based on the calculation results, the majority of employees have a high work satisfaction on self-esteem dimensions, self-efficacy dimensions, and the locus of control dimensions. The respondent has a lower score in neuroticism dimensions, but the score is quite close to the high margins. These findings confirm that highly educated workers have a relatively high level of anxiety. Since they have relatively long working time, this finding also confirms that longer work hours do put employees at a higher risk of distress. Based on the result of the index scoring from both of the test variables, we conclude that higher work time perception can lead to higher work satisfaction.

Table 5: Test variables index values

Test Variables	**Mean**	**St.dev**
Work Time Perception Variable	3.39	0.92
Work Satisfaction Variable	3.94	0.72
N = 320		

The descriptive analysis from this survey is consistent with the conclussion of most previeous studies on the meaning of worktime for workers. Employees prefere shorter working time. This finding also confirms the worker's perspective on the flexibility of work time. They perceived work time as the time they spent at the office to do activities that are related with their work. Therefor working overtime means the time that are spend to do work after official work hours, no matter where it takes place, eather in the office or other places. Thus, the ability to complete work task in the office, and not bringing work to home also support their work satisfaction.

Table 6: Linearity Test

Test	**F**	**sig**
Linearity	59.1188	0.00**
Deviation from Linearity	10.5	0.027

*p < .01; * p < 0.05; ***

perception variable and work satisfaction. The result shows that the Linearity *p* value is lower than 0.05 but the deviation from linearity *p* value is lower than 0.05 which means that the assumption of linierity model is not fully satisfied. Thus further analysis to test the linier model relationship is needed. We proceed to examine how exactly employees work time perception influence their work satisfaction by deviding work time perception variable to two categories using its mean value as the reference of separation. The model summary of the regression analysis is depicted in table 7.

Table 7: The Regression Model

Predictor	**R^2**	**F**	**B**	**SE B**	**β**
Higher Perception of Working Time	.141	26.416**	0.638	.124	0.375**
Lower Perception of Working Time	.004	.675	.093	.113	.066
Work Time Perception	.133	48.659**	.355	.051	.364**

*p < .01; * p < 0.05; ***

The test on the relationship model between two variables concludes that the work time perception variable only influence work satisfaction when it is perceived positively by the respondent. Based on the regression model, we interpret the appropriate model is that the perception of work time affects job satisfaction linierly. The model indicates the strength of the relationship between two variables is low, with an R-value of 0.364. The R^2 value indicates that the work time perception explains 13 % of their work satisfaction. Although work time perception only explains a limited amount of work satisfaction, the model is significant to represent the relationship between the two variables empirically.

The regression model developed from the survey results indicates a linear relationship between the test variables. It is reasonable to conclude that the higher attention of employees to their working time, the higher their work satisfaction would become. This finding is different from the group theory that stated working time have a nonlinear influence on employees' productivity (Beherens, 2013; Bannai and Tamakoshi, 2014). A linear model is more appropriate to explain the relationship between employees' working time perception and work satisfaction. There are two reasons explain this difference. First, the perception of work time is more complex than merely the amount of hours spent on work. Working time perception is a set of values compose from incentives, knowledge, discipline, and commitment regarding the working time. Each employee perceived the four components based on their personality. These multi-dimensional measurements can accommodate the contributions of the four factors which the employees consider when they allocate their daily time for work-related activities.

Second, this research also demonstrates how the work satisfaction could serve as a predictor of how workers respond to management flexibility. Employees are adapting to flexible work settings that are applied to serve employer's interests more than theirs'. A management culture with low trust has intensive control of employee behavior (Peetz, 2019). Management replaces hourly overtime wages with fixed monthly performance incentives. This makes employees are pursuing to meet all requirement to get a full incentive from their work, including working overtime. This phenomenon is becoming more intriguing because an individual-level each employee enjoys wage increases, but at the aggregate level, the employee's productivity decreases.

Workers' adaptation to working time arrangement reflected in the neuroticism dimensions. Based on the survey finding, the neuroticism dimension has the lowest value among the four dimensions of work satisfaction. These findings indicate a high intensity of management in regulating employees' behavior at work. Thus, workers understand that working hours are directly related to their income, so they are willing to work for a long time. However, long working hours are still limited only when they work in the office. Workers do not take their work home, so the time allocation for work, family, and recreation remains strictly compartmentalized.

Conclusion

A high-performance working system in a modern management system provides flexibility for work settings for employees. The implementation of this type of flexible work setting has created what is called numerical flexibility, which applied by arranging employees' working. Although every worker bounded by formal provisions enacted by their respective organizations, the respondents in this research responded differently to their working time setting arrangement.

Working time is significant because it is part of the daily lives of workers. The working time perception refers to the division of time allocation in one day, namely for work, family, and recreation. Moreover, work satisfaction can provide crucial information about the meaning of work time in the life of a worker.

Based on the research findings, there are several things to note between the effect of work time to work satisfaction:

1. The working time perception is more than mere knowledge about time. In a high-performance working system management, work time has become an integral part of the remuneration system. Thus workers also anticipate the incentive that they could receive form the amount of time they spend to work. It generates a complex perception that involves knowledge of benefit and behavior to achieve their interest.
2. Work time perception has a relationship with moderate intensity on work satisfaction. The nature of the relationship tends to be linear: the higher the working time perception, the higher the work satisfaction of an employee would become.
3. The majority of respondents involved in this survey were workers with a tertiary education background. So it is reasonable to assume that they are part of the blue-collar worker group that has relative freedom to determine their work arrangements. By considering the link between their working time perception, and their work satisfaction, the finding of this study support the theory of high-performance working system, which suggest that discretion for workers would raise their performance.

Abstract

The trend of students' food selection today has changed in line with the prevailing development. Food is no longer seen as only a necessity in life, but it also reflects the social status of students that sadly manages to overrule health issues and academic achievements. This study was conducted to examine the student literacy level on the effects of fast food consumption and the trend of fast food intake among students of University A. The results from the analysis found that the student literacy level on the effects of fast food intake was high with a mean value of 4.27 and most students only consumed fast food as snacks in the evening at their own residences. This fast food consumption trend shows that students did not consider fast food as their main meals but only as their light meals or snacks.

Keywords: food literacy, food consumption, fast food, academic performance.

Introduction

The current economic development of the world has caused a significant increase in the growth of fast food premises in many countries including Malaysia. This has also contributed to the changing lifestyle of individuals, especially on the food intake patterns and healthy eating habits. Today, food is not only seen as a basic necessity in life but is also associated with individual social status. Individuals who enjoy expensive food in luxury restaurants and fast food restaurants are said to have higher standard of living than those who cook their own meals at home. Not only that, the food trend at fast food premises has also become a culture of socializing, relaxing and meeting mediums to discuss business issues and completing assignments among students (Abdullah and Ali, 2011).

Life in the university has changed students' lifestyles. Students are responsible for determining their own food intake patterns comprising of healthy, balanced diets. This is because the food intake practices among students would affect their health and academic achievement (Abdullah and Ali, 2011). Imbalanced diet would cause psychological effects as well as chronic diseases and non-communicable diseases such as obesity, diabetes, hypertension and cardiovascular diseases (Ha and Caine-Bish, 2009). Unhealthy eating habits would cause the students to become lethargic and unable to focus during their learning session (Azeman, 2017).

Within four years, Malaysia has experienced an increase of 27% in obesity; from 10.5% in 2010 to 13.3% in 2014 (The Star, 2018). In 2015, Malaysia continued to be the nation with the highest rate of obesity in Southeast Asia with an increase of 18% (Bernama, 2019). This status reflected the health of Malaysians where many of them were vulnerable to the dangers of non-communicable diseases (NCDs) such as diabetes, cardiovascular diseases and hypertension. National Health Morbidity Survey statistics (NHMS) in 2015 once again showed that Malaysia has become an obese country, where one in two adults were overweight or obese. While in 2018, 5.5 million Malaysians (30.6%) experienced the problem of obesity (Bernama, 2019).

Cite this Article as: Khairunesa ISA and Asliaty ATIM "Trends of Fast Food among University Students" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

What is more alarming is that, if these statistics continue to increase, the population density of Malaysia will include a high number of obese people and the country will face the risk of having the highest record of non-communicable diseases. In addition to that, QSR Brand has planned to open at least 67 new KFC outlets and 60 Pizza Hut restaurants throughout Malaysia by 2021, along with 50 KFC drive- through at PETRONAS stations throughout the country during the same period (Bernama, 2018). In terms of students' food intake patterns, a well-balanced diet will affect their health, as well as their physical and mental developments or responses in the learning process. Therefore, this study was conducted to examine the level of student literacy on the effects of fast food intake and the trend of fast food intake among students of University A.

Literature Review

Food is a basic necessity for living things to survive. Other than enabling people to move and be healthy, food is also needed to help protect the body from being vulnerable to disease threats. The world of nutrition has transformed from cases of health problems that were due to lack of nutritional food to cases of food surplus such as obesity, cholesterol, diabetes, hypertension and heart diseases. The Lancet Journal in 2011 reported that nearly 350 million adults worldwide had diabetes, which had doubled since 1980 (Zhou *et al.*, 2016). Meanwhile, Malaysia is said to be the fattest nation with the highest obesity rate in Southeast Asia, besides ranking sixth in the Asia Pacific region and 17th in the world in terms of the number of people with diabetes (The Star, 2018). It is said that about 54 percent of adults are obese and this shows that seven out of 10 adults in Malaysia are suffering from chronic illnesses (The Star, 2018).

There are many factors that influence the trend of food selection among students such as food environment, habits, traditions, food traits and individual social status (Bailey and Tian, 2002). Students prefer to select and buy food based on a number of things such as the quality of service, price and buying incentives (Verma, Plaschka and Louviere, 2002). Meanwhile , argued that the selection of food can be influenced by psychological aspects, according to the individual psychological influence on food selection stated by (Yeung Ruth and Morris, 2001). Some view by (Abdullah and Ali, 2011) discovered six aspects that influence students' food selection which are the menu, meal time, eating venue, meal expenses and respondents' perceptions about the eating purpose and other food related matters.

There are two factors that affect the selection of food which are the internal factors such as individual physiological needs and health, and external factors which are social demand. According to (Li, 2011), the price of food and the suggestions given by parents are the factors that strongly influenced students in their food selection. However, the attitude of parents who are more likely to buy food than to cook meals at home has caused children to become obese. Therefore, it is not a surprise when the United Nations Children's Fund (UNICEF) study shows that child obesity in Malaysia is second highest in Southeast Asia, after Brunei (Liyana Hasnan, 2019).

Findings by (Maria Erica S.D. Dumlao., 2014) showed three main factors that affect the selection of food among students, namely demographic characteristics, food characteristics and the frequency of the food menus offered. She added that income level in the demographic characteristics is said to influence the selection of food amongst students, besides food characteristics such as food size, food presentation, cooking preparation and value for money (Maria Erica S.D. Dumlao., 2014). (Blešić *et al.*, 2018) also found that other factors such as food quality, food presentation, menu options, hygiene, service and distance influence individuals in selecting their food items.

Research Methodology

This study involved 130 students, who were randomly selected from University A. Questionnaire was used as the instrument to determine the level of student literacy on the effects of fast food consumption and the trend of fast food intake among students. All data was analysed descriptively using SPSS version 20. The 5-mark scale measurement which are 1- strongly disagree, 2-disagree, 3-neutral, 4-agree, 5-strongly agree were provide in the questionnaire items. It classified into low,

moderate and high with the indicator based on the Mean score as shown in Table 1 which indicate as student literacy level on the effects of fast food intake.

Table 1: Indicator of student stressor

Grade	Score Mean
low	0.00 - 1.66
moderate	1.67 - 3.33
high	3.34 – 5.00

Result and Discussion

A total of 130 students consisting of 61.5% women and 38.5% men were involved in the study. More than half of the respondents (62.3%) aged 21-26 years old while 36.2% were below 20 years old. Majority of the respondents were staying in the residential college. The demographic respondent is tabulated in Table 2.

Table 2: Demographic of respondents

Variables	Attributes	Frequency	Percentage
Gender	Male	50	38.5%
	Female	80	61.5%
	Total	**280**	**100%**
Age	≤20 years	47	36.2%
	21-26 years	83	63.8%
	Total	**280**	**100%**

The results of the analysis show that the student literacy level on the effects of fast food intake was high with a mean value of 4.27 where almost all students stated that fast food had a negative impact on health. Most respondents agreed that fast food such as snacks or junk food could contribute to kidney damage (67.7%) and dementia (36.2%), whilst majority of the respondents (93.6%) agreed that carbonated drinks may contribute to diabetes. In the context of fast food such as burgers, fries and pizzas, almost all of the respondents (94.6%) agreed that frequent intake of fast food could induce obesity. The findings show that although students were aware of the negative effects of fast food intake, more than half of the respondents agreed that the selection of fast food was made due to quick service (62.8%), good taste (58.9%) and cheap (31.4%).

Nevertheless, the analysis shows that the frequency of students' fast food intake was at a moderate level with a mean value of 2.50. This shows that most students consumed fast food in moderate quantities where most of them 'always' had instant noodles (21.5%) followed by fries (15.4%) and soft drinks (13.1%). Most respondents had these selections of fast food for dinner after 7pm at home (62%) compared to only a small number of students (4%) consumed fast food for dinner at fast food premises.In addition to that, the level of intake for other selections of fast food such as burgers (47%), pizzas (68.5%) and nuggets (56.2)was relatively low. This shows that students still had the awareness to choose a healthier meal options, rather than eating unhealthy food that taste good (Ika Suswanti, 2014).

Conclusion

In conclusion, it can be argued that University A students had a high degree of literacy on good nutrition practices and the negative impact of fast food intake. Respondents agreed that fast food

intake have negative impact on the health and body system, as well as the academic achievement of the students. According to 1 excessive fast food intake would affect the students' academic achievement. Even when there is no scientific evidence to confirm the findings, scientifically, the high content of chemicals and seasoning ingredients in the provision of fast food will have adverse effects in the long run. Because of this, only a small number of students consumed fast food such as instant noodles on regular basis as they found that fast food is quick, delicious and cheap 14. Meanwhile, the selections for other fast food such as fries, burgers and pizzas among students may be due to the influence of advertising on mass media and the rapid growth of fast food premises in the surrounding areas, besides their quick service and relatively low prices compared to other traditional food 11.

Acknowledgment

We are grateful to all of those with whom we had the pleasure to work during this project. Also, thanks to UTHM which is support this project

Abstract

Volunteering is not only give benefit to the recipients, this noble pursuit will also present a positive impact on individual self-development especially among youth. As youth, they are encouraged to be actively involved in voluntary activities in order to train themselves with good soft skills. However, youth participation in volunteerism is said to be at an unsatisfactory level. Therefore, this study was conducted to determine the youth' level of willingness to participate in voluntary activities and discuss the challenges faced by them in participating in the activities. The findings show that the students' level of willingness to participate in voluntary activities was positively high and the level of the challenges faced was only moderate. In conclusion, it can be suggested that a clear understanding and recognition of the concept of volunteerism need be emphasized in order to produce more youth who have the spirit of volunteerism.

Keywords: Volunteerism, Self-development, Willingness, Motivation, Challenge, Youth development.

Introduction

Volunteerism is a concept of work or service that provides aid willingly and sincerely without being forced by any party or intending to obtain any material compensation (Bahari, 2004). Voluntary work can produce an individual who are sensitive and accountable to the social and environmental issues of the community because they are motivated to help solve the imbalance in the society. Bezruchka (2000) defined volunteerism as a deed of serving the community with no expectation of either reward, payment or exchange of goods. Based on that concept, Houle and Kaplan (2005) found six core values required for the development of volunteerism, which include paying no attention to remuneration, sincerity or willingness, mental and psychological readiness, high commitment, selflessness and sacrifice.

Youth participation in various areas of volunteerism such as community service, technical, sports, health, publications and cultural arts can enhance their own identities. Youth is the time of life when

one is young, and often means the time between childhood and adulthood (Macmillan, 2009). As a student, they can confront more obstacles than others throughout the responsibilities that they faced while managing the campus life and adjust to the new challenges (Tinto, 1987). Based on the volunteerism concept, it is assumed that participating in voluntary activities will produce more disciplined and confident students as well as able to manage time more systematically (Haski-Leventhal and Bargal, 2008). Therefore, they are strongly encouraged to be engaged in voluntary activities. According to Mabry (1998) students who are involved in voluntary activities will undergo significant changes in terms of the social values that they have. This is because of the informal learning process acquire while interacting with the communities during their voluntary activities.

The spirit of volunteerism is considered as a core value for modern society especially among the younger generation (Batson *et al.*, 2002). Youth participation and engagement in volunteerism is an increasingly important issue in order to meet the development and challenges of individual and community well-being (Tamam and Hashmi, 2016) as it trains the youth to be selfless and more caring in helping to improve the quality of other human lives (Geiser *et al*, 2014). In addition, voluntary activities are also found to assist in reinforcing skills, socializing and having the passion to be with other people. However, according to Muhamad and Alauddin, (2013), besides committing to volunteerism, wanting to join and participate in any voluntary activities could also be challenging for youth. Because of this, the level of youth willingness to participate in voluntary activities is said to be disappointing (Suzanah *et al*, 2014). Although these activities promise experience, promoting good habits and good reputation of the youth, students are reluctant to play a role and contribute in charitable activities. According to Tamam and Hashmi, (2016), Warren *et al* (2014) and Abdullah *et al.* (2012) also demonstrated that youth involvement in social activities is still at an unsatisfactory level. Meanwhile Lim and Buntat (2006) stated that university students' participation in voluntary programmes is still inadequate and what more disappointing is that, some students consider voluntary programmes as a waste time and unbeneficial (Sarah, 2018). Hence, this study aims to determine the students' level of willingness to participate in voluntary activities and to discuss the challenges faced by students in participating in the activities.

Literature Review

Astin and Sax (1998) stated that students' engagement in voluntary activities will not only enhance their academic and co-curricular performance, but it also cultivates a sense of responsibility to help the needy communities. Similarly, according to Muhamad and Alauddin (2013), with volunteerism, youth can enhance their value in their self-esteem. By performing the volunteering activities, will reflected someone action and their leadership (Gibson, 2006) (Hartenian and Lilly, 2009). Hence, the positive vibes of volunteerism can be reflect not only to the students, but also to the university and community itself (Aizuddin, 2017). Meanwhile, Musick and Wilson (2003) pointed out that participation in voluntary work would have a positive impact on individuals, especially in improving their physical well-being, expanding and maintaining social connections as well as solving the social issues in the community. Besides, Palumbo (2015) and Miller (2014) found a significant relationship between volunteerism and performances in group in their previous studies on pro-social behaviors' literature. As a result, an autonomous motivation, leader self-sacrifice and self-independent will be produce by youth among university student in voluntary activities (Ogueji and Udegbe, 2019). The theory to dedicate more effort to volunteerism can help youth to gain the ability to understand others situation and empathy between the youth and others welfare (Bidee *et al.*, 2013).

According to Mohd Ismail Mustari (2005), the society considers youth as an age group that symbolizes speed, rejuvenation, strength, excitement, joy and all the beauty and perfection. In order to uphold these perceptions, youth are encouraged to be engaged in voluntary activities, which suit their emotional and physical abilities to help other people who are faced with problems. Furthermore, according to Wilson and Atangambuyu (2019) voluntary activities can be considered as a way to express gratitude and the way they can giving back to society to help ease the suffering that others were going through. Also moreover, voluntary activities can help to satisfy the desire of physiological and safety needs as state in Abraham Maslow's hierarchy of needs through communication in volunteerism (Johns and Saks, 2001). As according to Muhamad and Alauddin

(2013) engaging in volunteer activities can help to bring out the nature of altruism which means the desire to do good thing to others and feeling relieved to be able to help others (Clary *et al.*, 1998). As a result, youth development policies and agendas, either planned by the government or voluntary organizations or NGOs, will not be successful without any voluntary participation at various levels (Bang and Ross, 2009). In fact, it is difficult for these organizations to act without voluntary participation by youth. However, Chacon *et al.*, (2010) and Dorsch *et al.* (2002) argued that volunteering in terms of organizing, agenda development, community programme and its importance need to be more acknowledged by youth. This is because certain parties believe that volunteerism is an implicit manifestation that coexist in the work of youth societies instead of operating on its own.

According to Turiman *et al.* (2009), one of the mechanisms for young people to positively interact with the community is through youth organization. This is because the goal of youth organization include mobilizing youth resources; establishing networking among young members; developing the spiritual and physical strength towards morality; encouraging young people to be responsible citizens; developing the caring spirit; involving youth in the planning, implementation and evaluation of development programs; and developing the spirit of solidarity and volunteerism (Azimi *et al.*, 2002). Support that statement, Bahari (1995) state that another channel to train youth soft skill is through volunteerism activities.

Universities are among the best platforms that provide opportunities for students to train themselves in volunteerism. The implementation of university-community engagement (UCE) concept can be the basis for honing and instilling volunteering elements or behaviours amongst students (Isa, 2017) as the programme trains students to interact and deal with real-life environments. Through real- life experience of carrying out programmes with the community, students are trained to be more motivated to participate in voluntary work. According to Hussain and Yasin (2017), motivation is an important element in relation to students' participation and interest in voluntary activities (Chacon *et al.*, 2010; and (Geiser *et al*, 2014).

Participation in voluntary activities is closely linked to religious, cultural, and socio-political values as they are interconnected and influential in the success of volunteerism (Grönlund *et al.*, 2011), which not only involves the targeted groups but also the volunteers. According to Chacon *et al.* (1998), psychosocial factors such as caring, motivated, socially supportive and self- satisfaction in carrying out activities also influence students to be engaged in voluntary activities. On the other hand, Bowman (2009) and Fiorillo (2011) found that monetary rewards do not affect individual motivation in voluntary activities. However, Finkelstein (2008) found a connection between satisfaction and motivation in joining voluntary activities. According to Finkelstein (2008) volunteers who achieve high level of satisfaction in their voluntary work will be more motivated to continue volunteering. Supporting Chacon *et al.*, (1998), Van Vianen *et al.* (2008) also found that there is a relationship between culture and satisfaction in carrying out voluntary work while personality is not a dominant factor that influence individual satisfaction in volunteerism.

McBride *et al.* (2012) argued that voluntary activity is a programme that assists particular groups of people. It is not only beneficial to the assisted groups but also to the volunteers who provide the assistance. Therefore, in order to ensure that voluntary programmes benefit both parties, voluntary activities must meet the expectations of both parties and maximize the benefits to all (McBride *et al.* 2012).In the context of the volunteer, self-preparation should be taken seriously so that the goal of the voluntary activities can be achieved. According to Batson *et al.* (2002) and Dorsch *et al.* (2002), before volunteering youth should acknowledge certain aspects such as personality, society, environment, system, regulation and all relevant parties. Meanwhile Baum and Lockstone (2007) and Pearce (1982) argued that this requires certain strategies and agendas in order for youth to highlight their potential, for example training, exposure and encouragement so that they will eventually be motivated to voluntarily contribute to the society and the nation.

Besides, volunteers are individuals who spend lot of their time to help community members without being materially rewarded; they assume responsibility for voluntary activity, seeking personal satisfaction and acquisition of new experience (Adler and Benbunan-Fich, 2011). According to Cook *et al.* (2013), the need to volunteer is motivated by self-interest. It assumes that self-interest has no genetic basis. The theory hypothesizes that social exchanges comprise actions conditional on the

rewarding actions of others i.e. it can increase the probability that someone will help us in return in the future; it can relieve the personal distress of the bystander; and it can help us gain social approval and increased self-worth

Meanwhile, Gombe *et al.* (2015) found that benefits, needs and reasons to volunteer are important factors which influence an individual's decision to participate in volunteering activities. Even though Eley and Kirk (2003) state that young people volunteer for different motives and benefit than older people because young people always seek the opportunity to gain work-related experienced, skills and extra qualification that can help them in their education and career. With this in the long term, they will know what kind of benefits, needs and reason to focus in order to expend the number of potential volunteers.

Research Methodology

To obtain data from the respondents, the survey that utilised questionnaires was implemented in this study. This quantitative study involved 200 randomly selected students from University A. The development of an item was referred to the previous quantitative and qualitative research. The questionnaire was divided into three sections where section A contain two question that measured the respondents' demographic information and section B contain two question that was administered to determine the students' level of willingness to participate in voluntary work and the challenges in their participation in the activities. That two question were developed by providing with 5-mark scale measurement which are 1- strongly disagree, 2-disagree, 3-neutral, 4-agree, 5-strongly agree. The grade then is classified to low, moderate and high with the indicator based on the Mean score as shown in Table 1. The grade then is classified to low, moderate and high with the indicator based on the Mean score as shown in Table 1. Low, medium and high are indicated as level of stress of the students. Section C was provide eight random question, designed to comprehend better regarding the student's thoughts in their voluntary work. The answer was only provided with yes and no option to measure the frequency and the percentage. All data was descriptively analysed and interpreted using SPSS version 20.

Table 1: Indicator of student stressor

Grade	Score Mean
Low	0.00 - 1.66
Moderate	1.67 - 3.33
High	3.34 – 5.00

Result

A total of 200 students were involved in this study where 62.5% were females and the remaining 37.5% were males. This analysis manages to successfully support the findings of Murtaugh, *et al.* (1999) which stated that women are more motivated to participate in voluntary activities because women are more concerned about issues related to society and welfare than men. However, Ekerdt (1986) argued when it was found that men were more likely to participate in voluntary activities than women. Almost all respondents in this study were between 19 and 24 years old and only a few were over 25 years old. However, the age range of the respondents still represents the youth. Table 2 shows the number of respondents based on the demographic. The result for section B and section C were indicate in Table 3 and Table 4 respectively.

Table 2: Demographic of respondents

Variables	Atribites	Frequency	Percentage
Gender	Male	75	37.5%
	Female	125	62.5%
	Total	280	100%
Age	19-24 years	169	84.5%
	≥25 years	31	15.5 %
	Total	280	100%

Table 3: Mean score of student willingness and the challenge

Items	Mean
Students' willingness to participate in volunteerism	4.25
Challenges faced by the respondents to participate in voluntary activities	3.07

Table 4: The student's thoughts about their voluntary work

Items	Frequency	Percentage
Agree voluntary work increase their confident	255	91.0%
Agree voluntary work make them more responsible	242	86.4%
Ready to participate in voluntary work if had a chance	199	71.0%
Not expected any reward from doing voluntary work	209	74.6%
Being student not restricted them from joining voluntary work	163	58.2%
Family not obstructed them from joining voluntary work	234	83.6%
Self-confident was one of the challenges in joining voluntary work	209	74.6%
Transport was one of the challenges in joining voluntary work	226	80.7%

Discussion

This study complements the findings of Smith et al. (2010) that stated volunteerism is more beneficial to the youth. The findings showed that more than half of the respondents (62.1%) were staying in the residential college while the remaining respondents were staying in rental houses away from the university area. Thus, location was also one of the factors that influenced students' involvement in voluntary activities.

The analysis shows that students' willingness to participate in volunteerism was high with the min value of 4.25. This finding directly reflects students' clear understanding on the concepts and benefits of joining voluntary work. The result supports previous findings (Ibrahim and Amin, 2015; Hussain and Yasin, 2017; Smith *et al.* 2010; *Grönlund et al.,* 2011 and Chacon *et al*., 1998 which stated that the understanding of the concepts and benefits of participating in volunteerism would influence students' willingness to volunteer and participate in voluntary work. Stronger evidence can be seen when almost all respondents (91%) agreed that voluntary activities could increase their confidence and 86.4% believed that voluntary activities made them to be more responsible. Recognizing the benefits gained by joining voluntary work, majority of the respondents (86.5%) acknowledged that they would encourage their friends to participate in voluntary activities. According to Smith et al. (2010) individual tendency to participate in voluntary activities varies depending on the persuasion and influence of fellow volunteers

regardless whether they are active, semi-active, professional, non-skilled, spontaneous or associate volunteers (Bellamy, 2001).

In line with the concept of volunteerism, which is to provide aid willingly in any circumstances, more than half of the respondents (79.1%) stated that they were always ready to participate in voluntary work. 74.6% of the respondents opposed the idea of expecting rewards and material gains as the key goal to participate in voluntary activities. According to Hustinx *et al.* (2010), student volunteers were influenced by a mix of motivations and benefit. Nevertheless, Allen *et al.* 2008 found that most people who participated in volunteer-related work aimed at gaining intrinsic satisfaction and rewards such as found on Sani (2013) that other factors can motivate youth to participate in volunteerism include wealth, health status, level of socialization and family status. This finding shows that the respondents understood and successfully embraced the concept of voluntary work. In support of the findings, Hussain and Yasin (2017) also found that appreciation in the context of the spirit of volunteerism needs to be based on the understanding, feelings, beliefs, practices, attitudes and positive encouragement on how to alleviate the problems in the society.

In terms of the challenges faced by the respondents to participate in voluntary activities, the findings show that the respondents faced a moderate level of challenges with a mean value of 3.07. Half of the respondents (58.2%) stated that being a student did not restrict them from being involved in volunteerism. This shows that students were able to allocate their time between being a student and participating in social activities especially in helping those in need. Additionally, almost all respondents (83.6%) stated that parents were not an obstruction for them to participate in volunteerism. This finding further supports the findings of Hussain and Yasin (2017) who discovered that family factor had a high mean of 4.38 on the involvement of students in voluntary activities. This suggests that not only did students recognize the benefits gained from the activity, but parents were also found to be supportive of their children's participation in activities that could enhance their potentiality.

Although the students showed a high level of willingness to participate in voluntary activities there was still a little constraint for students to participate in the activities. This is because 74.6% of the respondents mentioned that self-confidence was one of the challenges for them to participate in volunteerism. This is probably because the respondents needed longer periods of engagement in voluntary work in order to enhance their self-esteem before becoming a professional volunteer. In the context of convenience, almost all respondents (80.7%) stated that transportation was also a challenge for them to participate in volunteerism. Staying in residential college and their status as first-year students who are not allowed to bring any vehicles to the campus limited the students' participation in voluntary activities. Sani (2013) added that high level of academic load, commitment with chores, assisting with domestic work and absence of immediate benefit from the community are some factors influenced low participant of youth. On the whole, the findings show that there were no major obstacles that hinder the students' participation in voluntary work.

Conclusion

The level of willingness to participate in voluntary activities among students was positively high. Recognizing the importance and benefits of such activities, especially in terms of self-enrichment, it was found that these students made an effort to manage their time in order to create a balance between academic and volunteerism. Hence, a clear understanding and recognition of the concept of volunteerism can produce a sincere youth in helping the needy. In addition, motivation in volunteering can be promoted once student discover the impact of their participation. The challenges and shortcomings faced by youth in volunteerism will not stop them from pursuing their participation and engagement in voluntary work, but it will be a great platform for them to serve and give their best impact to the community and the nation.

Acknowledgment

We are grateful to all of those with whom we had the pleasure to work during this project. Also, thanks to UTHM which is support this project.

Transparency in Banking Financial Reporting Evaluation System

Liviu-Adrian STOICA, Ph.D.

Bucharest University of Economic Studies, Bucharest, Romania
liviu.stoica@csie.ase.ro

Abstract

This paper analyses the public annual reports of different banks, published online each year and put to public disposition to be checked, on the data and information exposed about the bank financial indicators, to determine how the transparency is approached by each bank and the level of confidence that it creates. In the same time, the paper tries to define a system of best practices of transparency of data that should be exposed as a minimal requirement trying to propose a mathematical model for reporting evaluation system that show the level of transparency of the bank and same time trying to identify any misuse or trying to hide sensitive data. The scope of the mathematical system is to calculate the transparency level of reports that is a main component of the trust level that a person should or can have in the bank and, in the same time, showing the stability of the future of the bank.

Keywords: Transparency, Analysis, Bank, System, Evaluation model

Introduction

The reports published by the banks for the public transparency are prepared in order to meet the transparency and publication requirements provided by the Regulation of the National Bank of Romania no. 5/2013 on prudential requirements for credit institutions, as subsequently amended and supplemented, as well as Regulation no. 575/2013 of the European Parliament and of the Council of 26 June 2013 on prudential requirements for credit institutions and investment companies and amending Regulation (EU) no. 648/2012. The EU regulations 648 scope is the "strengthening of the Financial System calling for internationally consistent efforts that are aimed at strengthening transparency, accountability and regulation by improving the quantity and quality of capital in the banking system once the economic recovery is assured. The introduction of a supplementary non-risk-based measure to contain the build-up of leverage in the banking system, and the development of a framework for stronger liquidity buffers".

A well-informed public on the role and functions of the bank and understanding the economic reasons and data taken into account in establishing the bank decisions is an important factor in achieving its fundamental goal maintaining financial stability. Understanding the importance of transparency and institutional accountability, the bank should permanently provide the public with information, statistical data and detailed explanations on its own activity and the used system, as well as analyzes on domestic and international macroeconomic and financial future developments. The main instrument for assuming institutional responsibility is the presentation to the public, on the end of each year, of the activity report for the previous year, a document accompanied by the financial statements and the audit report.

The rules and regulations that requires bank to present the transparency reports about the decisions it makes, the planning on the future, the risks identified etc., let the bank choose what to expose and until what level they expose this information.

The need of this mathematical approach came from interpreting and analyzing the reports exposed by the banks to try and determine which bank is more transparent in the financial decisions. The model of the system tries to identify the exposed elements that are needed as a minimal necessity for the

Cite this Article as: Liviu-Adrian STOICA "Transparency in Banking Financial Reporting Evaluation System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

population to have an increased trust in the bank as stability and future and make the evaluation for it. In the analyze are taken under evaluation different banks statements from Romania, from different years.

The mathematical system proposed to quantify the total transparency level of financial indicators presented by the bank determine a main component of the total transparency level of bank, which include the other data presented by the bank to the customers such as detailed contracts, presentation of assets etc. The main decision on transparency based on the financial indicators presented by the bank to the public is because the decision is made before actually work or interact with the bank in any way. The other scoring coming from the easiness of reading and understanding a contract or information's offered in the offices about bank products or how detailed the customers are informed about bank assets come after the interaction with the bank.

Mathematical Approach

Based on the reports published by the banks, correlated with the rules and regulations imposed by the law the paper analyses the exposed financial indicators, how they are presented, the level of details about them and if they respect all the rules and regulations.

The system is composed from subsystems that can be identified as categories and for each category is proposed a formula of evaluation in points of measurement to try quantify everything unitary. The test cases and analyze is based on the documents provided in the bibliography. The minimal subsystems identified are:

1. Organizational structure (OS)

a. Overview that include (OW): type of organization of the bank, registered office address in clean and details, order number from the Trade Register, unique registration, number from Register of Credit Institutions. share capital value and others, all not under GDPR restrictions;

b. shareholding structure (SS) – under GDPR but was respected because on individuals is without name or other details, just as percentage;

c. management body (MB) – under GDPR, presented the organization - name and position but without physical address or other information, most of the persons can be linked between name and email address from the bank site and contact information;

d. subordinate committees (SCO) – under GDPR, but presented only the organization and what each committee attributes and duties have without exposing any name employee.

All the data of the overview presentation help to identify the exact location of the bank, so anyone can find and communicate with and all the data required for identification as a business. As mention is the value of the share capital which can increase or decrease the trust in the capacity of the business or crises coverage. The data of the shareholding present the expose of the investment of bank structure, the management body with the names detailed let the persons be identified, their curriculum vitae analyzed for public to check the experience of the management or any kind of background activity.

The subordinate committees present the decision structure and how the bank works, making a presentation of the future stability on the decisions took in the name of the bank.

The formula proposed is:

$$OS = OW + SS + MB + SCO, \text{ where:}$$

$$OW = \sum_{i=1}^{n} OWe_i \text{ , where:}$$

OWe = element of overview presentation that describe the bank, can have values from 1 to 3 depending of the data exposed as: identification parameters have value of 1, contact parameters have value of 2 and financial parameters have value of 3

i = current element and n = number of elements of overview presentation

SS – if it exists have a value of 5 if describe the overall structure or 10 based on how detailed it is, else 0
MB = NP * PD, where:

NP = Number of positions in management
PD = positions details, where 1 for no other information, 2 for name only, 5 for name and seniority in work and 10 for name, seniority in work and curriculum vitae

$$SCO = \sum_{i=1}^{n} NSCO_i * SCOR_i, where:$$

NSCO = subcommittee identified in report and described
SCOR = number of rights and decisions that a subcommittee can have
i = current element and n = number of subcommittees

2. Internal control framework (ICF) present the description, objectives, and functions (risk management function, compliance function, internal audit function) - not under GDPR restrictions. A very good mention is the 'Whistle Blowing' (as defined by EU rules and FIRST BANK report: "an inviolable basic attribute of the internal alert policy is the protection of the anonymity and the principle of confidentiality of the data of the persons submitting such reports, as well as the assurance that their current position and / or future professional development will not be affected as a result of issuing the report") that increase the trust in the security policies and efficiency of the bank – under GDPR and respecting the anonymity of the report sender.

The evaluation proposed is:

$$ICF = qDE + \sum_{i=1}^{n} Cf * FNC + WB, where:$$

qDE = coefficient of description, with values from 1 to 5 based on the elements included in description like objective, structure, rules, risks, organization, each element having 1 point
Cf = is coefficient for functions calculated based on the product of committees involved and objectives associated (CfCi * CfOa), each committee and objective exposed have a value of 1 point
FNC = function described

i = current function and n = number of functions

WB = recommendation of information classified and anonymous, with a value of 50 (this high value was chosen because it proves the intention of the bank to be serious and transparent without any flaws or bad practices)

3. Recruitment and remuneration practices (RRP) that include the description of selection criteria at hierarchical level, necessary competencies, professional experience and the remuneration model, performance, including penalties.

RRP = RLD + RSC + RRM + RDE, where

RLD = recruitment description level evaluated from 1 to 10 based on the information exposed, where 1 represents just the positions offered and 10 position with the full details of the job description and responsibilities, where each detail has a value of 1 point

RSC = recruitment selection criteria evaluated, as a product from 1 to 5 based on the selection criteria detailed on level in hierarchy and 1 to 5 on the competences and experience needed, where 1 represents just the minimum selection criteria (as example you need bachelor degree or competence in Office products) and for 5 the studies with specialization, years of work etc. or all the requirements needed as abilities, competencies etc. , where each element identified have a value of 1 point

RRM = recruitment remuneration model, evaluated from 1 to 20, where 1 represent just an evaluation of salary as good salary or good remuneration and 20 all descriptions based on the policies applied,

position detailed, salary composition, bonuses and penalties, where each policy described have a value of 2 points

RDE = recruitment detailed elements from 1 to 20, based on values and details exposed, where 1 describes just the organizational structure and 20 full details on the elements such as members of the management body in its supervisory function, members of senior management, investment services, retail services, management assets, corporate functions, independent control functions, other areas of activity, number of employees total employees full time, total net profit, total remuneration, total remuneration varies, where each element described have a value of 2 points

4. Objectives and policies regarding risk management (OPRRM) defined by risk management strategy and processes, types of significant risks and risk strategy parameters, including presentation and quantification of risks based on the identified risk level and establishing the general risk profile.

$$OPRRM = nS + nP + nTR + nPRS + 2 * GR$$

nS = number of strategies presented
nP = number of principles used
nTR = number of types of risks identified
nPRS = number of parameters for risk strategy
GR = general risk, from 10 to 50 where 50 is low, 40 is medium-low, 30 is medium, 20 medium-high and 10 is high or -100 if is not presented because that denote a hiding of risk exposure which affect the overall transparency level in the bank reports

5. Risks (REV), formed from Credit risk and associated risks (credit risk, risk of concentration, counterparty risk, residual risk, macroeconomic risk, the risk coming from the foreign currency lending activity of the debtors exposed to the foreign exchange risk, settlement risk, country risk), Market risk (interest rate risk, exchange rate risk), Liquidity risk, Operational Risk, Reputational Risk, Other risks (interest rate risk outside the trading book, strategic risk, regulatory risk, risk of excessive use of leverage) and each of them should include the actions taken by the bank, evaluation and identification methods, monitoring, reduction and control procedures and reporting procedures.

$$REV = \sum_{i=1}^{n} CR_i + nM + nRCP + nRP + vDR, where:$$

i = current risk and n = number of risks

CR = value of risk calculated as:

$CR_i = nActB_i * nEIM_i$, where:

nActB = value from 1 to 5 based on number of actions taken by the bank, each action has a value of 1 point

nEIM = value from 1 to 5 based on number of methods used for evaluation and identification, each method has a value of 1 point

nM = value from 1 to 10 based on number of monitored aspects, each monitored aspect have a value of 1 point

nRCP = value from 1 to 10 based on number of reduction and control procedures, each procedure has a value of 1 point

nRP = value from 1 to 10 based on number of reporting procedures, each report has a value of 1 point
vDR = value of 0 to 15+ depending if it has examples of detailed reporting, 5 points for each LCR (coverage liquidity requirements), NSFR (stable financing), ALMM (liquidity indicator and immediate liquidity), as example LCR should include stock of high-quality liquid assets, cash outflows, cash

receipts, net cash outflows = MAX ((Outputs - Inputs), 25% Outputs), liquidity requirement coverage indicator (%), or 0 if none, and more than 15 if more.

6. Own funds and capital requirements (OFCR) based on Regulation of the National Bank of Romania no. 5/2013 on prudential requirements for credit institutions and Regulation (EU) 575/2013 on prudential requirements for credit institutions and investment companies with subsequent amendments and completions.

It should include information about equity, adjustments fiscal impact, intangible assets (net value), subordinated loans, unrealized gains resulting from the fair value measurement of financial assets available for sale AFS (20%), prudential filter (20%) and own funds total. The main regulated characteristics of own funds based on level 1 own funds and level 2 own funds and the value of Tier I own funds and Capital requirements for credit risk, market risk and operational risk. The risk weighted assets (RWA) should be calculated in accordance with the provisions of Regulation (EU) no. 575/2013 of the European Parliament and of the Council, using the standardized approach. The value of the risk-weighted exposure is calculated using the fixed risk (RW) weights and depends on the type of debtors (company / retail) and the external rating (if available).

The value of OFCR is based on the number of the information presented, how many indicators are with their value, having 1 point for each indicator identified.

7. Quantitative and qualitative information (QQI) on credit and concentration risks exposing the details on remaining credit (past due), impaired credit, specific credit risk adjustments (SCRA) based on the concept of improbability referred to in Article 178 (3) (b) of Regulation (EU) No 575/2013 and total and average value of net exposures.

The table of details should contain information about exposures, a geographical breakdown of net exposures that should present information about central administrations or central banks, concentration of exposures depending on the activity sector and the types of counterparties, the expiry of exposures and the exposure credit quality depending on the exposure class. Other data tables that should be included in the transparency reporting should be, but not limited to the quality of the exposure credit depending on the activity sector, increasing the age of outstanding exposures, non-performing and restructured exposures, loans and advances depreciated individually. A presentation about the creditworthiness of the bank that include the situation of encumbered and unencumbered assets is as follows exploited loans, capital instruments, debt securities, loans and advances, other than spot loans, other assets structured on the carrying amount of encumbered assets, fair value of encumbered assets, the carrying amount of non-performing assets and fair value of unencumbered assets.

QQI is calculated based as sum of the number of tables presented, where each table have the value equals with the sum of elements inside the table, where each element has a value of 1 point.

8. Other reports and information (ORI) should include main indicators monitored as solvency indicator (total equity ratio), the leverage indicator, short-term liquidity coverage indicator – LCR, levels 1 and 2 of own funds, funds instruments, equity instruments, capital instruments and as many indicators as possible.

ORI is calculated as a sum of total elements exposed, with 1 point of elements identified and 2 points for elements identified that have a value associated.

Analyze on the proposed model for several banks

The total transparency level on reporting (TTLR) is the sum of the components identified, adjusted by the ponder of importance in the equation. For each category it was allocated a coefficient of importance in the final equation based on the data offered and how the data affects the transparency exposed.

$$TTLR = 0.5 * OS + 0.5 * ICF + 2 * RRP + OPRRM + REV + OFCR + QQI + ORI$$

The higher level of the indicator indicates a higher transparency in the reports offered by the bank. Combined with the level of transparency from other sources show the total transparency of a bank.

Using the proposed model, the article presents in the Table 1 an evaluation of measurement of the transparency, based on the reports offered by several banks for the public.

Table 1: Evaluation of transparency

Indicator/Bank	FIRST BANK	CEC	RAIFFEISEN
OW	8	4	0
SS	10	13	0
MB	16	18	35
SCO	15	4	2

Source: Author own research based on input tables and proposed method

It is necessary to verify if the bank respect and publish the statements according to Regulation of the National Bank of Romania no. 5/2013 regarding prudential requirements for credit institutions, Regulation no. 575/2013 of the European Parliament and of the Council on prudential requirements for credit institutions and investment companies and modification of Regulation (EU) no. 648/2012 (called CRR), Guidance on publication requirements under Part Eight of Regulation (EU) no. 575/2013 - EBA / GL / 2016/11 of 04.08.2017, Guidance on the publication of the liquidity coverage indicator (CSF) in supplementing the information on liquidity risk management under art. 435 of Regulation (EU) no.

575/2013 - EBA / GL / 2017/01 of 21.06.2017, Guidance on sound remuneration policies in accordance with Articles 74 (3) and 75 (2) of Directive 2013/36 / EU and information published pursuant to Article 450 of Regulation (EU) no. 575/2013 - EBA / GL / 2015/22 of 27.06.2016, Guidance on the threshold of significance, ownership and confidentiality and on the frequency of reporting under Articles 432 (1), 432 (2) and 433 of Regulation (EU) no. 575/2013 - EBA / GL / 2014/14 of 23.12.2014; BNR instructions from 28.10.2015 on the threshold of significance, ownership and confidentiality and on publication frequency, specified in Articles 432 (1), 432 (2) and 433 of Regulation (EU) no. 575/2013, Guidance on the publication of information on encumbered and unencumbered assets by tasks as well as the Delegated Regulation (EU) No. 2295/2017 on the technical standards of regulation for the publication of encumbered and unencumbered assets with tasks - EBA / GL / 2014/03 from 27.06.2014.

Conclusions

Based on the analyze we can check the results and try to make a ladder of bank transparency which help to quantify the total trustworthiness for the banks analyzed, to see which one is more stable, in which a person should invest the trust and money.

The algorithm and proposed method can be expanded or refined even more, based on the proposed scale of evaluation of each point with a more detailed point system for each equation based on the overall structure exposed by the reports and the regulations.

The evaluation method is proposed for a better understanding on the bank's behavior on transparency, on the self-awareness of the risks on which it is exposed, the strategies that it can take to countermeasure all the vulnerabilities and to offer a proper stability on the financial market. Especially a company need to know in what bank it should keep its money, which is more transparent when doing a business with it and not to risk the investment.

xdwang@bjtu.edu.cn

Abstract

With the continuous development of economy, China has already become the world's second largest life insurance market. In order to have a deep insight of the research hotspots and trend in the field of life insurance in China, this article analyzes 1,389 related articles of core journals, which were published from 2000 to 2019. This paper firstly analyzes the research status of life insurance in China from the perspectives of quantity evolution, the most cited articles, and the distribution of journal and institution, as well as the hotspot map of articles. Next, this research obtains the hot topics and trend in life insurance research by the frequency of keywords, co-word networks and the method of network modularization. These hot topics are life insurance market and products, life insurance company operation, life insurance finance and life insurance business processing. Finally, the trend analysis shows that life insurance company operation has the hottest trend in recent years.

Keywords: Bibliometrics, Life insurance, Research hotspots, Co-word analysis

Introduction

In recent years, global insurance premium income has continued to increase. Since the Economic Reform and Open Up, China's insurance industry has flourished, and China has now become the world's second largest insurance market. However, China's insurance industry still has problems such as weak service capabilities, outdated development concepts, and insufficient risk management and control capabilities, which are not conducive to sustained and stable development (Xu, 2019).

In response to hot issues and development trend in the insurance industry, many experts and scholars have conducted research from different specific fields and perspectives. For example, Huang et al (2016) used bibliometric methods such as knowledge graphs to study overseas agricultural insurance articles. They analyzed from the perspective of areas, institutions, co-citation networks, topic co-occurrence networks, keyword clustering, etc. Wang et al (2018) analyzed the research hotspots and trend in the field of engineering insurance in China with the method of co-word analysis etc. However, at present, few studies are focusing on the research hotspots of life insurance in China.

In order to understand the research hotspots and trend of life insurance in China, this article analyzes the articles related to life insurance in CNKI for the past 20 years. The analysis is conducted from the perspectives of articles quantity evolution, the most coted articles, and the distribution of journal, region, and institution. And hot topics of life insurance are also extracted with the methods of keyword co-occurrence analysis and modularization.

Data Collection and Indicator Construction

Data collection

The articles come from the Chinese academic journal database in China National Knowledge Infrastructure (CNKI). In order to ensure the high relevance of the selected articles and life insurance, the selecting method is to include "life insurance" in the title or "life insurance" in the keyword, starting from 2000. In order to ensure the influence and authority of the selected articles, the source category selects SCI (Science Citation Index) source journals, EI (Engineering Index) source journals, core journals, CSSCI (Chinese Social Science Citation Index), CSCD (Chinese Science Citation database). The selecting time was February 7, 2020, and 1,604 articles were selected. Irrelevant articles like advertisements are deleted, and then 1,389 articles are finally obtained.

Indicator Construction

In a network, the centrality of a node is an indicator to measure the importance of a node in the network. The greater the centrality of a node, the stronger the connection between this node and other nodes in the network, the more important the node is. The calculation formula of node centrality is as follows (Daly and Haahr, 2009):

$$BC(p_i) = \sum_{j=1}^{N} \sum_{k=1}^{j-1} \frac{g_{jk}(p_i)}{g_{jk}}$$

g_{jk} represents the number of shortest paths from node j to node k. $g_{jk}(p_j)$ represents the number of nodes p_j in the shortest path from node j to node k.

Through the measurement of the connection density in the network, the network is modularly divided, and the modularized value Q is used to measure the quality of the division. The value range of Q is [0,1]. When Q>3, the network division is reliable (Wang et al, 2019). The calculation formula of Q is (Blondel et al, 2008):

$$Q = \frac{1}{2m} \sum_{i,j} \left[A_{ij} - \frac{k_i k_j}{2m} \right] \delta(c_i, c_j)$$

Where A_{ij} represents the weight of the connection between nodes i and j, k_i is the sum of the weights of all the edges connected to node i, c_i and c_j represent the modules where nodes i and j are located respectively. If $c_i = c_j$. $\delta(c_i, c_j)$ takes 1, if not, it takes 0. m represents the sum of the weights of the edges in the entire network.

Research Status Overview

Trend in the amount of articles

Counting 1,389 articles by year, the annual number of articles is obtained, as shown in Figure 1. From 2000 to 2019, the average annual publication of the articles was 69.45. The number of articles from 2000 to 2003 was relatively high, with more than 110 articles. There was a sudden decrease in 2004 and a slow decline after a new peak in 2008. After a small recovery from 2010 to 2013, the number of articles declined year by year from 2013 to 2019. The number of articles has been declining in recent years, which is related to the standardization of life insurance research and the improvement of research methods. It also indicates that the research on life insurance will develop with high quality instead of high quantity (Wang, 2018).

Figure 1: Annual volume of articles

Journal Distribution

These articles we obtained were published by 267 different journals, the top five journals with the highest proportion are shown in Table 1. As can be seen from the table, the articles of *Insurance Studies* in the field of life insurance ranks among the best in terms of quantity and influence. *Insurance Studies* is an authoritative professional journal in the field of domestic insurance research. In addition, except for the comprehensive impact factor of *Shanghai Insurance Monthly*, which is only 0.142, the impact factors of other journals in the top five journals are all above 0.6, all of which have great influence. In addition, 209 journals out of 267 journals published three or less related documents within the statistical range, showing a significant long-tail effect.

Table 1: Journals with highest proportion of articles

Journal Title	Numbers of articles	Proportion	Impact Factor
Insurance Studies	327	23.54%	1.077
Shanghai Insurance Monthly	164	11.81%	0.142
Statistics & Decision	55	3.96%	0.638
China Finance	48	3.46%	0.603
Financial Theory & Practice	33	2.38%	0.606

Regional Distribution

Count the regions from which the articles originated. Among them, the documents of multiple authors are based on the region of the institution where the first author is located, and the articles of unknown regions are ignored. The hotspot map is showed in Figure 2. The darker the area in the hotspot map, the more papers are from there. The articles distribution covers 29 provinces and cities in China. Among them, Beijing, Shanghai and Tianjin have the largest numbers of articles, accounting for 19.9%, 13.6% and 8.2% respectively. In addition, Sichuan, Hubei, Guangdong, Jiangsu and Shandong publish more documents than other provinces or cities. Overall, life insurance research in southern and southeastern coastal areas of China is dense and concentrated in relatively economically developed provinces and cities, while the number of publications in the northeast and northwest is the lowest. This is not only related to the differences in the number of universities, research institutions and enterprises in various regions, but also related to the regional differences in the life insurance market demand (Huang, 2017).

Figure 2: Hotspot map of articles

Institutional Distribution

Count the institutions of articles, 405 institutions are obtained, including universities, enterprises, and public institutions. China Life Insurance Co., Ltd., a large state-owned financial and insurance company, published the highest volume of articles, accounting for more than 14%. Among the public institutions, China Insurance Regulatory Commission published the highest volume of articles. The rest of the top 5 are colleges and universities which are Nankai University, Shanghai University of Finance and Economics and Southwestern University of Finance and Economics, as shown in Table 2.

The Most Cited Articles

The five most cited articles are shown in Table 3. Among them, the most cited document is “Empirical analysis of China's life insurance demand”. This article makes assumptions and empirical analysis of the factors that affect China's life insurance demand, using multiple statistical regression as an empirical analysis tool. The conclusions drawn are that China's growing economic strength and constantly improving social security systems will make China's life insurance industry profitable. But the lower education level and inflation of the population may hinder the life insurance industry's development (Zhuo, 2001). In addition, among the five most cited documents, the most frequent keyword is "life insurance demand".

Table 2: Institution with highest proportion of articles

Institution name	Number of articles	Proportion	Organization type
China Life Insurance Co., Ltd.	201	14.47%	Enterprise
Nankai University	76	5.47%	College or university
Shanghai University of Finance and Economics	55	3.96%	College or university

Southwestern University of Finance and Economics	47	3.38%	College or university
China Insurance Regulatory Commission	43	3.10%	Public institution

Table 3: The most cited articles

Article Title	Journal	Year	Citations
Empirical analysis of China's life insurance demand	*Insurance Studies*	2001	312
On Establishing "Reverse Mortgage Loan" Life Insurance Service	*Insurance Studies*	2002	194
Empirical study on influential factors of life insurance demand in China	*China Soft Science*	2005	123
An Empirical Analysis of China's Life Insurance Demand in the Transition Period	*Insurance Studies*	2002	92
Examination on the Determinants of Life Insurance Demand in China	*Journal of Zhongnan University of Economics and Law*	2006	88

Analysis of Hotspots and Trend

The keywords of the articles show the theme, content, and method of articles research. By extracting, co-occurrence analysis and modularization analysis of the high-frequency keywords of the articles, the development trend of research hotspots in the field can be obtained.

Co-occurrence analysis of keywords

Count the keywords of the articles, and abandon the common keywords such as "life insurance" and "life insurance company", as well as some irrelevant keywords. Combine synonymous keywords. Keywords with the frequency greater than or equal to 15 are selected as high-frequency keywords, then 45 high-frequency keywords are obtained.

The co-occurrence analysis of keywords, which is also called co-word analysis, refers to counting the times that keywords appear in the articles together to measure the closeness of the links between keywords. Because the keywords of the articles generally represent the core research content and methods of the articles, so the evolution of the research topic can be further explored through the co-occurrence analysis of keywords (Feng and Leng, 2006). First, the co-occurrence matrix of high-frequency keywords is derived through the document management tool Note Press, as shown in Table 4.

Table 4: Keywords co-occurrence matrix (partial)

	Insurance premium	Insurance market	Demand	Life insurance products	Solvency	Agent
Insurance premium	93	9	3	4	1	3
Insurance market	9	89	7	8	2	7
Demand	3	7	72	3	0	0
Life insurance products	4	8	3	63	1	3
Solvency	1	2	0	1	62	1
Agent	3	7	0	3	1	58

Gephi is a free and open source network analysis software. By importing the co-word matrix into Gephi software, a visual co-word network can be obtained, as shown in Figure 3. The thickness of the connection between keyword nodes is determined by the number of co-occurrences between keyword pairs. The more the co-occurrences between two keywords, the thicker the connecting line between them, the stronger the relativity between them. The size of the keyword node represents the node centrality. The larger the node centrality, the larger the keyword node, the more important the node is. From the co-occurrence network, we can see that the keywords of "life insurance products", "insurance premiums", "solvency", "insurance policy" and "insurance market" are at the center of the network, and the frequencies of these words are also high. These keywords can represent hot research keywords in China's life insurance in the past two decades.

Figure 3: Keywords co-occurrence network

Extraction of Hot Topics

Gephi's modularization function is based on the algorithm proposed by Blondel et al (2008). This algorithm continuously iterates to maximize the connection density of points in each community, thereby achieving optimal modularization. The modularization function of Gephi was utilized to modularize the high-frequency keyword network and divide the network into 4 sub-communities. The modular value Q=0.314>0.3 indicates that the sub-community network structure is stable and the classification results are credible. The classification result is shown in Table 5. The high-frequency words and the words with high node centrality in each category represent important nodes of the sub-community and can be used for hot topic extraction. The result is also shown in co-occurrence network, as shown in Figure 4, the nodes have same colors are in same category. Summarize the articles topics of each category separately, and four research hot topics are extracted.

The first category refers to the topic of life insurance market and life insurance products. The main contents of these researches include the life insurance market, the factors affecting the demand for life insurance, the interest rate risk, strategy, and structural adjustment of life insurance products, the forecast of insurance premium income, and the life insurance marketing model and system. The methods used in this type of research mainly include empirical research and empirical analysis. For example, Yang et al (2005) used the time series autoregressive distribution lag model to conduct an

empirical analysis of the impact of GDP, maintenance rate, interest rate, expected inflation rate and education level on China's life insurance demand.

Table 5: Classification result of keywords (partial)

Category 1			Category 2		
Keywords	**Frequency**	**Node centrality**	**Keywords**	**Frequency**	**Node centrality**
Insurance market	89	44.10	Solvency	62	45.48
Demand	72	13.72	Risk	51	26.69
Life insurance products	63	61.96	Asset liability management	46	7.69
Agent	58	16.38	Actuarial	36	21.52
Premium income	45	16.99	Management	36	4.38
Category 3			**Category 4**		
Keywords	**Frequency**	**Node centrality**	**Keywords**	**Frequency**	**Node centrality**
Bank	48	28.36	Insurance premium	93	69.71
Funds	44	20.37	Insurance policy	57	35.51
Insurance business	31	23.88	Surrender	38	25.21
DEA method	28	0.28	Insured	35	6.04
Liability reserve	20	7.73	Insurance amount	35	4.07

The second topic category is life insurance company operation. The main contents of such research include the operating efficiency of life insurance companies, the analysis of the factors affecting the solvency, the monitoring and management of solvency, the impact of spread losses and the resolution methods, and the company's value assessment and interest rate risk analysis and prevention. The methods used in these researches mainly include factor analysis, principal component analysis, and actuarial techniques. For example, Jiang et al (2014) used the data envelopment model to measure the effectiveness of life insurance companies' operating performance, and explored the factors that affect the performance of life insurance companies.

The third topic category is life insurance finance. Such researches mainly include the use of funds for life insurance companies, investment, the development of banking insurance, the impact of bank interest rates on life insurance companies, and the financial risks of the life insurance industry. For example, Liu et al (2013) used a comprehensive evaluation model to study the efficiency of the use of funds in China's life insurance companies.

The fourth topic category is life insurance business processing. The main research contents in this category include discount, pledge and securitization of policy, surrender treatment, factors affecting the surrender rate, underwriting and claims, the rights and interests of policy holders and insured persons, insurance contract disputes and other legal issues. The prevention of fraud is also included. For example, Wang (2012) used negative binomial regression to conduct an empirical study on domestic life insurance products. Then it analyzed influencing factors of surrender of general, dividend and investment-linked life insurance.

Figure 4: Classification result of keywords co-occurrence network modularization

Analysis of Hot Topics Evolution Trend

The numbers of articles of four categories of research hot topics are shown in Figure 5. The four types of articles are time-sliced to take four years as a time period. The evolution trend of the number of four hot research topics is obtained, which is shown in Figure 6. The proportion of the number of articles in each period is also shown in Figure 7.

It can be seen from the figures that overall, the topics of life insurance market and life insurance products account for the largest proportion in the research of China's life insurance field, but in recent years, research on the operation of life insurance companies has replaced it as a new hot spot in this field. This might be affected by the issuance and full implementation of the "New Articles of the Ten Nations" and "Compensation for the Second Generation" on China's life insurance companies in recent years (Sun, 2018). At the beginning of this century, when China just joined the WTO, the volume of articles related to life insurance business processing had largest proportion, and the proportion of articles later declined slowly, which is in line with the continuous development of China’s life insurance industry and legal systems in recent years. Compared with the other three topics, the research on life insurance finance has the least weight, but its proportion is relatively stable.

Figure 5: Article proportion of hot topics

Figure 6: Trend of the article volume of hot topics

Figure 7: Trend of the article proportion of hot topics

Conclusions

This article analyzes 1,389 articles in CNKI related to life insurance. We obtained the evolution of articles amount, the most cited articles, as well as distribution of journal, region, and institution. By the method of co-word analysis, network modularization etc., this article also obtained hot topics of life insurance research in China which are life insurance market and products, life insurance company operation, life insurance finance and life insurance business processing. Among them, research on life insurance company operations is the hottest in recent years. Through this research, people can have an overall insight of research in life insurance in China. This research can also provide reference for relevant scholars to conduct further studies.

Abstract

Performance is a key concept for any organization, and lately, it has begun to become a priority for both business management and researchers. Managers want to provide the best products and services to customers, increasing the company's revenues, but at the same time, they aim to streamline their internal operations, reduce costs and increase the company's productivity. The researchers come to the aid of the companies and carry out activities to understand what influences the performance of the company, what is the level of performance of the company and what could be the most effective methods for a company to improve its performance. The problem is that there are not many papers that analyse how exactly some processes affect business performance and what processes contribute the most to increase business performance. Thus, the main objective of this paper is to determine the most important processes within the service companies that contribute to increase organizational performance. In this regard, the authors used quantitative research to analyse 8 main processes from a service company. The results highlighted the fact that every process can improve the organizational performance by improving its process performance, but there are a few processes that are more important for companies than others. Thus, the management of the service companies should pay more attention to processes like human resources management, marketing and sales, and the financial-accounting process, those being processes that influence the most the organizational performance.

Keywords: service company performance, business process performance, performance, processes performance

Introduction

In the last decades, researchers and managers all over the world have started to study different ways to improve business performance. They have analysed various dimensions of performance,

Cite this Article as: Andreea BARBU, Gheorghe MILITARU, Valentin-Andrei MĂNESCU, Ramona Alexandra NEGHINĂ and Mihaela-Rodica GANCIU "Analysis of The Influence of Process Performance on Organizational Performance: Evidence from Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

like finance, customers, processes, internal business processes, customers' satisfaction or employees' satisfaction.

Different studies highlighted the fact that employees are a valuable resource in a company. By ensuring a good level of employees' satisfaction, the management of the company can achieve good service experience level that will conduct to customers' satisfaction, loyalty, and profitability increases (Lam et al, 2001; Chi & Gursoy, 2009; Boswell & Boudreau, 2000; Barbu & Militaru, 2019). Focusing on processes, the authors noted that the most used key performance indicators are associated with time execution, level of flexibility and quality for the processes, activity costs, employee's productivity, number of recommendations received from customers, income of the company and company profitability (Fitzgerald. et al, 1991; Van Looy & Shafagatova, 2016; Ryu & Won Lee, 2014; Fajrina et al, 2019)

The problem is that there are not many papers that analyse how exactly some processes affect business performance and what processes contribute the most to increase business performance. Thus, the main objective of this paper is to determine the most important processes within the service companies that contribute to increase organizational performance.

Methodology

Through this paper, the authors propose to identify the processes that influence the most the performance of a service company. In this regard, the authors conducted a quantitative research on employees from the professional service companies from Romania, using a questionnaire to measure the perceptions of the people surveyed. The questionnaire can be divided into 10 sections: 8 sections focus on the main processes within a service company, one section analyses organizational performance, and one section is used to analyse demographic data.

The processes that were analysed in this paper are: supply process (P1), human resources management (P2), financial-accounting process (P3), marketing and sales process (P4), service delivery process (P5), customer service process (P6), management process (P7), innovation process (P8). For each process, as it can be seen in Tab. 1, the following variables were analysed: the perceived level of the process performance, the level of process importance within the service company, and the perceived performance level of the process according to Time, Flexibility, Quality, Cost, and Transparency. For the mentioned variables, the items were measured on a 5-point Likert-type scale ranging from 1 (total disagreement) to 5 (total agreement).

Table 1: Variables used in the paper

Items	P1	P2	P3	P4	P5	P6	P7	P8
Process performance	✓	✓	✓	✓	✓	✓	✓	✓
Process importance	✓	✓	✓	✓	✓	✓	✓	✓

Source: Authors' own research

The questionnaire developed for this study was applied online, in June 2019, the sample consisting of 150 employees working in the service companies in Bucharest, Romania. For the organizational performance concept, the authors studied different aspects of performance from different sources

like the awards for quality and organizational excellence (EFQM Leading Excellence, 2013, Juran et al,1974; JUSE, 2015), the Kaplan and Norton' s research paper (1996), and other papers that analyse the profit-service chain (Larivière, 2008; Heskett, et al, 1994). Thereby, the variables that were used to describe organizational performance are: Profitability, Income, Market share, Service quality, Customer satisfaction, Employee satisfaction, Processes, and groups of interest.

Results

The sample of the research paper was represented by 150 employees working in service companies in Bucharest, Romania. Out of the total respondents, 61% were female, while the largest share of respondents was having executive positions within the company (81%). Most of the companies surveyed are in the following domains: IT (25), Commerce (21), Financial and Banking (19), Construction (14), Transport (14) and Consulting (11). About half of the firms surveyed are on the market for more than 10 years, while 26% have less than 3 years since their establishment.

To test the internal consistency of the questionnaire items, the Cronbach Alpha coefficients were analysed (Tab.2). In terms of interpreting the value of the coefficient Alpha, Hair at al. (2007) recommended a minimum value of 0.7 for Cronbach Alpha, while there are some researchers (Fornell and Larker, 1981; Garson, 2010) who claim that these values are statistically significant when they exceed the minimum value of 0.6 in the case of exploratory studies. For our study, the Cronbach Alpha coefficients are higher than 0.7, which means that the variables included in the research have a good internal consistency.

Table 2: Cronbach Alpha's Coefficients

Items	Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	Number of Items
Supply process (P1)	0.707	0.711	4
Human Resources Management process (P2)	0.776	0.774	5
Financial- Accounting process (P3)	0.774	0.776	4
Marketing and Sales process (P4)	0.807	0.805	4
Service Delivery process (P5)	0.736	0.748	4
Customer service process (P6)	0.813	0.812	4
Management process (P7)	0.869	0.869	5
Innovation process (P8)	0.908	0.908	4
Performance	0.793	0.796	8

Source: Authors' own research

Table 3 presents the summary of the models between the organizational performance (the dependent variable) and the performance of the analysed processes (the independent variables).

Table 3: Summary of the models between organizational performance and the performance of the analysed processes

Model	The relationship between performance and company processes	R	R^2	Adjusted R Square	Standard error of estimation
1	Supply process (P1)	0.457	0.209	0.203	0.512
2	Human Resources Management process (P2)	0.612	0.374	0.37	0.455
3	Financial- Accounting process (P3)	0.558	0.312	0.307	0.477
4	Marketing and Sales process (P4)	0.626	0.392	0.387	0.449

5	Service Delivery process (P5)	0.459	0.211	0.206	0.511
6	Customer service process (P6)	0.453	0.205	0.2	0.513
7	Management process (P7)	0.556	0.309	0.305	0.478
8	Innovation process (P8)	0.513	0.263	0.258	0.494

Source: Authors' own research

In the case of model 1, the value of the R square coefficient is 0.209. This value indicates that the variation of the organizational performance (the dependent variable) is explained in a proportion of 20.9% by the performance of the supply process (the independent variable). In the case of model 2, the variation of the organizational performance is explained in a proportion of 37.4% by the variation of the performance of the human resources management process (R^2=0.374). Similarly, the coefficients from the other 6 processes were analysed. The smallest value was found in model 6, where the variation of the organizational performance is explained in a proportion of only 20% by the variation of providing support services performance.

Fig. 1: The relationship between organizational performance and processes performance

Source: Authors' own research

Thus, by analysing the 8 models (Figure1), it can be said that all the 8 processes influence the organizational performance, while the organizational performance is strongly correlated with the performance of the following processes: P2 (R=0.612, p<0.01) and P4 (R=0.626, p<0.01).

Table 4: Summary of tested models and variables entered

Model	Variables Entered	Variables Removed	Method
1	Supply process (P1), Human Resources Management process (P2), Financial-Accounting process (P3), Marketing and Sales process (P4), Service Delivery process (P5), Customer service process (P6), Management process (P7), Innovation process (P8)	.	Enter
2	.	Innovation process (P8)	Backward (criterion: Probability of F-to-remove >=.100)
3	.	Customer service process (P6)	Backward (criterion: Probability of F-to-remove >=.100)

4	.	Management process (P7)	Backward (criterion: Probability of F-to-remove >=.100)
5	.	Supply process (P1)	Backward (criterion: Probability of F-to-remove >=.100)
6	.	Service Delivery process (P5)	Backward (criterion: Probability of F-to-remove >=.100)
a. All the requested variables were entered; b. Dependent variable: Performance			

Source: Authors' own research

In order to see which processes can be considered to develop an equation describing the performance of service organizations, the authors used the SPSS statistical program to provide the statistical model corresponding to multiple linear regression (Table 4). It is found that for most models, the value of R square is about 0.515, which means that the independent variables associated with the tested models explain 51.5% of the organizational performance. The highest value of adjusted R square is 0.503 for model 6, which means that 50.3% of the variance of the dependent variable was explained by the variance of the independent variables.

Table 5 contains the regression equation coefficients for each model tested. Taking into account the value of Sig., it is found that the only statistically relevant model is model 6. Model 6 contains the following independent variables: the performance of the human resources management process (P2), the performance of the financial-accounting process (P3) and the performance of the marketing and sales process (P4).

Table 5: Summary of tested models

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	R^2	Adjusted R Square
		B	Std. Error	Beta				
1	(Constant)	1.397	0.273		5.119	0	0.515	0.488

a. Dependent variable: Performance

Source: Authors' own research

According to the analysis from Tab. 5, we discovered that organizational performance can be defined with the help of human resource management, financial accounting, marketing and sales performance (Eq.1).

Performance=1.493+0.220*HumanResourcesManagement+0.172*FinancialAccounting+0.267*MarketingSales (1)

This means that for each increase with one unit of the Human Resources Management process performance, the organizational performance will increase by 0.220, for each increase with one unit of the financial-accounting process performance, the organizational performance will increase by 0.172, and for each increase with one unit of the performance of the marketing and sales process, the organizational performance will increase by 0.267 (data extracted from Tab 5., Model 6).

Conclusion

The results of this study indicate that taken individually, each of the 8 analysed processes influences the organizational performance of the service companies. Moreover, 3 important processes need to come to the attention of the management of the service providers, these being: human resources management, marketing and sales, and the financial-accounting process, those being processes that influence the most the organizational performance. In this regard, the management of the companies should pay more attention to human resources to find specialists in the field, people with experience, who have both technical knowledge and soft skills to be able to interact as best as possible in a team. The correlations that were found in this study indicates that by improving the performance of the human resources management process, the management of a company can increase the organizational performance.

Also, companies should invest more in ensuring good financial-accounting processes, finance performance being one of the most important dimensions of the organizational performance. The good results obtained in the financial processes will determine in time good results in terms of the overall performance of the company.

Furthermore, marketing and sales processes are very important for every type of company, this department being that one that helps businesses to create added value, to develop services according to customers' needs, to grow the customer portfolio, to achieve profitability. Thus, the management of the service companies should focus on improving the activities from this department to increase the organizational performance.

Despite the information presented, the results of this study must be interpreted and put into practice, however, with great care, because this study is a pilot one and has some limitations. For example, the respondents of the questionnaire are employees with management and executive positions. Taking into account that this paper analysed the respondents' perceptions, the results might have been different if the respondents were only employees with management positions. Also, in the literature, there are a lot of ways to describe organizational performance, this concept being a complex one. For this paper, the authors used information from several papers and awards for quality and organizational excellence, the variables resulting from this research and chosen by the authors being: Profitability, Income, Market share, Service quality, Customer satisfaction, Employee satisfaction, Processes, and groups of interest. Furthermore, only 8 processes within a company providing services were investigated. Thus, in the future, the authors will focus more on the processes that will be individually analysed from several perspectives to determine how they can more accurately contribute to the improvement of the organizational performance in the field of services.

Abstract

The aim of the article is to present an analytical tool for measuring creativity in strategies formulated in innovative startups. It was assumed that the basis of these strategies are intangible resources, generated as a result of creative activity of technostarters (startup managers). The concept of this tool refers to three dimensions of the strategy: novelty, usefulness and time perspective of its development. A qualitative methodology was chosen, including literature and surveys conducted among 42 startups located at the Wroclaw University of Science and Technology. The developed numerical tool is simple, clear and economically justified. The constructed tool allows to assess the value of creativity in the generated and proposed strategic options even before choosing the right one, i.e. the one that will be effectively implemented. Technostarters, even those with little experience in strategy assessment, will determine the value of creating strategic options formulated in the strategic planning process by means of a list of questions (checklist) developed by the authors.

Keywords: startup, strategy, creativity, measuring.

Introduction

Social, economic and technical undertakings undertaken by human are related to creative activity. This kind of activity has accompanied man since the beginning of time. It enabled the invention of various tools and the transformation of natural resources found in nature. From the beginning, creativity was a process of searching for new values and formulating laws and rules that could be applied to various areas of human social life. In fact, until the end of the 19th century, creativity was understood as the activity of individuals equipped with special intellectual and cognitive abilities. In the twentieth century there was a radical change in the approach to creativity - both in the sense of process and the creative person. Currently, creativity is treated as everyday personal, group and professional activity manifested in every area of human activity, i.e. organizational, cognitive, productive, artistic, educational, caring, service, cleaning and sports. This perspective makes creativity an inalienable part of the functioning and management of a company, especially the formulation and implementation of strategies.

The aim of the article is to present an analytical tool for measuring creativity in strategies formulated in innovative startups. It was assumed that the basis of these strategies are intangible resources, generated as a result of creative activity of technostarters (startup managers). The concept of this tool refers to three dimensions of the strategy: novelty, usefulness and time perspective of its development. A qualitative methodology was chosen, including literature and surveys conducted among 42 startups located at the Wroclaw University of Science and Technology. The developed numerical tool is simple, clear and economically justified. The constructed tool allows to assess the

value of creativity in the generated and proposed strategic options even before choosing the right one, i.e. the one that will be effectively implemented. Technostarters, even those with little experience in strategy assessment, will determine the value of creating strategic options formulated in the strategic planning process by means of a list of questions (checklist) developed by the authors.

Defining Creativity

Human creativity has been the subject of research in psychology as well as in technical and economic sciences for many years. In the book by Nęcka (2003) indicates that there are four systemic approaches to human creativity in psychology:

- as a transgression (Kozielecki, 1997);
- as an investment (Sternberg and Lubart, 1995a);
- as a chance and a configuration (Simonton, 1997);
- as the system of an person, a field, and a domain (Csikszentmihalyi, 1996).

In technical sciences, intuition and imagination are the basic conditions for human creativity. Intuition is the ability to anticipate, without resorting to reasoning. It enables the anticipation of the course of physical phenomena or technical process under predetermined conditions. The instruments of intuition are: reasoning and experience. On the other hand, imagination means the ability to create certain images in thoughts. As Troskolanski (1978) writes, "Imagination [...] includes space and movement. No technical device may be created without the capacity for spatial vision: tool, instrument, machine, structure".

In the book by Pilawski (1990) claims that creative human activity cannot be strictly defined because it is a concept from the fields of economics, sociology, technology and law, as well as all these sciences simultaneously. In these disciplines, there is a lack of precise or axiomatically accepted elementary concepts - such as in mathematics - which would characterize human creativity in an unambiguous and exhaustive way. Taking such a point of view, it can be said that the work of both man and organization and other concepts used in management organization theory - e.g. strategy, organization, system - are by their very nature subjective concepts. They are the subject of research that uses the inductive method, which limits the "deductive precision of a strict definition based on a priori formulated axioms". Of course, this does not mean resigning from inventing, constructing, or verifying new concepts, in order to get to know the reality.

In economic sciences, on the other hand, creativity is defined as an economic process and compared to a transaction between the resources held and the needs of an individual (or groups of individuals), and the resources, needs and requirements of an environment in which shared resources are transformed in such a way that a new quality emerges to meet shared needs and requirements. In the book by Mirski (2011), this is done by transforming information, matter and energy into a useful, valuable, new and original product, in accordance with the requirements and needs of the environment.

In the book by Maslow (1957) characterizes creativity by searching for specific two levels: primary and secondary. Primary creation is a source of new discoveries, true novelty of ideas, which in their essence differ from the previous ones. On the other hand, secondary creation is characteristic of scientists and is visible in their common quest to discover new scientific phenomena. Secondary creation is achieved through cooperation and gaining experience from other researchers and shaping the basis for a new perspective on a given issue or idea.

Creativity can also be analyzed by distinguishing three levels of organization management:

- individual (cognitive abilities, knowledge, expertise, motivation);
- group (coherence of creative activities, group composition, accessibility to resources);
- the organization (legitimizing conflicts, encouraging high-risk activities, building a creative climate in the organization).

Each of these levels of creativity is described by a different set of factors that foster their development.

The level of individual creativity is a constant attitude of human to the world of things and the world of nature. Continuously and continuously, man generates something that can be new and valuable. Individual creativity is the ability to be constantly surprised, the ability to concentrate on a creative task, experience one's own self and sense of identity, it is also the ability to accept conflicts and tensions and the desire to "be born again" (Bratnicki et al, 2014). Individual creativity also means creating individual social bonds and shaping one's social advancement.

Group work refers to at least two people who interact directly with each other. Individuals - being one group - set common standards for thinking and acting, as well as a common goal. Thanks to this action, they have a sense of their own distinctiveness and equal access to resources and results of work. This kind of creativity is characteristic for startups, which are projects aimed at activities in completely new business areas. Creating a new product or service in such risky conditions requires organizing around creative ideas (Deren and Skonieczny, 2016).

Startup as A Creative Undertaking

The literature lists many characteristics of startups that characterize their essence as:

- a project created to produce new products and services in conditions of extreme uncertainty (Ries, 2011);
- an organization created to look for a repeatable and scalable business model (Blank and Dorf, 2013);
- a company in the first phase of development, which uses modern technological and innovative solutions (Kariv, 2013);
- a new company without an operational history, with a high degree of market and technology uncertainty (Giardino et al, ,2014);
- a new company in the growth and market research phase related to high-tech projects with high growth potential (Calopa et al, 2014).

Startups are based on the identification of a market trend or other problem giving new growth opportunities, for which an innovative solution has been found and a business model created (Chan Kim and Mauborgne, 2004). Startup should be disruptive, i.e. radically changing the market, and hyperscalable, i.e. characterized by a very fast growth of sales or number of customers, leading to a high valuation of the company (Skala, 2018).

Startups are mostly created by young, brave, passionate and committed people who want to use their skills creatively (Gontarek, 2017). Most often these people have an idea to solve the problem or fill the existing market gap, but they need help (financial, business) to do so.

In the case of startups two different approaches have been developed in the formulation of development strategies. The first one, traditional and borrowed from large companies, is based on a strategic plan. Formulating a strategic plan is a long and cumbersome process, which involves not only managers and specialists, but is also often the subject of conflict between different groups within and outside the company. A strategic process consists of several stages:

- strategic analysis;
- forecasting of environmental changes;
- developing a strategic vision of the company,
- to develop a strategy;
- develop a competition strategy;
- draw up an investment plan and develop a strategy.

The strategic plan (goals and objectives) act developed in this process shall be implemented.

An alternative approach to strategic planning is to use business models, e.g. Business Model Canvas (Osterwalder and Pigneur, 2010), Model Lean Startup (Ries, 2011) or Model Customer Development (Blank and Dorf, 2012). The last of these models contains two processes: search, implementation.
The search involves a stage of market research, where the creating vision is transformed into a series of hypotheses about the business model. Then the plan is developed to test customers' reactions to these hypotheses. On this basis facts and decisions are determined.

The next stage is market verification, where the defined business model is checked for repeatability and scalability. The stage of creating a customer base is the beginning of the business model implementation phase. This is where the demand among customers is created and sales develop.

Whereas building is the stage at which the organization changes from a start-up into an innovative enterprise focused on the implementation of a verified business model.

Both traditional, planning and model approaches have their advantages and disadvantages. In the case of strategic planning, the developed and adopted plan may become obsolete already at the time of implementation due to changes in the turbulent environment. The model approach is more flexible as it includes a pivot action. The weakness of this approach, on the other hand, is the quality and multiplicity of hypotheses to be verified.

In the opinion of the authors, a synthesis of these two approaches aimed at creating a creative space that will allow to generate, as for more strategic options (SWOT analysis), from which only those with the greatest value of creativity will be selected for implementation. Adopting such an assumption requires measurement of creativity in the developed strategy (strategic options).

Creativity in the Organization's Strategy

Creative processes trigger the ability of a person or a team to use their mental potential creatively when creating new, original ideas in the form of concepts, products or strategies (Ottemiller, et al 2014). In these processes different ideas are combined in an original way, new assumptions are made, new ideas are formulated which allow seeing old things in a new perspective.

The result of creative processes are new creative creations. According to Sternberg and Lubart (1995b) every new creative production "is original, unpredictable, capable of astonishing the viewer, because it is more than the next logical step".

In order for a given production to meet, literally, the requirement of 'creativity' must meet certain criteria. In the research study Cropley and Cropley (2005) claim that the basic distinguishing features of creative products (products) are: relevance and effectiveness - the product solves the problem it was supposed to solve; novelty - the product is original and "surprising"; elegance - the product is beautiful and pleasant; it goes beyond a simple mechanical solution by obtaining an additional bonus in the form of cost-effectiveness of the product; generality (generalizability) - the product has a wide range of applications; it can be used in other conditions and open up new opportunities to solve other problems (Cropley.

In the book Lipka, et al (2011) believe that the results of creative processes are diverse, which means that they can be both products and personal services for employees (present, future and former), whose properties are not imposed in any way. Such results should be characterized by the following features: novelty, originality, generosity (inspirational potential), value and social acceptance, i.e. recognition of usefulness at a given time. In their opinion, an example of a product with these characteristics is the Strategic Scorecard of Kaplan and Norton (2007). This charter presents a sequence of cause-and-effect activities as it helps to transform intangible assets into tangible ones in different functional areas of an organization. Initially, this charter has the characteristics of an original innovation which, through dissemination, becomes a mimicry innovation. Its subsequent versions, applicable in practice, are a transformation of the original in terms of specific features of the

organization's functioning. Such an action can be described as creative, and the implementation of this card in a given organization as reproducible.

In the book by Fazlagic (2015) proposes to use criteria relating to internal and external characteristics to assess creative products. Among the internal features he mentions: originality, value, novelty, uniqueness, logic, harmony, and the criteria relating to external features are: giving an impulse for changes in the environment, causing redefinition, changing the context or application, giving a new life or reconstructing, causing a change in the way of thinking, causing a synthesis of existing concepts into one new.

In business practice, multi-criteria assessment of creative products is basically avoided because it is a complex and costly process, which limits the choice of the 'most creative' product to be assessed. Most often the authors limit their choice to:

- one criterion, e.g. novelty (innovation) (Schumpeter, 1960);
- two criteria: product (existing; new) and market (existing; new) (Ansoff, 1957) or usefulness and price (Faukner and Bowman, 1995), or competitive target (broad; narrow) and competitive advantage (lower cost; uniqueness) (Porter, 1995), or novelty and usefulness (Puccio, el al, 2011).

In our opinion, three criteria should be used to evaluate creativity, i.e. novelty, usefulness and temporal perspective, in relation to strategy. The rationale for introducing the three criteria is the essence of the strategy, which in classical terms is defined as an action plan defining the long-term direction and scope of the organization's activities, achieving, thanks to its configuration of resources and competences, an advantage in a changing environment in order to meet the expectations of stakeholders (Johnson, et al, 2009). In addition, we believe that the creative process is natural for participants at all levels of management, so strategy is also a creative product. The more creative it contains, the more dynamic and flexible it will be with regard to changes in the startup environment. Any strategy is a creative product regardless of whether it is developed through a strategic planning process or through a business model.

Measuring creativity in strategy in practice

The analysis of the literature allowed the authors to assume that the fundamental role of creativity in strategy can be expressed in the synthesis of the strategic plan, market opportunities, organizational abilities and requirements for market success (Skonieczny, 2019). Based on this assumption, a survey was conducted among 42 small innovative companies and startups located in the Academic Incubator of Entrepreneurship at Wroclaw University of Science and Technology. The incubator was established in 2006 and promotes and supports the economic activity of students, doctoral students, employees and graduates and supports the creation of startups. At the same time, the incubator cooperates with experts who have knowledge of creativity and innovation and strategies to provide techno-starters with knowledge that supports new ideas, technical solutions and technologies that are the basis for the development of their startups in the academic environment. The incubator focuses on research, which are created at laboratories or scientific institutes. The results of their activities, e.g. in the form of new patents, can be used by commercial companies, once they have purchased appropriate licenses.

The prepared research questionnaire contained questions concerning the respondents' perception of the creative issues in the organization's strategy. The respondents, based on their knowledge and experience, had the opportunity to assess the value of creativity in the strategy, which is implemented in their startup. The value of creativity in the strategy was expressed by a simple formula:

$$V(C) = a_1\frac{\sum_{i=1}^{10} V(Ni)}{10} + a_2\frac{\sum_{i=1}^{10} V(Ui)}{10} + a_3\frac{\sum_{i=1}^{10} V(TPi)}{10}$$

Specification:
$a_1; a_2; a_3$ – indicators of novelty, usefulness and temporal perspective in strategy;

V(C) – creativity value in strategy;
$V(N_i)$ – novelty value in strategy;
$V(U_i)$ – usefulness value in strategy;
$V(TP_i)$ – temporal perspective value in strategy.

The value of novelty, usefulness and temporal perspective was calculated using the 7-point R. Likert scale. The study assumed that the share of novelty, usefulness and temporal perspective in the measuring of the value of creativity in the strategy is equal to 1/3 (a1 = a2 = a3). The calculated value of creativity in the strategy takes numbers in the range (1;7), where V(C) = 1 and means the lowest value of creativity in the creative V(C) = 7 is the highest value of creativity in the strategy. The study of novelty, usefulness and temporal perspective was based on the questions in tables 1-3.

Table 1: Measuring of novelty in the strategy

A novelty feature. Does the strategy allow for:
1. Generating new ideas, concepts and business models.
2. Monitoring existing, competitive, breakthrough and innovative solutions.
3. Transform and develop the generated ideas into ready-made market solutions and products.
4. Implementing and implementing the prepared solutions on the market.
5. Openness to new and previously unknown ideas, concepts and methods of operation.
6. Adaptation of new solutions created in other organizations.
7. Undertaking activities and undertakings in new market areas.
8. Patenting and protection of intellectual property resources.
9. Continuous improvement and development of resources of organizations oriented towards new solutions.
10. Eliminating factors constituting a barrier in generating and introducing new, innovative solutions.

Source: Own elaboration

Table 2: Measuring of usefulness in the strategy

A usefulness feature. Does the strategy allow for:
1. Undertaking market activities in the area of economic activity
2. Ability to act in conditions of uncertainty.
3. Moving forces and (economic) resources into areas with higher productivity and higher yield.
4. Recognizing opportunities and threats and making optimal choices.
5. Mobilization of material, intangible and relational resources
6. Searching for and using new resources that are in the organization and in its environment.
7. Searching for changes, responding to them and using them in the organization's activities.
8. Launching new business and organizational ventures.
9. Flexibility and the organization's ability to make sudden turns in business ("pivot").
10. Building a competitive advantage on the market.

Source: Own elaboration

Table 3: Measuring of the temporal perspective in the strategy

A temporal perspective feature: Does the strategy allow for:
1. Strengthening an organization's position in core market areas - local, regional, and global markets.
2. Providing additional benefits to customers.
3. Strengthening the organization's resilience to attacks from potential competitors.
4. Entering a strategic new market area (market development).
5. The organization's gaining a leadership position in a new market area.
6. Securing the achieved market position.
7. Monitoring and strengthening of the market position.
8. Responding to actions and attacks from competitors.
9. Expansion as the organization's strategy for functioning on the market.
10. Multiple options as an adopted strategy of the organization's operation and a condition of its success.

Source: Own elaboration.

The survey conducted among 42 startups showed that the dominant feature of their formulated strategies is the time perspective of (42.86% of responses), successively - novelty (37.715 responses) and usefulness (21.43% of responses). This sequence of features is surprising, especially in the context of innovations that should constitute the basis for the development of startups.

At the same time, half of the surveyed organizations (50% of responses) declare that intellectual resources are not secured in the analyzed strategy, for example by patenting. The verification of the proposed tool for measuring creativity in the strategy made it possible to collect important results regarding the use of strategies by the studied startups.

The most important of them are listed below. In the group of the examined startups:

- 40 startups declared that they have and implement their own strategy (95.24%). However, 2 organizations do not have and do not realize their own strategy;

- 76,1 % of the surveyed organizations (i.e. 32 startups) evaluate their strategy as more creative than the strategy implemented by competing organizations.

- 23.81% of the surveyed organizations (i.e. 10 startups) claim that the strategy of competitive entities is more creative than the strategy implemented by these organizations.

- 78.58% of the respondents identify creativity in strategy as a good method. However, 9 examined organizations (21.42%) do not identify creativity in strategy as a synonym of a good method.

- for 95.24% of the respondents, the key element identifying creativity in the strategy are choices concerning e.g. technology, market, customer, etc. Another important element in the opinion of the respondents is knowledge and understanding of the competitive environment (92.29%). Next, the respondents indicated: objective evaluation of possessed resources and desired resources (85.71%); simple, consistent and long-term goals (83.33%); simplicity, conciseness, comprehensibility and logic (80.95%); external and internal compatibility with the environment and possessed resources (80.95%);

- almost 62% of the surveyed organizations indicated six elements of strategy described in the literature on the subject as important, i.e: key choices concerning e.g. technology, market, customer, etc.; simplicity, conciseness, comprehensibility, logic, rationality; external and internal compatibility with the environment and possessed resources; simple, consistent and long-term goals; knowledge and understanding of the competitive environment; objective evaluation of possessed resources and desired resources as those that identify creativity in the strategy;

- 21.42% of respondents do not see the relation between the so-called good or successful strategy and creativity in the strategy.

The use of the above-described tool for measuring creativity in the strategy (novelty, usefulness and time perspective) in practice allows startups to diagnose market challenges, and then develop strategic options and choose the one that has the greatest chance of success. The developed questions also enable technostarters, resources necessary to achieve the assumed strategic goals.

Conclusions

Today's innovative companies operate in a turbulent environment, in which it is particularly difficult to predict changes. This requires creative action, especially in the formulation of strategies (strategic options). Due to the unstable environment, the generated strategic options must be subject to continuous assessment and creative modification. This assessment requires simple, clear and economically justified tools. The analytical tool for measuring creativity in strategy presented in the

article meets these criteria. The concept of this tool refers to three key dimensions of the strategy: novelty (innovative creation), usefulness (applied creation) and time perspective (long-term creation). The constructed tool was used to evaluate the strategy of startups operating in the Academic Enterprise Incubator located at the Wroclaw University of Science and Technology. These startups face the problem of uncertain demand, limited internal resources and the search for an innovative business model. In this situation, the success of the venture depends not only on the innovative potential and the possibility of its commercialization, but above all on a creative strategy which enables the formulation of many different, alternative strategic options and the selection of those which, if effectively implemented, guarantee the greatest success (the transition of the startup to the next phase of development).

Qualitative research carried out by the authors was based on examples of startups with regard to their development phases. The research used a configuration approach based on the managerial perception method obtained by means of a questionnaire, focusing on the creation and development processes for the startup model. The questions generated in the questionnaire are not only used to determine the level of creativity value in the strategy, but above all they are helpful in the evaluation of each of the proposed strategic options. The list of questions presented in tables 1-3 is not closed and can be supplemented with further ones, which will appear on the basis of knowledge and experience gained during startup operation.

The described tool for measuring creativity in the strategy allows not only to assess the value of creativity in the generated strategic options, but also to select those options that contain the greatest creative value. Creativity is a source of all innovation and entrepreneurship, and thus an important mechanism for the development not only of startups, but of all modern organizations. There are many instruments in the literature to measure creativity in organizations at different levels. Among them one can distinguish: the KEYS instrument, the creativity climate questionnaire (CCQ). KEYS is a tool developed by Amabile et al (1996) and used to measure the perception of the work environment both at the level of an organization and at the level of team and management. These tools focus on the analysis of different components and are based on different concepts that take into account the different dimensions of an organization. The described tool for measuring creativity in a strategy is a simple and universal solution aimed primarily at startups and small innovative companies. The concept of researching creativity in a strategy in configuration presented in the study provides a basis for further research aimed at explaining the role and impact of creativity in the strategy of creating and developing other organizations.

Abstracts

The study investigated the financial sustainability of the public federal higher educational institutions in Nigeria. The population of the study comprised twenty-five (25) Public higher educational institutions from four (4) geo-political zones and Abuja. Secondary data were sourced from Annual General Warrant from the Office of the Accountant General of the Federation and Audited Financial Statements of the Public Sector Entities. Data obtained were analyzed using Balanced Score Card techniques. The results showed that more than 92% of the sampled public higher educational institutions in Nigeria only attained a basic standard of sustainability test where the ratios of their Internally Generated Revenue to recurrent expenditure is between (40 – 60)% or 0.04 and 0.6 showing the ability of the institutions to generate sufficient revenue independently to cover only the operational expenses in the short-run. Also, the results equally showed that only 8% of the population attained an intermediate standard of sustainability whereby the ratio of Internally Generated Revenue to Recurrent expenditure is between (60 – 90%) or 0.6 and 0.9, indicating that 92% of the institutions heavily depended on central authority funding for their survival. The results further revealed that none of the higher educational institutions attained an advance standard of sustainability, that is, showing zero reliance on external funding. In conclusion, public higher educational institutions in Nigeria are financially dependent on central authority for survival. Therefore, the central authorities should roll out blueprints that will make the public higher educational institutions widen their internally generated revenue capacity and reduce the reliance on central authority funding for sustenance

Keywords*:* Financial Sustainability, IGR, Educational institution, Balanced Scorecard.

Introduction

The need for the prevalence of both the operating and financial sustainability within the financial system of the public higher institutions has been a major concern among stakeholders in Nigeria. Though, these institutions fall under the not-for-profit-making organizations, the delay or sometimes, the denial of financial inflows from the central authorities has weakened the capacity of federal educational institutions capacity to generate enough revenue to cover operational costs and still have sufficient balance for capital investment and plough backs for further developments. One of the biggest puzzles of a public sector entity is the attainment of sustainability. Either operating or financial sustainability is attained by a public higher educational institution where the needs of today are met without compromising future ability to meet different needs in the scheme of things within the organization for tomorrow (Hahn and Figge, 2011). Therefore, the drive towards both operating sustainability and financial sustainability becomes the daily dreams of public federal higher educational institutions in Nigeria. This realization is expected to serve as a panacea against an operational crisis in times of sharp cuts in central authority grants and financial releases from the supervising agencies or Federal Ministry of finance. To maintain, therefore, both the operating and financial sustainability, it becomes necessary for these institutions to increase their internal generating-revenue capacity to accommodate all operational costs, absorb recurrent expenditure,keep sufficient fund balance for physical project developments and also for executing quality academic

researches that will deepen the wealth of knowledge among the academia.This study was precipitated by the inability of the federal educational institutions to carry out basic statutory functions like payment of staff salaries,provision of basic amenities,maintenance and repairs of non-current assets etc with a delay or denial of government funding despite the IGRs by these entities.Many authors have written on the trends or patterns of internally revenue generated of the federal educational institutions in Nigeria,but there is a caveat.The linkage of the various inflows to the sustainability of the institutions has been left uninvestigated.This missing link is the focus of this study. This paper, therefore, investigated both the operational and financial sustainability of the public federal higher educational institutions in Nigeria. The remainder of this paper is arranged as follows: following the introductory session, session two reviewed the relevant literature while session three discussed the methodology. Session four focused on the interpretation and discussion of findings while session five concluded the paper and outlined the policy recommendations for all the stakeholders.

Literature Review

Sustainability is the ability of a going concern to meet the current obligation within its own resources without compromising meeting the future needs (Hahns & Figgae, 2011). It is the ability to meet the needs of today within the fiscal year which measures budget solvency, paying up current obligations, maintaining existing service levels and settling outstanding obligations of the entity to the sundry creditors (Onwuliri & Alozie, 2017). The steady slide in crude-oil prices in the recent years has resulted to statutory decline in national revenue generation in Nigeria(Okonkwo, 2014). The effect of fall in oil-prices has exerted liquidity pressure on the federal government driving her towards finding alternative ways of funding by public entities. Evaluating the ability of a public educational institution to meet its obligation as it arises within the organization therefore becomes imperative.

Financial solvency in government treasury is often associated to multifactorial factors ranging from environmental factors, financial factors and organization factors. Public educational institutions hardly maintain a balanced budget that will sustain the entity sustainability (Masengo, 2011, Mupunga and Leperox 2015,Rittona 2014, Alogoskoufis 2011, Kouretta 2010). Attaining corporate sustainability therefore entailing public entity's expanding the financial bottom line.It equally requires widening the financial resources base of entities into a triple bottom base to accommodate sustainable growth and development (Albertini, 2013, Rivera,Munoz& Moneva,2017). Therefore, how public entity positions itself to achieve sustainable development and balances financial discipline with human development is a great concern to the top echelons within the organisation (Shank & Shockey, 2016).

Corporate sustainability focuses on the ability to generate enough revenue to meet both capital and recurrent operating expenses within the entity (Nollenberger, 2003, Chaney, 2002, GFOA, 2003, Crawford & Associate, 2008,Yawar & Seuring,2017). It determines whether the entity will continue in operation or not, either in a short-run or in a long-run. The inability of an entity to generate inflows large enough within its internal resource to cover recurrent expenses and operational cost is a proof that the entities are not sustainable(Moldavska,2017). Such inability is also an indication of the entity's reliance on the central authority for external assistance to cover recurrent liabilities so as to keep afloat. Corporate sustainability, therefore, focuses on the expansion of the entity's financial base to include both the environmental and social aspects of organizational performance (Albertini,2013,Shah,Arjoon& Rambocas,2016). As the public federal higher educational institutions compete among themselves to remain relevant within their core values and competencies in the emerging markets, the challenge of sustainability has weakened the realization of these dreams. The reality of insufficient cashflows from the Federal government to cushion the effects of inadequate internally generated revenue has demystified the realization of the organizational goals(Grewatsch &Kleindienst,2017).This has propelled the search for survival and formulate strategies to keep aglow outside the operating environment of the organization for reliance and external funding (Dixon-Fowler, Slater, Johnson, Ellstrand, Romi,2013). The federal higher education institutions which are unable to generate enough fund within their production bases and sphere of influence to cover running expenses are therefore unable to stand alone in times of financial shocks (Crawford,2008, Truant,Corazza &Scagnelli,2017)). Also, such entities are susceptible to failure and in danger of winding up in the event of a continuous delay from the central authority in releasing financial

resources to the entities. Financial literature on sustainability contains different standards or tests established to determine the revenue-generating ability of the public entities. The standards address the entity's ability to meet current operational costs within the internally generated revenue (Ngomonu & Wang, 2015).

An entity, therefore, attains a basic standard of financial sustainability if its ability to raise revenue within its own internally generated resource to meet the operational cost in the organization falls between 40% and 60% (0.4 and 0.6) (GFOA, 2003). The institution is, therefore, able to muster the financial strength, to source for fund internally within its resource without reliance on external assistance for the entity's financial demands. The attainment of basic standard of financial sustainability, therefore, means that the entity satisfies the necessary condition for survival or prove its of ability to continue in operations. At this phase of the sustainability test, only 40% to 60% of the revenue demand for recurrent expenses are met internally.The entity is therefore able to provide basic needs,settle its bills as they arise etc in the short-run. However,where the going concern revenue generation's ability is higher and above the basic standard, the entity operates better and with greater results. At this advanced level, the entity attains an intermediate standard whereby its revenue generation ability ratio is between 60% and 90% (0.6 and 0.9). Institutions in this group have more ability to accommodate financial shocks, extend operations, absorb more running expenses and depend less on federal authority for funding. Lastly, a public entity attains an advanced standard when it's ability to generate revenue within own operations is greater than 90% (> 0.90) (GFOA, 2003). This stage is the target of all federal higher educational institutions in Nigeria. At this standard, all financing decisions and investing decisions are made without any external restraints or influence on the entity. Financial commitments or obligations are taken at this point without prejudice to the central authority's assistance. Therefore, this phase witnesses the ability of a public sector's entity to generate fund within the sphere of its internally generated revenue to meet all its operational costs and still have enough revenue to invest on different capital goods. The attainment at this level signals a major component of the financial sustainability of an enterprise.

Also, the sustainability test of an entity is determined by the level of its operating surplus ratios. A public higher educational institution is financially sustainable if it attains a positive operating surplus ratio with a stable financial plan in the long-run coupled with the ability to sustain this feat. The indication of a positive ratio for an entity is the percentage increase in total own revenue which are needed for the entity to attain break-even operating results at the current operation (Nollenberger, 2003, Cheney et al., 2002, GFOA, 2003, Crawford and Associate, 2008). A public higher educational institution, therefore, attains a basic standard of financial sustainability when its ratio is between 1% and 15% (0.01 and 0.15) during an operational year and advanced standard when its ratio is greater than 15% (> 0.15) (GFOA, 2003).

The fund mobilization capacity and the extent at which the entity is reliant on other government agencies for funding its operation is another component to determine the financial sustainability of a financial entity. An institution with a higher ratio is an indication of its heavy reliance on external resources for survival (Nollenbarger, 2003, Cheney et al., 2002, GFOA, 2003, Crawford and Associate, 2008). The study anchors on the theory of constraints to drive the rest of the work.According to the theory,every entity must identify its weakest link or constraints before it can improve its performance.

Methodology

The paper focused on the sustainability of the federal higher Educational Institutions in Nigeria. The population of the study comprised twenty-five (25) federal higher education institutions from four (4) geo-political zones and Abuja. Secondary data were sourced from Annual General Warrant from the office of the Accountant General of the Federation and Audited Financial Statements of the Public sector entities between 2008 – 2016. The balanced scorecard was adopted in analyzing the data. The evaluation of both the operating and financial sustainability of the public educational institutions was therefore carried out using the balanced scorecard proposed by Kaplan and Norton (1992). The use of balanced scorecard is famous in public sector entities' performance measurement. Previous studies by different authors like Kloof and Martin (2000), Moullin (2007), Askin (2004), Drury (2001), and Striteske (2010) adopted balanced scored card as the techniques of analysis. The balanced scorecard,

therefore, has been used copiously to analyse both the operating and financial sustainability tests of the public sector entities (MAB, 1997).

Measurement of the Operating and Financial Sustainability of Public Higher Educational Institutions

The financial metrics play a dominant role in the measurements and determination of sustainability of public entity and are therefore frequently used as predictors of financial performance in public organizations using relevant variables (Sheh, 2014, GFOA 2003, Craword & Associates, 2008). The financial metrics for public sector performance measurements are as follows:

$$OPF_{it}{}^{1} = IR_{it}/RE_{it}$$
(1)

$$OPF_{it}{}^{2} = TR_{it} - RE_{it}/IR_{it}$$
(2)

$$FMB_{it} - IGF_{it}/TRG_{it}$$
(3)

$$BUP_{it}{}^{1} = BTR_{it} - ATR_{it}/BTR_{it}$$
(4)

$$BUP_{it}{}^{2} - BTE_{it} - ATE_{it}/BTE_{it}$$
(5)

These are financial ratios computed based on the public sector entities' financial statements and fund statements. Financial ratios are valuable tools used in measuring an organization's financial behaviour and performance (Erdogan, 2013). The operationalization of the variables is presented in Table 1.

Table 1: Operationalization of Operating and Financial Sustainability Variables

S/N	Variables	Measurement	Apriori's expectation
1.	Operating Performance (OPF^1)	Internally Generated Revenue (IGR)/Recurrent Expenditure (RE)	1. Basic standard (40-60)% or (0.4 and 0.6). 2. Intermediate standard (60-90)% or (0.6 – 0.9). 3. Advanced standard more than 90% or > 0.9
2.	Operating Performance (OPF^2)	Total Revenue (TR) – Recurrent Expenditure (RE)/ Internally Generated Revenue (IR)	1. Basic standard between (1-15)% or 0.1 – 0.15. 2. Advanced standard > 15%
3.	Fund Mobilization Performance (FMP)	Total Intergovernmental Funds Received (IGF)/ Total Revenue including Grants and Contribution (TGR)	High ratio is an indication of high reliant on external resources for funding.
4.	Budget Performance (BuP^1)	Budgeted Total Revenue (BTR) – Actual Total Revenue (ATR)/ Budgeted Total Revenue (BTR)	High ratio is an indication of high performance and ability to meet revenue budget in internal and external source while low ratio means low performance and inability to meet revenue budget.
5.	Budget Performance	Budgeted Total Expenditure	A low ratio shows the ability of the

	(BuP[2])	(BTE) – Actual Total Expenditure (ATE)/ Budgeted Total Expenditure (BTE)	entity to minimize cost and attain the expenditure budget while high ratios show the inability of the entity to minimize costs.

Measurements of Variables in evaluating the Operating and financial sustainability of public higher educational institutions.

In interpreting ratios in equation (1) and (2), variable $OPF_{it}1$ and $OPF_{it}2$ represent the public sector entities operating performance ratios for entity i at time t. IR_{it} is the total internal revenue collected by the public sector entity from different internal sources. RE_{it} is the total recurrent expenditure of the entity at time t and TR_{it} is the total operating revenue excluding grants and contribution for the development by the public sector entity i at time t. In equation (3), variable $FMB_{it}1$ represents the fund mobilization performance ratio of public sector entity i at time t, IGF_{it} is the total intergovernmental funds received by the entity i at time t, and TRG_{it} is the total revenue including grants and contribution for the development by the public sector entity i at time t.

In equation (4) and (5), $BUP_{it}\ 1$ and $BUP_{it}2$, represent budget performance ratios for ith entity in time t for model 1 to 2. ATR_{it} is the actual total revenue collected for each public sector entity i in time t, BTR_{it} is the budgeted total revenue collected for entity i in time t, ATE_{it} is the actual total expenditure for entity i in time t and BTE is the budgeted total expenditure of public sector entity i in time t.

In equation (1), $OPF_{it}\ 1$ measures the operational sustainability of the public sector entity. It determines whether there is adequate revenue to finance the recurrent operational expenses. It is a measure of public sector financial performance. Inability of the entity to cover operating expenditure within its resources is a symptom of over-reliance on external borrowings and intergovernmental funds. When operating expenses are not met within the internally generated revenue, it is a signal that the entity is not sustainable. These entities are incapacitated to operate in a situation when the central government funds are unavailable or denied or delayed. Different standards have been established to recognize the varying revenue-raising capacities of the public sector entities. GFOA (2003) came up with three basis of measuring revenue-raising capacities of public sector entities as standard basic, intermediate basic and advance basic. A basic standard is achieved within an entity when the revenue-generating capacity ratio is between 40% and 60% (or 0.4 and 0.6). An intermediate standard is achieved when the ratio of internally generated revenue capacity of an entity is rated between 60% and 90% (or 0.6 and 0.9). An advanced standard for a public entity is achieved when the ratio of revenue generated capacity is greater than 90% (or > 0.9) GFOA (2003).

In equation (2), $OPF_{it}\ 2$ measures the ability of the public sector entity to cover its operational cost and have revenue available for capital funding or other purposes within the accounting year or thereafter in the organization. A public entity is sustainable if it can achieve a consistent positive operating surplus with long term sound financial plans and still have the potential to continue in that capacity shortly. A negative ratio indicates the percentage increase in total own-source revenue (principally rates) that would have been required to achieve a break-even operating result (Nollenbarger, 2003; Chaney, 2002; GFOA, 2003, Crawford & Associate, 2008).

The basic standard between 1% and 15% (0.01 and 0.15) is the benchmark while the advanced standard > 15% (> 0.15) is the recommended standard GFOA (2003). In equation (3), $FMB_{it}1$ measures the extent to which a public sector entity is reliant on other government for resources. A high ratio may indicate that a public sector entity is over-reliant on external resources, increasing risk as external providers may alter funding streams (Nollenberyer, 2003; Chaney, 2002; GFOA, 2003; Crawford & Associate, 2008).

Equation (4) and (5) represent BUP_{it} measure the ability of the public sector entity to manage the budgets which they set in the accounting period (Nollenberyer, 2003; Chaney, 2002; GFOA, 2003; Crawford & Associate, 2008). Two ratios are often used to assess the budget performance. The first ratio addresses the ability of the public sector entity to meet the revenue budget in terms of total revenue collected from both the internal and government's sources while the other ratio measures the ability of public sector entities to minimize cost and attain the expenditure budget.

Results and Discussion of Findings

Figure 1 presents the operational sustainability of the public sector entities in the education sector. It illustrates how the public educational institutions within the sector are more likely to sustain, with the ratios of revenue capacity generated ranging between 40% and 60%. The implication of this is that some of the institutions within the sector can muster strength with available internally Generated Revenue (IGR) in times of delay of personnel allocations and overhead costs from the central authority. In other words,the MDAs in this category are not heavily reliant on federal government subventions to cover their operational costs. Many of these educational institutions are able to cope in the short-run at the periods of paucity of fund from the headquarters, by paying its current obligations as and when due. At these levels of operations, the institutions can also maintain existing service levels as well as meeting outstanding obligations in the short-run.Also, the attainment of operational sustainability mean that the revenue base for the educational institutions is therefore relatively wide in scope and large in size to accommodate pressing operating costs without recourse to external funding. This ability to generate revenue independently from internal sources to cover the operational costs make the educational institutions able to weather the storm and insulate against all odds during the financial crisis. The wide sources of revenue generations make the institutions under the education sector less vulnerable to external control and less dependent on intergovernmental financial releases and local borrowings. The sector's operations are hardly stifled by federal government temporary delay in funding and releases for recurrent operational expenses. There are three attainable standards of operating sustainability: the basic standard, the intermediate standard and the advanced standard.

The Basic Standard portrays the educational institution's ability to operate in the short-run; covering both the overhead costs and operational costs. Therefore, the basic standard test for the institution is determined by the ability of the entity to generate sufficient revenue independently to settle organization recurrent expenses within the accrued internally generated revenue in the short-run. The inability of any educational institution to cover operating expenditure arising from the organization's operations in the short-run is an indication of overt dependence on external sources for survival (Nollenberger, 2003). It can be seen from the table that most of the institutions operated between (40%- 60%) which qualified them for the minimum sustainable standard of sustainability test.

However, the basic standard is a minimum level of sustainability test.It is a short-run effect. In the long run, some of the educational institutions could not cope with operating challenges of incurring running expenses. Therefore, in the event of central authority's delay in releasing personnel costs allocations meant for the payment of salaries, overhead costs releases for financing overhead recurrent expenditure, many of the institutions are unable to cope with the tide of stringent financial allocations.

Also, in the consideration of the number of educational institutions that attained the intermediate standard, out of the twenty-five (25) sampled organizations in the education sector, only two of them WAEC and JAMB attained an intermediate standard with the average sustainability test ratios of 70% which falls within the prescribed intermediate standard (60% - 90%) (GFOA, 2003). These two institutions represent just 8% of the sampled population. In other words, only two institutions out of a total of twenty -five institutions can finance their recurrent expenditure without allocation from central authority with little or no financial stress. The operations of these two institutions are clearly different from the remaining 23 educational institutions.West Africa Examination Council (WAEC) is an educational agency for the whole of West African countries.Its primary funtions include organizing the significant O' Level examination for West African students,deciding which

examinations are needed for school students from different countries in West Africa.This autonomous body is equally saddled with the responsibility of issuing of O'level certificates to successful students,ensuring that educational standards are met during various examintions and equally promoting and helping students understand how big their potential goes beyond the exams.Its operating activities are financed mostly through the charges collected from students and does not rely solely on governmental funding for survival.Also,Joint Admission and Matriclation Board (JAMB)is also an autonomous body.It was established in 1978.The core functions of JAMB includes conducting UTME(Unified Tertiary Mtriculation Exams to the secondary school graduates.It ensures that every student who wishes to study at a tertiary institutionmeets all the requirements totake UTME. JAMB is responsible for fixing the dates,duration and test-type of UTME examinations.Its operations are financed by the various charges derivable from students and does not rely solely on external funding for financing.

The other twenty-three (23) entities which represent 92% of the population in the sector only attained a minimum sustainability level between 40% - 60%. The implication is that in the period of adverse and prolonged financial inflows from the central bodies or central authorities, only two entities (8%) out of twenty-five could withstand the hardship of long paucity of funds from the federal government. The other twenty-three (23) entities whose sustainability test ratios fall within (40% - 60%) will experience difficulty in settling recurrent expenses without external funding. This group of institutions with a low fiscal sustainability index ran huge recurrent expenditure that cannot be sustained within the internally generated revenue. Many of the educational institutions run high recurrent bills mainly driven by the high allocations received from the federal government without counterpart funding from their IGR. The implication of low revenue to these institutions, therefore, means that the amount of money available for both human and physical developments would be restricted. Also, in case of any oil price fluctuations in the international markets which are the mainstay of all the entities, many of these institutions face the risk of downsizing of staff or suspension of core services due to inability to pay staff salaries. The third standard is the advanced standard whereby the ratio of revenue generation capacity is greater than 90% (or > 0.9). This is the sufficient condition for an entity to operate in order to attain optimum sustainability level to insulate against both short-term and long-term financial hardships from the central authorities or intergovernmental bodies. Unfortunately, none of the institutions within the sampled population achieved this feat. The implication is that the higher public educational institutions in Nigeria cannot adequately generate enough funds internally on their own to meet internal operating needs for a relatively long period without external funding from the central authorities.

Figure 1: Operational sustainability of public educational institutions in Nigeria

Figure 1 shows the spread of operational sustainability test values of the public higher educational institutions in Nigeria. From the sustainability index above, it shows that most of the institutions attained the basic standard of sustainability with the sustainability index ranging from 40%-60%.

In summary, therefore, the public higher educational institutions in Nigeria are clinically sick with weak financial bases for generating enough internal revenue to finance its legitimate core operations and cover all its operating expenses within its defined revenue base. The ability to generate fund for internal operations is only restricted to a basic standard which is the lowest attainable standard of sustainability. The inability to withstand financial storms occasioned by prolonged delay or absence of external funding is more pronounced among the entities.

Figure 2 presents the financial sustainability of the public educational institutions.The financial sustainability means that the entity has ability not only to cover operational costs but also sustain sufficient revenues thereafter within the organization for capital funding, investment purposes and ploughing back for other developments. According to Crawford and Associates (2008), a public entity is financially sustainable, if the entity consistently achieves a positive operating surplus ratio within the organization.Also,the entity must show evidence of a sound long-term financial plan for the foreseeable future, and a consideration of asset management within the institution. In this context, therefore, an entity that cannot sustain a positive operating surplus in the long-run with a sound long-term financial plan is not financially sustainable.

Differences, therefore, abound between operational sustainability and financial sustainability of an entity. Operational sustainability is a subset of financial sustainability. An entity can attain operational sustainability without achieving financial sustainability. Operational sustainability is a short-run concept whereas financial sustainability is a long-run concept. Therefore, an entity fulfils a necessary condition for attaining operational sustainability when sufficient revenues are generated to pay for recurrent operational expenses within the organization in the short -run. Attaining financial sustainability is a sufficient condition attainable when sufficient revenue generated by the entities covers the operational costs, with sufficient balance being left behind to be ploughed back into the organization for capital funding, project investments and the execution of different chains of capital contracts. Figure 2 therefore, presents the financial sustainability of the public higher under the study. For all the institutions under consideration, their positive operating surplus ratios recorded were above the minimum basic standard of 1% and 15%. All of them attained advanced standard where positive operating surplus is greater than 15% (> 0.15). They are therefore considered financially sustainable. At this level, the institutions can cover operational costs and still have revenues available within the entity for capital funding or capital project investment and ploughing back the surplus for future use (Crawford & Associates, 2008, GFOA, 2003, Wollenberger, 2003). This, therefore, suggests that these educational institutions have relatively large internal generated revenue base wide enough to accommodate physical and human development after covering the operational costs within the entities.

In times of financial crisis and economic meltdown which normally characterized by cuts in government capital project releases, these entities can still keep afloat in capital funding by expanding their capital development (Palley, 2006, Khattry, 2013, Kumar, Lagh & Plekhanvov, 2007, Mwakalobo, 2009, 2010, 2013).

Figure 2: Financial sustainability index of higher public educational Institutions in Nigeria

Figure 2 shows the sustainability index of federal higher institutions in Nigeria. The average operating surplus ratios are positive showing that institutions are financially stable with the ability to generate enough revenue internally to cover operational costs and still have sufficient for capital developments.

Also, in the period of adverse restrictive fiscal policies which impacts negatively on public spending whereby government infrastructure in many institutions suffer from government expenditure comprehension, this group of federal educational institutions can withstand the tide by expanding their capital physical development through the meager internally generated revenue (Kumar, 2007, Basu & Movrissey, 2007, Schade, 2010, Drether, 2012, Gupta, 2012). This is largely because the entities can demonstrate persistent ability to cover their operational costs within the scope of their operations consistently and still have sufficient revenue available for future developments such as road construction, building of more hostels and lecture theatres etc. More also, the attainment of financial sustainability by the public sector entities is a proof of an existence of a sound long-term financial plans within the organization coupled with a good asset management accommodated within the positive operating surplus ratio. The institutions under the education sector are therefore considered financially sustainable within the research periods.

In Figure 3, budget performance among the institutions in the education sector is displayed with the various percentages against the institutions during the research periods. Ninety-two (92%) of the federal institutions recorded low budget performance while eight (8%) recorded high budget performance. This imply that 92% of the population could not manage their budgets which they prepared in their organizations for the accounting period. The implication is that budget deficits and budget summersaults are grave consequences in the organizations. The personnel cost deficits will, therefore, lead to the inability of the institutions to pay the adequate salaries to the employees as at when due, resulting in personnel cost shortfalls. Besides, if the situation continues unchecked, the possibility of downsizing and right-sizing of both line and administrative personnel staff to maintain a sizeable payroll is imminent. The prevalence of high budget deficits in overhead cost budget will equally worsen the inability of the institutions to settle current obligations in the organization. The scenario also presents the lack of budgetary provisions for current obligation or when budgetary

provision is not backed up with the available cash to pay for it, which hinders public budgets translating governments' policies, commitments and goals into sound decision making. The fedaeral educational institution's budget focuses on how much revenue to raise, how it should be raised and modalities to use these funds to meet the organization's competing needs. An organization, therefore, needs a functional budget to develop sustainable financial policies and organizational growth. Federal higher educational institutions with financial problems are sometimes propelled by weak budget systems and faulty budget choices which result in debt overhangs to many institutions.

Figure 3: Sustainability Index on Higher Educational Institutions on Budget Performance

Figure 3shows the sustainability index of public educational institutions with budget performance. From the figure, the majority of the institutions (92%) recorded low budget performance while 8% of the population recorded high budget performance.

It can, therefore, be concluded that federal higher educational institutions in Nigeria suffered from weak budgetary system whereby allocated funds to specific programme or projects hardly reach the intended beneficiaries or accomplish the projects for which the fund are earmarked for.

Figure 4 measures the ability of the institutions to minimize cost and attain the expenditure budget within the accounting periods. The figure contains ratios that are used to assess the budget performance of the entities in the current year in addition to the previous year measurement. The cost minimization concept is a financial strategy aimed at achieving the most cost-effective way of delivering goods and services to the required level of quality in an organization.

Figure 4: Sustainability Index on Cost Minimization and Expenditure Budget

Figure 4 shows the sustainability index of the higher public educational institutions with their ability to minimize the costs of inputs. The graph shows that the propensity of the institutions to minimize costs is low thereby leading to redundancies and wastages.

The result of a reduction in cost is higher profits and better cash inflows. Public entity's problem sometimes behaves in the same direction with the private firm's problem which maximizes profits by choosing the optimal quantity of inputs to employ and output to produces. From figure 4, the capacity of the entities under the education sector appears lower in minimizing the costs of inputs among the various institutions. The stark reality is that wastages, redundancies, bureaucracies, perennial losses are the multiple effects in a low-cost minimizing organization. Therefore, the low propensity of the federal educational institutions to minimize the cost of both personnel costs and material costs are parts of gateways to perennial redundancies and wastages that characterize our higher institutions of learning in Nigeria.

Figure 5 presents a summary of the federal higher educational institutions' behaviour in fund mobilization and performance ratios within the sampled population. The fund mobilization performance ratios are stated between 24% - 25% at lower and upper limits. This is an indication that the educational institutions did not depend heavily on external fund providers for the execution of various projects. It also emphases the capacity of the entities to attract foreign aids or external fund with minimum efforts in addition to the streams of internally generated revenue available to meet up financial obligations as they arise. Therefore, the evidences of the low fund mobilization performance index for the educational institutions measure the extent to which the entities do not rely on government funding as the main sources of fund. The lower the fund mobilization performance ratios the better for the organization to survive in times of financial hardship. Also, any delay or denial from the central authority for releases, grants or/and financial allocations to the institutions will not strangulate the entity. Nigerian government presently faces three trade-offs in the process of public expenditure management which can affect the public higher educational institutions in Nigeria that heavily rely on the central authority for funding without alternative counterpart funding within the organization (Khattrg, 2013). The first trade-off is between the spending on physical infrastructure and human capital development within the organization which are sometimes mutually exclusive and makes capital rationing the only viable option.

However, because of the substantial costs expected of capital investments which government undertakes, a larger proportion of the costs on capital investment takes place to the inclusion of substantial resources on human capital investment in the organization (Mwakalobo, 2015). The second trade-off is allocating resources between public investment in both physical and human capital infrastructure and interest payments in the nation accumulated debt. A low level of

dependence on the central authority by the public higher institutions is, therefore, a panacea for the governments to focus on the multifaceted paradigm.

Figure 5: Sustainability Index of Fund Mobilization and Performance

The figure above shows the sustainability index for the public educational institutions on fund mobilization and performance. The low fund mobilization performance ratios indicate that the institutions were not dependent solely on external funding for survival.

Conclusion

The paper investigated the financial sustainability of the public higher educational institutions in Nigeria. The findings revealed that all the federal higher educational institutions operated at the basic standard level whereby they could generate enough revenue to cover operational expenditures while some of the institutions also attained intermediate standards whereby they could generate enough revenue for their operational costs and still have enough fund for capital investment and plough back for future usage. This feat, others could not achieve. The study, therefore, concluded that the central authorities should roll out blueprints that will make the federal higher educational institutions in Nigeria widen their internally generated revenue capacity and reduce the reliance on central authority funding for improved sustainability.

Recommendation

In order to improve the level of sustainability of the higher institutions in Nigeria, the following recommendations become imperative :

Central authority should roll out blueprints for all public higher institution to widen their Internally Generated Revenue base. These could be by building more of student hostels at lower commercial rates to students, operation of bakery services, bookshops, printing press, farm produce, maintenance of filling stations etc. The current trend now in the public sector entities funding is the introduction of public-private partnership arrangement whereby essential services that cannot be provided only by government's allocations are assisted through the involvement of private individuals who inject fund

and make the services available as at when due. The higher educational institutions can take advantage of this arrangement.

The cost minimization strategies have been proved to be potent in stemming the wave of wastages and redundancies in many organizations. As a way out of a financial crisis that bedevils many government higher institutions, workable plans to minimize costs should be introduced into the institutions to alleviate the challenges of cash crunch and liquidity problem. The education institutions should embark on rigorous fund mobilization drives in all areas of operations and activities within the organization. Less reliance should be placed on the dependence on financial allocations and releases from the central authorities.

The educational institutions should stop the lopsidedness in staff appointments to minimize wastages in personnel costs utilization. Also, due process should be followed in material procurements for all units in the various institutions to prevent double-dealings and enhance transparency in all financial dealings in the educational systems. There should be tight budgetary systems in all the educational institutions that would be strictly based on available revenue generation during the accounting year. Bounded goods should be discouraged in all the institutions as a matter of policy.

Confirmations of both budgetary provision and fund availability should always precede procurement processes for all items of purchases. Needs assessment strategies should be evolved in all the institutions to demarcate needs from wants. Each institution should identify areas of acute shortage of staff and material needs and focus on such critical areas. Efforts should equally be on deck to eliminate all slacks in both personnel cost allocations and overhead costs expenditure.

The federal government should create incentives for all the educational institutions to expand growth and earning potentials thereby enabling resources needed to improve educational facilities in the countries. The study, therefore, concluded that the central authorities should roll out blueprints that will make the public higher educational institutions in Nigeria widen their internally generated revenue capacity and reduce the reliance on central authority funding for improved sustainability.

Abstract

In Portugal, 90% of software developing companies are micro companies. In 2002, in the Brazilian market, about 60% of the software developing companies would start their activities with just a single developer (Pagotto, Fabrti, Lerario, and Gonçalves, 2016). The Scrum Solo methodology was developed having in mind, that there is a big need for organizing and managing the software development of teams comprised by a single individual. The underlying complexity of big systems and the underlying integration complexity makes the usage of techniques and processes that guarantee the control of the project vital. The methodology described in this document is validated with two application cases in a context of development. The first one is an extensive project, with strong integration component, and the second one the development of an application for process dematerialization. The Scrum Solo methodology performed well in both cases despite their differences. Nevertheless, more cases should be analyzed with the emphasis in using different contexts namely other organizations.

Keywords: Scrum Solo, Scrum, Software Development Process.

Introduction

In Portugal, 90% of software development companies are characterized as micro-enterprises ("Lista de Empresas de Desenvolvimento de Software em Portugal", 2018). In the Brazilian market, in 2012, about 60% of software companies started their activities with only one developer (Pagotto, Fabrti, Lerario, and Gonçalves, 2016).

Agile methodologies are widely used by many teams nowadays. Among these, Scrum is the most widely practiced Agile method/framework (Srivastava et al, 2017). From the respondents to the survey referenced in the 14th Annual State of Agile Report (2020), at least 75% of respondents practice Scrum or a hybrid that includes Scrum. However, as stated before, many of those teams, are a single person team. This was the main motivation to adapt the Scrum methodology to solo teams, thus Scrum Solo.

In this article, Scrum Solo is described, explaining the main activities, the actors involved, and the artifacts resulting from the process. Furthermore, two validation cases were developed and are also described in this paper.

These two projects where developed over a period of roughly six months each, for one of the biggest Portuguese's software development company. The first one's goal was to create a tool that generates code from a REST Web service (REpresentational State Transfer) automatically, based on the existing code of an ERP system (Enterprise Resource Planning), this way, removing the need of having 2 big teams in parallel, developing both the ERP, and the Web API solution. The second one's goal was to develop a mobile application prototype, which integrates with the aforementioned ERP through the

Web API, contributing to the dematerialization of processes such as a salesperson writing down sales details on paper, and typing it afterwards at the office.

This cross-platform mobile application targets sellers which are away from the company and cannot access the ERP directly, adding mobility and flexibility. With the conclusion of this prototype, they were able to access, create, edit, and delete different entities such as items, documents, suppliers, and customers, saving them the time of, for example, having to write everything in paper and typing it afterwards at the office.

Scrum Solo Methodological Approach

Scrum Solo is an adaptation of Scrum and PSP (Personal Software Process) for solo software development. Based on figure 1, it is possible to see the similarities with Scrum (Pagotto, Fabrti, Lerario, and Gonçalves, 2016).

Fig 1. Scrum Solo (Pagotto, Fabrti, Lerario, and Gonçalves, 2016)

Scrum's goal is to provide a convenient process for project development, presenting an empirical approach, which applies ideas based on the theory of industrial process control to software development, introducing additional ideas such as flexibility, adaptability and productivity (Soares, 2007).

Scrum was designed to allow normal developers to organize and form high development teams (Sutherland, Viktorov, Blount, and Puntikov, 2007). Scrum assumes that the systems development process is complicated and unpredictable, which can only be described as a general progression (Schwaber, 1997).

The workflow begins with the creation of a product backlog, which contains all the tasks necessary to implement the features desired by the customer. From this group of tasks, some are selected to be developed during the sprint (within a week). This sprinting process is iterative until the project's completion date arrives, or until all tasks are completed. During sprints, it is necessary to have management activities, which aim to plan and monitor the development of the project. After completing the tasks, the project is delivered, which will be reviewed by an evaluation group and, eventually, an orientation meeting will be held with the people who will use the developed product (figure 1).

This methodological approach has four main activities: definition of requirements, sprint, deployment, and management. The definition of requirements (figure 2) aims to define the scope of the product, the

product backlog and, if possible, a software prototype. These objectives will be achieved with the help of customer input and advisor that will assist the developer to achieve his goal.

Fig 2. Definition of requirements (Adaptation from Pagotto, Fabri, Lerario, and Gonçalves, 2016)

Sprints, represented in figure 3, are the activity where the development of a set of tasks selected at the beginning of the same, from the product backlog, occurs. These tasks must be completed within one week, resulting in a sprint backlog, part of the product, development plan, and minutes.

Fig 3. Sprint (Adaptation from Pagotto, Fabrti, Lerario, and Gonçalves, 2016)

During the sprints it is necessary to manage the status of the project. The project management activity has this objective. Using the product backlog, the developer, advisor, and client must discuss the status of the project. From this reflection, the project's analytical structure (WBS), project schedule and cost table will be generated.

Fig 4. Project management (Adaptation from Pagotto, Fabrti, Lerario, and Gonçalves, 2016)

Finally, as a last task, deployment is the activity in which the product is made available for use by the customer. It is also important, after delivery, to have an orientation meeting so that those involved understand in more detail how the product works.

Fig 5. Deployment (Adaptation from Pagotto, Fabrti, Lerario, and Gonçalves, 2016)

There are several actors in this process, namely the developer, who is responsible for developing the product and following the methodology; the client (product owner), who will be the owner of the final product, can be made up of one or more individuals who will interact with the product (example: managers, accountants, others ...); the advisor, who is responsible for helping to guide the developer throughout the process, so that the requirements are well met; and, finally, the validation group, made up of the end users of the product, who aim to evaluate the product and provide feedback.

The various artifacts generated throughout the process are as follows:

Scope: it serves to characterize the scope of the process and the aspects inherent in mapping the problems of the product owner, describing the scope of the product, the customer profile, and the functional requirements.

- Software prototype: consists of images of the user interface with the product. It is advisable to use the ".png" format and point the name of the product backlog item that represents the image.

- Product backlog: is a list of features that must be implemented in the software. Each line in this list must contain a feature code, description, insertion date and selection date for the sprint backlog.

- Process repository: it serves to store all documents related to the entire product development process in the cloud. It is important that the developer organizes the repository folders well and follow a set of rules for that purpose.

- Sprint backlog: it is a list of all the features that must be implemented in a given sprint. The sprint backlog must also store the feature code.

- Product or part in operation: a version of the product that gives the customer the possibility of obtaining a return on the investment previously made at the time he asked for its development.

- Minute: it is used to record the moments when a feature is implemented. Used in the sprint and delivery: in the sprint, the functionality is validated by the advisor; delivery is validated by the customer.

- Development plan: aims to gather the artifacts used in the specification of the functionalities. Scrum Solo suggests the use of diagrams of use cases, sequence, classes, and entity and relationship, always with the possibility of using others, if necessary, for the case.

- Analytical structure of the project: a hierarchical structure that subdivides the work of a project into smaller and more readable components.

- Chronogram: aims to organize work packages sequentially within a certain time frame. The person responsible for the execution of each activity can be appointed. It is suggested to use the schedule in the format of a Gantt diagram.

- Cost table: aims to map the effective cost generated during the execution of the project to be compared with the budget previously made.

A search was also made for "Scrum Solo" through the Google academic platform, however, the state of the art is still underdeveloped. Fonseca (2016) only generically describes what Scrum Solo is as a "methodology for dynamic project management that also allows the development of software in an agile way". Similarly, Sanches Kleim (2016) describes that Scrum Solo was developed with the scope of helping with the organization of software development by individuals, based on the good practices described by PSP and Scrum.

Application of Scrum Solo in an Extensive Project, with Strong Integration Component

The Scrum Solo methodology consists of an iterative and incremental process, which unites the best practices defined by the Personal Software Process (PSP) and Scrum, to promote the smooth functioning of the development of a project. This methodology was applied to the development of a project whose objective was to be able to create a tool that generates code from a REST Web

service (REpresentational State Transfer) automatically, based on the existing code of an ERP system.

This project allows users to access the ERP through a Web service and, eventually, through a dedicated website, which consumes the service. However, the value of this project lies in the fact that the conversion of the ERP code (developed over 25 years, by multiple teams, with about 4.5 million lines of code today) is done automatically, saving an enormous amount of resources in its creation and maintenance, since the ERP is constantly in development, the Web service would have to monitor, adding a level of complexity in the coordination of the ERP and Web service development teams.

In projects of this magnitude, there are added risks associated with work, which do not exist in traditional software development projects. The identified risks involve limiting access to the original ERP code and its complexity; code incompatibility between the ERP and Web service (the use of certain mechanisms for the use of assemblies by the ERP, caused a lot of problems due to the incompatibility of these mechanisms with the Web, resulting in the need to change the original ERP code); there were also problems in working with the version of ERP that was under development, sometimes bugs were found, resulting in time spent looking for the source of the problem; finally, the need to change the machine also proved to be a setback, due to the dimension of the project and the configuration of several components to support development.

The Scrum Solo methodology, although it has a project management task, does not respond well to these cases of high dependence on external factors, in this case, the ERP's underlying services. It is proposed to create a risk mitigation task, equivalent to a low percentage of the time spent per sprint, which can be replaced by a development task if time is available. This mitigation task can, for example, be added at the end of all sprints, costing two to four hours.

Scrum Solo goes through an initial moment of defining requirements, followed by sprints where the program is developed, followed by the deployment of the program to the client. During the development process it is also necessary to have project management activities. Next, the tasks developed for the particular case, previously mentioned, will be exposed.

During the definition of requirements (figure 2), several meetings were held with the client and advisor, to obtain an understanding of the necessary requirements of the application. This process resulted in a document called scope, which contains the definition of the scope of the problem and the customer's profile; and a document called product backlog, with 32 activities that, after completion, resulted in a product that will be delivered to the customer.

The Web API has the peculiarity of not having a traditional user interface. Instead, its interface is done through URL's ("{Domain}/api/{class}/{method}/{parameters}"). In other words, the software prototype is made up of this generic standard for the interface, which will then be used during code generation.

The process repository is divided into two parts. The artifacts generated regarding the use of Scrum Solo were filed in a folder in the cloud, using Google Drive services. The code developed, was saved on the client's local network, and was managed through the TFS tool (Team Foundation Server).

It was defined that the sprints (figure 3) would consist of five working days of development, however, a sprint does not necessarily represent a week, due to the interruption of development for external reasons, such as writing scientific articles, holidays, events, among others. This aspect brings a uniformity that will have an impact on the representation of the sprints, since everyone has the same amount of working time.

It is understood that, according to the work Pagotto et al. (2016), after a sprint, a development plan is supposed to be generated. In this case, the Web API already respects all the business rules imposed by the ERP. This fact comes from the exclusive use of the ERP business layer in the Web API, that is, all business rules will be respected, just like in the ERP, making the elaboration of the artifact unnecessary.

As for the product, new versions were saved on TFS regularly, allowing access to the code by authorized persons, and having access to the records of all changes made.

The sprint backlog aims to identify which product backlog tasks were executed in a given sprint, its start date, and the time spent on its completion. Although it is important for the future to have this artifact well documented and readable by people other than the developer, there is no need for complex tools for its management, a simple sheet of paper or a word document is sufficient (figure 6).

The development of the project was completed in June 2018, with the deployment activity (figure 5) already completed.

Fig 6. Example of a sprint backlog

Application of Scrum Solo in a Project, with Strong Component of Process Dematerialization

The Scrum Solo methodology was also used in another project, which aimed to achieve a process dematerialization of already existing processes. The solution was to develop a mobile application prototype, which integrates with the ERP mentioned in the previous example.

This cross-platform mobile application targets sellers which are away from the company and cannot access the ERP directly, adding mobility and flexibility. With the conclusion of this prototype, they were able to access, create, edit, and delete different entities such as items, documents, suppliers, and customers, saving them the time of, for example, having to write everything in paper and typing it afterwards at the office.

The major benefits are the highly performant load times and the ability to access all the above-mentioned features even offline (keeping in mind that some information might be outdated because it has not been synchronized).

With any project, comes different difficulties. In this case, the main one with the ERP and its Web API was the incomplete/undetailed documentation, which lead to adversities while trying to integrate different information and setting up a test server for deployment testing. With these issues, the project activities were adapted accordingly, and they were reported to the product team which made many improvements based on the inputs given.

As a side benefit, being one of the first projects using the ERP's Web API, a series of optimizations and quality of life updates were done in parallel with the development of this project. With Scrum Solo, it was easy to adapt to the constant changes to the Web API.

To carry out this project, the risk mitigation task referred to in the previous project was followed, being implemented in order to monitor the progress of the project, serving to carry out a retrospective of the prototype in relation to the scope. This task was divided into two distinct parts. The first part was dedicated to the identification of possible features that could be explored through those already carried out in the previous sprint, enhancing the responsiveness of the prototype in relation to the respective application processes.

One of the main goals of the development, was to use concept of Rich Internet Applications (RIA). RIAs combine the Web's lightweight distribution architecture with desktop applications' interface interactivity and computation power, and the resulting combination improves all the elements of a Web application (data, business logic, communication, and presentation) (Fraternali, Piero, Rossi, and Sánchez-Figueroa, 2010).

In this case, the product backlog was constructed by further detailing an already existing document, provided by the company. The sprints were done weekly, independently of having one or five workdays. Despite this fluctuation in length, the methodology was able to be customized to fit the project management needs.

At the end of each sprint, a functional prototype was presented, containing all the new and previous features developed, maintaining a complete artifact that allows viewing the prototype's state in relation to its final target.

Conclusion

After describing the main activities, their actors and artefacts resulting from the process, and the use of the Scrum Solo methodology, it is conclusive that a good adaptation was really made from the methodologies on which it was based. However, as the name "methodology" indicates, Scrum Solo is not exempt from adaptations to the specific cases of each individual and each project, such as setting the sprints as one week (regardless of having one or five workdays), or setting the sprints as five days, even though they might not be consecutive.

The number of scientific articles on Scrum Solo is still scarce, in addition to the work of Pagotto, Fabrti, Lerario, and Gonçalves (2010), the few references found are about specific applications of the methodology and were described in section 2.

Regarding the application of this methodology to cases described, the success obtained is notable. It was possible to organize and manage two projects carried out separately, lasting half a year each from start to finish without jeopardizing the delivery date or any requirement requested by the organization, despite some unexpected problems from the ERP's underlying services, which were fixed after giving feedback.

Finally, it is proposed to create a risk mitigation task, equivalent to a low percentage of the time spent per sprint, which can be replaced by a development task if time is available. This mitigation task can, for example, be added at the end of all sprints, costing two to four hours.

Abstract

The article is devoted to the analysis of the issue of customer service in logistics. The article indicates theoretical aspects relating to the issues of logistic customer service defined in the literature. Customer service finds close connections with all logistic processes taking place in the enterprise as well as between enterprises operating in modern supply chains. The wide nature and scope of logistic customer service activities determine the necessary coordination, especially monitoring the areas and relations between the company and the customer, in terms of the system it is the coordination of relations between all elements of the system. Having and managing logistics in an enterprise and supply chains will not be complete without the location and proper treatment of customer service (Wasielewska-Marszałkowska, 2014). The article aims to identify the essence of logistic customer service and to characterize its elements. The set goal is accompanied by the following research question: What is the role of logistic customer service in companies' operations? The systematic literature review method was used to review the literature on logistics customer service. The review was carried out following the methodology described in the publication of W. Czakon, Fundamentals of research methodology in management sciences, Wolters Kluwer, Warsaw 2015, pp. 119-139. The authors conducted a literature review in 5 stages, i.e. defining the purpose of the research, selecting basic literature, selecting publications, developing a publication database, and analyzing the content. The resources of popular databases containing scientific publications, including post-conference articles, were analyzed. Full-text foreign databases such as Emerald Insight, SinceDirect, Scopus®, Springer Nature Journals, Web of Science, Wiley, and Polish databases - BazEkon and Ceon were analyzed. The EBSCO Discovery Service tool was used to search for publications.

Keywords: customer service, logistics customer service, businesses,

Introduction

One of the basic tasks of the company that wants to achieve success is marketing and focusing attention on a potential customer. The customer should be seen as a central link, a driving force whose satisfaction is the main goal of the company's operation. It is up to the customer how long the enterprise will remain on the market. This is emphasized by Ph. Kotler, arguing that a company that focuses on the customer can be more successful (Kotler 1994). However, to achieve this goal, the company must not only produce and deliver products of increasingly higher quality but above all, still strive for the favor and recognition of new and existing customers by ensuring the best customer service.

Competition forces companies to constantly search for new solutions and activities to maintain competitive advantage. Competing on the market is not only creating an attractive offer, but also presenting it on the market in such a way that this offer (not the offer of a competitive company) is chosen by the customer. The customer is the decision maker and the addressee of the offer, he chooses the offer between competing companies. The decision made by the customer is stimulated by the receipt of the offer. The source of competitive advantage of the selected offer may be, among others price

advantage or value advantage. On the one hand, the customer expects a high quality product, and on the other an attractive price for the product offered. Customers deciding about the selection of a specific offer also pay attention to a number of other additional benefits offered by the company under the proposed offer. These are not only material benefits, they are also aspects of commercial and legal service, after-sales service related to warranty and post-warranty service as well as the level of customer service offered by the company.

The wide scope of proper coordination of logistic customer service somewhat determines the functioning and even the existence of an enterprise in a market economy. Making any decision in the structure of the company is associated with customer orientation, without which the company cannot exist, which primarily determines the monitoring of customer service (Wasielewska-Marszałkowska, 2014). Thus, any service provider should recognize the consumer as the focal point of its business. Caring for the customer and concern for his satisfaction contributes to maintaining long-term relationships, and thus becomes an important factor in the success of enterprises (Samek, 2016).

In the last several years, customer service has become an issue of increasing attention among both theoreticians and business practitioners. T.J. Peters and R.H. In their bestseller In Search of Excellence, Waterman emphasized the importance of "approaching the customer" as a recipe for business success (Coyle, Bardi, Langley, 2010). This approach to the customer had several meanings, but without doubt one of the important aspects of this guideline was to have a logistics system that was sensitive enough to customer orders and would take their needs into account. With regard to the basic principles of 6W logistics (the right quantity, right condition / quality, right place, right time, right price / cost, right customer) and considering each of them as a criterion for measuring customer service, one could put forward the thesis that the fulfillment of each of these principles gives the company a position of competitive advantage. In practice, however, compliance with these basic principles does not give full customer satisfaction. In the era of progressing globalization and the ruthless competitive struggle of enterprises cooperating in the supply chain and entire supply chains, one of the most important elements is optimal (rational) logistics management of customer service (Wasielewska-Marszałkowska, 2014).

The essence of logistic customer service (LCS)

The issue of customer service has many dimensions and is interpreted in different ways. It covers not only logistics but also marketing, financial and many other aspects (Ciesielski, 2006). Companies can use logistics customer service as a differentiating element to compete more effectively in the marketplace (Yazdanparast, Manuj and Swartz, 2010; Leuschner, Charvet and Rogers, 2013).

One of the first definitions of logistic customer service was published by La Londe and Zinszer (1976). In defining customer service, the authors point to:

- punctual delivery of goods, in accordance with customer orders (including timely delivery of sales documents),
- certainty and reliability of delivery of materials to the customer in accordance with his expectations,
- comprehensive action involving all business spheres, which aims to supply goods in a way that satisfies the buyer and enables the supplier to achieve his goals,
- necessary actions that are aimed at the receipt, preparation, implementation and financial service of customer orders and clarification of irregularities that may occur at the same time,
- performance of the contract, which includes communication with the customer, shipping, transport, invoicing process and full product control and warranty service.

In conclusion, it can be concluded that the authors focused on defining logistic customer service in the traditional sense, indicating ways of meeting customer needs, which are key in the service provided. The studies of La Londe and Zinszer contributed to the further evolution of research on customer service issues.

Scientific research from the late 1980s to 1990s indicated a strategic shift in the way companies define the appropriate level of customer service from a cost-based approach to a proactive approach by using customer service to "retain the customer" (Langley and Holcomb 1991 [in:] Daugherty et. al, 2018).

According to M.B. Schary (1984), defining the LCS as: "a system of solutions that provide the customer with a satisfactory relationship between the time of placing an order and the time of receiving a product." In his research, the author points to the importance of delivery time and skillful management of the ordering cycle. By contrast, Fawcett, McLeish and Ogden (1992, in .: Melović, Mitrović, et al. All, 2015) present the customer service through several definitions that illustrate very well the breadth of the extent of this term, without opting for any of these particular visions:

- customer service is the quality of performances of the distribution system,
- delivery service represents different dimensions of the implementation of the process of ordering along with the sales promotion,
- customer service means adjusting a part of offers to a specific demand,
- customer service is a direct result of the connection between sales activities and the delivery process, which begins with the order and ends with the delivery, but in some cases it continues with the post-purchase stage of the product usage.

Moreover, J. Petrykowska additionally claims that “from the point of view of logistics service the client to the ability or ability to meet the results and expectations of clients, especially as to the time and place of the clients ordered, using all the terms of logistics employment, i.e. transport, warehousing, inventory management, information and packaging” (Petrykowska, 2009).

The importance attached to logistics customer service is reflected in the prominent role played by this stream of research within the supply chain management field (eg, Georgi, Darkow & Kotzab, 2010, in: R. Leuschner, F. Charvet, DS Rogers, 2013). While most of the literature found on this topic is in logistics (eg, Daugherty, Stank & Ellinger, 1998; Mentzer et al., 1989; Novack, Rinehart & Langley, 1994), researchers in other fields have studied this subject as well (R. Leuschner, F. Charvet, DS Rogers, 2013).

Research by Daugherty et. al. (Daugherty et. al, 2018), indicate that the subject of logistic customer service (LCS) was undertaken by many researchers in the "early 90s and 2000s". They also notice a significant decline in the interest in LCS in academic journals since the end of 2000. In their conclusions, the authors emphasized: "a wide range of topics that can be addressed in customer service research in logistics, in particular concerning changes in customer and consumer service expectations brought about by omnichannel and online commerce (as well as traditional stationery)". The wide range of subject areas, the authors say, “present related opportunities - from inventory management to after-sales support and returns management. Also, the authors point out "the need to pay more attention to important areas of customer logistics services in the omnichannel and e-commerce supply chains".

Based on the literature review, the authors in Table 1 presented selected interpretations of logistic customer service.

Table 1: Selected interpretations of logistic customer service in the literature

Author / Year	Interpretation
Haessler i Talbot (1991)	The authors emphasize the concept of the "delight" of the customer - in this aspect, companies must "go beyond what is expected and provide services that are unexpected in a positive way and provide value to the customer."
Livingstone (1992)	In the author's opinion, “customer service does not materialize merely through the dedicated efforts of front-line staff, although ‘people power’ can work miracles. To provide excellent customer service continuously, the order management cycle must have service built into the total process.”
Christopher (1998)	The researcher describes logistic customer service as "providing the customer with the right product at the right time and in the right place."

Kempny (2001)	The author points out that logistic customer service is: "the ability or the ability to meet customer requirements and expectations, mainly as to the time and place of ordered deliveries, using all available forms of logistics activity, including transport, storage, inventory management, information, and packaging".
Dadzie i in. (2005)	According to the authors: "As the consumer market segment of the Internet economy continues to grow, the role of customer service in the emerging logistics supply chain systems will continue to change."
Ciesielski (2006)	The author emphasizes that:"The essence of logistic customer service is that a customer who buys a specific product simultaneously acquires other related benefits. The value of the product according to the customer is related to the entire offer, ie the sum of the value of the product and the standard of customer service".
(Davis-Sramek et al., 2008).	The researchers point out that "customer loyalty is usually conceptualized as a consequence of customer satisfaction that is driven by long-term commitment, mutual dependence and trust."

Source: Own elaboration based on: Christopher (1998); D. Kempny (2001); Ciesielski (2006); Livingstone (1992), Haessler and Talbot (1991), Dadzie et al. (2005), (Davis-Sramek et al., 2008) [in:] Daugherty et al. al, 2018.

In conclusion, the considerations relating to the essence of logistic customer service, according to Ciesielski, the authors believe that every company striving for success on the market should adopt customer orientation in the management process, thus formulating its mission. As well, companies should also monitor and measure their achievements in this area and define the course of the service process, distinguishing certain tasks, and assigning them to individual employees (Ciesielski, 2006). The role of logistic customer service for the functioning and "existence" of modern enterprises is enormous, it somewhat determines the functioning of the company on the contemporary market.

In our opinion, the level and quality of customer service offered by enterprises is a priority for enterprises in relation to newly acquired clients and a guarantee of retaining existing clients (Wasielewska-Marszałkowska, 2014). Enterprises through better customer service activities gain an advantage in a competitive market, which also allows companies to compete effectively in more demanding and new domestic and foreign markets. In the current market situation, customer relationships are a major focus for businesses. Multi-criteria optimization of logistic processes is not limited only to space, time, cost and physical distance, but also has a fundamental quality parameter in mind: customer service maximally possible in given conditions. It is not only about the external customer appearing at the beginning and end of the integrated process (logistics chain), but also every internal customer appearing on the logistics channels. The modern client is an intelligent client, his requirements and interests become more individualized. The requirements of today's client include offering professional and fast service, openness and friendly attitude, above all, professional advice, solving existing problems related to the purchase / delivery of products / services. The client expects that meeting his requirements will guarantee him a sense of security, certainty and comfort from the cooperation with the company, a modern client expects the company to provide individual and comprehensive service.

Moreover, the authors share the opinion of Daugherty et. al. (Daugherty et. al, 2018) that nowadays, scientific research on the logistics of customer service should be focused on aspects related to logistics services provided for customers under omnichannel and e-commerce supply chains.

Elements of logistic customer service

For contemporary enterprises as part of activities in the field of logistics customer service, its measurement and control focused on increasing efficiency in customer service is important. The four logistic elements of customer service - time, reliability, communication and convenience - are the basic premises for creating a reasonable and effective customer service program. These elements also form the basis for the standards of logistics customer service (J.J. Coyle, E.J. Bardi, C.J. Langley Jr., 2010).

All customer service elements can be divided into three groups: pre-transaction, transactional and post-transactional elements (Fig. 1). It should be noted, however, that there is no complete agreement either

as to the number of elements, nor as to their content, nor how they are classified and interpreted (Ciesielski, 2006). Lalonde and Zinszer (B.J. Zinszer, B.J. LaLonde, 1976) gave an important contribution by identifying and classifying elements of the customer service in three groups - pre-transaction, transaction and post-transaction ones.

Pre-transaction customer service elements do not have much relation to routine logistics activities (order processing, storage, inventory management, transport), but they significantly affect the volume of product sales or the level of services. They also signal the company's policy regarding service. Formulating the assumptions of this policy requires managers to come out with a certain offer "outside" and create a convincing vision of service, taking into account its most important criteria: time, delivery reliability, access to information and convenience.

Fig. 1: Elements of logistic customer service
Source: Own study based on D. Kempny, Logistic customer service, PWE, Warsaw 2001, pp. 19-27.

Pre-transaction elements traditionally include (Ciesielski, 2006, Kempny, 2001):

- **service policy formulated in writing** - it should take into account the real needs of customers, on the basis of which service standards are set; it also specifies who to whom reports on the implementation of the service and with what frequency and the method of measuring performance; companies placed under strong competitive pressure and struggling to maintain their position on the market attach great importance to this; it can also be seen that the more competitive the market, the more readable the customer service policy, the more precise the measures of its implementation and the more frequent the control and measurement of the service;
- **clear service declarations submitted** to the client that protect him from unrealistic expectations, actions to raise the level of service make sense when customers are informed about it; written declarations and declarations submitted to clients also contain information on how to contact the company in the event of non-compliance with the assumed level of service;
- **organizational structure of the operating company** (suppliers); there is no organizational structure that is most suitable for a particular service policy, but such

structures should be shaped, as they should facilitate communication and cooperation between the cells responsible for implementing the service policy, which results, among others, from the classic relationship between the structure and the strategy of the company; in addition, the supplier should provide the customer with the name and telephone number (fax, e-mail, internet address) of the departments that will provide him with the necessary information and explanations;

- **system flexibility** - should be taken into account and planned already in the pre-trade phase; it ensures efficient and proper service even in difficult, unforeseen conditions (natural disasters), with shortages and strikes; the need to adapt to the atypical requirements of significant, profitable clients is also currently emphasized;
- **instructions and practical training (seminars)** to help customers improve inventory management, ordering or brokering are also included in the customer service components before products are sold.

Transactional elements defined as the most important from the logistic point of view, i.e. determining the efficient and consistent with the client's expectations of the transaction - from the moment the order is placed until the product is received. This group includes:

- **delivery time** - the time elapsing from the moment the order is placed until he receives the ordered product;
- **delivery flexibility** - understood as the ability to adapt the time, range and delivery method to the needs of customers;
- **product availability from stock** - readiness to immediately release products remaining in stock at the supplier's;
- **completeness of deliveries** - understood as the implementation of a full order - full specification of ordered products;
- **delivery frequency** - this element is particularly important in the case of fast-moving products, e.g. perishable foodstuffs, whose stock should be replenished on a regular basis
- **reliability of deliveries** - the essence of which is customer confidence that the quantity, quality, type of products ordered will be delivered at the agreed time;
- **access to more complete information** - readiness to answer customer questions, put at the disposal of recipients competent personnel representing the company, presentation of equipment and facilitation of contact with the use of media, IT tools for efficient contact with the client;
- **order placement convenience** - means simplicity and adaptation to the client's needs of documents related to ordering, taking into account legal requirements.

Also in this element, technical support and availability of substitution products for the customer are indicated. However, they do not exhaust the list of elements important in customer service. What happens after the transaction is also important.

Post-transactional customer service elements, like pre-transactional ones, are more in the sphere of marketing than of logistics interest. In traditional marketing, after-sales elements were identified with customer service, while they are now being treated. much more widely. Some of the services offered to customers after the sale of products, such as the supply of spare parts, are just as important to logistics professionals as transactional elements. Post-transaction services ensure customers correctly use products, and in many cases - protect their interests and health. Suppliers and manufacturers can tell if a product sold is functioning as intended when the customer begins to use it.

Post-transaction control elements usually include:

- **installation, warranties, replacements, repair and delivery of parts**, which means that the customer in the after-sales phase is guaranteed: availability of tub parts and repairs, documentation explaining the operation of the products (operating instructions) and after-sales guarantees, as well as dismantling and reinstallation of the product after repair or

exchange; these are elements of service that significantly affect purchase decisions, which is why they are planned, just like the other after-sales elements, in the pre-transaction phase; service standards provided or declared for these elements help in gaining customers; their performance is assessed and monitored in the same way as transactional elements;

- **observation of the product in operation, consumption or personal use**; this is an important element for some new pharmaceutical, chemical, cosmetic and food products being placed on the market, as they can sometimes be;
- **threat to the life and health of customers**; in order to avoid legal complications (lawsuits, arbitrations, complaints) and related losses, enterprises offering new products that are not fully tested and widely used should be prepared for immediate removal from the market if they prove to be potentially dangerous;
- **complaints, complaints and allegations that are traditional elements of customer service**; already in the pre-sales phase, standards and rules for handling returns, complaints and complaints should be defined, since the handling of returns that almost every producer deals with is costly, and also burden the manufacturer's logistics system and disrupts its proper operation; Returns service serves the flow of products in one direction - to the customer, and damaged and defective products flow against the tide.

Ordinary manufacturers offer customers standards for the implementation of after-sales service elements, including strictly defined standards for the time of delivery of spare parts, deadlines and time for handling complaints and complaints, warranty and guaranteed service periods, etc. The standards should take into account the technical and economic capabilities of the manufacturer, competition and expectations customers.

Customer service consists of the elements listed in all three phases of the commercial exchange of goods and services. However, in logistics, and especially in supply chain management, the most attention is paid to transactional elements. These can be successfully called logistics. This is where one of the more visible dividing lines of interest for customer service in marketing and logistics runs. Logistics is mainly interested in transactional elements in combination/mix logistics elements, the others are the domain of marketing, although they are also not out of the question for logisticians. However, how we will ultimately understand customer service and what elements will be involved in a particular situation or individual case will be decided by the customer himself (Kempny, 2001).

Three groups of elements should be taken into account in proper customer service. Omission of any group may have serious consequences for the company (Ciesielski, 2006, Kempny 2001). The essence of offering a high level of logistic customer service by companies is to control the quality of customer service. The company should establish appropriate procedures to measure, monitor and control the quality of customer service. Such methods can be used as Statistical Process Control (SPC), analysis of feedback and taking necessary corrective actions. When customer service standards are ineffective, the company should not delay modifying or rejecting them, depending on the situation (J.J. Coyle, E.J. Bardi, C.J. Langley Jr., 2010).

Conclusions implications, limitations and recommendations for future research

Today's reality is characterized by a high rate of change and a constant increase in customer expectations. The effects of market globalization, growing competition, technological and IT progress and others set high demands on enterprises. The described tips and elements of logistic customer service can only indicate which path should be taken by the company in pursuit of market advantage. Because the concepts of even the best specialists and practitioners about the directions in which the world will be heading, as well as skills, knowledge and behavior that will allow to achieve market success may slightly differ from the reality, which is characterized by high variability. What today is a guarantee of success and an indicator of proper customer service may cease to be one after some time. Regardless of the formulation of the service policy, development of standards or continuous control and monitoring of the process, if the company does not introduce changes aimed at eliminating errors arising in customer service, and does not start to treat the customer as a source of benefits for the company, implementing a value system that puts the right customer service will be impossible.

Today's customer is a demanding customer, customers don't want to and won't wait "They don't want to wait -" Consumers are looking for that immediate delivery option "(Beckwith 2017, p. 44). Hence, the task of enterprises is to strive for compliance with customer expectations.

When discussing the issue of logistics customer service, one cannot ignore the role of the customer in creating the quality of logistics services offered by enterprises. The role of the customer in creating the quality of services is undeniable. Based on their own experience, preferences and needs, the recipients choose the enterprise whose services they will use. The quality aspect is currently the most desired by customers. What counts in the competitive struggle is the service provider who not only meets the needs of the client at the highest level, but above all does it better than the competitors. The issue of customer impact on shaping the quality of logistics services is therefore an interesting direction for future scientific research.

In this article, the authors did not raise the issue of IT systems and social media used in logistic customer service. On the other hand, maintaining high quality customer service is possible thanks to dedicated IT systems such as ERP and CRM as well as social media that help manage logistics processes in the company. Investigating the impact of these IT systems on the quality of logistics customer service is therefore an important issue for future research, especially for modern businesses.

Extremely important for logistics service is its evaluation and measurement system, which enables reliable assessment of errors and successes. In this article, the authors of the article intentionally did not address the issues of customer service quality measures (quantitative instruments for measuring the level of logistic customer service, methods of analyzing dependencies in the assessment of customer satisfaction or methods of customer preferences in relation to logistics service). They intend to address this issue in the future.

Summary

Historically, Hesket indicated more than 40 years ago that "Logistics can mean the difference between success and failure in business" (Hesket, 1977). Besides, Flint and Mentzer (2000) in their research will emphasize "understanding how customers'" logistical needs change over time is a key component to predicting what customers may value in the future "(Daugherty, Bolumole, & Grawe, 2018). Today, the importance of logistics customer service in the enterprise is becoming increasingly important. The management is aware that proper customer service is an effective competitive tool. Therefore, they subordinate their activities to numerous standards contained in quality books. The guidelines described there enable companies to efficiently and quickly customer service, which affects their satisfaction.

Enterprises in the era of progressing globalization are forced to take multidirectional actions in order to achieve competitive advantage, of which the quality of the level of customer service is becoming a natural element in the competitive struggle. Competitive activity of the organization boils down to winning the fight in three areas of activity: profitability, efficiency and effectiveness, i.e. winning the fight in the sphere of negotiations on supply markets, in the sphere of competition in terms of costs and quality of production of goods and in the tender sphere on the market of consumption of goods (Chaberek, 2002). The issue of logistics customer service is closely related to the overall enterprise management system, not only the adopted mission and company philosophy, but also through integrated logistics activities, whose coordination and optimal use leads to the desired effect in customer service. The process of customer service in modern enterprises is subordinated and focused on the main goal, which is customer satisfaction.

Evolution and Modern Solutions in Managing Sales Competitiveness Based on Trade Calculation

Vladimir A. CHERNOV

Nizhny Novgorod, Russia,
E-mail address: Chernovva@rambler.ru

Abstract

The main competitive advantage of the world economy at the present stage is the ability to reduce costs in the competitive struggle of the world market participants. For the most accurate cost management, calculation is necessary, which, according to the hypothesis of the study, is the main means of effective, competitive management of trade processes, sustainable innovative development of the sphere of commodity circulation. In the coming digital economy of the information society, calculation methods are becoming an important intellectual asset as a means of designing information for decision-making by artificial intelligence in cloud services. Calculation is a necessary condition for the introduction of new technologies of "lean production". These methods of controlling allow the most rational, complete and effective management of costs, prices, product range, financial results and competitiveness in the sphere of circulation and serve as an algorithm for neural networks in creating digital economy technologies. The present article dwells on the questions of profit management on the basis of trade calculation. It gives the historical overview of development of calculation methods and their application in the most acute issue of regulation of sales competitiveness. The article shows out that issue of distribution chain is treated in the fullest way in Russian sources.

Keywords: Calculation; competitiveness; action; distribution cost; cost capacity; income capacity; commodity groups accounting.

Introduction

In the conditions of market saturation, toughening of competition toughening observed in many countries and aggravated with the crisis phenomena in the world economy, a part of trading companies is forced to yield a position in the market to more competitive representatives of the sphere of a commodity circulation.

In recent decades, researchers from different countries have proposed many methods and mechanisms to improve the competitiveness and sustainability of production and sales. On the way to increase innovation activity and commercialization of innovations, it is proposed to activate the development of network platforms of cluster structure, digital interaction that form innovative ecosystems; crowdfunding financing, various types of joint spaces for organizing the work of people with different jobs are created – coworking based on interdisciplinarity, openness and collaboration. Lean technologies are being introduced, and methods of cost and profit analysis are being proposed aimed at eliminating typical errors, especially in situations where the probability of making such errors and miscalculations is implicit and not obvious. Several governments have proposed joint development of seven modern official cost-benefit analysis (CBA) guidelines on eight main cost-benefit issues. The implementation of all these initiatives will be most accurate and successful if data on the costs of circulation are most accurately presented for each product group and product name. Such data cannot be obtained without special calculation and distribution methods of trade calculation. The article considers the evolution of these methods from the first developments, reveals the successes of past periods, examines the historical transformation and highlights the developments of recent years in

solving the problems of reducing cost intensity, increasing sales competitiveness. The latest developments in improving the methodology of trade calculation most take into account the needs of a modern dynamically developing economy on the way to implement innovative development of trading operations.

Problems of The Modern Market and The Role of Trade Calculation in Their Solution in The Historical Perspective

The situation on international and national markets has become more complicated in recent years. Consolidation of views and approaches to measuring efficiency at various levels of social reproduction is possible only on the basis of a dynamic assessment of social wealth, since it is precisely this factor that reproduces the human community that can be measured at all levels of human activity. In a number of leading countries (the United Kingdom (great Britain), Japan, and Italy), there is a decrease in household income (table 1), which leads to a decrease in demand for goods. In other countries, we see a small increase in household income (table 1), but the growth rate of physical volume of retail trade turnover (table 2) exceeds the growth of the population's income (table 1). This trend will lead to a shortage of money supply in the population and a reduction in effective demand. And this is the path to a recession. To these problems should be added the huge business losses due to the COVID-2019 pandemic.

Table 1: Growth rate of real wages of employees (2010=100)

Countries	Years		
	2016	2017	2018
Russia	108	112	121
USA	103	103	-
France	103	104	
United Kingdom (Great Britain)	98	98

Italy	95	94	94

In the conditions of market saturation, toughening of competition toughening observed Not to lose their positions in the market trade companies apply more and more refined, sophisticated ways of increasing its sales competitiveness. However when running various marketing campaigns to attract customers, it is not always possible to attain a detailed and exact assessment of costs, losses, the rate of payback and result of the campaigns. To control the costs of the marketing campaigns aiming at increasing the demand and attracting customers, to evaluate financial feasibility and economic

benefits of such actions, trade accounting should be used which, is unfortunately far from being regularly applied in the trade. If a competitive advantage on the market is not expected to be attained by unnatural reconstruction of the market by illegitimate ways, but is due to maximizing of sales effectiveness, accounting is necessary. Only on the basis of calculation it is possible to define in a rather exact way the possibilities to increase a competitiveness of sales in the trade sphere.

Under the calculation of distribution expenses one should mean the evaluation of expenses capacity by groups of products or items. To get information about profitability of the item groups, except for the costs one also needs to know the income capacity per item group. Calculation of expenses capacity and income capacity of the product or item groups is called trading calculation.
In national and foreign book editions and separate articles there is a set of publications on methods of accounting management of industrial enterprises and calculation of prime cost of production. An absolutely another situation is observed in the distribution sphere. The topic of trade accounting is extremely rare in national and foreign publications.

The importance of the solution of this problem has been noted by practitioners of the American business in the article "On What the Shop Makes Money?". The article states: "We bring to your attention one more part of a basic research, carried out by the Marsh supermarkets of the American network. This fragment is devoted to the most intriguing question of modern retail business – profitability. From what the shop makes money? What goods in assortment are profitable and what less? How to define it? How to correct the current approach on the bases of the received results?"

And, according to authors of the article, this research represents and absolutely unique in the world not presented earlier level of penetration into basic concepts of retail process.

Claims of the researches of the American network of the Marsh supermarkets for uniqueness of the approach naturally raise doubts as scientific works with comparable results in this area were carried out much earlier, than they were started by Marsh association.

The first attempts to study product-by-product-group distribution expenses in trade, made in the early XIX century, associated with the name of Professor Sher. According to the Russian scientists. Cher has analysed in 1910 calculations of the Basel society of consumers in Switzerland on 12 groups of goods in 11 years – from 1898 to 1908. Calculation was considered on 8 groups of food goods and 4 groups of nonfood goods. The research was conducted with the following aim:
• definition of an expenses capacity and profitability of trade on separate commodity groups,
• estimation of competitiveness of trade unions,
• search of means of cost reduction in the trade device, improvement of system of prices.

Later in the USA and Germany special investigations were run on this topic, mainly in wholesale trade. In the USA such researches were conducted by the Ministry of Trade under J. Millard's guide, as well as by the ministry of agriculture.

The American research and developments in the sphere of the early thirties were published in Russian scientific publications. Developments of that time didn't give satisfactory methods of calculation. Expense capacity by commodity groups was determined very vaguely. Distribution of joint costs between groups of goods was made in proportion to the volume or cost of commodity stocks, commodity turnover, weight of the sold goods, etc. The method of the accounting of direct costs wasn't applied.

In the consequence the attention of foreign economists to the large wholesale and retail enterprises diminishes. Decrease of interest in this problem according to the prof. M. I. Bakanov is explained by more and more developed specialization on certain goods and appearance of departments and sections, thus the accounting departments of firms have an opportunity to obtain reliable data about distribution costs on each of these divisions and thus on each of the commodity groups.

Later on in foreign economic literature methods of calculation of trade expenses on commodity groups in small and medium-sized retail enterprises started to be discussed with a greater interest. The objective of the study was to develop a practically acceptable methods of calculating the self-cost of commodity circulation, which became an object of research of Marianne Betting in her doctoral dissertation.

The first attempts to investigate product-by-product-group expenses in the USSR have been made in the late twenties, in the early thirties. In 1931-1932 Central Union of Consumer Societies and the central institute of economic research of the people's Commissariat of trade of the USSR developed methodical instructions according to which distribution costs on commodity groups in several regions of the country. The data collected by them, though gave some ideas about the structure of the prices of separate goods, nevertheless were very inexact as expenses were generally distributed by commodity groups by means of a number of roughly estimated coefficients.

In the late 30-s the topic of product-by-product-group distribution expenses were studied by the scientific-research Institute of trade and public catering (NIITOP) of the people's Commissariat of trade of the USSR. A researcher of the Institute N. N. Ryauzov participated in the development of the methodical materials. The institute recommended two completely different methods of studying of distribution costs: the first one was a calculation method for food trade organizations, the second one was called reporting accounting – for the industrial trade companies. The first way smoothed distinctions between shops. Its results had rather low reliability. The second way had an excessive labor input.

Attempts of the scientific-research Institute of trade and public catering to establish a systematic study of distribution expenses by commodity groups were not allowed by the respective competent authorities.

The method of coefficients, method of economic-mathematical modeling, method of the direct accounting have been also developed for definition of an expenses capacity. However comprehensive experimental check has shown that the method of economic-mathematical modeling doesn't provide necessary reliability. When using a method of coefficients in the course of the experiment it has been revealed that the level of expenses was overestimated by 35-80% on one goods, and underestimated by 40-85% on others that proves this method to be unsuitable too.

The idea of a systematic accounting product-by-product-group calculation of costs was first expressed and justified M. I. Bakanov. The first articles in which these questions were treated in details were published in 1938. Its feasibility was experimentally confirmed. Results of the experience were published in the “Accounting” magazine by M. I. Bakanov and N. I. Sakhanovsky – the senior accountant of shop of Mosgastronom where the experiment was run. This article dwells on the methods of the accounting and distribution of separate items of expenditure.

The greatest accent to the problem of a expenses capacity of goods, income capacity, profitability in trade and public catering is made in PHD and doctor's theses of M. I. Bakanov, and also in his numerous journal publications (45 articles). Both theses of M. I. Bakanov are published by independent books.

M. I. Bakanov developed and gave the necessary theoretical justification to scientific-distributional method of item-by-item and item-by-item-group study of distribution expenses.

Later professor Bakanov involved teachers of the department, many graduate and postgraduate students in obtaining unique data on this topic. The cumulated materials are used by governmental institutions for justification of trade discounts (margins) in wholesale and retail trade, public catering that presumably has provided additional gain of 2,6 billion rubles for the trading organizations of system of the Ministry of Trade of RSFSR (The letter of Ministry of Trade of RSFSR of 09.11.76 No. 17/94-590).

The ways of the problem solving "A research of profitability of public catering, the wholesale and retail trade" having important practical application continued to be developed by the department of accounting and the economic analysis of the Correspondence institute of the Soviet trade under the leadership of the Doctor of Economics, professor Bakanov M. I. The research materials on the optimal profitability in different economic regions, commodity groups, as well as projects of new trade and wholesale marketing discounts were presented to the Ministry of Trade of RSFSR and found its practical application for what the head of the research and his researching group were officially thanked in 1978. (The order of Ministry of Trade of RSFSR of 12.01.78 No. 12).

A rather deep study of the problem of the commodity groups accounting and the analysis of an expenses capacity, income capacity and profitability in public catering was highlighted in the researches of D. I. Ilinzer (1973), G. A. Chistyakova (1974) and A. I. Levina (1978).

The most detailed analysis of the methods of calculation of distribution expenses in trade was made by M. I. Bakanov and S. M. Kapelyush's (1987)

The interest in this subject is explained by an increasing relevance of trade accounting in economy not only in our country, but also abroad. One of ways of gaining a competitive advantage is the reduction of prices of goods. To ensure a profitable work of the enterprises of trade when a trade margin is decreasing it is necessary to:
* to know the sum of the expenses for each type of goods to determine the maximal possible reduction of price taking into account expenses per type of goods;
* to exclude from the commercial turnover the goods which aren't in sufficient demand at the current price if further reduction of prices of these goods is impossible due to high expenses on these goods;
* to establish a trade margin differentially by each type of goods not below the costs of their realization (if the demand allows it);

In the conditions of inflation, usually there is no absolute reduction of prices, but to increase in demand, the sales volume and profit their relative decrease can be required. The relative price decrease in the conditions of inflation means that the prices change in such a way as an increase in the prices of concrete goods of a given enterprise is lower than the price increase caused by inflation in the market on the same goods.

But it is possible to reduce the prices only up to the amount which isn't exceeding the sum of the expenses demanded for production and realization of these goods. Otherwise the enterprise will suffer losses. And the choice of the most profitable goods is possible only in case their expenses capacity, to define it a ccalculation is necessary.

The calculation of distribution expenses is required in the distribution sphere for the reason that almost in all trade companies it is impossible to consider directly the expenses of each type of goods, and there are no other ways of exact definition of the expenses related to delivery and sales of concrete types of goods.

Trade calculation allows establishing the prices in the distribution sphere (a trade margin) for goods not only from the point of view of demand, but also from the point of view of payback, and also to choose the goods bringing profit, to reveal and exclude unprofitable types of goods from the turnover.

At the time of the Soviet economy the potential of calculation was not fully used. At planned and distributive system accounting was necessary generally for justification of the margins and discounts regulated by the state to control their compliance to the expenses on each of commodity groups. In the market economy the potential of accounting is more used to resolve the following tasks:

• increase in competitiveness of goods due to economically reasonable reduction of prices (a trade margin) of goods;
• definition and choice of the most profitable goods;

• identification of unprofitable commodity groups for development of recommendations on the increase in their profitability or for their exception from the turnover;
• determination of the optimal price from the point of view of payback, demand and competitiveness on separate goods due to change of a trade margin.

In this regard we will address experience of the American network of the Marsh supermarkets again. The American researchers quite reasonably note complexity of the matter. They note that in the concept of profitability of retail business there is nothing obvious, simple or rectilinear. The goods can be represented in one light when you measure his "dirty" margin (gross profits) and to look absolutely in a different way from the point of view of net profit.

For example, according to the researches "Marsh" perishable goods and goods of nonfood sector play a larger role in formation of gross revenue, than in sales volumes. Turnover of groceries, on the contrary, is high, however their margin is small. Complexity of the concept of profitability also consists in it, according to the researchers of network of the Marsh supermarkets. A lot of things depend on what and how to measure, what expenses to consider and how.

Marsh supermarkets developed special projects for buyers to increase profitability of each separate item and the whole enterprise in general. For example, many companies will never lower the price below 99 cents for a 2-liter Cola drink, but Marsh does it and finally wins on the increased of the consumer stream. In general more than 60 percent of soft drinks in Marsh shops are sold at the price below or equal prime cost.

Obviously, it is possible at skillful balancing of the income and expenses on each commodity group. For the most exact and effective coordination the calculation of an expenses capacity and income capacity for commodity groups is needed. How does the Marsh association perform similar calculations?

Further from article we see, that both for domestic retail business, and for Americans' the formula of profit on a concrete product (DPP – direct product profit) is very simple – the income minus expenses. What remains inexplicable and hardly accountable is a formalization of a shop expenses.

Then the statement follows that the research "Marsh" represents the first attempt to separate DPP and a dirty margin on each category in a shop. The research department of "Marsh" meticulously collected the formation on all components of expenses, including the maintenance of a warehouse and other rooms, labor expenses, expenses on inventory etc. The indirect expenses connected with management weren't considered. These data then was entered into the formula created by Institute of Food Marketing.

Further on, the authors give an example of collection of data on expenses: The entering bill for tenancy in which 735 boxes of a product are stored is about $5.43. Obviously, having the data on the total amount of the rent and quantity of the stored products it is easy to count expenses on rent on a unit of production. Delivery of 11 boxes of this product in shop costs 58 cents that also allows calculating expenses on delivery per piece. As we know, this is far from being new to the Russian economy. The electronic registration of each pack of products in the base takes about 2 seconds, also 2 seconds are spent for reading of a bar code of a product upon his purchase. 60% of all packings of this product pass through baggers hands (the employee packing goods into packages near the cash desk), and 1,7 seconds at the same time are spent for each packing. This time, obviously, is considered at calculation of expenses on packing, sales. The result of such a meticulous work is entered in the table in which the gross revenue (%), profit (%), average retail price for the sold unit ($), average gross revenue for the sold unit ($), average profit for the sold unit ($) are reflected per group of goods.

As we see, data on expenses, expenses capacity, income capacity on commodity groups aren't provided, and the understanding of expenses for each unit of a product is suggested to be made by a

making a difference between the income and profit that in itself doesn't solve a problem of calculation of expenses for groups of goods.

This technique also treats the calculation of the rent per the number of packings of product stored in the room. But if there are various groups of goods in the room, then it will be better to use the calculation technique mentioned earlier developed by Russian authors. For distribution of expenses on packing in Russia calculation a more rational and universal approach is presented too. Besides, in methods of Marsh association additional calculation of delivery of a certain number of separate commodity group in shop is required that is very difficult in practice, but this problem is effectively solved by the methods of trade calculation developed in Russia.

An important drawback of the American technique is also that as it has been told, indirect expenses aren't considered. But in trade there are a lot of such expenses which can't be correlated to any certain goods directly. And if they drop out of an accounting field of vision, calculation will be highly distorted.

Generally, a positive experience of calculation of profit by network of the American supermarkets for commodity groups should be noted. In comparison with management without accounting it is an important business tool. In this sense domestic researchers called the calculation "sailing directions in the ocean of free prices". But to calculate profit on commodity groups and skillfully balance prices on the level of prime cost it is indispensable to have rather exact data not only on direct expenses, but also on indirect expenses, expenses capacity and income capacity per commodity groups. For the sake of objectivity, it is necessary to point out the weakness of this very important part of the problem in the American researches.

The importance of calculation of distribution expenses in trade is also confirmed "… by the most necessary and up-to-the-minute recommendations and practical advice …" and calculations of the German author Manfred Weber. His opinion on calculation, generally, doesn't differ from the opinions given earlier. Trade expenses, he writes, are overhead costs as the reason for their appearance is one or several goods. They can't be correlated to any concrete good and therefore they can't be directly attributed to a certain item as single-element expenses, for example, to transportation costs. However, each item of goods should have a corresponding share of trade expenses. According to Weber's recommendations at calculation of expenses of separate items of goods trade expenses are calculated by means of a trade extra charge on their purchase price. And actually the calculation is presented only in the form of distribution of variable expenses in proportion to the weight of goods, and constant expenses – in proportion to the size of the settlement sums (the general cost of commodity group). As we see his system also doesn't give full and rather exact calculations.

Besides, the technique of the American Marsh supermarkets, as well as the calculations of the German – M. Weber don't represent methods of distribution of costs of storage, development, sorting, packing, etc. while distribution of similar expenses is proportional to the weight or cost by Weber's method won't give real values.

Thus, we have the reasons to claim that in the history of domestic researches there are more powerful results, than those of Marsh association and the calculations of the German author Manfred Weber declare.

The best solution of this problem is carried out by the methods presented in M. I. Bakanov and S. M. Kapelyush's work specified earlier. "Calculation of distribution costs in trade".

The technique of Calculation of distribution expenses in relation to market economy with overcoming one of the main disadvantages – high labor input by means of application of the spreadsheets "Microsoft Excel", was described in 1999 in the "Audit and Financial Analysis" magazine. The management of competitiveness of sales on the basis of accounting in combination with the analysis of elasticity of demand to expenses and the price is revealed.

Studies of problems in the application of cost and profit analysis methods and typical errors observed over many years have revealed ways to eliminate them, especially in situations where the probability of making such errors and miscalculations is implicit and not obvious. But in order to prevent such hidden miscalculations, you need more thorough and detailed information about costs, which can be provided by a trading calculation.

The UK Treasury, European Commission, U.S. Environmental Protection Agency, New Zealand Treasury, Infrastructure Australia, NSW State Treasury, and Victorian State Department of Treasury and Finance have developed seven current official cost-benefit analysis (CBA) guidelines for the eight main cost-benefit issues.

While all the guidelines are quality guidelines for the CBA, the paper concludes that each of these guidelines has room for improving theory and practice in various aspects. An important refinement and detail in the calculation of costs and benefits will be the data of the trade calculation. Modern achievements in the use of accounting for the management of profit, demand and competitiveness of sales are revealed in the monograph (Bakanov M.I., Chernov V.A., 2018).

Features of Applying Trade Calculation Methods in the Digital Economy

The methods of calculation of distribution expenses are simple in their content. They are based on distribution of expenses in proportion to the specific weight of these or those indicators. However on volume they are very bulky and without use of computer facilities they are very labor-consuming. Now, when use of personal computers became the widespread phenomenon in practice of the enterprises, trade accounting becomes one of the elementary and not labor-consuming methods to be used in management accounting and the analysis. For a user of personal computer it is enough to type the program of calculations in system of the spreadsheets "Microsoft Excel" once that, of course, demands certain efforts. For further use of the programs it is enough to replace the start data, and the results will be automatically calculated and shown in the corresponding cells with automatic change of the illustrating graphs. And a set of such program doesn't require an expertise in the field of programming. The user owning system of the tables "Microsoft Excel" is capable to make such program. It is also possible to use other programs made by professional programmers.

The automated program of calculation of expenses can be used not only for calculations, but also as an effective model for forecasting of an expenses capacity and profitability of groups of goods. If, for example, at the enterprise in the forthcoming period a change of any cost item or levels of trade margins on any goods is being planned, then for the forecast of results of changes it is enough to enter the estimated changed data into initial spreadsheets. The table of results will automatically show the calculated predicted values of an expenses capacity of commodity groups and their expected profitability. The expected results of changes will be automatically illustrated by "Excel" graphs and charts.

Thus, we approach formation of the knowledge base in management accounting. Traditionally management accounting operates with the database. At the same time on the one hand there are data. To make correct decisions on the basis of these data, the accountant carries out the corresponding calculations. The knowledge base contains not only data, but also set of methods and means of the organization, accumulation and use of knowledge for the solution of complex administrative challenges. Generally, the knowledge base in the form of expert system contains registration data of a task and offers the result of their processing – the ready decision in the automated mode.

Under the knowledge base we understand a set of knowledge on this domain structured for formalization of the decision-making process. The knowledge base contains an algorithmic basis of information technologies as expert (intellectual) systems. Proposing ready solutions, they act as artificial intelligence that is very applicable in the management of competitiveness of sales on the basis of trade calculation.

So, we see that the problem of expenses capacity, income capacity of commodity groups and profitability acquires the greatest relevance with a growing competition in the market. The calculation of expenses is necessary as it is impossible to consider expenses directly by each type of goods in trade enterprises, and there are no other ways of rather exact definition of expenses related to delivery and realization of concrete types of goods.

Trade accounting allows to establish the prices in the sphere of trade (a trade margin) for goods not only from the point of view of demand, but also from the point of view of payback that is especially important for improvement of the financial result; it helps to choose the goods bringing profit, to reveal and exclude unprofitable types of goods from the turnover.

Operating with a certain idea of development and guided by its level at a particular moment in time, in the financial management system it is possible to achieve the most preferable degree of development of commercial structures through the application of certain tools that form a specific mechanism. This mechanism will be most accurate, rational and efficient if it uses detailed information about the cost of circulation, obtained on the basis of commercial calculation, that proves a practical importance of the solution of this problem for trade enterprises of different countries. Modern information technologies allow solving the specified problems by means of artificial intelligence.

The author's approach (methodology) to the distribution of costs for goods, the formation of retail prices and the calculation of profit, which can serve as the basis for an algorithm for calculating these parameters through artificial intelligence are presented in detail in the source (Bakanov M. I., Chernov V. A., 2018). Previous developments are disclosed in the book (Bakanov M. I., Chernov V. A., 2012). Due to their large size they can not be considered in the framework of the conference. The source of information for controlling sales is accounting data, forms of accounting and statistical reporting. However, the main supplier of cost data for product groups is the trade calculation methods themselves, since they allow you to get information that is not available in any sources, and that can only be obtained by processing accounting data using trade calculation methods. Trading methods are becoming an algorithm for automated calculations of indicators and management decision - making by artificial intelligence.

Abstract

Effective and efficient project management is essential at all times to ensure projects meet goals, within given constraints. This paper seeks to determine how cloud computing can enhance project management with respect to the ten project management bodies of knowledge (PMBOK). Results show there are various cloud project management tools available, having the potential to perform better than traditional project management tools in all areas of the PMBOK. A qualitative analysis performed on relevant literature by discovered the overall concept of cloud project management is generally positive. Observations from this research and analysis resulted in some recommendations which may help ensure successful project management using cloud computing.

Keywords: Cloud Computing, Project Management, Qualitative Analysis.

Introduction

Technology is constantly advancing and providing new ways to make our personal and professional lives more efficient. The "cloud" is one such component of this rapidly evolving technology (Arora & Parashar, 2013). In its simplest form, the cloud can be described as storing your memory and CPU (Central Processing Unit) power elsewhere i.e. in the "cloud", but taking their advantage on your machines. Cloud use can range from personal use, such as Google Docs to make your documents, to professional use such as running virtual machines on your clients. Project management (PM) is a critical component of any organization's success, even when dealing with complex problems such as pandemics (Ruan *et al*., 2019), and it has been found good project management leads to successful projects (Schwalbe, 2018). PM also needs to keep adapting to technological changes in order to provide effective solutions, which are vital to a project's or organization's performance. In this instance, change refers to cloud computing. This paper examines the integration of cloud computing and project management and how the cloud can help in project management, vindicating the arguments by performing qualitative analysis.

Cloud Computing

Cloud computing is believed to be the 'silver bullet' of IT in the 21st century, but it is also a complex subject (Bredenkamp, 2012). On-demand computing resources are available because of cloud computing, including computing power and data storage without having to perform management on a daily basis. Cloud computing has led to "portable" data centres made available to internet users. Broadly, clouds can be divided into four types – the private cloud for a single organization, the public cloud for the general public, the hybrid cloud and the community cloud (Verma & Sharma, 2019). Cloud computing providers usually offer their services in three categories – Infrastructure as a Service (IaaS) (Preimesberger, 2015), Platform as a Service (PaaS) (Hurwitz, 2012) and Software as a Service (SaaS) (Pocatilu *et al*., 2010). Other categories include Mobile Backend as a Service (MBaaS) (Monroe, 2013), Serverless Computing (Miller, 2015), Function as a Service (FaaS) (Avram, 2016), Content as a Service (CaaS) (Doglio, 2012), Data as a Service (DaaS) (Olson, 2010), Desktop as a Service (Rouse *et al*., 2013), Integration Platform as a Service (IPaaS) (Thoo *et al*., 2011), Network as a Service (NaaS) (Frank, 2011), Security as a Service (SECaaS) (Olavsrud, 2017) and Business Process Management as a Service (BPMaaS) (Barnawi *et al*., 2015). Customers can choose their preferred

service based on what they desire. Dropbox, Google Drive, Salesforce, etc. are some of the famous cloud applications. As a lot of terms were introduced above, below are three figures classifying these terms, making these concepts easier to understand (figures 1, 2 and 3). These types and categories, as well as Dropbox, are discussed after the figures, beginning with the Private Cloud.

Figure 1: Cloud Classification

Figure 2: Deployment models

Figure 3: Service Models

Deployment Models

A *private cloud* involves a secure and distinct cloud based environment created exclusively for the specified client. It is explicitly built for providing services within an organization to maintain privacy and security (Verma & Sharma, 2019). Examples of a private cloud include Microsoft's Azure and Amazon's AWS cloud. A private cloud removes the need to have on premise hardware or data centres for the client organization. *Public Cloud* can be defined as cloud services offered by companies over the public internet, thus making it available to any interested user (Verma & Sharma, 2019); this can be free or paid, depending on provider and user requirements. Examples include Google Drive and Microsoft's OneDrive. The paid versions can be set-up in such a way the customer pays only for what they use; this can be based on CPU cycles used, amount of storage required, bandwidth consumed and so forth. Using a combination of private and public cloud is known as the *Hybrid Cloud* (Verma & Sharma, 2019). The driver to use this type of cloud is the combination of privacy and availability for multi-tenancy. Examples of hybrid cloud are the US Microsoft Hybrid Cloud (Cybercon.com), IBM Cloud App Development (Bluemix.net) and so on. *Community cloud* allows sharing and management of information by a number of related organizations (Verma & Sharma, 2019). Community Cloud is operated by a community of organizations which share common concerns such as storage and security. Some examples of community clouds include Salesforce and QTS Data Centres.

Service Models

With regard to service models, *Infrastructure as a Service (IaaS)* refers to online services providing high level Application Program Interfaces (APIs). Typically, a hypervisor - a virtual machine monitor, runs the virtual machines as guests. One of the most common hypervisors is VMware's ESXi; others include Microsoft's Hyper-V, Citrix's Xen, KVM, etc. Some of them are open source such as the Kernel-based Virtual Machine (KVM), whereas most are proprietary such as ESXi or Hyper-V, to name but a few. IaaS is used frequently nowadays, for example a company called GoGrid manages

cloud and dedicated hosting for more than 15,000 customers claiming to deploy more than 600,000 virtual machines for those customers using IaaS (Preimesberger, 2015). *Platform as a Service (PaaS)* provides a platform to users for running, developing, and managing applications without building and maintaining infrastructure which would otherwise be required. PaaS can be delivered as a public cloud with the customer controlling software development with minimal configuration as a private service behind a firewall, or as a software deployed on public IaaS (Hurwitz, 2012). *Software as a Service (SaaS)* is a subscription-based and centrally hosted cloud computing service for software licensing and delivery. For example, SaaS Customer Relationship Management (CRM) is used by many large enterprises across the world instead of on-premise systems, for managing sales opportunities and actions of sales personnel (Chen *et al*., 2018). Salesforce is one of the successful organizations in the field of CRM. They focus on areas of marketing automation, analytics and application development, along with ways to improve customer service. *Mobile Backend as a Service (MBaaS)* - also known as "Backend as a Service" (BaaS) (Monroe, 2013), enables application developers to link their applications to backend cloud storage and APIs exposed by backend applications. MBaaS also provides useful features such as integration with social networking services and user management.

Other models include *Serverless Computing* - a cloud computing category in which the provider runs the server, dynamically allocating machine resources; this is unique as pricing is actually based on resources consumed by the application, rather than pre-purchasing units of capacity (Miller, 2015). Serverless computing has the potential to be cheaper than purchasing or renting servers (Jamieson, 2017). *Function as a Service (FaaS)* provides a platform on which customers can run, develop and manage application functions without the need to build and maintain infrastructure. Thus, it is similar to PaaS, however FaaS does not require any constantly running server process, thus differentiating itself with the former (Avram, 2016). AWS Lambda is one of the earliest FaaS offerings by a major provider (Eyk *et al*., 2017). *Content as a Service (CaaS)* otherwise known as "Managed Content as a Service" (MCaaS), is where the provider is responsible for delivering content to the customer via licensed internet services under a subscription model. This is an on-demand service. The primary benefit of this service is that the client has the ability to centralize content, as well as make it easily manageable (Doglio, 2020). *Data as a Service (DaaS)* accesses the provider's data product and is used by the client on demand (Olson, 2010), that is to say beyond geographical and organizational borders. As this service is focused on data with access being controlled via data services, quality is improved due to a single point of updates by the provider. *Desktop as a Service* refers to the concept of remote desktop virtualization and virtual desktop infrastructures, or VDIs. In essence, desktop virtualization involves a logical operating system or a virtual operating system isolated from the client used to access it (Rouse *et al*., 2013). Desktop as a service tends to be used amongst public cloud providers. *Integration Platform as a Service (IPaaS)* addresses data, processes and application integration (Thoo *et al*., 2011) and can also be described as a suite of cloud services enabling customers to govern, develop, and execute integration flows between different applications. Such an integration is critical to the needs of certain businesses.

Other approaches use *Network as a Service (NaaS)* for network transport connection; this service is often combined with mainstream services such as IaaS, PaaS and SaaS (Frank, 2011). NaaS considers computing resources and networking as a single point for optimizing resource allocations. At times NaaS can involve a virtual network service as well. *Security as a Service (SECaaS)* sees a provider integrate their security services into an infrastructure accomplished on a subscription basis. In fact SECaaS is more cost effective when compared to running one's own security services when taking total ownership cost in to account (Olavsrud, 2017). Additionally, SECaaS negates the need for on-premise hardware (Furfaro *et al*., 2014). *Business Process Management/Monitoring as a Service (BPMaaS)* is a runtime business process compliance monitoring framework incorporating a broad range of high level compliance patterns for abstracting the specification of relevant constraints (Barnawi *et al.,* 2015). End users benefit from the friendly interface provided by BPMaaS to monitor their business. One application of these service models is *Dropbox*, a popular American cloud service company allowing users to host files (Li *et al*., 2013). Dropbox has computer applications for most mainstream operating systems such as Microsoft Windows, Linux computers, Apple macOS, iOS and Android. Dropbox offers cheap storage and thus has the potential to generate high amounts of internet traffic (Drago *et al*., 2012).

On-demand resources, along with portable data centers, are very helpful for today's organizations, making cloud computing critical for the IT industry (Bredenkamp, 2012). The four types of cloud computing discussed earlier were the Private, Public, Hybrid and the Community Cloud. We also divided the cloud into different categories (Pocatilu *et al*., 2010). The three major categories discussed were Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS). Some seldom used categories were also reviewed, namely Mobile Backend as a Service (MBaaS) (Monroe, 2013), Serverless Computing (Miller, 2015) Function as a Service (FaaS) (Avram, 2016), Content as a Service (CaaS), Data as a Service (DaaS), Desktop as a Service, Integration Platform as a Service (IPaaS), Network as a Service (NaaS), Security as a Service (SECaaS) and Business Process Management as a Service (BPMaaS). A particularly well-known application called Dropbox was also discussed. Let us now turn our attention to the topic of project management with a cloud focus.

Cloud Project Management

Project Management has existed in a formal western sense of the term since the Manhattan project, producing the world's first atomic weapons (Schwalbe, 2018). The goal of project management is to achieve all project goals within given constraints. Traditionally this has been accomplished manually or via on-premise systems (Preimesberger, 2019). However, most projects require the management of numerous documents and related work, which can be made easier by implementing cloud based solutions (Baird, 2015). Cloud is a relatively new concept, and thus its integration with project management is an even newer concept. As a result SaaS is the only area of cloud computing where considerable literature exists for discussion of the integration of cloud and project management; which is what the following section explores. Following this discussion, specific tools related to cloud project management are introduced, such as BaseCamp, Zoho Projects, etc. Finally, coverage with regard to PMBOK is undertaken.

PM with SaaS

SaaS project management can specifically refer to delivering project management software on demand, in an environment where cloud computing is in place. As every business requires the ability to manage projects effectively, SaaS is an appropriate delivery model for project management software. SaaS project management applications consist of comprehensive tools for managing projects throughout their lifecycle, such as bug trackers and tickets, change management tools, online chats, virtual conference rooms, cost and budget trackers, dashboards, contact management tools, reporting tools, templates, collaboration tools, audit tools, scheduling tools, resource management tools and so on. Companies such as Gehry Technologies (Post, 2012), Autodesk (Maher, 2009) and Newforma (Joyce, 2012) have been developing such SaaS tools. Using SaaS project management service adds significant advantages. In fact Arnold (2009) suggests using Google Sites (an example of SaaS) for management after the project is completed. He describes Google Sites as a collaborative tool with a very good trouble ticketing system. Some other tools described are Zoho Projects and BaseCamp. In contrast to on-premise project management tools, SaaS PM tools are a popular alternative, as on premise tools lack the ability to serve remote clients effectively (Chen *et al.,* 2018); such PM Tools also remove all barriers to team collaboration as people can simply connect to the internet and start working, regardless of their location (Arnold, 2009). Another collaboration benefit is the use of a central repository to track and synchronize projects, unlike on-premise systems. Some examples of such centralized repositories are GitHub, BitBucket etc.

SaaS PM Tools also have an advantage over traditional tools regarding costs; this is due to SaaS applications running in the cloud, as this in turn helps SaaS vendors distribute maintenance costs over time, making prices affordable for their clients. Tiered pricing structures also help in lowering costs for clients (Abaffy, 2013). SaaS vendors also handle upgrade works and costs, lessening the workload of clients. Such benefits are more applicable to start-ups as they usually lack funding for on-premise systems. One major advantage is also the high scalability of SaaS tools; this can be as simple as subscribing to more services and power from the respective vendor. Finally, SaaS tools demand little training since they only require people are comfortable using internet as most complex jobs are the vendor's responsibility (Chen *et al.,* 2018). In recent times, Customer Relationship Management (CRM) has become a widely studied concept. CRM is related to SaaS as it traditionally uses SaaS to function (Chen *et al.,* 2018). Large enterprises across the world use SaaS CRMs instead of on-premise

systems to manage their sales departments. The driver for this behaviour are the low costs of SaaS, such as zero investment in machinery and equipment. Companies such as Salesforce rely on their CRM business for generating revenue (Arnold, 2009). Let us next examine some examples.

BaseCamp provides core project management and collaboration features. Third party applications are available to extend their features, such as introducing time tracking, accounting and charts to the core BaseCamp application (Arnold, 2009). Useful components of BaseCamp are the messaging and whiteboard features which help in collecting ideas from large groups of people. One can post and reply to messages via email from BaseCamp. Messaging threads are also available. *Zoho* [www.zoho.com] consists of a full suite of inexpensive and high quality business applications and can be considered a one stop shop for any business (Arnold, 2009). Basic features such as time tracking and progress charts have been incorporated in Zoho, which takes a more traditional approach in project management when compared to BaseCamp (Arnold, 2009). The popular *Google Sites* is originally a tool called JotSpot that Google acquired many years ago (Arnold, 2009). Google Sites is an array of applications such as Docs, Spreadsheets, Presentation, Calendar etc., effectively comprising all routinely used applications. Other useful tools include ticketing systems and file storage (Google Drive). One major advantage of Google Sites is that it makes project documentation easy due to the abovementioned features. Microsoft's Azure is another major cloud product (Sawyer, 2011), although typically used by larger organizations. Having explored cloud options, let us turn our attention to the management of projects in the cloud space.

Cloud vs. Traditional PM and the PMBOK

According to the Project Management Institute [pmi.org], there are 10 bodies of knowledge with respect to project management (Huda & Maliki, 2019): Project Integration, Scope, Time, Cost, Quality, Human Resource, Communication, Risk, Procurement and Stakeholder Management. Dillon & Scanlon (2011) comprehensively described how the cloud can contribute to making PM easier compared to traditional PM. As the cloud allows integration at a centralized place easily and this data can be seamlessly shared, along the lines of GitHub, integration and stakeholder management can benefit from this strategy.

Cloud tools such as BaseCamp can quickly determine if the scope of project is feasible or not by utilizing its third party applications; this can help in the case of scope management. Tracking tools such as Atlassian's Jira can help with time management (McDuling, 2019). In the cloud, live changes of anything including costs, can quickly be circulated among the team members as described earlier, helping with cost management. Using tools such as Zoho projects and BaseCamp, strict quality management can be enforced and improved with tools such as audit manager and document manager. Tools such as Workday also consist of additional features (Preimesberger, 2019) helping with timesheet submissions, vacation requests and performance reviews, clearly decreasing the workload of the human resources (HR) department. Tools such as Google Sites enable rapid communication thus improving communication management. The third party application - BaseCamp (Arnold, 2009) can also have features providing information about operation inefficiencies, thus improving risk management. These tools (Preimesberger, 2019) also allow for total oversight and control of service spending, improving procurement management. The aforementioned arguments indicate the cloud helps improve traditional on-premise project management (Dillon & Scanlon, 2011) in each of the ten areas of the PMBOK. Table 1 summarizes the above.

Cloud project management is a new but useful concept helping businesses thrive. Compared to traditional approaches to project management, cloud project management can be particularly helpful. SaaS is so far the only cloud service which project management has adopted. SaaS project management offers a range of benefits such as low costs, tension free clients, centralized repositories, CRM software and so on. BaseCamp, Zoho Projects, and Google Sites are a few examples of specific tools related to cloud project management. The cloud - particularly SaaS, improves every area of the PMBOK in different ways (Dillon & Scanlon, 2011).

Table 1: Project management bodies of knowledge (PMBOK) vs. cloud offerings

PMBOK	What makes cloud PM better than traditional PM?
Integration	Ability for centralized data (Arnold, 2009) integrating everything into one place.
Scope	Advanced tools like BaseCamp consisting of fully functional scoping tools (Arnold, 2009).
Time	Tracking tools such as Jira, ensure time is managed wisely (McDuling, 2019).
Cost	Live changes to costs provided instantaneously to all stakeholders (Chen *et al*., 2018).
Quality	Zoho delivers audit and document management tools improving quality management (Arnold, 2009).
HR	Workday consisting of timesheet submission and vacation request features, ensuring easier HR management (Preimesberger, 2019).
Communications	Google Sites enable quick communication among participants making communication management easier and quicker (Arnold, 2009).
Risk	BaseCamp provides information about operational inefficiencies thus improving risk management (Arnold, 2009).
Procurement	BaseCamp allows for total oversight and spending control (Preimesberger, 2019).
Stakeholder	Ability for centralized data (Arnold, 2009) means stakeholders access data easily.

With the cloud (especially SaaS) expected to keep expanding, cloud project management can only grow further (Farb, 2011). We wanted to do more than just establish the boundaries of project management and cloud computing, and sought to undertake some qualitative analysis of the literature around this topic to see if we could uncover hidden concepts overlapping the two areas. We turn our attention to this exploration of concepts next.

Qualitative Analysis of themes

Qualitative analysis is the analysis of qualitative data such as text from journal articles. NVivo is an example of qualitative analysis software (Lam & Busch, 2019), able to provide useful insights into any topic, provided you feed it with enough raw data. Forty articles (included in the reference list), from 2009 to 2020, were loaded into a new NVivo hermeneutic unit. The papers were gathered from 40 library databases such as Academic Search Premier, ACM Digital Library, Advanced Technologies & Aerospace Database, AIS Electronic Library, Computer Index Australasia, Elsevier, ENGINE, IEEE, O'Reilly, Scopus, Springer and Wiley. The keywords used to find these papers were "cloud computing" AND "project management". Some papers were also obtained from Google Scholar using the keyword "cloud project management". Auto-coding was performed at the sentence level looking for themes. In auto-coding, NVivo automatically recognizes themes and topics or concepts present in the given files. The output of this operation appears in various forms – tree maps, bar graphs and so on. The following section shows those reports generated by NVivo auto-coding and their discussion. Figure 4 shows a tree

map generated from NVivo auto-coding. Bigger tiles indicate higher dominance of that topic in the literature gathered.

Figure 4: illustrating themes from auto-coding cloud vs. project management.

Nodes and Sentiment Analysis

Sentiment analysis was also conducted in Nvivo where sentiment represents a critical way of undertaking qualitative analysis illustrating the tone of an article or a topic. NVivo can generate themes or nodes from all provided documents by auto-coding keywords. Eighteen themes or nodes were auto-generated and after merging some terms e.g. merging cloud and computing, project and management etc., 14 final themes were determined. A sentiment analysis was then conducted resulting in figures 5, 6 and 7. Each major box in figure 5 corresponds to a particular theme. Inside those are four boxes corresponding to different sentiments about that theme: neutral, mixed, positive and negative. Clearly the neutral majority demonstrates the neutrality of all themes, but also fails to offer more insight. For a deeper analysis, figure 6 illustrating a bar graph is shown; this figure shows bars of each themes, separated into four different colours for very negative, moderately negative, moderately positive and very positive sentiments. It is clear the green - “moderately positive” category dominates. This result is

vindicated by figure 7, which shows the darkest shading in the same category. Both the graph and table also show exact auto-coding counts.

Figure 5: Box Chart illustrating sentiment vs. themes

To determine how the concept of cloud project management changed over the 2009 to 2020 time period, papers were equally divided into two categories: 2009-2014 and 2015-2020. Sixteen papers were from the 2009-2014 period and 24 from the 2015-2020 period as these were the numbers found from searching the library databases. Shown below in tabular form are both the reports starting with the 2009-2014 report (figures 8 and 9). These reports analyse sentiments provided in individual papers, and classify them into four different categories: Very Negative, Moderately Negative, Moderately Positive, and Very Positive. As an example, phrases like "cloud PM is the worst" would indicate a very negative sentiment, "cloud PM is bad" would be a moderately negative sentiment, "cloud PM is good" would be a moderately positive sentiment, and "cloud PM is the best" would be a very positive sentiment. Darker shading indicated a category's higher dominance for that article. Numbers shown in the figures are the count of how many times a sentiment was shown. In figure 7, sentiment was moderately positive as indicated by the darker shading. It is however difficult to determine overall sentiment in figure 8 due to mixed shadings. Hence, it is best to determine total count of each category for accurate analysis. The count was 127 for very negative, 324 for moderately negative, 419 for moderately positive and 166 for very positive. Now, it is clear a similar result of moderately positive was obtained for figure 9 as well. Therefore it can be said the attitude towards cloud project management has remained fairly consistent since 2009. The primary pattern noticed was the neutrality of the topic; even when it swayed towards negative or positive side, there still existed "moderate" sentiment. Whenever the topic was not neutral, the overall sentiment was found to be moderately positive. It must be noted the sample size was 40 documents, although these were gathered from a variety of sources. Also under the comparison reports section, the split of documents was not exactly the same, as there were 16-24 in favour of the 2015-2020 category. It was found that the overall outlook on the topic of project management in the cloud was moderately positive.

Discussion

One of the findings was that while many companies adopt SaaS PM, very few adopt PM with other cloud service models. One reason could be that SaaS is easier and quicker to setup then other mainstream services - i.e. IaaS and PaaS (Pocatilu et al., 2010). However, companies in the ICT industry such as VMware, Citrix and Nutanix for example, have certain very successful IaaS products such as hypervisors. Companies could benefit from utilizing other specialized services for specific needs, rather than adhering to SaaS PM only. For example MBaaS is useful when dealing with backend cloud storage, for CaaS helps clients centralize their content whereas DaaS focuses on data quality. Mainstream services may not always be able to perform at the same level when dealing in such specialized circumstances. It can be inferred from the NVivo output that documents mentioning “risks” in relation to Cloud PM had considerable negative sentiment, inferring cyber security may be an area of concern. Recent data breaches of government databases and systems make this issue more severe. For example,

the Australian National University (ANU) suffered data breaches at least two times in recent years, compromising the data of many students (Giggacher, 2019); which in turn resulted in huge reputational loss. Hence cloud providers would certainly benefit from strengthening their cyber security, giving consumers the confidence to use them as a substitute for traditional project management. While there are plenty of tools available making cloud PM better than traditional PM, there is no one tool providing all-encompassing functionality. An all-in-one tool would definitely be more encouraging to people and prompt them to switch to cloud PM. For example while tools such as Zoho projects specialize in providing auditing tools, BaseCamp provides useful scoping tools. However neither of them provide both, potentially detering customers from using them. If there are reservations about moving into a cloud project management environment from a traditional PM setup, one can also perform a gradual transition by moving one of the PMBOK to the cloud. This can act as a trial of cloud PM, and if successful be expanded to all ten PMBOKs.

Figure 9: Sentiment analysis articles published 2015-2020

For example a company can transition all its communication management strategies to the Google Suite or an equivalent cloud tool; if this enhances communication management, then cloud PM tools such as BaseCamp can be applied to other fields of the PMBOK. As evident from figures 8 and 9, the overall outlook on cloud PM is moderately positive, however there are a few areas, such as risk, having major negative sentiments. If the aforementioned solutions are implemented, then these negative sentiments can further be reduced. As seen in table 1, the cloud is already enhancing PM with respect to the ten areas of the PMBOK because of various cloud tools. Again, implementation of the aforementioned solutions will further improve cloud project management.

Conclusion

Cloud computing is still new and on the upward adoption trajectory. It is very flexible (Schneckenberg, 2014) and can be applied to a variety of areas - project management being one of them. Project management is key to organizational success. Enhancing PM with cloud services has benefits. This paper discussed both, cloud and project management in detail, before considering their integration. Cloud computing may be distinguished by two categories – Deployment Models and Service Models. These categories can be further broken down into specific terms. There are four deployment models – private, public, hybrid and community cloud. There are plenty of service models, 13 of which were covered. The mainstream services, i.e. IaaS, PaaS and SaaS were part of these 13 service models. Project Management is about accomplishing all project goals within given time and cost constraints. The cloud increases the capabilities of project management in every area of the Project Management Bodies of Knowledge (PMBOK), such as scope, integration, time, cost, due to the advanced tools for cloud project management such as BaseCamp and Zoho Projects. We then conducted a qualitative analysis. Results obtained were discussed in depth and patterns in the raw data identified, such as many documents having neutral sentiment. A limitation was the uneven distribution of documents based on time period, but in general cloud project management has been positively received in the articles qualitatively examined. Some recommendations are promoting use of non-mainstream services such as CaaS, MBaaS, etc.,

strengthening cyber security, creating tools with a broad range of functionality, and making a gradual transition to cloud. It may be concluded cloud project management is here to stay and in fact will only become more popular (Bianchini et al., 2020).

Reducing Exchange Rate Risk on The Example of ERP Software

Marek GAŁĄZKA

Adam Mickiewicz University, Poznań, Poland
galazka@amu.edu.pl

Abstract

Companies that transact in different currencies face financial risk because of unpredictable exchange rate fluctuations. Exchange rate risk constitutes one of the most common forms of risk that firms in the international arena encounter and, in recent years, the management of this risk has become one of the key factors in overall financial management. Measuring and managing exchange rate risk exposure is important for reducing a firm's vulnerabilities from major exchange rate movements, which could adversely affect profit margins and the value of assets.
The purpose of the article is to show how to implement and provide a solution in SAP ERP or S/4HANA systems that significantly reduces exchange rate risk.

Keywords: ERP Systems, Foreign Exchange Risk, Risk Management

Introduction

Today, the economic environment in which most firms operate is highly volatile and uncertain. One of the main factors effecting this process is the increasing market globalization and internationalization, which is reflected in increased exchange, interest, inflation rates fluctuations as well as in high competition, demand levels etc. Big multinational companies are particularly exposed to exchange rate fluctuation; therefore, special attention should be paid to exchange rate management.

Exchange rate risk management is an integral part in every firm's decisions about foreign currency exposure (Alayannis, G., Ihring, J., and Weston J., 2001). They analysed the effectiveness of operational and financial hedging by U.S non-financial multinationals (1996-1998). They found that on an average operational hedging does not reduce exchange rate risk exposure on its own. Financial hedges are effective on their own, and so is a combination of financial and operational hedging. (Debashish, S. S., 2008) focused on foreign exchange risk management practices and derivative product usage by large non-banking Indian based firms apart from techniques of risk hedging, the risk evaluation methods adopted and the risk management policy. (Nagendran, R., 2008) studied the foreign exchange rate movements in India for the major currencies like U.S Dollar, GB Pound Sterling, Euro and Japanese Yen from 1999 to August 2007 and attempted to give solutions to this exchange rate challenge using Technical Analysis. (Goel, M., Gupta, S. L., and Goel, L., 2011) made a comparative analysis of management of foreign exchange exposure by banking and non-banking as well as foreign and Indian MNCs operating in India. (Afza, T., and Alam, A., 2011) showed that firms having higher foreign sales are more likely to use derivative instruments to reduce exchange rate exposure. Moreover, financially distressed large size firms with financial constraints and fewer managerial holdings are more likely to use foreign exchange derivatives. (Hon, T. 2013) studied the ways that the Hong Kong companies in the Hong Seng Index Constituent Stocks manage their financial risk with derivatives. By analyzing the companies‟ annual reports and financial reviews, it was found that 82.6% of these companies used derivatives in 2010. Specifically, 58.7% of them used swaps to hedge interest rate risk, and 54.3% of them used forward contracts to hedge foreign exchange risk. (Mbabazize, P. M., Daniel, T., and Ekise, I. E., 2014) examined the role of foreign exchange risk management on performance management of exporting firms in developing countries taking Uganda as the case study. (Chaitanya, C.H., and Radhika, T., 2015) attempted to study the impact of exchange rate on select Indian IT companies, Market Price Of Share (MPS) and the tools and techniques used by Indian IT majors to net their foreign exposures. An analysis of the data collected from various secondary sources revealed that

Cite this Article as: Marek GAŁĄZKA" Reducing Exchange Rate Risk on The Example of ERP Software" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

foreign exchange rate had significant impact on market as a whole. (Assad, M. J. 2016) attempted to study the capacity to manage foreign exchange risk among businesses and to identify the attributes which explain the divergence among individuals/firms. It emerged from the study that the perception within the country to manage foreign currency risk was weak and it was not a normal practice for local firms to have a policy for guiding the practice with respect to foreign currency risk management. (Ito, T., et al, 2016) investigated the relationship between the Japanese firms' exposure to the exchange rate risk and risk management, such as choice of invoicing currency, and financial and operational hedge. (Sikarwar, E., and Nidugala, G. K., 2018) examined the relationship between the value of the firm and unanticipated changes in exchange rate. (Dash, M., 2019) studied the impact of currency fluctuations on cash flows of IT service providers and analysed and evaluated the foreign exchange risk management strategies to find out which of the strategies was appropriate in particular situations.

Many companies use the ERP systems. The term ERP abbreviated from "Enterprise Resource Planning", was introduced by the Gartner Group in the early 1990s (Arif, M., Kulonda, D. J., Proctor, M., and Williams, K., 2004) and represent computer and software systems that combine and integrate all related processes of the enterprise, and serve users for the management of all functions within the enterprise (Swartz, D., and Orgill, K., 2001). Researchers referred ERP systems as enterprise system (ES), enterprise resource management (Cobarsí, J., Bernardo, M., and Coenders, G., 2008), and business system respectively (Davenport, T. H., 1998, 2000). (Klaus, H., Rosemann, M., and Gable, G. G., 2000) conceptualized ERP System as comprehensive packaged software solutions of Information System (IS) designed to integrate all business processes and work to present a complete outlook of the business from a singular IT and information architecture (Klaus, H., Rosemann, M., and Gable, G. G., 2000). (Davenport, T. H., 1998) also described ERP an information strategy that merge all information within an organization and create a comprehensive information infrastructure involving all organizational units and functions. (Marnewick, C., and Labuschagne, L., 2005) clarified that ERP system is more than just a product or software and they further conceptualized ERP into four components. The first component is software component (Finance, Human Resources, Supply Chain Management, Supplier Relationship Management, Customer Relationship Management, Business Intelligence), which is the visible part to users and seen as ERP product. The second component is process flow, which deals with the information flow among modules within ERP system. Third is customer mind-set, that define the influence of ERP system on users, team, and organization. And the final component is change management, this component deals with the adoptability of ERP system implementation within the organization, that are user attitude, project changes, business process changes, system changes.

Many international companies that trade around the world and conduct transactions in different currencies use the SAP ERP system. For such companies, it is very important that the exchange rates that are available in the system are updated daily. Incorrect exchange rates in the system significantly increase the exchange rate risk for companies. In this article is described an example implementation of loading daily current exchange rates from the European Central Bank to the SAP system.

Description of the solution in the SAP ERP or S4/HANA system

This section is divided into functional description and technical description

Functional Description

Exchange rates are to be maintain in SAP to allow transactions in other than the company code currency or book value in additional local currencies in the New G/L accounting. SAP has a dedicated table for maintaining exchange rates. The name of the table is TCURR.

MAN...	KURST	FCURR	TCURR	GDATU	UKURS	FFACT	TFACT
100	EURX	USD	EUR	09.05.2020	/1,08430	0	0
100	EURX	USD	EUR	08.05.2020	/1,07830	0	0
100	EURX	USD	EUR	07.05.2020	/1,08070	0	0
100	EURX	USD	EUR	06.05.2020	/1,08430	0	0
100	EURX	USD	EUR	05.05.2020	/1,09420	0	0
100	EURX	USD	EUR	01.05.2020	/1,08760	0	0

Fig. 1: SAP Exchange Rate Table (TCURR)

Exchange rates can be entered and updated manually (Transaction OB08).

Change View "Currency Exchange Rates": Overview

New Entries

ExRt	ValidFrom	Indir.quot		Ratio(from)	From		Dir.quot.		Ratio (to)	To

EURX	18.04.2020	1,08600	X	1	USD	=		X	1	EUR

Fig. 2: Transaction OB08- changes in exchange rates

Manually changing exchange rates is obviously not a very smart solution. This article describes how to automate this process. Central banks provide current exchange rates every day (often in XML or JSON file format). The solution proposed in the article uploads exchange rates from the European Central Bank into TCURR table. This operation takes place every day after 16 CET because exchange rates are usually updated around 16:00 CET on every working day, except on closing days. All exchange rates published by ECB use indirect quotation. Indirect quotation expresses how much foreign currency you get/pay for 1 EUR.

Technical Description

The solution contains ABAP class that show how to load daily currency exchange rates provided by the European Central Bank into the corresponding customizing table of the ABAP system. The class retrieves currency exchange rates from the ECB's own XML API (https://www.ecb.europa.eu/stats/eurofxref/eurofxref-daily.xml). To do this, you need to create the RFC connection to ECB, that is, start the sm59 transaction.

Fig. 3: Transaction SM59

Note that retrieving ECB data is just an example; there are other central banks or services that provide different or enhanced data on exchange rates for which the retrieval needs to be altered appropriately, with respect to service link and format, of course.

The class perform the exchange rate retrieval, convert the retrieved data into the internal storage format and write it to the currency rate customizing table using the respective BAPI 'BAPI_EXCHRATE_CREATEMULTIPLE'. On execution as "console app" the ABAP console provides notice on write. Note that appropriate write authorization must be supplied to actually perform the customizing update (Authorization Objects for V_TCURR).

The application should be run in the SAP system automatically as a job every day after 16 CET.

Implementation of the solution in the SAP ERP or S4/HANA system

In this section is showed the source code of the class that show how to load daily currency exchange rates provided by the European Central Bank into the corresponding customizing table of the ABAP system. These example class provides currency exchange rates to the currency rate type EURX which is the "standard exchange rate type" provided in the regular system deployment of an SAP environment system. The source code is written in ABAP (programming language in SAP system).

Quality Cost Calculation as Data Source for Kaizen Costing System

Abstract

The automotive industry sets new standards not only for quality management (ISO/TS 16949:2016) but it also inspires to search for effective production methods such as lean production, agile production and tools supporting their management processes in a global car supply chain. One of such tools is the loss reduction system (Kaizen Costing). The purpose of the paper is to present the issues of quality cost accounting which determine the level of quality costs to sales value, preventive costs, control and assessment costs, and cost of losses. On the basis of the loss cost account, the types of internal and external failure costs were determined in reference to the cost components that affect the losses and should be subject to the improvement process within the Kaizen Costing system. In the surveyed enterprises, they implemented the quality management system based on the IATF 16949 standard but they use different management accounting systems as they do not have the same owners. Moreover, their quality management systems are mature enough to be able to consciously assess the existing situation in reference to loss cost and determine the necessary improvement actions for products that are already in the production and delivery phase to the customer. However, their IT systems only include the main internal failure costs in the costs of foundry and mechanical departments, and in the case of external failure costs these are costs of complaints and special transports. The cost of losses of individual products require additional calculations outside the system.

Keywords: Quality Costs Calculation, Loss Cost, Kaizen Costing.

Introduction

Modern production enterprises pursuit to excellence in constant globalization and internationalization of the world economy. It mainly relies on searching for new markets, cheaper labor and new locations in less developed countries where it is possible to adapt already implemented technologies from modern workplaces. A good recent practice is automotive industry. Due to changes in the environment its global representatives adopt a new strategy and business models that are more focused on emerging markets, new consumer needs and concepts of mobility. According to the KPMG's report - Global Automotive Executive Survey (KPMG, 2018) the basic factors of change are globalization and production increase, environmental challenges (development of electric drives, application of environmental friendly technologies), change of consumer behavior (in reference to economic solutions, safety innovations, applied ergonomic solutions, comfort) and urbanization and development of mega cities (i. e. urban car design).

The automotive industry is dominated by supplier market, which produces about 80% of the parts for the assembly of new cars, which has to deal with changes in the global environment, respond to the needs of car concerns and their customers, and create favorable conditions for changes (Grzybowska & Łupicka, 2019). These changes result from the development and technological innovations, shortening life cycle of products, reduction of production costs or shorter delivery times. It is

Cite this Article as: Jozef GRUSZKA And Beata MRUGALSKA "Quality Cost Calculation as Data Source for Kaizen Costing System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

supposed be achieved, among others, by the development of ERP information and information systems, Enterprise Resource Planning, which create new opportunities for access to information, e.g. on quality costs and their use in decision-making processes, which are often already at the operational level, as long-term strategies quickly lose their relevance (Lenart, 2016).

The increasing global competition makes the companies to change their manufacturing practices. In order to achieve their goals they start to implement advanced methods and techniques such as just-in-time, lean manufacturing, productivity improvement and total quality management to name a few (Górny, 2020; Mrugalska, Konieczna & Wyrwicka, 2020; Mrugalska, 2020). They pursuit to reduce cost, cycle time and improve quality (Modarress, Ansari & Lockwood, 2005). This paper presents a case study of Kaizen Costing in two automotive companies. The purpose of this study is to show the issues of quality cost accounting which determines the level of quality costs. In both of the enterprises the quality management system is based on the IATF 16949 (2016) standard but they use different management accounting systems. It let us show relevant data supporting production decisions which can be useful for practitioners in reference to Kaizen Costing system.

Kaizen Costing

Kaizen Costing (KC) is a system which facilitates the cost reduction at the manufacturing process of the existing components or product by a pre-specified amount (Drury, 2004). It is an extension to the production of the cost management activities performed using Target Costing which is applied to the development stage of a new product (Iii & Smith, 2000). KC derives from Japanese word "Genkakaizen" and its meaning is a little bit different than English word "improvement". It denotes continuous accumulations of small betterment actions rather than improvements by innovations (Afonso & Leite, 2016; Monden & Hamada, 1991). Therefore, it refers to the changes focused on either the increase of the effectiveness of the production process or reduction of costs of an individual product without altering its functionality (Copper & Slagmulder, 1997). It is implemented outside the standard cost system as a part of the overall budget control system. It denotes the actual cost per product for the most recent period and it must be decreased in the succeeding period to meet the target profit (Monden & Hamada, 1991). It is recognized that Kaizen Costing activities may have an impact on approximately 10% of a product's costs, in contrast to approximately 90% which can be achieved within target costing (Cooper, 1996).

Kaizen Costing can be implemented to manage diverse costs in an organization. It can refer to the cost of the supply chain (i.e. administration, order procurement, inventory and transportation costs) or regulate the cost gained in the production of goods/services (i.e. cost of machinery, tools, equipment, raw material and labour). It can be also applicable to the cost of acquiring a patent, license, registration fees, hiring of chartered accountant and all other legal formalities. In a case of redesigning of a product it encompasses cost on research, analysis, hiring of expert personnel, etc. (Prachi, 2019).

KC allows to find opportunities for cost efficiency by engaging all workers in the enterprise (Afonso et al., 2008). It is a team-based approach integrating staff from various functional organizational units (Baykasoglu & Kaplanoglu, 2007). In order to implement it, it is needed to introduce and sustain supportive organizational culture which enable to build positive relation between people, work and organization (Medinilla, 2014). The motivation of the employees should be oriented to continuous improvement, achievement of goals which are defined in strategic plans, and provision of information support for project leader (Rojek & Sobańska, 2011).

Kaizen Costing consolidates the gains in the existing markets as it is used for steady and determined cost optimization to maintain a competitive advantage. It refers to the existing products which functionality cannot be altered simply (Ahn, Clermont & Schwetschke, 2018). Moreover, it can be treated as a solution to introduce strategic products which standard costs are higher than its target costs (Agndal & Nilsson, 2008). It changes the market perspective of target costing by stressing an internal focus. However, it has to be emphasized that KC helps to achieve a long-term profit for a company as it can be applied to a new launched product, which costs are too high, or a mature

product, which selling price is decreasing (Cooper & Slagmulder, 1999). The summary of key features of Kaizen Costing is depicted in Figure 1.

Fig. 1. Key features of Kaizen Costing

As far as the benefits of Kaizen Costing are discussed, it is worth to emphasize the improvement of business efficiency (product, process, project and organization) due to the reduction of various types of cost in all kinds of organizations (service industry or manufacturing industry). It protects against waste of time and resources. Its application allows to solve the identified problems to reach perfection in business operations. Furthermore, it is a customer-oriented technique which concentrates on providing better service to the consumers. On the other hand, the attention is paid to a positive work environment for the employees and the management. In order to fulfill a common aim the advantages of team work are emphasized where employees with different skills and knowledge are engaged.

Despite positive aspects of KC there are also some disadvantages such as difficulty to adopt the change in process or product for the bottom level management. It requires expertise and training to lead it smoothly, and if it is not implemented strategically, it can even lead to negative effects. The implemented change is irreversible, and it requires efforts and cost in withdrawing such decisions (Prachi, 2019).

Research Methodology

Characteristics of Enterprises

The research was done in two companies called (1) and (2) with the international capital from automotive industry. Both of them have aluminum foundry and machinery department. They have implemented quality management systems based on the standard of the quality management system in the automotive industry - IATF 16949: 2016. The enterprise (1) has a separate quality cost account as the part of the IT system which directly lets to obtain data related to individual items of quality costs (internal and external failure costs, cost assessment and preventive costs). It produces highly specialized aluminum castings (Fig. 2a) which are subjected to a machining process. The enterprise (2) does not have a separate quality cost account as part of the IT system used, from which only data related to the internal and external failure costs could be obtained directly. The data regarding cost assessment and preventive costs were adopted from previously conducted research in the field of quality cost accounting (Gruszka & Kurzawski, 2018). Similarly to the company (1), the company (2) deals with the production of highly specialized aluminum castings (Fig. 2b) which are then subjected to a mechanical machining.

a) b)

Fig. 2. a) piston for commercial vehicle engines, b) joke brake caliper

Technological Processes

The surveyed enterprises have technologically similar processes. Both the foundry and machining processes are carried out in the automated foundry lines. The piston parts (Fig. 2a) and corpus (Fig. 2b) are gravity cast into reusable metal molds. The cast products are thermally improved in the process of super saturation and aging, and are the subject to control for the presence of foundry defects. Then the details are transferred to the mechanical department where they are processed in numerical machining centers.

After machining, the details undergo a washing process. The finished products (2a and 2b) are sent to the customers where the remaining components are installed in the internal combustion engine for pistons and for the joke brake in the casting body and then these products are assembled in the passenger cars.

Research and Results of Quality Cost Analysis

As the purpose of this paper was to conduct the research and analysis of quality costs in the field of cost structure, the authors investigated the sources of the largest failures indicating the possibility of them reducing through product quality improvement processes. The research was carried out using selected qualitative methods and tools (Raßfeld at al., 2015; Zymonik, 2003). The results of the investigation of quality costs are illustrated in Figure 3.

Fig. 3. Structure of quality costs

For the enterprises (1) and (2) the total quality costs are at the level of 5.85% and 10.7% of the sale value, respectively. It is worth to emphasize that the data from the European industry research shows

that they should be in the range of 4-8% (RWTUV, 1993). Furthermore, as it can be noticed on Fig. 3 the data show that the companies have a wide range of opportunities to take improvement actions, particularly, it is the enterprise (2). For both surveyed enterprises the dominant component of the quality costs are total loss costs (for enterprise (1) at 50% share in quality costs and for enterprise 2 at 83%). It differs significantly the enterprise 2 from the European industry data as they achieve the level of 45-55%.

On the other hand, the external failure cost of enterprise (1) is relatively low as it is 1.5%. According to Malik et al. (2018) it is the effect of using control procedures of shipped products. In this case it results from the analyses and related improvement activities (once a week) by quality engineering (QE) in the field of foundries and machining. In order to clarify the problem of significant loss cost in the enterprise (2) further research and analysis of the share of costs in the internal and external failure costs was made what is depicted on Figures 4 and 5.

Fig. 4. Structure of internal failure costs (company (2)).

Fig. 5. Structure of external failure costs (company (2)).

In the internal failure costs the dominant role plays loss cost due to defects and quantitative difference, at the level of PLN 8.9 million per year and PLN 2.3 million/year, respectively. The main cost is the foundry department (PLN 10.6 million/year). In the external cost it is possible to differentiate transport cost of parts due to delays in delivery on time in the amount of PLN 0.7 ml/year and complain cost due to delivery of nonconformities. In the foundries loss costs are at the level of PLN 0.5 million/year and in the mechanical department they are at the level of PLN 0.2 million/year.

The result of the further research in the enterprise (2) was cost analysis of losses related to non-compliant products, which have the largest share in the loss cost in the foundry area (Fig. 6) and in the area of the mechanical department (Fig. 7).

Fig. 6. List of TOP 10 products with the highest share in the loss cost (thousand PLN) in the foundry processing department.

Fig 7. List of TOP 10 products with the highest share in the loss cost (thousand PLN) in the mechanical processing department (2)

A list of TOP 10 products was determined by the Pareto analysis to indicate the possibility of undertaking improvement actions in the scope of reducing the costs of losses. The basis for the program of improvement actions should be the following methods: Process Failure Mode and Effects Analysis (PFMEA), 5 Whys method and the 8D problem solving process for particular products.

Conclusions

As the results of the investigation show the implementation of the quality management system based on the IATF 16949 standard does not have to let the company fully benefit from the opportunities for improvement in reducing loss costs. In particular, the enterprise 2 does not use the full quality cost accounting in its management accounting system. The IT system contains only the main carriers of the internal failure costs in the scope of the costs of deficiencies in the foundry and mechanical department, and in the scope of external failure cost these are the costs of complaints and special transports. The data related to the cost of losses of individual products require additional calculations outside the system, which was used in research, among others. The situation is opposite in the company 1 which has a full set of cost data. The controlling department prepares for QE for weekly meetings of production management in order to establish programs of improvement activities on individual production lines in both the foundry and machining area.

Today, the principle of reducing costs of losses as part of quality management is already a well-known and practiced rule in particular automotive companies. In the case of the examined enterprises, the area of the aluminum foundry department of the enterprise 2 should first be included

in the improvement action program and at the same time it would be necessary to implement a quality cost account under management accounting.

Abstract

Organizational performance is one of the most approached topics in the last period, this concept being attractive to both scientific and economic worlds. Also, this concept is analyzed concerning a lot of dimensions, factors and other concepts, including organizational processes. The goal of this paper is to analyze the relationships between the processes of different types of service companies and organizational performance. For this paper, the authors developed a questionnaire that was applied to a group of employees from the Romanian service companies. Based on their responses and perceptions, there were highlighted the most important processes that can contribute to improving organizational performance and also the most important or unimportant processes for each analyzed type of company. This study is an exploratory one, with evidence from Romania.

Keywords: organizational performance, service company performance, business process performance

Introduction

Organizational performance is a very popular topic in the last years. This concept is presented in both business and scientific environment. All of the researchers and managers are looking for all kinds of solutions to improve business performance. A part of them is looking for answers in the ecosystem, while the rest of them is analyzing the internal part of the business.

The interest in business process performance and organizational performance can be also seen by looking at more of the 3.3 million papers about this subject on Google Scholar. For example, since the beginning of 2020, on Google Scholar you can find more than 44500 papers that are about business process performance and also organizational performance.

Even though there are a lot of papers on this subject, it is quite hard to find information about the processes from different types of service companies and their interaction with business performance. Thus, the goal of this paper is to analyze the relationships between different types of service companies, the business processes and organizational performance.

Literature Review

Organizational performance is a complex concept that is widely debated (Andersen, Boesen, and Pederson 2016; Abdallah & Matsui, 2009; Lee et al., 2019). Over time, different scales of measuring performance were developed that considered a variety of dimensions, sources and types of elements

Evidence from Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(George et al., 2019), but from all the measuring model developed the simplest way used to define performance refers to achieving the organization's goals (Abubakar et al., 2017).

In a recent paper that analyzed how employees' satisfaction can improve business processes within professional service firms (Barbu & Militaru, 2019), the authors used 8 main processes for which they determined the level of importance, the performance according to time, flexibility, quality, cost and transparency. The analyzed processes were: supply process, human resources management process, financial-accounting process, marketing and sales process, service delivery process, customer service process, management process and innovation process. Considering each process as an individual it can be said that:

Supply process - The relationship between the supply process and organizational performance has been researched in the literature for over 3 decades. In this regard, the existence of a positive link between proximity to suppliers and organizational performance has been researched and demonstrated (Powell, 1995; Carr & Pearson, 1999), a close link between supply process and long-term organizational performance was determined (Tan et al., 1998), while Johnson (1999) shows that this link directly contributes to the increase of sales and market share.

Human Resources Management process - Researching the literature and various meta-analyses (Saridakis et al., 2017), it can be seen that between human resource management practices and business performance there is a positive association, that is highlighted through studies transverse or longitudinal.

Financial-accounting process - By analyzing various published papers in the financial field (Kerzner, 2011; Okes, 2013; Militaru, 2015; Horváthová, 2010; Huang, 2010; Chang et al., 2016) it can be seen the deep interest given for financial processes in relationship with organizational performance. The implications of the financial – accounting department on the company are widely studied since their influence determines the course of action for later activities.

Marketing and sales process - Through the study of O'Leary-Kelly and Flores (2002), general support was found for the model proposed by them, which showed that the impact of integrating the manufacturing and marketing/sales decision on organizational performance is moderated by a company's business strategy and the uncertainty of demand. Also, many studies analyze how social media influences marketing and sales strategies, having direct impacts on the financial performance of the organization (Niedermeier et al., 2016; Wang et al., 2016; Rodriguez et al., 2016).

Service delivery process - Regarding the process of providing services, most of the papers in this field refer to the quality of the service provided (Ali & Raza, 2015; Del Alonso-Almeida et al., 2013; Jaca & Psomas, 2015; Thorpe, 2014) and highlight the fact that quality practices significantly affect competitiveness, but also the financial performance of service companies.

Customer service process - Scientific literature presents that the customer service process is also associated with customer relationship management, which is analyzed mainly in terms of interaction with Social Media networks (Wang & Kim, 2017; Rodriguez et al., 2014; Wang et al., 2016). These operations are used to improve the performance of companies, the use of Social Media platforms playing a moderating role by increasing the positive impact of CRM social capabilities on the company's performance (Wang & Kim, 2017).

Management process - In the case of the management process, various studies analyze the strategic involvement of managers in companies, their results indicating that the involvement of managers in the formation of strategy is associated with improved organizational performance (Wooldridge & Floyd, 1990).

Innovation process - The study of innovation in service sectors is a process that has not been explored as much as other processes. For example, Prajogo (2006) analyzed the relationship between innovation and business performance, conducting a comparative study between production and

service companies. The results expressed that there is no significant difference between production and service firms in terms of product or process innovation performance, but indicated a stronger correlation between manufacturing firms and service firms between innovation and business performance, especially in terms of process innovation. Also, through this study, it was found that process innovation shows a relatively stronger relationship with enterprise performance than product innovation in production sectors.

Thus, having this overview of the existing connections between the selected processes and the organizational performance, the authors wanted to test how the type of service companies determine the influence of those processes in the relationship with the organizational performance. The literature review was conducted from a wide range of publications because various processes were involved in the analysis. The publications were chosen based on the close connection to each type of process and based on the similar manner in which the research was done by the authors.

Methodology

The goal of this paper is to analyze the relationship between the type of services, type of processes and organizational performance. For this study, it was developed a questionnaire that was sent to different employees from the professional service companies from Romania, measuring their perceptions about the impact of different processes on the company performance. The analyzed processes are P1-supply process, P2- human resources management, P3- financial-accounting process, P4-marketing and sales process, P5- service delivery process, P6-customer service process, P7- management process, P8- innovation process. The targeted types of services were in the following domains: IT, commerce, financial and banking, construction, transport, support services, consulting, telecommunication, tourism and hospitality industry, medical and pharmaceutical services, hygiene and beauty services, security, energy production, education, entertainment (the most important types of services according to the State Office for Inventions and Trademarks -OSIM, 2020). For this study, the authors received 150 responses from employees of service companies from Bucharest, Romania, this study being a pilot one. Half of the analyzed companies have more than 10 years on the Romanian market, while a quarter of the companies analyzed are on the market for less than 3 years. The authors received answers both from those in executive positions (81%) and from those in management positions (19%). Most of the answers came from those working in the IT field (25), Commerce (21), Financial and Banking (19), Construction (14), Transport (14) and Consulting (11). The respondents' perceptions were measured on a 5-point Likert-type scale ranging from 1 (very unimportant) to 5 (very important).

Results

Figure 1 shows the impact of the processes depending on the nature of the services provided by the sample companies.

Fig 1. The impact of processes depending on the nature of the services
Source: Authors' own research

In the case of IT companies, the most important is the process of providing services, with an overall score of 4.72, followed by the process of providing support services, the financial accounting process and the innovation process. The order of these processes indicates that this type of service is one that can be included in the category of professional services, where the value of the service increases as the attention of managers and employees goes to the areas mentioned. The lowest score (3.92) is obtained in the case of the supply process, which indicates that in this type of companies, this process is not a very important one, as it does not require a constant supply of materials or raw materials, the most important resources being human resources, mainly the people knowledge and capabilities, the technical equipment and computer programs owned by the companies.

For companies in the commerce area, the highest score is recorded in the case of the service delivery process (4.81), followed by the supply process (4.76). These two processes are the most important, being the ones that bring value to the company, without which the clients could not benefit from the services of the analyzed company. Support services are also important, the score being 4.57. It is noted that all processes have a score above 4, the management process having a very important role

for this type of company, with a score of 4.67, which even indicates a favorable position in front of processes such as human resources management, innovation or the financial-accounting process.

In the case of financial-banking services, the highest score is found in the financial-banking process, which suggests that this is the most important type of process for companies in this field. The lowest score is 3.74 for the marketing and sales process, which means that from the perspective of employees in this field, the process does not play a very important role when it comes to the company's performance, focusing on the financial aspect to maximize revenue. Innovation is also less important, with a score just below 4, while high weights can be found in the case of service delivery processes (4.58), human relations management process (4.26), or supply process (4.53). Because we are talking about companies in the financial field, the score obtained for the supply is a suspiciously high one, this result being based on the answers of the employees in that field, who may have considered the supply process differently from the way it is expressed in the paper, maybe as supplying the banking units with money or papers, tonners and other stationery used daily when concluding financial contracts, which does not represent the analyzed purpose.

The scores obtained for the companies in the area of construction, repairs and installations are located in the range 4.00-4.64, the lowest score being associated with the human resources management process, and the highest with the service delivery process. We also find low scores for the processes of innovation, supply and management, which should represent an issue for the company's management that must pay more attention to employees and the quality of products used in providing services.

In the case of transport companies, the highest score is 4.5 for the service delivery process, which is considered by respondents to be the most important process for this category of services. On the other hand, the lowest score is 3.79 for the innovation process, suggesting that from an employee’s point of view, innovation does not play an important role in this type of service. A fairly high score (4.36) can be observed for the supply process, which indicates that the transport of materials influences how transport can be made, the logistics part being essential in this case. The marketing and sales process has a score of 4, indicating a level of importance below that of human resources management, financial-accounting or support services.

In the case of consulting companies, it is noted that the processes of human resources management, financial-accounting, service provision, but also the provision of support services have the same level of importance (4.45), which is a very high score, indicating the complexity of this type of service. The lowest scores are found in this case for the supply process (3.91) and innovation (3.82).

For companies that provide support services to other companies on the market, the most important processes are marketing and sales and of course the process of providing the support services, which in this case coincides with the actual provision of the service (4.78). However, these scores are exceeded by the innovation score (4.89), which suggests that in the case of this type of service, innovation, research and development play a special role leading to finding the most appropriate solutions for companies that use the services of these companies. The procurement process has the lowest score (3.91), indicating that in this area it is not necessary to purchase various products or materials for the actual provision of the service.

In the case of telecommunications companies, it was found the maximum score of 5 for the marketing and sales process, which shows the special importance of this process for companies in this sector. Also, there are important processes of innovation, financial-accounting, effective delivery of services, but also support services (4.71), all of which directly contribute to the organizational performance in this sector. The lowest scores are 4.43 which are high scores, which indicates that the field of telecommunications is very complex, where each of the analyzed processes is very important, contributing to the smooth running of activities within the analyzed companies.

In the case of companies in the tourism sector and the hospitality industry, the most important process is the supply (4.71), which together with the process of providing services, but also providing support

services adds value to companies. The lowest score is associated with the innovation process (3.57), indicating that in this sector, more attention needs to be paid to other issues, such as management (4.43) or marketing and sales (4.14) than to waste resources in the area of innovation.

Healthcare companies also indicate a low level of importance for innovation (3.60), relying on processes such as financial-banking (5) or the supply of necessary medical supplies (4.8). It is interesting that, unfortunately, the respondents consider the marketing and sales process more important than the actual provision of medical services or the provision of support services, the difference between the scores being 40 percent.

For companies operating in the field of education, training and entertainment, the delivery of the service has the greatest role (5), this being in fact what brings value to the organization. The management process (4.75), but also the human resources management process (4.5) also plays important roles, the human resource being the most valuable resource of the companies in this sector. The supply process has a surprisingly high score (4.25), this having as a possible explanation the fact that employees still focus on the classic elements of stationery in the educational process or training and entertainment, not using the advantages of technology, which is argued and the low innovation grade (3), which indicates the respondents' perception of the importance of discoveries and their application in the analyzed environment.

In the case of pharmaceutical services, there are low scores for the analyzed processes, the human resources management process and the marketing and sales process having scores such as 2.67. Although respondents believe that the marketing and sales process does not play an important role in their companies, there is massive advertising on the market of drugs and pharmaceutical chains, which are intended to be noticed by as many people as possible, pharmacies resorting to customers' loyalty strategies. Thus, the results obtained are somewhat in contradiction with what is observed on the market, this could be due to the quality of data collected from respondents, who are in principle in positions of execution, and at this level, have a different perception of the importance of various processes. The highest grades are 4, found for the supply process, and management. These operations of planning, organization, management and control, together with the timely supply of medicines are in the view of the respondents the most important aspects desired in the case of pharmaceutical companies.

Companies in the hygiene and beauty sector stand out with very high scores, over 4.67, where the maximum score is reached in terms of marketing and sales processing, financing-accounting, provision of services and provision of support services, and also the process of innovation. Services play a very important role since the service delivery work itself and personal care of things must use the best service offerings to cope with the schedule. Those in leadership positions known about the importance of communication with customers especially in this sector of services, but also the fact that for the customers the waiting time to benefit from the desired service is very important and can influence their whole experience. Thus, the score for innovation is maximum, since it is necessary to create new solid solutions or prominent brands in this market, coming up with all kinds of original ideas to attract the attention of customers. The procurement process is also an important role (4.67), within this category of services because of both specific utensils and materials needed for hygiene and beauty processes. The management process and human resource management process have the same importance, the way the management manages the work team being very important.

In the case of companies that provide protection of goods and services, planning, organization, management, control of actions, as well as human resource management have the most important roles, along with the effective provision of the service (score 5), followed by providing support services (4.67). The least important are the supply process (2.33) and the innovation process (3), these not being specific to the analyzed companies in this field. For companies specific to the area of transport and use of energy, the highest scores are in the case of the supply process (5), marketing and sales, management and service delivery (4.5), while the lowest scores are recorded for the management process of human resources (2.5), support services (3) or innovation (3). Unfortunately,

the quality of these results is influenced by the small number of respondents in this area (3 respondents), the data provided representing the perception of employees in this field.

In Figure 2, it can be seen that the highest performance is recorded by companies in the area of hygiene and beauty services (4.46), followed by those in the area of IT, support and telecommunications services (with a score of approximately 4.4). The lowest performances are registered in the case of pharmaceutical services (3.38), education, training and entertainment (3.53), consultancy (3.7) and medical services (3.73).

Fig 2. The performance of organizations depending on the nature of the services
Source: Authors' own research

Conclusion

Analyzing the industries where the grades related to the influence of processes on organizational performance exceed the value of 4.5, it is found that the most important processes are the Service delivery process (with 11 grades above 4.5), Financial-Accounting process (9 grades above 4.5), Customer service process (8 marks above 4.5), and Marketing and Sales process (7 marks above 4.5). On the other hand, the processes that respondents consider to have a lesser impact on organizational performance are Human Resources Management (4.12 average score) and Innovation process (3.88). These results presented should be seen by people in management positions as a chance to oversee and give more attention to these situations and take measures in terms of developing an organizational culture based on communication and collaboration between employees, but also innovation. These two processes contribute to bringing added value to any organization.

This study is not without limitation, for which the results must be used with care. For this study, were received only 150 responses from employees of service companies from Bucharest, Romania. The respondents work in 15 distinct categories of services, for several of them registering only a few responses, which is why some of this data may not be so representative for the whole industry, this fact imposing on the study some limitations. The article provides an exploratory study, where we collected answers from both management and executive positions holders. Their responses based on their perceptions could be influenced by their experience and positions, which is why the authors plan on conducting a more extensive study on 2 different groups of people, then analyzing the different perceptions between those in management positions and those in executive positions.

Acknowledgment

This work has been funded with the support of the University POLITEHNICA of Bucharest through the project "Engineer in Europe" in an online system, through the Financial Agreement registered at the Ministry of Education and Research with 457/GP/06.08.2020, which is a found for financing special situations that cannot be integrated into the financing form for higher education state universities.

Abstract

Coronavirus pandemic has affected the normal work routine of individuals across the globe. Majority of governments have responded to this pandemic by imposing curfews and lockdown to flatten the curve of virus spread. This situation has helped to minimize the virus spread but movement restrictions coupled with fear of getting infected may increase mental stress and depression. Therefore, in this paper, we report the results from an empirical study carried out in Pakistan and Saudi Arabia. The findings suggest that in this lockdown has negatively impacted individuals' health. The results also suggest that demographic factors contribute to the psychological impact of lockdown resulting in negatively affecting work and personal life of individuals. The findings will help the governments to establish support systems to improve mental health in Pakistan and Saudi Arabia in case of similar future conditions. In future, we intend to develop user centric prototypes for psychological support of public in pandemic situations.

Keywords: COVID-19, Mental health, Empirical study, Pakistan, Saudi Arabia

Introduction

Coronavirus (COVID-19) started in China in late 2019, and quickly spread across the world. World Health Organization upgraded the COVID-19 to pandemic on 11th March 2019. As of today, there are 19187943, confirmed infected cases, 716075 deaths in 217 countries ("World Health Organization (WHO)", 2020). Due to unavailability of any vaccination and approved medicine against COVID-19, social distancing is considered as optimal approach to reduce the spread of this virus. To enforce social distancing different countries have taken different actions which include curfews, quarantine, closure of business activities and movement restrictions. To control violations of these public safety rules, different countries introduced special legal provisions pertaining to fines and imprisonment.

Social distancing and quarantine results in loneliness and boredom, frustration and depression which negatively affects the mental health of individuals (Venkatesh and Edirappuli, 2020). These implications are equally relevant for public irrespective of their job role. Anxiety and depression are two key factors which negatively affect the mental health. We were particularly interested to understand how COVID-19 pandemic and corresponding government actions have impacted on mental wellbeing of people. To acquire the answers of our questions we particularly focused on responses from two countries Pakistan and Saudi Arabia. The reason for selecting these two countries was based on their strict and lenient adherence to COVID-19 lockdown violations. In Saudi Arabia there were strict legal penalties and in case of Pakistan such strictness was not implemented.

Saudi Arabia started the lockdown from Qatif region on 8th March 2020 and it was extended to a nationwide curfew for 21 days lasting from 7 PM-to 6 AM from March 23rd, 2020. The nationwide

Cite this Article as: Hina GULL, Saqib SAEED, Sardar Zafar IQBAL, Madeeha SAQIB, Albandary Mohammed ALAMER, Wiem Abdalmonem Bin KHALEFA "COVID-19 lockdown and Mental Well Being: A Study of Pakistan and Saudi Arabia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

curfew timing was extended from 3PM to 6 AM on April 8 till further notice. Due to the beginning of holy month of Ramadhan the curfew timings were revised to 5 PM to 9AM from April 26th, 2020. The curfew was extended to 24 hours from 22nd May to 27th May 2020. Recently, from 28th May 2020, governments have announced gradual removal of curfew. To ensure, public adherence to these laws strict laws were introduced e.g. a fine of SR 10,000 for first curfew violation which is doubled for each subsequent violation ("Arab news", 2020). In case of Pakistan, the first Corona case was reported on 26th February and lockdown was imposed by different provincial governments starting from 24th March 2020 and it lasted till 9th May. The government lifted the lockdown mainly to facilitate daily wage workers who were badly affected due to closure of economic activities. In case of Pakistan there were no heavy penalties on violations of lockdown, although violations of these lockdown were arrested but the government responded softly by releasing all violators ("Pandemic in Pakistan", 2020).

In the next section related work is discussed followed by problem statement, hypothesis and methodology in sections 3 and 4. Section 5 confers the findings followed by discussion and conclusion in section 6 and 7 respectively.

Related Work

Although, there is a significant body of knowledge on impact of diseases on human health but the recent COVID-19 pandemic significantly attracting the attention of researchers. There have been numerous studies about coronavirus disease and its impact on society since its first case was diagnosed in late 2019. Galea et al (2020) (Galea et al., 2020) have studied the consequences of COVID-19 and physical distancing on mental health. According to them COVID-19 has subsequently increased anxiety and depression in United Kingdom, that they have to issue psychological guide for their general population. They also discussed several methods for early intervention and prevention of disease. Ornell et al (2020) (Ornell et al., 2020) have discussed the fear of COVID-19 which results in burden on mental health of people. According to them the number of people effected psychologically by the pandemic were greater than people infected with virus. Therefore, they propose number of strategies to deal with psychological effect of this pandemic. Similarly, Wang et al (2020) (Wang et al., 2020) have studied the psychological effect on people in China in the early stage of COVID-19 spread. They have analyzed several factors related to mental health such as stress, anxiety and depression among the general population of China. Online survey was conducted to gather data, which results in half of the population having moderate to severe anxiety, while a substantial number of people were suffering from severe depression. They also identified number of factors that have significant relationship with depression and anxiety. Mazza et al (2020) (Mazza et al., 2020) have conducted an online survey to analyze mental health effect of COVID-19 on people in Italy. According to them quarantine has caused huge psychological stress in general population of Italy. As per study, anxiety, depression and stress seemed to be elevated in people who have their family members effected with virus or the people who are working away from their family. They also identified several risk factors related to mental wellbeing of people in this pandemic. Similarly, Colizzi et al (2020) (Colizzi et al., 2020) have studied some medically unexplained symptoms during COVID-19 pandemic and lockdown. According to them, in addition to infection, there are several psychological risks associated with COVID-19, especially in people who are already suffering from serious mental issues. They report a detailed case of a person who was tested negative with virus but there was immediate need for his admission to psychiatric unit of hospital. Later, he was diagnosed with SSD (Somatic symptom disorder). Jung et al (2020) (Jung, 2020) have conducted an online survey in Germany to analyze the mental health of Germans in pandemic of COVID-19. They specifically analyze mental state of people in Germany in response to the lockdown. Results showed significant higher values associated with depression and anxiety in Germans. In this study the mean score was beyond 50 which indicates higher possibility of depression in people in lockdown. According to study German women showed more depression and anxiety than men. Other symptoms of mental health problems such as sleep disorders and poor appetite were also identified in the study. Ammar et al (2020) (AMMAR et al., 2020) have conducted multi country survey to analyze the effect of home quarantine on mental wellbeing of people. Result of this study has shown negative impact on mental and emotional state of people in quarantine with higher proportion of respondents having several emotional and mental disorders. They identified several rationales associated with this emotional and psychological impact such as unhealthy lifestyle, no physical and social activity and joblessness. Respondents also showed elevated use of technology

to kill boredom and monotony. Authors suggested to implement technology-based solutions to help relief in psychological stress during quarantine period. Naser et al (2020) (Naser et al., 2020) have conducted a cross sectional study in Jordon to investigate the impact of COVID-19 and quarantine on mental condition of university students, healthcare workers and general population of Jordon. Survey results highlight that higher proportion of people of Jordan suffering from anxiety and depression. As per evaluation, females are more vulnerable and especially divorced females having history of chronic disease were more likely to have anxiety and were at higher risk of getting depression. Kang et al (2020) (Kang et al., 2020) explored the mental state of nursing and paramedic staff in Wuhan (epicenter of pandemic). Study revealed that 34.4% of respondents suffering from mild disturbances, 22.4% suffering from moderate disturbances and 6.2% had severe disturbance. Majority of people having severe mental distress were females and most of them approached psychological literature and other resources to cope with stress. Many of them also tried several self-help methods to keep themselves out of anxiety and stress. A substantial number of people also visited psychiatrists to cure their condition of severe depression. Ahmed et al (Ahmed et al., 2020) also studied the mental health of Chinese people in early days of pandemic outbreak and imposed lockdown in China. Due to severe lockdown, only self-reported cases were used to examine the state of people in China. Results showed preeminent percentage of anxiety, depression, hazardous and harmful alcohol use, and lesser mental wellbeing in Chinese people. They also suggested that there is need to implement several health care approaches such as counseling sessions and other mental health related services.

Despite these studies, there is no specific study explaining the mental situation of people from the developing countries. The citizens of developing countries are normally confronted with weak psychological support and health systems. Furthermore, the economic worries pose additional tension for these individuals. So, it will be interesting to understand the mental health situation in such settings.

Problem Statement and Hypothesis

Our main research question was how COVID-19 lockdown has affected the mental wellbeing of people in Pakistan and Saudi Arabia. Our secondary question was whether demographic attributes like gender, marital status and education have any role in increase or decrease of depression and anxiety. Furthermore, we also intended to explore whether environment variables such as presence of infection in an acquaintance, or strict legal control by government of lockdown has any significant role in variation of depression and anxiety. Lastly, we were interested to understand that whether lockdown related anxiety and depression affects work and personal life. To get answers of these questions we have developed following five hypotheses to evaluate the results of our study.

H1: COVID-19 lockdown has significant impact on mental health of public.

H2: Personally, knowing a corona patient (like relative, family member) increases the anxiety and depression?

H3: The strict/lenient adherence of lockdown is insignificant to mental wellbeing.

H4: Gender, Marital status and education have significant psychological impact on people?

H5: COVID-19 lockdown resulted anxiety and depression negatively affected work and personal life.

Methodology

For our study, we intended to conduct a cross sectional quantitative study and we rolled out our questionnaire during 20th May 2020 -27th May 2020. The survey questions were based on previously validated and widely used questions by health practitioners to measure anxiety and depression. Generalized Anxiety Disorder (GAD-7) is a set of seven questions used to determine anxiety and patient health questionnaire (PHQ-9) is a set of nine questions used to measure severity of depression (Löwe et al., 2008)(Levis et al., 2019). We included these questions in our questionnaire and questionnaire was created on Google forms. The survey link was distributed through social media apps (Facebook, Twitter and WhatsApp) and all the participants were volunteer. As snowball sampling method was used (Naderifar et al., 2017), so first referral was started with 15 individual who took part in the study and then were asked to distribute the survey in their contacts. A total of 490 responses were

collected during data collection phase. 394 responses passed our qualification criteria which included completeness and geographical location of either Pakistan of Saudi Arabia. There were 189 responses from Pakistan and 207 responses from Saudi Arabia. Majority of our respondents were female (52.8%), between age group 18-29 (67.7%) and single (68.9%). In terms of academic qualification 36.6 % respondents were Pre-Bachelors, 33.9% having a bachelor's degree whereas 29.2% were either having master's or higher degree.

In order to analyze the data, we used partial least square analysis (Lowry and Gaskin, 2014) using SmartPLS (Ringle et al., 2015) and developed models to understand the pass or failure of our hypothesis. As already mentioned, we used the PHQ-9 and GAD-7 questions, so we established models to understand the casual relationships among different factors. It is worth mentioning that based on PHQ-9 and GAD-7 there were 9 factors which were contributing in the depression while 7 factors were contributing in anxiety, However, during factor analysis it was found that two factors (Feeling bad about yourself or that you are a failure or have let yourself or your family down and Thoughts that you would be better off dead, or of hurting yourself) were not significantly contributing in the results having values less than 0.7. So, these two factors were removed from the model and PLS was applied again to get the significant model. In anxiety all factors were significantly contributing. The mapping of questions in questionnaires and corresponding attribute used in model for factors contributing to depression and anxiety is shown in figure 1.

Findings

Figure 2 shows the structural model for H1. Mental health is based on depression and anxiety and after partial square application R2 value for the latent variable mental health is found to be 0.991 which is substantial value according to Hair et al (2014) (Hair et al., 2014). Therefore, these findings highlight that there is a direct correlation of mental health and anxiety due to COVID-19 lockdown. Furthermore, based on PHQ-9 and GAD-7 grading sales we categorized the levels of depression among respondents. Depression is categorized into Minimal Depression (rating 1-4), Mild Depression (rating 5-9), Moderate Depression (rating 10-14), Moderately Severe Depression (rating 15-19) and Severe Depression (rating 20-27) (Levis et al., 2019). As Figure 2, suggests 20.41% respondents reported minimal depression, 26.53% mild depression, 22.45% moderate depression, 10.61% moderately severe depression and 1.02% severe depression given in figure 3. Similarly, anxiety is also categorized into four categories which are None/Minimal (rating 0-4), Mild (rating 5-9), Moderate (rating 10-14) and Severe (rating 15-21) (Löwe et al., 2008). In our survey,30.61% respondents reported minimal anxiety, 31.63% mild, 22.65% moderate and 15.1%sever anxiety, as shown in figure 4.

Factors Related to Depression		**Factors related to Anxiety**	
Questionnaire Question	**Name used in models**	**Questionnaire Question**	**Name used in models**
Little interest or pleasure in doing things?	Interest	Feeling nervous, anxious or on edge	Nervous Anxious
Feeling down, depressed, or hopeless?	Depressed	Not being able to stop or control worrying	Control Worry
Trouble falling or staying asleep, or sleeping too much?	Sleep Problems	Worrying too much about different things	Worrying over things
Feeling tired or having little energy?	Tired	Trouble relaxing	Trouble relaxing
Poor appetite or overeating?	Poor appetite	Being so restless that it is hard to sit still	Restless
Feeling bad about yourself — or that you are a failure or have let yourself or your family down?	Failure	Feeling afraid as if something awful might happen	Afraid Awful
Trouble concentrating on things, such as reading the newspaper or watching television?	Newspaper/ TV	Becoming easily annoyed or irritable	Annoyed
Moving or speaking so slowly that other people could have noticed? Or so fidgety or restless that you have been moving a lot more than usual?	----------		
Thoughts that you would be better off dead, or thoughts of hurting yourself in some way?	----------		

Fig. 1: Mapping of Factors Related to Depression and Anxiety (Questionnaire-Model)

Furthermore, bootstrapping was conducted for the level of path coefficients analysis with about 5000 subsamples. Results shows that there is a significant impact of COVID-19 lockdown on mental health of public ($p<0.01$ where β (anxiety)=0.577 and β(depression)=0.499). Predictive relevance is used to examine the model's capability to predict each latent variable or factor. Predictive relevance (Q^2) was calculated by applying blindfolding. Blindfolding with omission distance D=7 results gives $Q^2 = 0.849$ which is greater than 0.5, showing that the model has predictive relevance. Q^2 is also obtained by using cross validated communality (obtained by predicting the questionable blocks using latent variable) (Akter et al., 2011). All construct cross validated communality value is greater than zero which is set threshold. Therefore, results given in the table 1 shows the values of cross validated redundancy and cross validated communality indicating that the model has acceptable predictive relevance.

Fig. 2: Structural Model for H1

Fig. 3: Percentage of depression levels among respondents

Fig. 4: Percentage of Anxiety Levels among respondents

Table 1: Predictive Relevance -H1

Factors	Construct Cross validated Redundancy			Construct Cross validated Communality		
	SSO	SSE	Q^2(=1-SSE/SSO)	SSO	SSE	Q^2(=1-SSE/SSO)
Anxiety	3409.000	349.000		3409.000	1471.730	0.568
Depression	3409.000	349.000		3409.000	1828.616	0.464
Mental Health	974.000	146.886	0.849	974.000	489.513	0.497

We were also interested to explore whether any known COVID-19 infection in friends and family has any impact on the anxiety and depression. Figure 5 and 6 shows the structural model for H2 (known case in acquaintance Yes and No). After partial square application R2 value for the latent variable mental health (in case of Yes) is found to be 0.989, whereas in case of No 0.991 both of which are substantial values. Initially there were 9 factors which were contributing in the depression while 7 factors were contributing in anxiety. After factor analysis it was found that two factors (Feeling bad about yourself or that you are a failure or have let yourself or your family down and Thoughts that you would be better off dead, or of hurting yourself) were not significantly contributing in the results having values less than 0.7. So, these two factors were removed from the model and PLS was applied again to get the significant model. In anxiety all factors were significantly contributing. Bootstrapping was conducted for the level of path coefficients analysis with about 5000 subsamples. Results shows that there is a significant impact of COVID-19 n mental health of general public whether you know any patient personally ($p<0.01$ where β (anxiety)=0.562 and β(depression)=0.504), or you don't know any ($p<0.01$ where β (anxiety)=0.582 and β(depression)=0.50). Results clearly indicates that there is significant relationship between COVID-19 lockdown and mental wellbeing of people irrespective of personal relationship with corona patient. Bootstrapping also indicates strong value of anxiety than depression. Predictive relevance (Q^2) was calculated by applying blindfolding. Blindfolding with omission distance D=7 results gives $Q^2 = 0.856$ for knowing patient and 0.844 for not knowing patient, both of which are greater than 0.5. Also, cross validated communality values are greater than threshold zero, showing that the model has predictive relevance. Table 2 shows cross validated redundancy and cross validated communality values (Yes case). Table 3-shows cross validated redundancy and cross validated communality values (No case).

Table 2: Predictive Relevance-H2-Yes

Factors	Construct Cross validated Redundancy			Construct Cross validated Communality		
	SSO	SSE	Q^2(=1-SSE/SSO)	SSO	SSE	Q^2(=1-SSE/SSO)
Anxiety	931.000	931.000		931.000	331.230	0.644
Depression	931.000	931.000		31.000	473.895	0.491
Mental Health	266.000	38.188	0.856	266.000	130.182	0.511

Fig. 5: Structural Model-H2-Yes

For hypothesis 3, we have taken data from Saudi Arabia (strict adherence of lockdown) and Pakistan (lenient adherence of lockdown). Figure 7 and 8 shows structural model for Saudi Arabia and Pakistan respectively. Similar trend can be seen, after partial square application R2 value for the latent variable mental health (KSA and Pakistan) is found to be 0.996 and 0.984 which are both substantial values. In both cases, initially there were 9 factors which were contributing in the depression while 7 factors were contributing in anxiety. After factor analysis it was found that two factors (Feeling bad about yourself or that you are a failure or have let yourself or your family down and Thoughts that you would be better off dead, or of hurting yourself) were not significantly contributing in the results having values less than 0.7. So, these two factors were removed from the model and PLS was applied again to get the significant model. In anxiety all factors were significantly contributing. Bootstrapping was conducted for the level of path coefficients analysis with about 5000 subsamples. Results shows that there is a significant impact of COVID-19 lockdown on mental health of general public in Saudi Arabia ($p<0.01$ where β (anxiety)=0.543 and β(depression)=0.53), while for Pakistan similar trend can be seen ($p<0.01$ where β (anxiety)=0.604 and β(depression)=0.453). Results clearly indicates that there is significant relationship between COVID-19 lockdown and mental wellbeing of people irrespective of adherence for lockdown in both countries. Bootstrapping also indicates that in both Saudi Arabia and Pakistan, People are more anxious than depressed having values (%age) (SA= anxiety= 64.83, depression= 56.06, Pakistan= anxiety= 43.31, depression= 31.31). Predictive relevance (Q^2) was calculated by applying blindfolding. Blindfolding with omission distance D=7 results gives Q^2 = 0.869 for Pakistan

and 0.851 for Saudi Arabia which are greater than 0.5. Table 4 shows the cross validated redundancy for KSA and Pakistan respectively.

Table 3: Predictive Relevance-H2-No

Factors	Construct Cross validated Redundancy			Construct Cross validated Communality		
	SSO	SSE	Q^2(=1-SSE/SSO)	SSO	SSE	Q^2(=1-SSE/SSO)
Anxiety	2478.000	2478.000		2478.000	1160.931	0.532
Depression	2478.000	2478.000		2478.000	1364.025	0.450
Mental Health	708.000	110.658	0.844	708.000	364.230	0.486

Fig. 6: Structural Model-H2-No

Table 4: Predictive Relevance (Cross Validated Redundancy)-H3

Factors	Construct Cross validated Redundancy KSA			Construct Cross validated Redundancy Pakistan		
	SSO	SSE	Q^2(=1-SSE/SSO)	SSO	SSE	Q^2(=1-SSE/SSO)
Anxiety	1435.000	1435.000		1323.000	1323.000	
Depression	1640.000	1640.000		1134.000	1134.000	
Mental Health	410.000	60.703	0.852	378.000	49.329	0.869

Table 5 shows the cross validated communality for KSA and Pakistan respectively. Therefore, results given in both tables shows the values of cross validated redundancy (>0.5) and cross validated communality (>0) indicating that the model has acceptable predictive relevance. Figure 9 shows structural model for Hypothesis 4. Similar trend can be seen, after partial square application R2 value for the latent variable mental health is found to be 0.986 which is substantial value. Initially there were 9 factors which were contributing in the depression while 7 factors were contributing in anxiety. After factor analysis it was found that two factors (Feeling bad about yourself or that you are a failure or have let yourself or your family down and Thoughts that you would be better off dead, or of hurting yourself) were not significantly contributing in the results having values less than 0.7. So, these two factors were removed from the model and PLS was applied again to get the significant model. In anxiety all factors were significantly contributing. Bootstrapping was conducted for the level of path coefficients analysis with about 5000 subsamples. Results shows that Gender, Marital status and education have significant psychological impact on mental health of general public ($p<0.01$). Bootstrapping also indicate strong values for depression =5.106 (Figure 10). Predictive relevance (Q^2) was calculated by applying blindfolding. Blindfolding with omission distance D=7 results gives Q^2 = 0.846 which are greater than 0.5. Similarly, cross validated redundancy has values greater than threshold 0, therefore indicating that that the model has predictive relevance (Table 6).

Fig. 7: Structural Model-H3-Saudi Arabia

Table 5: Predictive Relevance (Cross Validated Communality)-H3

Factors	Construct Cross validated Communality KSA			Construct Cross validated Communality Pakistan		
	SSO	SSE	Q^2(=1-SSE/SSO)	SSO	SSE	Q^2(=1-SSE/SSO)

Table 6: Predictive Relevance-H4

Factors	**Construct Cross validated Redundancy**			**Construct Cross validated Communality**		
	SSO	**SSE**	**Q^2(=1-SSE/SSO)**	**SSO**	**SSE**	**Q^2(=1-SSE/SSO)**
Anxiety	3409.000	3362.168	0.014	3409.000	1471.868	0.568
Depression	2922.000	2804.294	0.040	2922.000	1541.303	0.473
Factors	1461.000	1461.000		1461.000	1360.871	0.069
Mental Health	974.000	150.231	0.846	974.000	489.517	0.497

Fig. 10: H4- Bootstrap

Figure 10 shows structural model for Hypothesis 5. Similar trend can be seen, after partial square application R2 value for the latent variable Impact on Personal and professional life is found to be 0.408 which is substantial value. We have taken two factors anxiety and depression to see the impact on personal and professional life which has three factors (Do work, get along with people and do things at home). Bootstrapping was conducted for the level of path coefficients analysis with about 5000 subsamples. Results shows that COVID-19 lockdown resulted anxiety and depression negatively affected work and personal life. ($p<0.01$). Bootstrapping also indicate that work is most negatively affected having value 63.13 as compared to do things at home (34.18) and get along with people (27.97) being least. Predictive relevance (Q^2) was calculated by applying blindfolding. Blindfolding with omission distance D=7 results gives Q2 = 0.846 (Mental Health) which are greater than 0.5, showing that the model has predictive relevance, while Q^2= 0.26(Personal and Professional Impact) which indicated relatively weak relevance. While Q^2 value in case of cross validated communality is greater than 0 in each case. Table 7 shows cross validated redundancy and cross validated communality values for H5.

Fig. 11: Structural Model-H5

Factors	**Construct Cross validated Redundancy**			**Construct Cross validated Communality**		
	SSO	**SSE**	**Q^2(=1-SSE/SSO)**	**SSO**	**SSE**	**Q^2(=1-SSE/SSO)**
Anxiety	3409.000	3409.000		3409.000	1472.686	0.568
Depression	3409.000	3409.000		3409.000	1827.469	0.464
Personal and Professional Impact	1461.000	1079.050	0.261	974.000	489.539	0.497
Mental Health	974.000	146.641	0.849	1461.000	988.244	0.324

Discussion

Based on the analysis result three of our hypotheses have been supported by data whereas H3 and H4 are not support by data given in table 8.

Table 8: Hypothesis Results

Hypothesis	Result
H1: COVID-19 lockdown has significant impact on mental health of public.	Supported
H2: Personally, knowing a corona patient (like relative, family member) increases the anxiety and depression?	Not Supported
H3: The strict/lenient adherence of lockdown is insignificant to mental wellbeing.	Not Supported
H4: Gender, Marital status and education have significant psychological impact on people?	Supported
H5: COVID-19 lockdown resulted anxiety and depression negatively affected work and personal life.	Supported

Mazza et al., (2020) (Mazza et al., 2020) highlighted that stressed is elevated to people who have some infected patient in their family but in our case, we did not observe this finding. The stress in both groups remained same whether they have someone infected in their acquaintance or not. Colizzi et al., (2020) (Colizzi et al., 2020) and Nasser et al., (2020) (Naser et al., 2020) found that women have more depression and anxiety compared to men, this trend was found in our study as well. In their early work in China, Kang et al. (2020) (Kang et al., 2020) highlighted that majority of the health workers experience mild disturbance and our study supports that similar trend is observed across the public, as majority of respondents in our survey were also in that category. More specific analysis of the data indicates interesting insights. As far as depression is concerned among (1.02% of population) having severe depression, females (62.5%) are more prone to severe depression. To our surprise most of them were between age 18-29 and were university students. Opposite pattern can be seen in people having moderately severe depression. Majority of male (58%) are having moderately severe depression. Most of them are between age of 18-29, single and are university students. No evidence of having severe and moderate severe depression was found in people of age more than 50. In case of anxiety, 15.22% of total participants suffer from severe anxiety. Analysis indicates that majority of them having severe anxiety are female (57%). Again, most of them are single, between age of 18-29 and are university students. Another trait that is common between people having severe anxiety and severe depression is that almost all of them are worried about getting infected with virus or transmit it to family members.

Conclusion

COVID-19 and its adverse effects have brought major changes in national and international behavior patterns and closure of daily functioning. Curfew, lockdown, and self-imposed quarantine have been observed all over the world. COVID-19 has drastic effect on both physical and mental wellbeing of population of almost every country. Our study highlights the empirical results from Pakistan and Saudi Arabia, which are in line with other studies conducted in other geographical regions. There is enormous potential in technological systems to support people in such difficult times and situations (Farooqui et al., 2019)(Elhussein et al., 2018). However, there is a need for in depth user studies to formulate user requirements to appropriately design technological solutions(Saeed et al., 2016)(Saeed et al., 2014). Such systems then need to be rolled out in practice to evaluate their effectiveness. In future, we intend to conduct detailed qualitative studies to deeply understand the requirements for psychological support systems supporting end users and develop guidelines for the governments and practitioners to support the public in such crisis situations in the future. Furthermore, based on these requirements we intend to design prototypes for online psychological support of public in pandemic situations.

Abstract

The purpose of this paper is to study the effect of the four types of employee well-being based on the circumplex model: work engagement, job satisfaction, burnout, and workaholism, to turnover intention. This study also explored the role of religiosity in turnover intention. The study involved a survey of 300 millennial employees in Jakarta, Indonesia. The data were analyzed using a moderated regression model using AMOS 23.0 software. The results suggested that burnout and workaholism were positively and significantly affect turnover intention. However, there was no significant effect found on work engagement and job satisfaction on turnover intention and the mediating role of religiosity. This study also showed that employee well-being significantly affects the turnover intention of millennial employees. It implied that organizations should concern about their employee well-being and ensure to lessen their burnout and avoid them to become workaholics to minimize the turnover intention.

Keywords: Employee Well-Being, Turnover Intention, Religiosity

Introduction

Turnover is one of the topics of concern to many researchers and practitioners in the field of human resources management as turnover influences the functioning of an organization. The researchers found that turnover can interfere with various productivity-related results and have an impact on overall company financial performance (Park & Shaw, 2013). Voluntary turnover is often surprising and cannot be managed by organizations (Shaw et al., 1998) so voluntary turnover tends to be negatively related to organizational performance. Various other studies later found that turnover intention was the strongest antecedent of voluntary turnover (Hom et.al., 2017). If turnover data is not known, then the turnover intention is considered as the best predictor to represent it.

A meta-analysis study of predictors of turnover intention in social workers found that stress, burnout, and job satisfaction were predictors with high effect sizes, and well-being was the strongest predictor among other demographic predictors (Kim & Kao, 2014). Employee well-being is an important determinant of organizational growth. Various studies have shown that high levels of employee well-being reduce employee turnover rates and increase employee performance (Ilies, Aw, & Pluut, 2015).

Even though there is quite a lot of research has been done to look at aspects of well-being in workers separately such as job satisfaction and burnout, there is not much research on interdependent constructs well-being. Bakker & Oerlemans (2011) then apply a model of interdependent constructs of well-being from Russell (1980) to the specific context at work. There are four types of employee well-being that can be included in this model, namely work engagement, job satisfaction, burnout, and workaholism.

The effect of interdependent constructs of employee well-being on turnover intention has been investigated before (Wu, Rafiq, & Chin, 2017). The study showed that there are relationships between two interdependent constructs of employee well-being namely work engagement and life satisfaction to turnover intention. The study also found the influence of moderation of religiosity on Muslims as the subject of his research or Muslim religious beliefs. The finding of religiosity showed that religious belief rooted in people's unconscious shared values and norms and affect their daily life, including at work.

This paper selected millennial employees in Jakarta as a study context, as a study showed that millennial employees in Indonesia are identical with high employee turnover (Deloitte Indonesia, 2019). Based on the report, the average industry turnover is currently above 10%. Millennial is a population born between 1980-2000 and by 2020, they will be in the age of 20-40 years. Thus, millennial is at the most productive age to contribute to the world of work and the economy. The high rate of millennial employee turnover could be associated with several millennial characteristics. Studies suggest that millennial are independent, tech-savvy, have a high entrepreneurial spirit, need continuous feedback always wants new responsibilities, has a low tolerance for boredom, requires work-life balance, a comfortable work environment, flexible work and working hours, and does not like working overtime (Martin, 2005; Pinzaru, et.al., 2016; Smith & Nichols, 2015).

The primary theoretical contribution of this study is to propose a model that characterizes the relationships of interdependent constructs of employee well-being based on the circumplex model with turnover intention from a new angle by incorporating religiosity. In addition, as millennials will be the major representation of the workforce in the years to come, it is important for management to understand them and prevent the negative effect of turnover intention.

Literature Review

Employee Turnover and Turnover Intention

Employee turnover refers to employees who leave their organization and are replaced by new employees (Li, Sawhney, & Tortorella, 2019). Employee turnover can be divided into two, voluntary turnover that reflects an employee's decision to leave an organization and involuntary turnover that reflects an employer's decision to terminate employment (Shaw et.al., 1998). Voluntary turnover is the most common form of turnover to be studied (Hom et al., 2017) because voluntary turnover tends to be negatively related to organizational performance. Various studies found that turnover intention was the strongest antecedent of voluntary turnover (Hom et.al., 2017). If turnover data is not known, then the turnover intention is considered as the best predictor to represent it.

Turnover intention can be described as the intention of individual behavior consciously and deliberately to leave the organization that employs it (Bothma & Roodt, 2013). Turnover intention is considered as the last step in the decision-making process before someone actually leaves the workplace. A meta-analysis study of predictors of turnover intention in social workers in the United States found that there were four predictors that had a high effect size, namely stress, burnout, job satisfaction, and organizational commitment (Kim & Kao, 2014). In the same study, well-being was found to be the strongest predictor among other demographic predictors. Previously, there was not much research on interdependent constructs of well-being on turnover intention, although quite a lot of research was done to look at aspects of well-being in the work world separately such as job satisfaction and burnout (Scanlan, Meredith, & Poulsen, 2013).

In the well-being approach, there is a circumplex model of affect that shows that well-being varies on two axes, namely pleasure, and activation or arousal (Russell, 1980). Bakker & Oerlemans (2011) then apply this model to the specific context at work. There are four types of employee well-being that can be included in this model, namely work engagement, job satisfaction, burnout, and workaholism. The four types of employee well-being have characteristics according to their quadrants. Work engagement has a high level of pleasure and activation. Job satisfaction has a high level of pleasure and low activation. Burnout features a low level of pleasure and activation. Meanwhile, workaholism has a low level of pleasure and high activation.

Work Engagement and Turnover Intention

Work engagement is defined as a positive state of mind related to work (Schaufeli & Bakker, 2003). It refers to affective states that are more persistent and settled. In general, high work engagement will be reflected in the positive behavior of employees. This work engagement is characterized by vigor, dedication, and absorption (Schaufeli & Bakker, 2003). Vigor is characterized by a high level of energy and mental endurance at work and willingness to give full effort when working. Dedication refers to deep involvement in work and feeling enthusiastic, inspired, proud, and challenged. Absorption, characterized by being fully concentrated and dissolved in work, where time passes quickly so reluctant to break away from work. Various studies have shown that high work engagement is associated with a decrease in turnover intention (du Plooy & Roodt, 2010; Gupta & Shaheen, 2017).

H1. Work engagement has a negative effect on the turnover intention for millennial employees in Jakarta.

Job Satisfaction and Turnover Intention

Job satisfaction is a positive feeling of employees towards their work (Brayfield & Rothe, 1951). Other definitions mention job satisfaction as the extent to which employees have a positive affective orientation towards the work given by the organization (Price & Mueller, 1986). Over the past twenty years, a lot of research has been done to develop a voluntary turnover prediction model, with job satisfaction being one of the most common antecedents (Tett & Meyer, 2006). Employees who have high job satisfaction, have satisfaction with their work, and do not feel burdened with their work. Several studies found a negative effect of job satisfaction on turnover intention (O'Connor, 2018; Kim & Kao, 2014).

H2. Job satisfaction has a negative effect on the turnover intention for millennial employees in Jakarta

Burnout and Turnover Intention

Burnout is a syndrome of emotional exhaustion and cynicism that often occurs among working individuals (Maslach & Jackson, 1981). Burnout has three main aspects, namely increasing feelings of emotional exhaustion, developing negative and cynical attitudes and feelings towards works, and a tendency to evaluate themselves negatively. Various studies have found that overall burnout as well as its three dimensions namely cynicism, emotional exhaustion, and professional efficacy have an influence on turnover intention (Jung & Kim, 2012). The dimensions of emotional exhaustion and cynicism have a positive effect on turnover intention while the professional efficacy dimension has a negative effect on turnover intention. While in several other studies it was found that only two dimensions of burnout namely cynicism and emotional exhaustion were significant predictors of turnover intention (Lee & Ashforth, 1996; Liu & Lo, 2017)

H3. Burnout has a positive effect on the turnover intention for millennial employees in Jakarta.

Workaholism and Turnover Intention

Workaholism is defined as a strong inner drive to work too hard and become obsessed with work (Schaufeli, Taris, & Rhenen, 2008). There are three general characteristics of workaholics (Scott, Moore, & Miceli, 1997). First, workaholics spend a lot of time on work activities when given the freedom to do so. Second, workaholics are reluctant to break away from work and they constantly think about work when they are not working. Third, they work hard beyond their organizational or economic needs. Some researchers suggest that workaholics are very productive workers, but there are studies that show the opposite (Taris, Schaufeli, & Shimazu, 2010). A study showed that workaholism also has a positive relationship with turnover intention because they do not feel that their work is a pleasant thing (van Beek et.al., 2014).

H4. Workaholism has a positive effect on the turnover intention of millennial employees in Jakarta.

Religiosity and Turnover Intention

Religiosity is considered difficult to measure because there are various definitions and there are no experts who can capture the meaning of the term as a whole (Scutte & Hosch, 1996). Existing definitions of religiosity use a sociological approach, rather than psychological concepts (Huber & Huber, 2012). Huber (2003, in Huber, Huber, & Allemand, 2011) states that religiosity is the construct of the religious system in individuals who are part of the personal construct system. Huber and Huber (2012) propose the division of the dimension of religiosity into five dimensions. The dimensions are the intellectual dimension, the ideological dimension, public practice, private practice, and religious experience.

Religiosity has positive impacts on work-related outcomes such as better job performance (Osman-Gani et al., 2013) and lower turnover intention (Beehner & Blackwell, 2016; Wu, Rafiq, & Chin, 2017). Specifically, Wu, Rafiq & Chin (2017) found that religiosity moderates the negative relationship between two markers of employee well-being namely work engagement and life satisfaction, with employee turnover intention.

H5. Religiosity moderates the negative relationship between work engagement and turnover intention in millennial employees in Jakarta.

Based on the hypotheses above, the research model can be depicted in figure 1.

Figure 1: Research Model

Methods

Participants and Procedures

In this study, data collection was carried out using the primary survey method using a questionnaire. Questionnaires were administered through social media and instant messages. Participants were millennial employees ranging in age from 20 to 40 years in 2020, or who were born between 1980 and 2000, with a minimum one year of permanent employee status on a company in Jakarta, Indonesia. For ensuring that all the participants meet the characteristics, we asked screening questions to the participants and also asked them to report their relevant demographic information. The data were collected over a period of two months. Before testing the relationships among constructs, the authors used the Mahalanobis Distance, Cook's Distance, and Leverage Point methods to detect outlier data in SPSS 25. Hypothesis testing was tested using structural equation modeling with AMOS 23.0.

Measures

To measure the constructs, this study used previously validated items. A five-point Likert-type scale was used for all items, with the exception of demographic items. Work engagement was measured with the nine-item scale based on the shortened version of the Utrecht Work Engagement Scale or the UWES-9 (Schaufeli et al., 2006). Job satisfaction was measured with the 20-item scale based on the Minnesota Satisfaction Questionnaire - Short Form (MSQ-SF) developed by Weiss, et.al (1967). Burnout was measured with Maslach's Burnout Inventory - General Survey (MBI-GS), developed by Schaufeli et al., (1996). This research only used two-dimensions from this scale, emotional exhaustion, and cynicism. Workaholism was measured with a ten-item scale based on Dutch Work Addiction Scale or DUWAS (Taris & Schaufeli, 2003). Religiosity was measured with a 15-item scale Centrality of Religiosity Scale (CRS) developed by Huber (2003, in Huber & Huber, 2012). The turnover intention was measured with the six-item scale based on the shortened version of the Turnover Intention Scale or the TIS-6 (Bothma & Roddt, 2013).

Result

In this study, a total of 354 responses were retrieved by the cut-off date for data collection. Sixteen responses were eliminated due to participants did not meet the characteristics needed. Out of the 338 respondents, 214 participants (63.3 percent) are females. The majority of respondents work in private companies, with a percentage of 75.7 percent or a total of 256 respondents. Based on religion, the majority of respondents stated that they embraced Islam with 78.99 percent of respondents. From these 338 respondents, there were 38 responses that counted as outliers and therefore were taken off from data analysis.

Table 1: AVE and CR for each variable

Variables	AVE	CR
Job Satisfaction	0,429	0,84
Work Engagement	0,956	0,977
Burnout	0,777	0,874
Workaholism	0,49	0,657
Religiosity	0,743	0,919
Turnover Intention	0,653	0,79

The measurement model was evaluated through confirmatory factor analysis (CFA) to test the validity and reliability of the constructs. Validity can be seen from the value of the loading factor (standardized loading) and the reliability can be seen from the value of composite reliability (CR) and average variance extracted (AVE) (see table 1). A re-estimation was made on the model after being reduced to produce a valid indicator, that have values of the standardized loading factor for each

indicator are greater than 0.6. Then, the reliability test was performed using AVE and CR. The CR values of all latent variables are more than 0.7, and the AVE values of all variables except job satisfaction and workaholism were greater than 0.5. Fornell & Larcker (1981) argues that if AVE values are below the minimum standard of 0.5 but CR values still meet the minimum threshold, then the construct is considered to have sufficient reliability or convergent validity.

Figure 2: Hypothesis Testing

***significant at 5%*

Figure 2 showed the results of the hypothesis testing. In terms of *H1* and *H2*, we expected that work engagement and job satisfaction would negatively affect turnover intention in a millennial employee in Jakarta. However, this study suggested that there was no significant negative effect of work engagement on turnover intention ($p>0.05$) and job satisfaction to turnover intention ($p>0.05$). Therefore, *H1* and *H2* were not accepted.

This study found that burnout was positively and significantly affect turnover intention ($\beta=1.162$, $p<0.05$). Therefore, *H3* was accepted. In addition, workaholism also positively and significantly affect turnover intention. ($\beta=0.273$, $p<0.05$). Thus, *H4* was accepted.

The moderated regression analysis showed that there was no moderation effect of religiosity to work engagement and turnover intention relationship ($p>0.05$). Therefore, the *H5* was not accepted.

Table 2: Hypothesis Test Result

Hypothesis	Variables	Estimate	S.E.	P-value	Result
H1	Work Engagement → Turnover Intention	0.762	0.632	0.229	Not Significant
H2	Job Satisfaction → Turnover Intention	-0.475	0.286	0.098*	Not Significant
H3	Burnout → Turnover Intention	1.162	0.388	0.003**	Significant
H4	Workaholism → Turnover Intention	0.273	0.122	0.025**	Significant
H5	Work Engagement*Religiosity → Turnover Intention	0.121	0.207	0.559	Not Significant

*Note: **: Significant at 5%, *: Significant at 10%*

Discussion

Based on the results of this study, there are findings that support the theory of employee well-being and turnover intention in millennials, but there are also findings that do not support previous studies. This study suggests that there is a positive direct effect of burnout on the turnover intention of millennial employees in DKI Jakarta. These findings are in line with previous studies which also found a positive effect of burnout on turnover intention (du Ploy & Roodt, 2010; Liu & Lo, 2017). This shows that the higher the millennial employees feel burnout, the higher the employee's intention to do voluntary turnover. This research also shows that sometimes millennial employees feel emotionally exhausted, but rarely think that the work is not important

The results of this study also indicate a positive direct effect of workaholism on the turnover intention of millennial employees in DKI Jakarta. Previous research on workaholism showed inconsistent results. The results of this study support research which states that workaholism has a positive effect on turnover intention (van Beek et al., 2012). This shows that employees who are workaholic and obsessed with their work is prone to have the intention to leave their jobs. In addition, millennial employees often do two or three things at once, such as lunch while writing memos and talking on the phone.

It was found that work engagement had no negative effect on the turnover intention on Y generation employees in DKI Jakarta. The results of this study did not support various studies that found a negative influence of work engagement on turnover intention (du Plooy & Roodt, 2010; Gupta & Shaheen, 2017). Previous studies have shown that employees who have an engagement in their work will have a low intention for turnover. The contrary results of this study may be influenced by the characteristics of millennial employees who constantly want new responsibilities, feel bored easily. and prefers to meet new people and new opportunities (Martin, 2005; Pinzaru, et. al., 2016). These characteristics can indicate that the intention of millennial employees to change jobs can be caused by wanting to find a new atmosphere regardless of the positive state of mind for a job.

The results of this study also showed that job satisfaction did not have a negative effect on the turnover intention for millennial employees in DKI Jakarta. This is not in line with several studies that found the negative influence of job satisfaction on turnover intention (O'Connor, 2018; Kim & Kao, 2014). This result can also be caused by the condition of PSBB in DKI Jakarta due to the Covid-19 pandemic. This condition can affect the condition of employee well-being and the intention of employees to do voluntary turnover. This is shown in the employee's answers regarding turnover intention. Specifically, millennial employees often wish to find other work that better suits their personal needs and consider leaving their job. However, they rarely think that their current work does not provide satisfaction for their personal needs. This shows that although they consider their work has satisfied their personal needs, millennial employees often wish to leave their current jobs.

This study also did not find the moderator role of the religiosity variable on the effect of work engagement on turnover intention. This result does not support the study of Wu, Rafiq, & Chin (2017) who found that religiosity moderates the effect of work engagement on turnover intention. This result can be caused by the diversity of the work field of the companies in this study. Contrary to the study of Wu, Rafiq, & Chin (2017), a study conducted on Bank employees in Pakistan, found the positive influence of religiosity on turnover intention (Zafar et al., 2012). The research found that the higher a person's religiosity, in this case, Islamic religiosity, the more likely the individual is to intend to get out of his place of work, which is a bank. This can be caused by the characteristics of banks that have a riba system which is prohibited in Islam. Thus, the field of work can also influence the direction of the influence of religiosity on turnover intention.

Practical Implications

The implications of this study are related to the important role of employee well-being in managing employee’s turnover intention. Employees who have high emotional exhaustion and feel cynical about the work have a vulnerability to make a turnover. In addition, employees who work too hard

when they are not happy about what they do are also vulnerable to turnover. In this study, many employees often feel tired at the end of the day after work, but they rarely feel that their work is not important. Therefore, managers can make programs to reduce the exhaustion at the end of the day. One program that can be done is to include the value of work-life balance in company culture. The value of work-life balance can be applied through routine programs, company regulations and appeal from managerial.

Limitation and Suggestions

This study has several limitations. First, this study did not explore much about the relation between the four constructs of employee well-being based on the circumplex model, because this study focused on the influence of the four constructs on turnover intention. Therefore, research on interdependent constructs of employee well-being needs to be carried out further and more deeply, such as to look at the relationship between the employee well-being constructs and their relationship with various job outcomes such as job performance, turnover intention, and so on.

Second, the study of religiosity in the workplace is still limited. In this study, researchers only focused on the role of religiosity on the relationship of work engagement and turnover intention in accordance with the results of previous studies. Therefore, more studies about religiosity in the workplace need to be done, as religiosity can affect individual values and attitudes. In addition, future studies of religiosity should focus on a certain field of work. Based on previous research, differences in the company's work field can influence the direction of the influence of religiosity on turnover intention.

This study has a focus on millennial, born in 1980 to 2000, in DKI Jakarta as research respondents. For more elaborate studies about millennials, future studies can conduct comparative research to see the difference between employee well-being and turnover intention in the millennial generation and other generations. Further research can also be carried out with a specific sector of work to have more similar characteristics on participants. The use of secondary data can also be considered in future research.

Digital Transformation of The Procedure of Admission to Russian Universities

Alexey Ivanovich PYKHTIN, Oleg Victorovich OVCHINKIN, Vladislav Vladimirovich FURSOV and Irina Victorovna SHCHIGOLEVA

Southwest State University, Kursk, Russia

Abstract

The article deals with the problems faced by university applicants and universities in modern conditions in the framework of the admission campaign: the complexity and opacity of the admission procedure, the risks of incorrect submission of consent to enrolment by applicants, the restriction on the number of universities and majors chosen by incoming applicants, the lack of the system of priorities for selected areas of training, the need for decision-making by applicants in the conditions of time pressure and uncertainty. The article proposes three approaches to the digital transformation of the procedure of admission to universities: a conservative one (a version of which is used in the Superservice "Admission to University Online"), an evolutionary one (based on the centralization of competitive selection in all the universities of Russia in the conditions independent of a great deal of target figures of admission), and a revolutionary one (involving conducing nationwide competition for each area of training across the country). A comparative analysis of the advantages and disadvantages of each approach in comparison with the Superservice of the Ministry of science and high education of Russia "Admission to University Online", which is currently being developed, is carried out. It is shown that technical tools and algorithms for implementing any of the approaches have already been created. Financing of the procedure of digital transformation is possible both at the expense of the Ministry of science and high education of Russia and at the expense of the resources saved by universities.

Keywords. Admission procedure, Digital transformation

Introduction

Standardization and strict regulation of the requirements for the university admission process by the regulatory institution (the Ministry of Education and Science of the Russian Federation and Rosobrnadzor) related to the transition to the widespread accounting the results of the Unified State Exam (USE) as entrance examinations in 2009, the stage-by-stage improvement and typification of the legal framework, the development and introduction of a federal information system to ensure the conduct of the state final certification of students and the admission of citizens to educational institutions to get vocational secondary and higher education (FIS GIA (Federal Information System of State Final Examination)) opened the prospects for addressing issues of digital transformation of the process of work with the applicants throughout Russia [1, 2].

In this regard, in 2019, the Ministry of Education and Science of Russia began to implement the ambitious project of Superservice for Admission to University Online [3]. Let us note that similar attempts were carried out by the Ministry of Education of Russia in 2004 [4] and by Rosobrnadzor in 2006 [5], but as a result, both projects did not receive further development. Similar ideas are typical for the states with the systems of national exams similar to the Unified State Exam both in the former Soviet republics and in Asia and Latin America [6, 7, 8].

The resurgence of interest in the topic within the framework of the project of Superservice of the Ministry of Education and Science of Russia is associated with a number of existing problems faced by universities and applicants which could be solved by means of a potential digital transformation of the procedure of admission to Russian universities.

Materials and Methods

Firstly, the existing admission procedure is complex in its arrangement and opaque to applicants in many situations. Moreover, the existing difficulties arose as a side effect of the increasing role of control over universities by regulatory institutions in an attempt to ensure greater unambiguity and transparency for applicants. In 2009, applicants could apply for admission to an unlimited number of universities for an unlimited number of majors. As a result, the number of applicants increased in universities by at least 2-3 times although totally, approximately the same number of students were enrolled as compared to the pre-reform period. For example, in 2005-2008, approximately 1,700 people applied for 700 full-time state-funded places at the Southwest State University (SWSU), but since 2009 the number of applications increased to 3,000. The Russian Ministry of Education and Science responded to universities' calls concerning a sharp increase in 'idle' work with document processing and limitation of applicant's simultaneous participation in the competition only in 5 universities in 3 areas of training in each. It should be noted that in SWSU, the measures taken did not affect the situation concerning the number of applicants and applications.

From the applicant's viewpoint, this restriction is negative; the same can be said concerning the ban on the use of the priority system by universities, which was replaced with a system of consent to enrolment by the Ministry of Education and Science. The essence of the system of priorities is that an applicant arranges the chosen majors in descending order taking into account his/her interests (the first major in the list is the most preferable, the last one is the least preferable). In this case, university enrolment is also carried out strictly in accordance with the compiled list: if an applicant can be enrolled according to the competition for major 1 then he is enrolled at it, if he does not pass the competition, then he/she is considered in the competition for the 2nd major and so on. The priority system is algorithmized, scaled in the inter-university competitive space, allows universities to abandon the stages ('waves') of enrolment, allows applicants not to perform certain actions in the conditions of limited information and time restriction [9]. The only drawback of the priority system is the possibility that an applicant in his/her application for admission puts his/her preferences incorrectly in the list of majors. According to statistics on admission to SWSU since 2005, on average, about 1 out of 1,000 applicants applied to the admission office with claims that they had not understood how the priority system worked at the time of enrolment.

Secondly, at present, due to the imperfection of the current admission procedure related to the need to submit consent to enrolment by a certain date and time in the conditions of uncertainty, an applicant with a high USE scores may fail to be enrolled to study at the expense of state funds, choosing the university and/or the major incorrectly when submitting the original documents on previous education (only applicants with very high USE scores who are at the top of the ranking lists of applicants can accurately predict the results of their enrolment). In other words, there is a high risk that an applicant, giving his/her consent to enrolment in one of the universities he/she chose for one of the three majors, will not be enrolled to state-funded education at university, despite the fact that with another option of applying for consent to be enrolled (perhaps within the same university), it would be a real option.

Thirdly, since regulatory documents allow applicants to choose no more than 3 majors at no more than 5 universities at one time, applicants have to travel from one university to another many times during the admission campaign; moreover, these universities can be located in different cities of Russia, which cause time and material expenditures. In many cases, an applicant does not have enough time to bring the original documents from one university to another.

Fourth, there are periods during which an applicant is forced to spend time in the admission office or continuously analyze the competitive situation on the university's information services to reduce the risks of losing a potential state-funded place for training. Such key periods include the date and time of the end of the submission of consent to enrolment to the university. The current regulatory framework allows universities to use various options for informing applicants. Many universities seek to ensure maximum transparency and accessibility of information concerning the current competitive situation; at the same time, some educational institutions just fulfill formal requirements and

applicants have to process massive amounts of information from university websites manually to calculate and predict their chances of enrolment.

To overcome the above problems, it is proposed to solve the following tasks: to consider approaches to organizing a centralized competition in Russian universities; propose algorithms for processing applicants' data on a Russian scale; to find sources of financing the implementation of the selected approaches; assess the need for legislative changes; choose a platform to implement the optimal approach.

The first of the existing approaches is a conservative one; it involves modernizing the FIS GIA and admission into a single automated information system for admission to Russian universities, i.e. digitalization, not digital transformation of the current admission regulation. It is this approach that is the basis for the development of the Superservice for Admission to University Online. As part of it, in addition to traditional options for applying for admission to university (personally, by proxy, by courier or by regular mail (Russian Post)), applicants are provided with the service of accepting applications on the Public Services Portal of the Russian Federation (EPGU in Russian) as well as in a network of Multifunctional State (Municipal) Services Centres. Generally, changes in the regulatory framework are not planned, with the exception of certain aspects (replacing the submission of the original document (certificate) on education with electronic consent in the user's personal account in the Superservice, etc.). Competitive selection is carried out separately in each university according to the previously approved admission quotas. The implementation of the approach necessitates digitalization of some related areas of activity: systematization of certificates of disability, sports achievements of Russian citizens, etc. It should be noted that due to the peculiarities of the current regulations concerning admission to universities, the digitalization process in this case can be much more complicated and expensive than digital transformation. One of the 'bottlenecks' is the point in time related to the end of the period when an applicant can give his/her enrolment consent. During these periods, the attendance at the sites of each of the universities in Russia increases several times, so on August 1, 2019, more than 3,000 people visited the SWSU admission office portal, including more than 500 people at 18:00. For comparison, on July 31 and August 2, at the same portal traffic amounted to no more than 1,500 visitors. Thus, implementing a large-scale Russian information system, it is necessary to provide technical capacities that can withstand peak loads. If the regulatory framework is changed, it is possible to implement the system using the existing equipment of the FIS GIA and admission.

The model of the evolutionary approach presupposes that in the period of the application for passing the USE, future applicants indicate a priority list of universities they want to enter and areas of training (majors). The distribution of applicants is carried out according to the previously approved university admission quotas; the competition is held centrally throughout Russia. The approach ensures that an applicant with a sufficient USE score will enter the university he/she is most interested in from the list of his/her priorities.

The revolutionary approach allows applicants to indicate a priority list of areas of training (majors) that they want to be enrolled in during the period of applying for the USE. In this case, the distribution of applicants is carried out in areas of training on a Russian scale without the need to distribute admission quotas among universities; the 'winners' of the competition get the right to study at the expense of budgetary funds.

Research Results and Discussion

Table 1 presents the results of assessment of the advantages and disadvantages of each of the above approaches.

Table 1: Characteristic features of applying different approaches to the admission procedure

Characteristic feature	Superservice	Conservative approach	Evolutionary approach	Revolutionary approach
The need to amend regulations	Insignificant	Insignificant	Significant	Significant
The need to change the mechanism for distributing admission quotas	No	No	No	Yes
Possible technological platform	FIS GIA and admission + Public services	FIS GIA and admission + Public services	FIS GIA and admission + Public services	FIS GIA and admission + Public services
Additional expenditures for the modernization of information systems by universities	Yes	Yes	No	No
Number of actions performed by applicants	Large	Large	Small	Small
Guaranteed admission of the best trained applicants to the state-funded places	No	No	Yes (for universities chosen by applicants)	Yes

It should be noted that algorithms for competition enrolment on a Russian scale already exist and have been tested on a data set equal to the average annual number of applicants (about 1 million people). It was shown [9] that the time spent on calculating the competitive situation on a Russian scale for any of the selected approaches does not exceed several minutes, even if there are no restrictions on the number of universities and majors chosen by applicants. In the case of using Superservice, such information processing must be carried out repeatedly; in case of a conservative approach, it must be carried out before each stage of enrolment; and in other approaches – once a year during the period of organizing the admission.

The systems currently used (primarily, FIS GIA and admission) contain applicants' personal data, their USE results, the number of state-funded / non-state-funded places in universities according to majors, information on winners / prize winners of school olympiads. Modification of the FIS GIA and admission will require taking into account such additional information as the priorities of the universities / majors selected by applicants (the priority system of majors is implemented in the FIS GIA and admission but it is not currently used due to the cancellation of this opportunity in the regulatory framework), data on the availability of privileges for admission to places within the special quota and target quota, data on individual achievements, overall grade point average of the Certificate on secondary education (for admission to secondary vocational education programs). It should be noted that the collection of this information is already provided for in the framework of the Superservice project.

To finance the implementation of this project, resources allocated annually to support the FIS GIA and admission and creation of Superservice can be used. If the FIS GIA and admission replaces the admission campaign block of university information systems, the partial funding can be transferred to universities by saving their funds to support their own or third-party automated information systems and the work of the admission office. In this case, it will be necessary to make changes to the

regulatory framework regarding the implementation of the procedure for admitting citizens to universities. When implementing the revolutionary approach, it will also be necessary to make changes to the procedure for distributing state-funded places among universities.

The possible problems related to the digital transformation of university admission procedures and possible solutions are analyzed in Table 2.

Table 2: Possible problems related to the digital transformation of university admission procedures and their possible solutions

Problem	Solution
Admission within the quota	Quotas are allocated on a Russian scale; a separate competition is held for these quotas
Admission to Master's Degree programs	Introduction of a unified exam for bachelors / entering exam results that do not affect other universities into the general system by universities
Unwillingness of some universities to enrol applicants according to the results of the All-Russian competition / admission to creative training programs (majors)	Conducting additional entrance tests (examinations) in the selected universities (now this procedure is implemented in universities that have the right to conduct additional entrance tests in majors)
Admission of foreign citizens	Admission based on the USE results / entering of exam results that do not affect other universities in the general system by universities
Incorrect major prioritizing by applicants	Active awareness-raising work in schools especially when future applicants choose USE subjects; social advertising campaign
A sharp decline in enrolment in 'low rated' universities	Creation of large scientific and educational centres and university campuses through aggregation / merging / reformation of universities

Now, let us consider the advantages of the proposed approaches to digital transformation of the university admission procedure.

Applicants do not have to visit the university several times in person to apply or submit consent to enrolment, which leads to saving in time and resources for travelling around Russia. An applicant gets a guarantee of enrolment for state-funded education at least in one of the selected universities, if an applicant has enough points according to the results of entrance examinations.

Universities reduce material and labour costs for admission campaigns, that is why they gain the opportunity to strengthen the marketing component.

The Ministry of Education and Science of Russia guarantees the enrolment of the best students to state-funded training programs (majors), gets an opportunity to reduce the load on the FIS GIA and admissions servers on peak days, and acquires a new tool for regulating the number of students, including those who apply for education on a non-state-funded basis, and a new approach to ranking universities and supervising the admission procedure.

Conclusion

Thus, the paper considers the problems faced by applicants and educational organizations in the framework of universities' admission campaigns: the challenges of the admission procedure, the risks of making the wrong decisions by applicants in the conditions of time limits and uncertainty, and the

lack of a priority system in the application for admission. Three approaches to the digital transformation of the university admission procedure are proposed: conservative, evolutionary and revolutionary. From the point of view of cost optimality and the resulting social effects for applicants, the implementation of either evolutionary approach or revolutionary one seems to be the most promising. The FIS GIA and admission system can be used as the core for any of the approaches, but in the case of the conservative approach, it will be necessary to modify the technical capacities of the system to resolve the problems of peak traffic arising in the days when applicants submit consents to enrolment. Possible challenges of digital transformation of the admission procedure and their solutions are presented.

The publication was made within the framework of the state task for 2020 N 0851-2020-003.

Abstract

The article describes the method of preparation and education of future military professionals in the field of direct leadership in the conditions of the University of Defence in Brno. The first part describes the process of preparation and education of students of the University of Defence in Brno in subjects related to direct leadership (applied behavioral science, leadership, military leadership and field preparation). The second part describes their interconnection, which is the result of a combination of identified requirements and competencies for military leadership.

Keywords: communication, Czech Armed Forces, leadership, military leader, military professional ethics, military psychology, University of Defence.

Introduction

The current security environment in which a military professional moves is accompanied by dynamic changes. The basic characteristics of this environment include the difficult predictability of threats and risks, instability, the asymmetry of conflicts, the lack of a continuous battlefield, the low predictability of further development. The importance of the linear concept decreases and the importance of holistic conception increases. This environment is characterized (Spilý & Hrnčiar, 2013) by blurred the boundary between war and politics, the military and civilians, were traditional states have lost their monopoly on the conduct of armed conflicts.

Systems, processes, methods and models of selection, education and training of professional soldiers and commanders must constantly reflect these changes, analyse them, evaluate them and adapt them to their character.

Ability to face current and future threats from military required to perceive the specific nature of the security and operating environment, its context, the participants, their goals and motivations. The achievement in current conflicts is determined by the aplication of a different thinking, use a different approach with quite different sort of power (lethal, non-lethal), fully different military capabilities, and therefore a essentially different form of military education and training (Hrnčiar, 2017).

Cite this Article as: David ULLRICH, Jan ZEZULA, Vratislav POKORNÝ And Miroslav POLACH " Leadership in Staff Training in the Armed Forces of the Czech Republic " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

This environment brings new challenges (Prisecaru, 2017), same as new requirements for the competence of managers and leaders – competence for industry 4.0 (Hecklau, et al., 2017). Teachers face the question how to usefully modify their programs and education forms. (Grabowska, 2018). Therefore how to adapt education for today's environment requirements (Santos & Benneworth, 2019), plus at times when organisations are willing to invest into the development of leadership and education of their employees (Crawford & Kelder, 2019).

Theoretical background

In the system of personnel training, leadership training also has an irreplaceable role. Three levels of leadership can be defined for the needs of education, and training of members of the Czech Armed Forces:

- tactical (direct) leadership;
- organizational leadership;
- strategic leadership.

Tactic (direct) leadership, or "face to face" command, is typical of team commanders, platoons, companies, and senior company sergeants, i.e. sergeant, technical sergeant, senior sergeant, lieutenant, senior lieutenant, and captain. Organizational leadership is typical of commanders and senior ensigns of battalions, regiments, brigades, and divisions, i.e. the rank of ensigns, lieutenants, majors, lieutenant colonels, and colonels. Strategic leadership represents the highest level of leadership and is typical of senior officers and senior warrant officers of the HQ, the general staff and the Ministry of Defence, i.e. the rank of staff ensign, colonel, brigadier general, major general, lieutenant general, army general and top civilian officials of the Ministry of Defence. For all three levels of leadership described above, the common, inseparable basis is the value framework and the commander's character formed by him. There are fundamental differences in the type and level of knowledge, skills, and activities involved.

The training of leadership at the University of Defence

At present, military professionals are preparing for the basic command functions, i.e. platoon commander and deputy company commander, or the basic staff function, i.e. the Chief of Staff as part of the accredited military bachelor and master studies at the University of Defence. They are expected to accurately fulfill their obligations under military orders and regulations and to carry out activities set by their superiors. It is preparation for the implementation of direct leadership. The training of leadership staff is defined at the University of Defence as a process comprising three basic sub-processes.

The content of the first education subprocess is a social science basis. It contains a block of applied behavioral sciences whose purpose is to provide a sum of knowledge of applied psychology, sociology, andragogy, moral philosophy (ethics), and the basics of communication.

„The development of leadership concepts brings a significant finding that it is important to recognize the overall direction of the leader´s behaviour in managing people. To assess his/her role it is useful to know which values he/she appreciates, whether his/her behaviour leads up to the realization of welfare or quite the opposite.“ (Mikulka, et al., 2018). For this reason, the first semester of study is designed to study the military professional ethics, focused on the area of "internal relationship" to the military profession and the role of military leader in connection with combat ethos, values of military profession[1], the need for

[1] It is a responsibility and a sense of duty, justice, dedication, courage, loyalty and honor.

the moral integrity of professional soldiers[2] and interpersonal relations and bonds within the internal culture of the Army of the Czech Republic and society.

The second semester is focused on military psychology with a focus on the degree of self-resilience and stress management techniques in connection with conducting military activities, and on applied sociology in the military environment.

The third semester is focused on mastering the principles and techniques of effective social communication in the management of subordinates, the development, and management of communication and information flow in specific conditions of the Army of the Czech Republic.

The content of the second subprocess is a summary of activities that will allow updating the available knowledge. An important role in this subprocess is to monitor the knowledge, abilities, and skills of students in challenging conditions within the subject Field Preparation. The content is to determine the disposition of individuals for coping with the demands and burdens associated with conducting military activities. Monitoring carried out of:

- dispositions for decision making under the pressure of time;
- the level and selected dimensions of personality, value orientation and self-knowledge in relation to the military profession;
- prerequisites for the development of group cohesion and combat ethos;
- overall ability to act as commander-leader.

Complex interconnection of personality, psychophysical, psychological, social, neurophysiological and physiological methods to identify competencies of the individual for direct leadership will be used in the model Preparation in the Field of the 4th semester. The methods will be carried out in a three-day continuous experiment, as well as in rest conditions a week before and after the experiment. Students will be exposed to model situations that most closely match the real stress conditions of the training.

The content of the third subprocess in the 5th and 6th semesters is the evaluation of the above-mentioned dispositions and the development of competencies to lead people for direct leadership in the mentioned topics below.

1. Leadership as a process
2. The role of the leader in the security environment, concepts of professionalism, leader and the change
3. Leader – perception versus observation, reflection, and action
4. Leader and power
5. Leadership, ethics, and values
6. Features of a leader
7. Personal leader´s credit and influencing the others
8. Leadership in a wider context of a military organization
9. Stress management and problem-solving
10. An individual, groups, teams and the management
11. Methods of identification of the commander-leader competencies
12. Commander´s-leader´s competencies Appraisal in individual students
13. Leader´s self-development and development of others

[2] The moral integrity of a military professional is a binding link between the military role and the value system of the armed forces, enabling moral action and the creation of a combat ethos.

14. Commander-Leader competencies development

Leadership competences, on the tactical level, are primarily developed in 'Preparation in the field' training courses during the 5th and 6th semesters (four weeks). Students in the infantry branch are trained, with regard to tactical professional tasks (i.e. troop leading procedures, defensive and offensive operations, and patrolling), as platoon leaders. Students are evaluated on the basis of tactical knowledge and skills, and their individual predisposition for platoon leader level leadership in the final stage of their training. Additional training in the 7th and 8th semester is offered to mechanised infantry branch leaders, in order to further develop their competences. Part of this additional training relies on virtual reality simulations of the environment in which infantry vehicles operate. Training sessions with actual infantry fighting vehicles are only introduced in the final stages.

Leadership is also the content of the career training of NCOs, Ensigns and junior officers, which is carried out at the Training Command - Military Academy and for senior officers at the Center of Security and Military Strategic Studies of the University of Defence has an irreplaceable role. Materials developed abroad have been used creatively to create the subject of leadership in career courses, in particular by an international group of experts and academic workers from NATO and PfP (Generic Officer Professional Military Education Reference Curriculum, Partnership Action Plan on Defence Institution Building – Reference Curriculum, Non- Commissioned Officer Professional Military Education Reference Curriculum).

The training of Petty Officers and NCOs is divided into three levels that are interrelated to develop the knowledge, habits, and skills necessary to perform lower command and staff functions. Preparation of non-commissioned officers (commander of a squad, station, tank, mortar, team) is performed within the subject of "Leadership and Ethics", which is aimed at providing the theory of leadership, developing attitudes to the values and character of non-commissioned officers so that they are able to lead and develop their subordinates at the lowest tactical level and in mixed groups in the Czech Armed Forces and the international (coalition) environment. In the preparation of the NCO´s, the experience gained at the lowest command positions is developed in the basic course in the subject "Leadership and Ethics". It further develops an understanding of leadership theory, identifying and actively promoting and defending the values and character of NCO´s so that they can lead and develop their subordinates on a tactical level and in mixed units of the armed forces and an international (coalition) environment. In the Higher NCO´s course, the subject of "Leadership and Ethics" uses the experience of the course participants in performance in lower command and senior staff positions. It further develops an understanding of leadership theory, identification with active implementation and advocacy of the values and character of NCO´s so that they can lead, develop and educate their subordinates even in mixed units of the armed forces and in the international (coalition) environment. It also deals with the transfer of experience, mentoring and an important aspect of the distinction of command power of authority and the possibility of influencing decisions.

The training of officers is newly divided into four courses, which build on each other and develop gradually acquired knowledge habits and skills for the performance of basic, middle and senior command and staff functions.

In the basic officer course, the subject of "Leadership and Military Ethics" is focused and military education to military professional ethics, understanding the moral aspect of an officer, personal example of a commander, management theory of organization, and human rights education. It includes training of presentation skills and performing practical tasks in combat play and practical tactical training-exercises.

The course for lower officers is intended to introduce the "Leadership" course to students in the theory and practical application of leadership in the army as an organization and develop the theory of military ethics in practice. In this section, the rules on the use of force (ROE) in the context of the application of the law in armed conflict (LOAC) are practiced.

In the course for senior officers, the subject of "Leadership" ensures the transition from direct to organizational leadership. The preparation is focused on mastering the application of management theory skills in command and control, application of management and leadership styles, control skills, analysis, and action. An essential part is an understanding of the moral, ethical, conceptual, interpersonal and technical components of the skills needed to organize change management. The study also includes knowledge and skills of team building, evaluation of their effectiveness and solution of interpersonal conflicts, gender policy, etc.

The General Staff course in the subject of "Leadership" develops strategic leadership and adds it with the knowledge and skills of the so-called mediated leadership and management of large organizations at the interdepartmental, cross-departmental and international levels. It includes the study of management theory and leadership in an environment of uncertainty, creation of visions, concepts, setting goals and values. Officers will understand the importance of ethics at the strategic level of decision making in studying historical examples.

Methods for identification

In model situations that correspond with real situations of deployment in security environment will be used a complex networking of personality, psychophysical, psychological, social, neurophysiological an physiological methods for identification of competence of an individual for direct leadership. Methods will be realized in 3-day continuous experiment then in calm environment one week before and after the experiment.
Methods for identification:

1. Methods of personality disposition;

2. Methods of psychical and executive functions (mental level) - attention, memory;

3. Methods of social disposition;

4. Methods of moral-value disposition: a) measuring of value orientations by means of Schwartz Value Survey (SVS) and Portrait Values Questionnaire (PVQ); (b) measuring moral decision-making and reasoning using the Moral Competence Test (MCT) and interpreting how to deal with model and situational moral dilemmas in stressful situations; (c) measuring the level of prosocial moral reasoning by the Prosocial Tendencies Measure (PTM and PTM-R); d)determining the level of communication skills and personality prerequisites for communication using the Social Competence Inventory (SCI);

5. Methods of psychophysical dispositions: a) spectral analysis – measuring of spectral analysis of heart rate variability; b) measuring of the autonomic nervous system - Blachghost system;

Conclusion

The analysis of the current security environment has indicated specifics that affect the quality and potential requirements of the capabilities and skills of commanders, professional managers, and leaders, i.e. people who perform functions and activities related to the organization and management of human systems environments. The characteristics, influences and possible trends of the development of the current security environment place specific requirements not only on the preparation of military commanders and leaders to operate in this environment but also professionals who already operate in this environment. Professionalism is not only given by professional skills (hard skills) and social skills (soft skills) but above all by personal quality, on the background of which are cultivated and continuously developed natural potentials of people to personal competencies (subtle skills).

The goal of the Czech Republic, as stated in the Defence Strategy[3] is to have armed forces of motivated, trained, universally prepared and properly equipped personnel, who will be provided with all the prerequisites to perform work. These are, in terms of competencies - education, training and other forms of preparation in the armed forces for the fulfillment of specified tasks of the armed forces. According to the Conception of the Construction of the Army of the Czech Republic 2025,[4] the Czech Army uses departmental, military, off-ministerial and foreign facilities, and institutions to prepare its personnel. The Army will continue to deepen its cooperation with the University of Defence Brno, which is not only a research institution but also an educational facility for the lifelong training of officers and civilian personnel.

Trends in changing the quality requirements of people's skills are profiled mainly in two areas of professional skills that are interrelated. One area is the military-professional and specialized competencies and quality of a professional as an expert in a special activity, function, or field of military activities. The second area is the competence, quality of the professional involved in the command and control of processes and systems. Changes in requirements take place both at the individual level (abilities, qualities, thinking, individual values) and at the system level (relationships, decision making, communication, achieving goals, sharing meaning, values, etc.). That is why leadership is the basic framework and accented topic of training and education for military professionals, commanders and leaders.

Abstract

The primary goal of the paper is to assess the production potential and incomes of very small farms in the European Union, with particular emphasis on Polish entities. The basic source of data were statistics collected as part of the accountancy data collection system from agricultural holdings - European Farm Accountancy Data Network (European FADN). The analysis took into account the years 2012-2017. The spatial scope of the study covered the area of the European Union, with particular emphasis on Poland. Very small farms were distinguished based on the criterion of their economic size. It was assumed that a very small farm is one whose economic size does not exceed EUR 8,000 Standard Output (SO). The obtained results show that the value of assets of very small farms in Poland amounted to an average of around 73 thousand EUR in the analyzed period and was on average 66% higher than the value of assets used in the production process by very small agricultural holdings in the European Union (EU). At the same time, family farm income expressed per family labour unit (EUR / FWU) was almost 25% lower in very small farms in Poland than in the EU. It was also found that fixed assets dominate the assets structure of very small farms, and in the case of Polish entities this share amounted to 92.3% on average, while for EU farms the value of this ratio was slightly lower and amounted to 87.4%. The surveyed entities both in Poland and in the EU use primarily equity capital to finance agricultural activities. Furthermore, it was established that the relation of total production (total output) to total costs (total input) in the case of EU farms was higher than 1 throughout the entire analyzed period. On the other hand, very small farms from Poland from 2014 were characterized by a level of costs exceeding the value of production. This proves the importance of external support (in the form of operating subsidies) for creating agricultural income of very small farms in Poland.

Keywords: very small farm, family farm income, production potential, operating subsidies, FADN, Poland, European Union

Introduction

Research results presented in the literature show that there are many different factors determining the level of income obtained by agricultural holdings. The underlying production factors affecting farm income include land, labour and capital (see, e.g. Carls et al., 2019; Gummi and Mu'azu, 2019; Kurdyś-Kujawska et al., 2019; Murawska, 2019; Kocsis and Major, 2018; Średzińska, 2018; Soliwoda, Kulawik and Góral, 2016; Beckman and Schimmelpfennig, 2015). However, the profitability of the agricultural sector depends to a large extent on direct payments. Studies presented in the literature indicate that the vast majority of farms are unable to cover total costs without receiving payments under Pillar I and Pillar II. The inability to cover total costs means that farmers are unable to remunerate family labour and assets as in the other sectors of the economy. Among the

Cite this Article as: Agnieszka STRZELECKA And Danuta ZAWADZKA "Production Potential and Income of Very Small Farms in the European Union and Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

factors determining the level of income obtained by agricultural holdings, those that relate to the farm's production potential are of significant importance. However, the impact of some factors, as evidenced in research results, can be differentiated depending on the economic size of a given farm (see, e.g. Średzińska, 2017).

Large farms in the pig & poultry, horticulture and permanent crop sectors are more profitable and less reliant on direct payments (European Commission). The income of very small farms is, in most cases very low, so that small changes in revenue or costs can cause high relative changes in income. Very Small farms are also becoming more diversified into off-farm sources of income, often because they are too small to make a decent living from farming. On the production side, the available evidence still supports an inverse relationship between land productivity and farm size.

Small-scale farms typically achieve their higher land productivity using labour-intensive methods rather than capital-intensive machines. The results of Średzińska's research (2017) prove that in the case of very small and small farms (separated on the basis of the economic size criterion), there is a negative relationship between income and the value of assets. Our previous study (Strzelecka, Zawadzka and Kurdyś-Kujawska, 2019) showed that in the case of very small farms (included in our study), there is a positive relationship between the productivity of plant production and livestock production, as well as the productivity of the labour factor and the level of agricultural income. Moreover, we found that too high value of fixed assets per employee and too high intensity of production (measured by the use of fixed and current assets per hectare) have a negative impact on the level of very small farm income (Strzelecka, Zawadzka and Kurdyś-Kujawska, 2019). This confirms the results of research conducted by Średzińska, which demonstrated that for small-scale units in the agricultural sector there is a negative relationship between the value of assets and the level of agricultural income (Średzińska, 2017). Therefore, we found it important to analyse and assess the production potential and incomes of very small farms in the European Union, with particular emphasis on Polish entities.

The rest of the paper is structured as follows. Next section presents the survey methodology and data sources. Third section presents the results of the study, which consisted of three main stages. The first stage refers to the assessment of the production potential of the very small farms surveyed. Changes were found in the level and structure of assets and financing sources of the examined entities in the years 2012-2017. Subsequently, the profitability of production was assessed. To this end, the relation between the production value and the level of costs incurred was examined. The last stage of the research covered the assessment of the effectiveness of using the production potential of very small farms. For this purpose, changes in the level of income obtained by these entities per family labour unit were assessed. The importance of financial support, in the form of operating subsidies, in creating agricultural income of very small farms was also established. The last section concludes.

Data Sources and Research Methodology

The research covered very small individual commodity farms. The primary source of data were statistics collected as part of the accountancy data collection system from agricultural holdings - European Farm Accountancy Data Network (European FADN). The analysis took into account the years 2012-2017. The spatial scope of the study covered the area of the European Union (EU), with particular emphasis on Poland. Very small farms were distinguished based on the criterion of their economic size. According to the criterion, it was assumed that a very small farm is one whose economic size does not exceed EUR 8,000 Standard Output (SO)[1].

The following categories of data were used in the study (according to FADN definitions): a) *assets* - sum of fixed assets and current assets. Only assets in ownership are taken into account; b) *sources of financing*: sum of net worth and liabilities (value of long-, medium- or short-term loans still to be repaid); c) relation of total output (*total production*[2]) to total input (*total costs*[3]); d) *family farm income* - the remuneration for fixed production factors of the farm (work, land and capital) and remuneration for the entrepreneur's risks (loss/profit) in the accounting year; e) *family farm income*

expressed per family labour unit (EUR/FWU[4]); f) *total subsidies* (excluding investments) - subsidies on current operations linked to production (not investments). All data presented in the study are the average values for the considered groups of farms.

To achieve the aim of the study, the following research methods were used: a) literature analysis, b) empirical data analysis using descriptive and comparative methods, as well as statistical methods (average, structure indicators, dynamics indicators). The results of the analyses are presented in tabular and graphical form.

Results

When assessing the production potential of very small farms, the level and structure of assets involved in the agricultural production process were first determined. Figure 1 presents changes in the value of total assets in very small farms in the EU and Poland during the period under analysis.

Fig. 1: Total assets of very small farms in the European Union and Poland [EUR]
Source: Authors' own study based on EU FADN data

The obtained results show that in the entire period considered in the analysis, very small farms in Poland used assets of higher value in the production process than the entities from the EU (average 66% higher). The average value of assets involved in the production process in the case of Polish entities averaged 73.5 thousand EUR over the years analyzed. For comparison, an average very small farm in the EU during the same period used assets whose value was on average 66% lower, of an average value of 44.5 thousand EUR. It was also observed that entities conducting agricultural activity in Poland increased the value of assets from year to year, however, the pace of these changes varied (from 0.25% in 2015 to 11.46% in 2013). Next, the structure of assets of very small farms was examined, with particular emphasis on fixed assets, which in the case of entities from the agricultural sector were decisive in the production potential of a given entity.

Table 1: Assets structure of very small farms in the European Union and Poland from 2012 to 2017

Total current assets	8.94	8.31	6.99	7.14	7.47	7.38

** Share ratios for individual fixed assets were calculated in relation to the total value of tangible assets (internal structure of fixed assets).*
Source: Authors' own study based on EU FADN data

During the period under analysis, permanent assets were dominant in the structure of assets in both groups of very small farms under consideration. In the case of Polish entities, this share amounted to 92.3% on average, while for EU farms, the value of this ratio was slightly lower and amounted to 87.4%. The predominance of fixed assets in the structure of assets is a characteristic feature of units from the agricultural sector (see, e.g. Kołoszko-Chomentowska, 2018). Particular importance in this aspect is attributed to land, which will become an essential factor of production used in agricultural activities.

In relation to capital used in agricultural activities, the structure of financing sources for very small farms in the EU and Poland in 2012-2017 was also examined (Table 2).

Table 2: Sources of financing structure of very small farms in the European Union and Poland from 2012 to 2017

** Share ratios of individual components of liabilities were calculated in relation to the value of total liabilities (internal structure of liabilities).*
Source: Authors' own study based on EU FADN data

It was found that the surveyed entities both in Poland and in the EU use primarily equity capital to finance agricultural activities. As in the case of the dominant role of tangible assets in the structure of assets, financing of operations primarily with equity is a characteristic feature of entities from the agricultural sector (see, e.g. Mądra-Sawicka and Wasilewski 2017; Vučković, Veselinović and Drobnjaković, 2017). The results obtained for very small farms covered by the analysis showed that foreign capital is of marginal importance in financing the agricultural activity of these units. It was also found that both very small farms in the EU as well as in Poland, when using foreign capital, primarily decide on medium or long-term liabilities, which in both groups of entities constituted an average of 2/3 of foreign sources of financing. It was also observed that the importance of short-term financing increased in 2017 compared to the first year included in the analysis, as indicated by the changes noted in the structure.

Income from the agricultural activity depends, on the one hand, on the value of production created, and, on the other hand, on the amount of incurred costs related to agricultural activity. Our previous study (Strzelecka and Zawadzka, 2019) showed that farms, regardless of production type, are characterized by high cost-intensity indicators. The results obtained for very small farms (Fig. 2) confirmed previously observed dependencies.

Fig. 2: Ratio of total output to total input of very small farms in the European Union and Poland [ratio]
Source: Authors' own study based on EU FADN data

In the case of EU farms, the relation of total production (total output) to total costs (total input) was higher than 1 throughout the entire analyzed period. Conversely, from 2014, very small Polish farms were characterized by a level of costs exceeding the value of production. Therefore, if these farms did not receive financial support in the form of subsidies on current operations linked to production, then the family farm income would have had a negative value.

Next, the value of family farm income expressed per family labour unit of very small farms in the EU and Poland was assessed (Fig. 3).

Fig. 3: Value of family farm income expressed per family labour unit of very small farms in the European Union and Poland [EUR / FWU]

Source: Authors' own study based on EU FADN data

Throughout the period under analysis, the average very small farm in the EU was characterized by a higher level of agricultural income per family labour unit, than Polish entities. The level of the discussed income category in EU farms amounted to EUR 2,600.8 / FWU on average (in 2012-2017), and was on average 43.4% higher than the average value recorded for Polish farms. The most significant difference was observed in 2017 when family farm income expressed per family labour unit in the EU amounted to EUR 2807.1 / FWU and was 83.7% higher than the value of the discussed income category in very small Polish farms. The obtained research results show, on the one hand, that very small farms in Poland are characterized by higher asset equipment than EU units (Fig. 1), on the other hand, that Polish farms are characterized by lower financial efficiency and obtain a relatively lower level of agricultural income per family labour unit, compared to very small EU farms (Fig. 3).

The significance of financial support in the form of operating subsidies in creating agricultural income of the analyzed very small farms in the EU and Poland was also examined (Table 3).

Table 3. Ratio of total subsidies (excluding on investment) to family farm income of very small farms in European Union and Poland [%]

Specification	Years					
	2012	2013	2014	2015	2016	2017
European Union	48.94%	53.50%	38.30%	72.23%	69.99%	54.55%
Poland	70.26%	87.76%	98.32%	167.11%	148.73%	142.55%

Source: Authors' own study based on EU FADN data

In the case of very small farms from the EU, subsidies constituted on average from 38.3% (in 2014) to 72.23% (in 2015) of income from a family farm. In comparison, starting from 2015, the income of very small farms from Poland came entirely from financial support in the form of operating subsidies. Moreover, these farms allocated a part of the received financial support to cover the high costs incurred in connection with their agricultural activities. It proves that very small farms in Poland are characterized by a lower ability to generate income from operating activities than entities from the EU.

Conclusions

The aim of the research was to assess the production potential and incomes of very small farms in the European Union, with particular emphasis on Polish entities. The results of our study showed that the value of assets of very small farms in Poland amounted to an average of around 73 thousand EUR in the analyzed period, and was on average 66% higher than the value of assets used in the production process by very small agricultural holdings in the EU. At the same time, family farm income expressed per family labour unit (EUR / FWU) was almost 25% lower in very small farms in Poland than in the EU. It was also found that fixed assets dominate the assets structure of very small farms; in the case of Polish entities this share amounted to 92.3% on average, while for EU farms the value of this ratio was slightly lower and amounted to 87.4%. The surveyed entities both in Poland and the EU primarily use equity capital to finance agricultural activities. Furthermore, it was established that the relation of total production (total output) to total costs (total input) in the case of EU farms was higher than 1 throughout the entire analyzed period. Alternatively, from 2014 very small Polish farms were characterized by a level of costs exceeding the value of production. This proves the importance of external support (in the form of operating subsidies) for creating agricultural income of very small farms in Poland.

Endnotes

[1] Standard Output (SO) is the average monetary value of the agricultural output at farm-gate price of each agricultural product (crop or livestock) in a given region (FADN).

[2] Total production - total of output of crops and crop products, livestock and livestock products and of other output (FADN).

[3] Total costs - Costs linked to the agricultural activity of the holder and related to the output of the accounting year (FADN).

[4] FWU - Family work unit = Family AWU. Total unpaid labour input. Refers generally to family labour and is expressed in FWU (FADN).

Heart-Brain Communication:
The Way To Build Resilience and Improve Performance

Tereza Trnkova
University of Defence, Czech Republic, Brno
Tereza.trnkova@unob.cz

Abstract

This paper describes several facts about the heart-brain connection and how the heart influences brain function and performance. Research studies show that it is not true that we have limited control over the mind and emotions. If we adopt and train self-regulation skills, the emotional system can be regulated and brought into coherence. Understanding of heart-brain connection and communication means, that we can increase our capacity, performance and become more resilient. We have also information on how to shift and reset our inner systems and default settings and operate more effectively and with greater capacity and within daily interactions. Most organizations nowadays face to constant organizational changes and transformation is part of the daily life of many companies. The pressure to deliver results, work remotely and independently and make important decisions have a huge impact on business performance and health of employees. Numerous scientific studies have now shown that excessive pressure directly impacts the internal physiological processes of individuals. This has an impact on the performance of an individual and consequently on the organisation itself. Heart – brain communication shows what is happening with people internal functions and describes that we can do with our default settings, how to train them and subsequently to improve personal performance, staff turnover, personal health and thereby organizational effectiveness. Aim of this paper is to introduce some research outcomes of the HeartMath Institute and explore the importance of heart-brain communication on individual performance.

Keywords: Heart, Resilience, Performance, Brain, Emotions, Organization Effectiveness, Coherence, Heart Rate Variability, Performance, Baseline.

Introduction

The world has changed. Continuous change and pressure on performance have become the norm in a global economy. The pressure to deliver and operate in the environment of last-minute changes have a major impact on performance and the health of people working in organisations. Several research studies show how we can change our default settings and extend our ability to perform, become more resilient and increase our capacity and amount of energy.

The importance of emotions and heart rate variability is more than significant when speaking about resilience, performance, and capacity. Emotions define what we care about and what motivates us. Emotions and resilience are closely related because emotions are the primary drives of physiological processes involved in energy regulation. This is a reason why the key to sustaining good health, optimal function and resilience is the ability to manage emotions.

We can shift our physiology into a coherent state and increase physiological efficiency and alignment of the mental and emotional systems that accumulate resilience across all four domains (emotional, spiritual, physical, mental) by learning self-regulation techniques and learn and understand heart-brain communication.

No matter in which organisation people work, all firms want to have employees who can make a good decision when needed, people who can communicate with others, cooperate and contribute to a firms goals and overall efficiency. For the majority of people if not for all people in the world, there is a need to cooperate with others to achieve goals, meaning that teamwork is part of it all and essential element. Teamwork is happening in a group of people working together. When members of the team are not self-regulated, acting in their interest or seeking only their acknowledgement, the whole team is impacted by this behaviour. Stressful conditions in a given group act to increase emotional stress among its members and can lead to social pathologies such as violence, abuse, inefficacy, increased errors. [1] Based on the research, job stress is estimated to cost American companies more than $300 billion a year in health costs, absenteeism and poor performance. [2] Daily interactions with others at work or home has an impact on how we feel, how we act, how we communicate with each other and it has also impact on physiological processes in our body that affect our health.

As per the above, the way we live and interact with others have a direct impact on our performance and our health. Good teamwork and cooperation mean that individuals have to become more capable of self-management and self-aware of their own emotions for the group to work effectively.

This paper brings several research findings and explains how is it possible to improve workplace communication, cooperation, productivity, problem-solving by using practical steps and techniques and also explains heart-brain communication which is what is happening in our internal systems when practising these techniques over the certain time. Research task was to map out what is happening on the heart-brain axis and how these processes influence individual performance which can subsequently influence teamwork, communication and organisational effectiveness.

The Human Heart, Brain And Emotions

The heart is an organ, which pumps blood through the blood vessels of the circulatory system. This organ is still not well known outside the fields of psychophysiology and neurocardiology and still waits to be fully discovered and unfolded. New studies show that the human heart has its brain and the source of emotion, courage and wisdom. [3]

HeartMath Institute Research Centre has been involved in research of physiological mechanisms by which the heart and brain communicate and how the activity of the heart influences our perceptions, emotions, intuition, and hearth, for more than 25 years. It is known that emotions affect the autonomic nervous system, hormonal and immune system. What was explored by HeartMath institute was the fact, that heart rate variability or heart rhythms are the most dynamic and reflective indicators of emotional states, current stress, and cognitive processes.

It was proven that depleting emotions cause disorder in the higher-level brain centres and autonomic nervous system and are projected to heart rhythm patterns and affect the function of all systems in the body. This helped to better understand the communication between heart and brain and was explored that heart acts as having own mind (called heart brain) and even independent nervous system that sends a signal to the brain, specifically to the amygdala which is emotional processing centre and to the thalamus that synchronises our cortical functions and affects our brain centres and are responsible for clarity of thoughts and decision making. Heart and brain are in permanent communication. On top of that, the heart is an electric organ that creates a magnetic field around the body which can be measured by magnetometers even outside the body. These fields contain information about our feelings thanks to emotions we feel. Different magnetic fields can exchange information so people sitting next to each other ar entering the magnetic field of the heart of someone else. The magnetic field that we produce can affect others in our environment. There were also several examples done in this area, one of them showing that mother's brainwaves were synchronised to the baby's heartbeats when the mother was asked to focus her attention on her baby without touching the baby.

Figure 1: Mother's Brainwaves Sync to Baby's Heartbeats

Coherence and Resilience

Coherence has several definitions but it is always connected with correlations, connectedness, consistency, and efficient energy utilization. It is wholeness and global order. The whole is great than the sum of its individual parts. [4]

Researchers have proven that heart coherence is:, „an optimal physiological state associated with increased cognitive function, self-regulatory capacity, emotional stability, and resilience." [5]

Another research showed benefits of coherent field environment showing that when we are in a coherent state, it can help others become more balanced and composed more quickly. It explains that our emotional energetics influence people around us whether we are aware of it or not. The best way we can od to influence team atmosphere at work is to maintain our own personal coherence and focus on ourselves and our emotional reactions. This also explains why we feel the tense atmosphere when we enter a room and we don't know why and vice versa.

For humans apply four main domains of resilience, we speak about physical, mental, emotional and spiritual. Coherence does not mean that all parts are doing the same thing at the same time. We speak about a specific level of harmony and stability in the various rhythmic activities within living systems. [6]

When these domains of resilience are in harmony, the body is functioning optimally and is related to the ease and flow in life processes. Heart coherence can be measured by heart rate variability and heart rhythm pattern can be analysed (whether a pattern is chaotic-looking or smooth). When a person is in a coherent state, there is a change in autonomic balance toward increased parasympathetic activity and increased heart-brain synchronization. Based on the research, in this state body's systems operates effectively, are in harmony and facilitate natural regenerative processes. Research conducted in the USA in HM research institute shows that rhytmic – breathing methods can get the organism to the coherent state for a specific time and when self-generating positive emotions, people can achieve physiological coherence for an extended time.

When going back to four domains of resilience, there is one, responsible or key in building resilience and ability to increase human capacity. Capacity is, in fact, the resilience or in other words, resilience is capacity to prepare for, recover from and adapt in the face of stress, challenge and adversity. This definition was created by HeartMath instituted with cooperation and contribution of US Navy. [7]

Resilience doesn't come from rare and special or extraordinary qualities or processes. Resilience develops from the everyday magic of ordinary resources. It is not a sign of exceptional strength, but a fundamental feature of normal coping skills. [8]

Emotions play an important role when speaking about health, stress, resilience and coherence. It was recognized that the heart, overtaxed by constant emotional influences or excessive physical effort, suffers disorders of function and become vulnerable to disease. [9]

From a psychophysiological perspective, emotions are central to the experience of stress. It is the feelings of anxiety, irritation, frustration, lack of control, and hopelessness that are actually what we describe ourselves as stressed. It can be a minor inconvenience or difficult life situation, situations are experienced as stressful to the extent that they trigger emotions such as annoyance, irritation, anxiety, and overwhelm. [10]

Research in neuroscience shows that emotion and cognition can be thought of as separate but interacting functions and systems that communicate via bidirectional neural connections between the neocortex, the body and emotional centres such as the amygdala and the body. [11]

These connections allow emotions to reshape cortical activity while cognitive input from the cortex reshapes emotional processing. Research shows that the neural connections are stronger and transmit information from the emotional centres to the cognitive centres in the brain. This explains the strong influence of input from the emotional system on functions such as attention, perception.

Impact of heart-brain communication on employee performance and organizational efficiency

Why are these findings important for organizations and business environment? When we are coherent, we can make smarter choices, enhance focus, creativity and ability to problem-solve. Getting into sync and coherence can help us to react appropriately to everyday situations (like difficult conversations at work, meeting with someone with who we disagree, having an important conversation with someone, making important decision etc.), give us greater situational awareness and access to creativity.

This is an important message for the business environment and the way how employees in organizations act, how they decide, how they behave under pressure. Depleting emotions and incoherent heart rhythm inhibits brain function and directly affect physical and mental performance.

By heart-rhythm coherence training, workplace communication, productivity, innovative problem solving can be improved and employees turnover can be lowered which bring not only economic advantages but also social and teamwork benefits. There are already build and developed tools and techniques that can be implemented in employees training programmes and can build organisational coherence and resilience. There is an increasing number of private companies, hospitals, schools and military units which are working towards increasing their team or company coherence. [12]

A team consists of its members and to train team coherence, we have to begin with individuals and train them so individuals can understand its benefits for their own life, health but also for their cooperation within the team and they can achieve their goals more effectively. Recent HeartMath studies conducted with over 11,903 people have shown improvements in mental & emotional well-being in just 6-9 weeks using HeartMath training and technology. Data are based on individuals responding often to always on normed and validated pre and post Personal and Organizational Quality Assessment (POQA-R). [13]

- 24% improvement in the ability to focus
- 30% improvement in sleep

- 38% improvement in calmness
- 46% drop in anxiety
- 48% drop in fatigue
- 56% drop in depression

Change of Familiar Neural Patterns

As known from the emotional intelligence field, simply knowing something does not change people‘s behaviour. And when thinking about the body’s default settings it is more than true.

Our body behaves as set points of default settings. Even if we know that there are emotions that deplete and renew our energy and influence heart-brain communication, it can be difficult to think about the possibility to change our default settings. Based on the research we can reset our default settings and establish a new baseline but it requires discipline and our attention.

Human bodies are systems of physiological and behavioural baselines that keep our system regulated and operating optimally. The heart and brain communicate together in four ways – via the nervous system, hormones, pulse waves, and electromagnetic fields. For all these baselines we use our familiar patterns or baselines that our body strives to maintain. Default settings, in the majority of cases, are not optimal and healthy. Research shows that we can reset and shift our inner baselines and establish a new, healthier baseline by using self-regulation techniques that help us replace depleting emotions with positive attitudes and feelings. This can have a huge impact on the way how people behave from a long term perspective. The good news is that we can change our reactions if we train our internal systems regularly and pay attention to our emotions.

Amygdala is an organ that stores all memories and is connected with the heart via a strong nervous system. It is also a key brain centre that is involved in emotional experience. The input from the heart and body to the amygdala helps create a current feeling of an emotion. Simply, it is a type of memory that forms a baseline reference.

The process of establishing a new baseline takes place at the physiological level, which is imperative for sustained and lasting change to occur. It is possible to shift the baseline when practising becoming more coherent often regularly, but ideally every day.

Outcomes examples after implementation of coherence building techniques

Below is an example from the research that illustrates 2 high school students and their heart-rhythm patterns. The left side shows HRV before they learned and regularly practised the coherence techniques and practised them over four months. On the right, there is visible HRV at the end of the study. At the time of measurement they didn't use any technique, they were sitting still. The graphs show the change in HRV which means that after the study students were more resilient, thein rhythm was more coherent and they were able to shift their baseline.

Figure 2: Example of the Research – Intervention School

Another example shows measurable and sustainable improvements in personal performance, staff turnover, personal health and organizational effectiveness. Research and data below were gathered with the cooperation and through projects at Shell, BP, Unilever, Cisco, Boeing and others working closely with their medical and organizational development staff. Research shows improvements in several aspects before, six weeks and six months after the intervention.

Conclusion

The psychophysical fitness of an individual relates to the balance and harmony of the individual's inner environment. If our psychophysical fitness is good, we can manage more easily not only stressful working days, but we are also more resistant to stress. The inner environment can be also explained as inner battery and our own capacity to be prepared for, recover from and adapt in the face of stress. The most important strength that the majority of people need to build is the capacity to self-regulate their emotions, attitudes, and behaviours. [14]

The pivotal aspect of the challenging situations is, as described by Pokorny, Pindesova, Sieger - the human mind. From it, there are aspects such as mental state or mental resilience, as well as mental competence for meaningful decision making and action. [15]

It may take some time for resilience and positive changes to emerge, but there several ways and methods on how to train resilience through resilience-building skills. We should remember that we are unable to influence the events themselves, but we can influence our reactions to them and there are ways how to learn and archive our inner capacity and shift our default settings and establish a new baseline. The novel element of it's all is, that we can change our behaviours and reactions, we have

techniques to do it, but it is only up to us if we decide to learn and practise these techniques to access our connection with our heart and follow the guidance that heart is telling to us. Our heart is our guide through our daily interactions as well as a guide showing our direction on our life‘s journey. It is a process of self-discovery.

Research describes and shows how emotions change our heart rhythm patterns. Positive emotions create coherent heart rhythms. In contrast, negative emotions create chaotic, erratic patterns. Using a heart rhythm monitor, we can see our heart rhythms change in real-time as we shift from stressful emotions like anger or anxiety to positive feelings like care or appreciation. Coherent heart rhythm patterns facilitate higher brain function, whereas negative emotions inhibit a person’s ability to think clearly. Coherent heart rhythms also create a feeling of solidity and security.

These findings can have a major impact on the performance of employees and organisational effectiveness. When we consider the implementation of these programmes and methods to training programmes for companies we can see improvements in several areas of work and life. From long time-period, we can experience increased situational awareness in relationships, meetings and projects, enhanced ability to focus, process information and solve problems or increased ability to handle challenging clients and situations.

And just to mention at the end, except for personal and social coherence there is also a global coherence and global coherence initiative (GCI). We already know that we radiate out into the field environment through the magnetic field around us and we can therefore influence the field of people around us. Global coherence undergoing research believes that the heart’s magnetic fields around the world are connected meaning we are all connected together around the world along with earth’s magnetic fields. This shows that interconnectedness between humanity and the earth’s energetic systems exist and when we create a personal coherent field environment, it can benefit others and help offset the current planetary-wide discord and incoherence. [16]

Assessment of Complaint Processes at A Distribution Company Using Logistic Regression

Marcin ŚLĘZAK
Motor Transport Institute, Warsaw, Poland, marcin.slezak@its.waw.pl

Daria WITKOWSKA
Military University of Technology, Warsaw, Poland, daria.witkowska01@student.wat.edu.pl

Abstract

Manufacturers compete and constantly expand their offers, but the technological level and market opportunities mean that the quality and technical differences between the offered products are less and less visible. The result is an increase in intangible assets, in particular proper customer service, which has recently become a necessary condition in building customer satisfaction and loyalty. A satisfied customer will come back to make a purchase again, what's more, he can encourage other people. That is why reverse logistics and related to it after-sales service, which has become the subject of the examination of this article, play such an important role in the operations of enterprises. Based on the empirical data regarding complaint decisions, the impact of selected predictors on the binary dependent variable was assessed, i.e. complaint consideration or rejection. The logistic regression model was used for this purpose. The analysis presented allowed to assess the reliability of complaint processes at the examined company.

Keywords: complaints, logistic regression, complaint time, complaint cost.

Introduction

The progressing globalization and growing scale of production of goods with simultaneous environmental degradation make it necessary to introduce the concept of sustainable development in modern enterprises. The objective of such activities is not only to achieve competitive advantage, but also to ensure social, economic and environmental sustainability.

Reverse logistics and related to it after-sales service play a particularly important role in the operations of distribution companies. Customer orientation and awareness that a well-organized system of returns and complaints will ensure maintaining regular customers makes it a constantly evolving field. Complaints submitted by consumers are an expression of their dissatisfaction and an assessment of the quality of services provided, which is why their analysis is a common topic in the literature. The research focuses primarily on the possibility of translating the expressed claims into market success, through continuous improvement of implemented processes and improving their quality [4, 5], or implementation of tools supporting the consideration of complaints [7, 23]. Therefore, learning about certain consumer behaviour patterns, their nature [2, 3] and factors accompanying filing complaints [9, 10] is widely discussed in the literature. Information on the size of the complaint, the number of complainants and the reasons for the complaint are being considered [1, 9]. Key performance indicators of such processes are assessed, e.g. articulation rate/non-articulation rate, registration rate/non-registration rate, proportion of convinced/disappointed complainants, recommendation rate/warning rate and repurchase rate/churn rate [10]. The time and location of the complaint are being investigated [12], as well as its form (channel) [11].

In the research available in the literature, various mathematical methods and tools are used in this respect, e.g. : Supervised Machine Learning [3, 6, 14], analytical Customer Relationship Management (CRM) [12], time series [9], emotional classification model, statistical process control (SPC) model [13], statistical testing [22, 25]. Similarly to this article, logistic regression is also used, allowing to

study of qualitative variables [4]. As a result, comprehensive complaint management systems are presented [8].

Therefore, the available research concerns mainly dependencies that contribute to the customer satisfaction and the likelihood that he will make a purchase again. Consideration of a complaint should always be a process consistent with consumer law and dependent solely on the subject of the dispute. Meanwhile, this article examines the impact of factors that should not affect the complaint decision, such as the price of the product being complained about, the duration of the complaint, or a calendar month. The obtained results allow to assess the reliability of the complaint process at the examined company.

Methodology - Logistic Regression

Logistic regression is one of the most commonly used tools for analyzing qualitative dependent variables [3, 16, 11]. It has practically unlimited scope of application in various fields of science, especially in medicine [16], biology, sociology, psychology, economics as well as marketing and banking, but also in logistics [5] and transport [4].

In the logistic regression, values of the explained variable usually indicate the occurrence or absence of the analyzed event. Logistic regression then allows to calculate the probability of this event, called an opportunity. This is the ratio of the probability that an event will occur to the probability that this event will not occur. Thus, in classical probability, the ratio of the number of successes to the number of attempts is determined, while in the logistic regression, the chance, is determine, i.e. the ratio of the number of successes to the number of failures [12].

For case A the quoted definition can be expressed by the following formula:

$$(Chance)\ S(A) = \frac{P(A)}{P(not\ A)} = \frac{P(A)}{1-P(A)} \tag{1}$$

The logistic regression model is based on the logistic function described by the formula (2):

$$f(x) = \frac{e^x}{1+e^x} = \frac{1}{1+e^{-x}} \tag{2}$$

The logistic function takes values between 0 (when x tends to minus infinity) and 1 (when x tends to plus infinity). The shape of the logistic function graph resembles the extended letter S (Fig. 1).

Figure 1: Graph of the logistic function

source: https://www.datacamp.com/community/tutorials/logistic-regression-R

We can distinguish three stages that describe how the value of this function changes:

- at the beginning the function is close to 0 for some time,
- there is a sharp increase from the threshold value,
- finally it strives towards value 1.

Relying on the logistic function, we can define a logistic regression model. Let Y denote the dichotomous variable, taking the values:

1 - for the event that interests us, most often survival, obtaining a loan, passing an exam,
0 - otherwise, for example death, not obtaining a loan or not passing an exam.
Then the logistic regression model is determined by the equation:

$$P(Y = 1|x_1, x_2, \dots, x_k) = \frac{e^{\alpha 0+\sum_{i=1}^{k} \alpha_i x_i}}{1+e^{\alpha 0+\sum_{i=1}^{k} \alpha_i x_i}} \quad (3)$$

where: $\alpha_i, i = 0, \dots, k$: are regression coefficients,
$x_1, x_2, \dots, x_k$ are independent variables (quantitative or qualitative)
The left side of the equation is the conditional probability that the variable Y will take a value of 1 for the values of independent variables $x_1, x_2, \dots, x_k$.

The confusion matrix is used to evaluate the classifier. The rows of this matrix determine the correct decision classes, and the columns predict the model. In this way, the correct classifier decisions are described, i.e. the size of the TP class - *true positive* and the TN class - *true negative*, and the errors made, i.e. the FP class - *false positive* or FN - *false negative*. The classification results for a given decision rule are presented in the Table below. It compares the actual state and indications of the model.

Table 1: Confusion matrix

	The distinguished state has been observed	**The distinguished state has not been observed**
The distinguished state was anticipated	TP	FP
The distinguished state was not anticipated	FN	TN

A good model is therefore the one that minimizes the number of errors, namely FN and FP. Additionally, we distinguish two main measures of the quality of decision rules:

- Sensitivity, which is a truly positive fraction, determining the test's ability to detect the studied feature, it is the ratio of true positive results to the sum of truly positive and falsely negative ones.
- Specificity, which is a truly negative fraction, measures the percentage of real negatives that are correctly identified as such.

Sensitivity - TPR (*True Positive Rate*) is described by the formula:

$$\text{TPR} = \frac{TP}{TP+FN} \quad (4)$$

Specificity – FPR (*False Positive Rate*)

$$\text{FPR} = \frac{FP}{FP+TN} \quad (5)$$

The sensitivity and specificity are the basis in the construction of ROC (*Receiver Operating Characteristic*) curves, which illustrate the relationship between sensitivity and specificity of the model under study. It allows to evaluate and compare classification models with each other. Such analysis is possible due to the calculation of the area under the ROC curve graph, referred to as AUC (*Area Under Curve*), which is defined as the measure of goodness and relevance of a given model. The AUC index ranges from 0 to 1. An AUC value of 0.5 can be described as a random action, while a value of 1 is an

ideal indicator. It follows that the higher the value, the better the model. Comparing two models cannot be limited only to comparing the AUC indicator, because the ROC curve itself, its shape and course speak a lot about a given model. The more convex the graph, the better the classifier.

The Wald's test is used to assess the significance of the parameters of the logistic regression model. The null hypothesis assumes no predictor influence on the result variable H_0:$\alpha_i = 0$). Wald test statistics are calculated according to the formula:

$$W = \left(\frac{\alpha_i}{SEE}\right)^2 \tag{6}$$

where: α_i – coefficient next to the explanatory variable i,
SEE – standard error.

The statistics distribution is approximately consistent with the normal distribution in large samples. However, squared it is consistent with the chi^2 distribution (with one degree of freedom).

Regression models of the studied enterprise

The subject of the study is a branch of a large spare parts distributor. The dependent variable analyzed was information on whether the complaint was rejected (O) or approved (F), while the independent variables used to construct the model of logistic regression are:

- number of items - means how many products were submitted as one complaint (e.g. four same glow plugs were submitted under one complaint number),
- number of days - length of complaint handling (in days),
- price - the purchase price of the product under complaint.

The estimated parameters of the model are presented in Table. 2.

Table 2: Values of model I parameters

Effect	Parameters	Error Standard	Wald Stat.	GU upper 95,0%	GU lower 95,0%	p-value
Number of items	-1,11	0,09	138,07	-1,29	-0,92	$< 2{,}2*10^{-16}$
Number of days	-0,03	0,01	19,71	-0,04	-0,02	$< 2{,}2*10^{-16}$
Price (PLN)	0,003	0,001	251,79	0,002	0,003	$< 2{,}2*10^{-16}$

Whereas the odds ratios are presented in Table 3.

Table 3: Odds ratios - model I

Effect	Odds ratio	GU upper 95,0%	GU lower 95,0%	p-value
Number of items	0,33	0,27	0,39	$< 2{,}2*10^{-16}$
Number of days	0,97	0,95	0,98	$< 2{,}2*10^{-16}$
Price (PLN)	1,003	1,002	1,003	$< 2{,}2*10^{-16}$

Characteristics of parameters is limited only to assessing the direction of its impact. A negative factor for the variable - number of items means that the more items of a product in a given complaint, the smaller the chance of rejection. Similarly, a negative factor for the variable - number of days means that the longer the complaint is processed, the less likely it is that it will be rejected. The higher the price of the product, the chance of rejection increases.

The predictors' strength can be assessed using the calculated odds ratios. According to Table 3, the following conclusions can be drawn:

- if the number of items increases by 1, the chance of rejecting a complaint decreases by 0.3,
- if the number of days on which the complaint is considered increases by 1, the chance of rejecting the complaint decreases by 0.97,
- the unit price increase, increases the chance of rejection by 0.3%.

The classifier was assessed by plotting the ROC curve (Fig. 2). The area under the curve - AUC is 0.82 and means that the classifier is very good.

Figure 2: ROC curve Model I

Later in the study, Model II was proposed, which was created by extending Model I with a new (qualitative) variable - a month. This is justified by a frame chart showing the cost of complaints in individual months, which, as shown in Figure 3, varies considerably for individual months.

Figure 3: Frame diagram of the price variable grouped by month

After estimating the model parameters, the following results were obtained (Table 4).

Table 4: Calculated parameters of the model II

Effect	Rating	Standard Error	Wald Stat.	GU upper 95,0%	GU lower 95,0%	p-value
Number of days	-0,02	0,01	5,26	-0,03	0,00	0,02
Price (PLN)	0,00	0,00	285,87	0,00	0,00	$< 2{,}2*10^{-16}$
January	-1,54	0,22	47,80	-1,97	-1,10	$< 2{,}2*10^{-16}$
February	-1,67	0,24	49,24	-2,14	-1,20	$< 2{,}2*10^{-16}$
March	-1,65	0,23	50,61	-2,11	-1,20	$< 2{,}2*10^{-16}$
April	-1,63	0,26	39,60	-2,13	-1,12	$< 2{,}2*10^{-16}$
May	-1,63	0,23	50,94	-2,08	-1,18	$< 2{,}2*10^{-16}$
June	-1,66	0,25	43,42	-2,15	-1,16	$< 2{,}2*10^{-16}$
July	-2,27	0,26	78,96	-2,77	-1,77	$< 2{,}2*10^{-16}$
August	-1,74	0,24	51,76	-2,21	-1,27	$< 2{,}2*10^{-16}$
September	-1,94	0,23	70,30	-2,40	-1,49	$< 2{,}2*10^{-16}$
October	-2,01	0,24	69,51	-2,49	-1,54	$< 2{,}2*10^{-16}$
November	-1,71	0,28	36,64	-2,26	-1,16	$< 2{,}2*10^{-16}$

The odds ratios were also calculated for model II (Table 5).

Table 5: Odds ratios - Model II

Effect	Odds ratio	GU upper 95,0%	GU lower 5,0%	p-value
Number of days	0,98	0,97	1,00	0,02
Price (PLN)	1,00	1,00	1,00	$< 2{,}2*10^{-16}$
January	0,21	0,14	0,33	$< 2{,}2*10^{-16}$
February	0,19	0,12	0,30	$< 2{,}2*10^{-16}$
March	0,19	0,12	0,30	$< 2{,}2*10^{-16}$
April	0,20	0,12	0,33	$< 2{,}2*10^{-16}$
May	0,20	0,13	0,31	$< 2{,}2*10^{-16}$
June	0,19	0,12	0,31	$< 2{,}2*10^{-16}$
July	0,10	0,06	0,17	$< 2{,}2*10^{-16}$
August	0,18	0,11	0,28	$< 2{,}2*10^{-16}$
September	0,14	0,09	0,23	$< 2{,}2*10^{-16}$
October	0,13	0,08	0,21	$< 2{,}2*10^{-16}$
November	0,18	0,10	0,31	$< 2{,}2*10^{-16}$

In model II, all variables are also significant. The continuous predictors in model II are: number of days and price. The extension of the model with a qualitative variable caused a slight change in the odds ratios of the predictors. The month of December is the reference level. The assessment of the parameters shows that all the studied months have a negative value, which means that compared to December, all of them reduce the likelihood of rejecting a complaint. The probability of rejecting a complaint:

- in January, compared to December it is 0.21 smaller (21%),
- in February, March and June compared to December it is 0.19 smaller (19%),
- in April and May, compared to December it is 0.20 smaller (20%),

- in July, compared to December it is 0.10 smaller (10%),
- in August and November, compared to December it is 0.18 smaller (18%),
- in September, compared to December it is 0.14 smaller (14%),
- in October, compared to December it is 0.13 smaller (13%).

As results from the classifier evaluation using the ROC curve and AUC meter (Fig. 4), model II is better than model I. The area under the curve is 0.85.

Figure 4: ROC Model II curve

The analysis presented shows that the decision regarding the acceptance or rejection of a complaint in the examined company depends on factors that should not affect it, such as the price of the order to which the complaint relates, the time of considering the complaint or the number of products submitted for
a complaint. The study shows that the high price of the goods gives a greater chance of rejecting the complaint. Different impact, in turn, has the number of complaints and the time of consideration process, whose increase decreases this chance.

Model II showed that the calendar month also has a significant impact on the decision to reject or accept a complaint. It turned out that the biggest chance of rejection was in December. This may result, for example, from the accumulation of tasks associated with the end of the calendar year. Nevertheless, all the predictors selected for the study should not affect the complaint decision, and the presented analysis shows some worrying bias in their consideration. Further research should focus in detail on the reasons for this at the company in question.

Summary

Enterprises wanting to operate on today's market must be open to information from outside (both from competitors and contractors). An efficient complaint handling system ensures the retaining regular and loyal customers, which is necessary to achieve a competitive advantage. Enterprises should strive for the highest possible results in terms of customer satisfaction, guaranteeing the high quality of products and services offered, professional service and developing after-sales service. Currently, with such intense competition, price ceases to be the sole criterion for customer selection. As a modern method of acquiring and retaining clients, is regarded, so-called, post-transaction security. Customers who "come back" to the company to make a return or complaint are a source of very valuable information

about the products distributed. Such knowledge directly translates into increased sales by increasing trust in the company that responds appropriately to the feedback received from customers.

At the examined company, the complaint process is influenced by factors that should not affect the decisions taken. The logistic regression analysis used showed how individual variables shape the likelihood of complaints being rejected. It turned out that the price of the advertised product acts as a stimulant. On the other hand, the destimulants were the number of days on which the complaint was examined and the number of items complained about. The month in which the complaint is considered was also significant. The biggest chance of rejection is in December.

The results obtained suggest the need to verify the complaint handling process at the examined company and consider introducing changes. The presented method can also be used to evaluate this process after making corrections. Additionally, the universality of the method allows its application in any similar enterprise.

Abstract

The always on-going technological changes that we are subject to on a daily basis mean that there is a need for adaptation and evolution on behalf of all public education establishments with regards to the computerization and digitization of various student's day-to-day processes. The motivation for the Digital-Student application arises precisely from this fact, where direct contact between student-institution is required, offering permanent availability to satisfy students' requirements. The active school's participation will always be an effective mean of promotion and development of the institution. In this evaluation work, an application is developed using the Microsoft PowerApps and Dynamics365 platform, aimed at all students at any higher education institution. It is an application that allows users to share with each other relevant information about their academic path. From basic information such as Skills and Soft skills to more elaborate information such as training courses attended or documents such as curricula and certificates. At the end of the work, it is expected that the final solution to be considered as an example of success with regards to the theme of modernization.

Keywords: PowerApps; Dynamics365; mobile; modeling; development.

INTRODUCTION

The aim of this work is to develop a mobile application, Digital-Student, that allows students from any educational institution to organize and share everything they have accomplished over their academic path. This includes basic information such as skills and soft skills and even more detailed information such as attendances in training courses, certificates and/or other documents.

The specific goals for the project are the following:

•The possibility for each student to have a personal area to add their private information and academic (curricular) information (not shared with others) - a section was created for this purpose in the application where users could add, view and edit three sections: "About," "Skills" and "SoftSkills.".

Cite this Article as: Miguel RAIMUNDO, David MOTA, Cristina WANZELLER, Filipe SA and Pedro MARTINS "PowerApps and Dynamics 365: Developing Digital-Student, A Self-Promotion App" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

•The possibility of adding to their profile training courses that the student attended - as indicated in the previous point, each student would have a personal area and, for each student, there would also be the possibility of having an application area where he could add to the training that he attended - this would be done automatically. Such functionality would be performed using the QRCode technology. At the end of each workshop, the user would be able to read a QRCode that would automatically add to the list the training course that he attended. Afterwards, the user can scan the training course certificate and upload it to the application.

•The possibility of adding documents and certificates to the student's profile - in addition to being able to add new training courses that the student attended, it would also be possible for the student to be able to add documents and certificates to his/her profile.

•Possibility of sharing profiles – finally, in addition to all the features described above, there would be an opportunity for each user to search and view information, documents and training courses of other users.

This paper describes how Microsoft PowerApps and Dynamics365 can be used to leverage a fast-mobile application development. Preliminary results show that the development process is much efficient due to the low-code platform inherent to PowerApps and Dynamics365.

The paper is organized as follows. Section 2 resumes the related work and makes a summarized comparison of tools used at the development stage. In this Section it is also compared the main final products competitors. Section 3 introduces the project from a technical point of view, as well as the use cases. Section 4 explains how the prototype and the final app was developed. In section 5 the tests and results are discussed. Finally, in Section 6, the conclusions and future work guidelines are provided.

RELATED WORK

In this section are analyzed some related applications. This analysis enabled to examine the status of applications where it was possible to conclude that many had different intentions, for instance, many were more oriented towards the post-student life.

Aiming to develop mobile applications, three tools were studied. Table 1 compares the three main development tools available to speed applications development. In the first column, Android Studio is the Official Integrated Development Environment (IDE) for developing Android apps and is based on IntelliJ IDEA. In addition to IntelliJ's Code Editor and Advanced Developer Tools, Android Studio offers even more features to increase productivity when building Android apps (Zapata, B. C., 2013). OutSystems is a fast delivery platform for low-code applications that speeds up the delivery of mobile and web applications. Developers use an integrated development environment that covers the entire life cycle of development: development, quality assurance, implementation, monitoring and management (Golovin, D., 2017). Power Apps is the central technology used to do this project. It is a suite of apps, services, connectors and data platform that provides a rapid application development environment to build custom apps for business needs. Using Power Apps, you can quickly create custom business apps that connect to your business data stored either in the underlying data platform or various online and on-premises data sources (Rymer, 2019).

Table 1 : Comparison Table - At Development Level

Comparison Table - At Development Level			
Functionality	Android Studio	OutSystems	Powerapps
Low Code	✗	✓	✓
Easiness Listing Entity Data	✗	✓	✓
Date/Time Pickers easy to use	✗	✓	✓
Easiness Data inserting	✗	✗	✓
Local Data Base	✓	✗	✓
Search For Specific Queries	✗	✓	✓
User Friendly	✗	✗	✓
Development Speed	✗	✓	✓
High Security Level	✗	✓	✓
Automatic real-time Data Verification	✗	✗	✓
Affordable Price	✓	✓	✓

From Table 1, it is possible to conclude that PowerApps is the most suitable tool for fast development of mobile application since it offers all the “must have” requirements from a developer point of view. Android Studio and Outsystems, are both equally outstanding applications. However, they don’t offer such versatility and efficiency.

In Table 2 is presented a comparison of final products that directly compete with the proposed application. LinkedIn is a social business network founded in December 2002. It is comparable to other social networks and is mainly used by professionals in order to present their skills, in a way that other professionals from the same company can approve, giving credibility to the content. This application is relatively important because it has the ability to expose the capabilities of users so that third parties and companies can find more quickly and efficiently any person suitable for the job in question (Skeels, 2009). In more detail, the “Personal Profile” includes a sub-menu devoted to showing basic information about the user. The “Shared Profiles” is related to the social nature of LinkedIn and the “Add Certifications and training Courses” is linked to the idea that LinkedIn allows users to add Certifications and Training Course attendances to their profile.

Sumry uses each user's unique story to create connections. Helps to create job portfolios and online resumes. It is a platform that highlights education, specialization, certifications, user's professional experience and presents recommendations from people who may have worked with them in their previous work. As soon as the user finds a vacancy of interest, it offers an opportunity to be introduced to the company even before the user officially submits an application (Alexander, S., 2016). In this case the “Personal Profile” includes a sub-menu devoted to showing basic information about the user and the “Shared Profiles” is related to the social nature of Sumry. Finally, the “Add Certifications and training Courses” is linked to the idea that users are allowed to add Certifications and Training Course attendances to their profile.

The proposed application, Digital-Student, supports the most essential features present in LinkedIn and Sumry. At the same time, Digital-Student improves the ease of finding out which more students from the same educational institution attended the same Training Course and supports additional adding of those Training Courses automatically via a QRCode.

Table 2: At Final Product Level

Comparison Table - At Final Product Level			
Functionality	**LinkedIn**	**Sumry**	**DigitalStudent**
Personal Profile	✓	✓	✓
See which students attended the same training courses	✗	✗	✓
Shared Profiles	✓	✓	✓
Add Certifications and training Courses	✓	✓	✓

PROJECT ANALYSIS AND USE CASES

This chapter will include an in-depth analysis of the project structure, a brief discussion of the application architecture, an explanation of the use cases and an analysis of the database model.

Figure 1 describes the communication model between the various applications used to develop this project. In (1) is represented the "power automate" that is responsible for helping create automated workflows between applications and services for file synchronization, notifications and data collection. It provides a simple code platform for process and workflow automation. Communication from (1) to (2) and (2) to (1) is done automatically and from (2) to (3) is done by connecting both the application and the Data Base to the same repository (what is called "Solution" in PowerApps).

Figure 1 : Communication Scheme

The application is developed on the PowerApps platform and will communicate with the PowerAutomate service, which is part of the PowerPlatform cloud services. In order to prevent the data from being stored locally, the application will also communicate with a database in the CDS (Common Data Service) where it will store and read data that is crucial to its proper functioning.

The use cases, Figure 2, were collected from both customer and developing team. The input from the customer was recorded in the format of a low detail prototype (Figure 3). Other use cases, suggested by the developing team were translated into extra features in the final app, such as, DarkMode and search functions throughout the app.

In order to gather the use cases of the proposed application, throughout the development of the project, several (Scrum) meetings were held with all intervenient (programmers and users).

Figure 2 : Use Cases

Throughout the development of the project, several meetings were held with both advisors. In these meetings, various subjects were discussed such as: the student's qualification in the project, main points about the development, difficulties encountered and discussion of steps to overcome such difficulties.

PROTOTYPE AND APPLICATION

After the requirements, prototypes were made in order to idealize the application structure. Following an intensive study of the technologies and tools to be used in the implementation of this project, the specific goals of the project were elaborated on the prototypes illuminating the interface of contact with the user. Paper and pencil were used to make these prototypes.

In the depicted prototype, Figure 3, we can see the sketch version of the user's Profile on the left and the Shared Profiles on the opposite side.

Figure 3 : Example of a Low Fidelity Prototype

After the first prototypes finalized, the final application design was created. It is presented in Figure 4, bellow.

Figure 4 : Example of the final Application Design

Database Model

The application database model is presented in Figure 5. The Relational Data Model represents the tables and the relationship between them, schematically in order to obtain a representation of the existing Database. XMLToolBox tool was used to generate the Data Model. This model represents how all the data that is collected through the app is being stored.

Figure 5 : Database Model

The database table “User” is used to store the data of the users of the application. Its primary key is the “systemuserid” field. It consists of the "About" field that represents the About section of the user profile and the "Skills" and "SoftSkills". It also consists of "Primary Email" and "full name" which represent the unique email of each user and the Full Name.

The database table “Friends List” is used to store the data of the shared profiles. Its primary key is the unique id “Friends_list” field. The fields "User1" and "User2" represent foreign keys resulting from the relationship with the "User" table.

The table “Others_Docs” is used to store the documents and certificates of each student. Its primary key is the “Others_Docs” field, which represents a unique id for each record. The fields “cr164_imagem_secundaria” and “cr164_imagemid” represent foreign keys resulting from the relationship with the “User” table. The fields "Name" and "About" refer to the name and an About section of the document.

Finally, the “Formacao” table is used to store the training courses that each user attended. Its primary key is the “Formacao” field, which represents a unique id for each record. The “cr164_document_digitalizado” field represents a foreign key resulting from the relationship with the “User” table. The “id_formacao” field represents a unique id for each record too. The fields "Name" and "Sobre_formacao" refer to the name and an About section of the training course.

Application

The objective of the current section is to demonstrate the implementation of the features developed for the application in accordance with the requested requirements.

Right after logging in, into the PowerApps application with Office365 credentials provided by the educational institution and opening the DigitalStudent application, the user is presented with the home page (Figure 4), which is the profile. When editing the profile (and after filling in all the required fields), with the intention of saving its changes, the user will have to select the “Save” button. After

selecting this button, in addition to navigating to the “Profile” screen again, it will acquire all the information that was written in the text fields above and will perform an Update in the Users table. This is accomplished using the PowerApps “Patch” command. A notification is also presented to the user that the profile has been saved successfully.

The “training courses and other documents” are available to the user to add the training courses they attended and other documents, such as the certificates or curricula.

When the student intends to be present at a training course, he will need to read a QRCode generated by the person responsible for the training course. GPS coordinates restriction has been implemented in order that someone outside of the educational institution can’t read the QRCode. Note that, because GPS is not accurate inside buildings, other methods based on Bluetooth (BLE) beacons and WIFI are currently being implemented, for indoors precise location detection.

Thus, if the coordinates of the user's device match the coordinates of the educational institution installations, a warning will be shown saying “Training Course added successfully”. Otherwise, the warning shows a message “You’re not at the correct location”. It is also possible to see which more students have taken part in a certain training course. After selecting the training course, the student attended, there is a "More People" button which brings us to a new screen that shows all users who have attended the same training course. The "Certificate" button is also visible, which is used to upload the training course certificate.

The other documents section, as already mentioned, is intended to provide the possibility of adding documents and other certificates to the students’ profile. Here you can add a name to the document, a short description and the document itself (in JPG or PNG format). As in the User Profile, a previously added document can also be edited or deleted.

Finally, shared profiles are the last subdivision of the application. Here, the student has the opportunity to consult information about other users. This possibility is limited depending on the student's presence in the list of students with a profile shared with the student who is logged in. That is, each user will have a list of shared profiles in which all users share the profile with the user logged in to the application. The user who logs in may consult information about the other user, such as Skills, SoftSkills, documents and even training courses. Subsequently, all users on this list also have the opportunity to consult all this information about the user logged in.

To add users to this list, the student will only need to select the "+" icon as shown in Figure 6 and a list will be presented with all students who use the application and who are not yet in their shared profile list. From there, "Add" must be selected by the student. Of course, after adding a new shared profile, the user is always free to delete the "relationship" between them.

Figure 6 : Adding a Shared Profile

In the process of adding a shared profile, the user that is added receives a notification on his device that informs him of the addition made by another user. This is done by using PowerAutomate which allows the automatic workflow creation that minimize the programming required for certain features. In this case, it was used to automate the notification sending process. Analyzing Figure 7, bellow, the notification is shown on the mobile phone where Francisca Raimundo is logged in.

Figure 7 : Notification

It is worth noting the DarkMode implementation on this application. Bearing in mind that it is an application that takes ideas and certain characteristics from certain social networks and that it will not only be used during school hours, DarkMode has been discussed and implemented. It allows the application to be used (even) more comfortably and saves the battery (when using OLED screens).

The Figure 8, below, shows the DarkMode application screen. It can be switched on and off via a toggle on the main screen.

Figure 8 : DarkMode

RESULTS AND TESTS

This chapter describes the experimental setup and testing phase, one of the most important in the development of software. This is a process that has the goal of verifying whether the developed project performs the functionalities for which it was intended, in which both functional and non-functional requirements are validated.

Table 3: Nielsen Heuristcs

Nielsen Heuristics		
Number	**Heuristic**	**Adopted Solution**
1	System status visibility	In the application, the bottom bar or navigation bar shows the section icon where the user is in blue.
2	Correspondence between the system and the real world	Intuitive buttons were chosen, and the information was presented in a logical and natural way. The sub-menus are properly identified with suggestive text.
3	User control and freedom	In order to provide the user with escape mechanisms in the event of an error, the user can always use the “Back” option.
4	Consistency and standards	All menus and buttons are used in the application in the same way, so that the user, when already used to, immediately looks at and intuitively realizes its action.
5	Prevention of Error	Error or information messages are shown to the user as soon as he performs an operation involving other processes. Offering feedback to the user means that he is constantly informed about the actions he performs.
6	Recognition instead of remembering	To minimize the amount of information to be memorized by the user, the application provides skeuomorphic buttons that can be easily recognized.
7	Flexibility and efficiency of use	Experienced users can take advantage of "accelerators" to be able to act more quickly. An example could be to search for a specific shared profile instead of viewing all shared profiles.
8	Aesthetic and minimalist design	Taking advantage of the design of some existing application platforms, it was possible to achieve a very minimalist and easy-to-use design. Note the addition of DarkMode for even better viewing convenience.
9	Error recognition and recovery	Error messages are provided in plain text, so there is no error on the part of the user.
10	Help and documentation	Some screens have a “?” Icon which can be selected for help on that specific screen.

Bearing in mind that this application will be used in an educational institution environment the following devices have been used for the Experimental Setup: a emulator on the PowerApps platform running on Google Chrome on an MacBook Pro 2.7 GHz Dual Core i5 Intel Core, iPhone 11 PRO 256 GB, iPhone 6 32 GB and Google Pixel 3.

Among the many possible tests, the most relevant were taken into account, depending on the needs of the project. These are Usability tests and Acceptance tests

Usability tests, which are carried out by real users, provide very important information on the functioning of the final product. The quality attribute Usability has a high priority and, as such, the 10 Nielsen Heuristics were followed during the development of the application. Heuristic evaluation is an informal method in which a number of people or evaluators are asked about different aspects of the design (Nielsen J., 1995).

In order to satisfy the 10 Heuristics presented below in Table 2, the following solutions have been considered. From Table 3, it is possible to conclude that all Nielsen Heuristics were considered. Consequently, all the proposed solutions were well adopted by the final user. Highlighting the minimalist design and the consistency of menus and buttons. Note the efficiency of search bars to give the final user a more effective and quicker method of finding out the specific Shared Profile/Document/Training Course.

Acceptance tests were carried out by the customer and by a selected group of students, after the usability tests presented in Table 4. Although customers were in direct contact throughout the development of the project (i.e. during Scrum meeting), the functional requirements have been validated in the end. The requirements have been set out and, if implemented, it has been checked whether the behavior was as expected.

Using the MoSCoW prioritization technique the following priority levels were used to classify the functional requirements: *Must Have, Should Have* and *Could Have*. The *Must Have* are the most wanted requirements of the customer. The *Should Have* represents the programing team suggestions. Finally, the *Could Have* are more related with future features the app could integrate (Tufail, 2019), (Khan, 2015).

Note the presence of a requirement that has not been implemented but that presents a medium priority and thus does not invalidate the success of the project. The "Requests" feature to confirm that the user really wants to be added could not be implemented as a higher priority has been given to all other features. This feature will be described and discussed in greater detail in the next chapter.

Note that, at the current date the app is already in “production” available for a Polytechnique school in Portugal, and there is ongoing negotiation to make available in other 7. Statistical usage metrics are being collected, some of them are presented in chapter 6, “Conclusions”.

Table 4 : Acceptance Tests

Acceptance Tests - Functional Requirements			
Requirement	**Priority**	**Implemented**	**Result**
View profile	*Must Have*	Affirmative	Positive
Profile Editing	*Must Have*	Affirmative	Positive
Add a new document	*Must Have*	Affirmative	Positive
Add a new Formation via QRCode restricting via GPS coordinates	*Must Have*	Affirmative	Positive
Possibility of adding Certificate to the training course that the student attended	*Should Have*	Affirmative	Positive
Possibility to see which more people attended the same training course as the user logged in	*Should Have*	Affirmative	Positive
Possibility to remove training courses from the list of training courses the student has attended	*Must Have*	Affirmative	Positive
Possibility to remove documents from the student's document list	*Must Have*	Affirmative	Positive
Restrict viewing of other users' information if they are not in the "shared profiles" list	*Must Have*	Affirmative	Positive
Add a new user to the list of shared profiles for the logged-in student	*Must Have*	Affirmative	Positive

Notify user that was added by another user	*Must Have*	Affirmative	Positive
"Requests" to confirm that a user wants to be added	*Should Have*	Negative	Negative
"Search" function on all screens that makes sense	*Could Have*	Affirmative	Positive
Dark Mode	*Should Have*	Affirmative	Positive
Development of a separate desktop application to be used by the person responsible for the training course to create the QRCode	*Must Have*	Affirmative	Positive

CONCLUSIONS AND FUTURE WORK

The aim of this chapter is to provide the reader with a general perspective on the development of the project, accomplished results, and presenting a critical reflection, including a brief description of the future work.

The various phases of development were followed through the Software Engineering processes, where the functional and non-functional requirements of the project to be developed were identified and prioritized, formalized and approved through meetings with the client.

Bearing in mind that one of the most competitive applications of the application developed in this project is LinkedIn, one of the major advantages of the Digital Student application is greater personalization with regard to specific features for each educational institution. We also consider that, the learning curve to start using the mobile application is also very low when compared with solutions such as LinkedIn.

The application developed in this project is already deployed and being used in a polytechnic in Portugal, with an acceptance, in the computer science department, of approximately 91.45% (based on usage logs cross-referencing, with a questionnaire to which 300 students responded). We expect another 7 institutes to adopt the platform within a year and based on the application usage logs, 70% of users have a profile with 87% of personal information filled out. It is also noted that the average time that each user spends weekly in the application is 14 minutes (with a standard deviation of 3 minutes).

Overall, the proposed application presents the following contributions: in 3 months after the release of the app, 15 users gave positive feedback, reporting that they got a job and 33 users reported that they would suggest the app to a friend. Globally all users found the app easy to use and a good/fast way to keep the curricular information always organized and updated.

Future Work

The life cycle of a software project is never really completed, there is always something more that can be done to improve the quality, complexity and efficiency of the project. This project is no exception.

During the implementation of the project, situations leading to the formation of ideas for future implementation have been idealized and analyzed. Some of these ideas are outlined below.

Firstly, the missing functional requirements will be implemented, namely the "Requests" to confirm that the user really wants to be added. In the future, and in a longer period of time, it would be very useful to be able to integrate this functionality in order to make an even stronger application available to any educational institution.

Also, for future work, one of the most interesting features would be the addition of three more applications. One of these applications is used to mark the attendance of students in the classroom, the other for the purchase of food at the bar, and finally the last one for booking books in the library. These features were discussed with all team members who developed the applications described above, and it was concluded that there were numerous advantages added to all applications if they were unified or

at least interconnected. One of these advantages would be that students would not need to have more than one application to do everything the three do.

Another important point, of course, would be the combination of the functionalities developed in this project with the interface and user experience developed, for example, by professional application designer. This would eliminate any flaw our team of development couldn't eliminate.

Consequently, the importance of referring to the improvement of the complementary application of the creation of the QRCode. This could then present dynamic fields in which the user would choose which and how many would be presented in the QRCode for improvement and greater complexity.

Finally, we also propose an automatic darkmode, based on illumination and time of the day. Additionally, and already under development, indoor accurate location detection, based on BLE beacons and the WIFI signal fingerprinting (Martins P., 2019).

ACKNOWLEDGEMENTS

Abstract

Features analysis such as, sentiment, colors, faces, objects are nowadays provided by web services which are dedicated to text analysis, images, video, and face recognition services. These services are a part of an overall Cloud-Vision process to determine the match-likelihood of each object/text/face to a template element from a database. Microsoft Azure is a growing suite of services in the cloud that provide among other services face recognition, video analytics, image analytics, text analytics to the general public, for instance: banking, public services, private companies, cellphone users. All of these potential users raise the interest in services that can be easily used and if necessary, to scale without a substantial initial investment.
In this article are tested and compared four cognitive (Azure based) services, first oriented to text, second oriented to detect general purpose objects in images, third for face recognition applied to photos, and finally, the fourth service oriented to video. All the services are described, tested and compared, regarding, how to set up, pros and cons, points in common, and their learning curve.

Keywords*:* Azure; Visual computing; Text analysis; Face recognition; Video; Sentiment; Cloud service; Cognitive.

Introduction

For the last decade that, cognitive applications can automatically identify emotions, objects, and faces on captured everywhere (e.g., images or videos), for instance in applications such as surveillance, airport security, law enforcement, and border patrol. Recognition algorithms analyze texts, images, faces, and videos, to extract information such as the shape, size, and position features, and then use these extracted features to search for matches. The algorithms of highest accuracy (e.g., over 90% for face recognition) typically require intensive computation (Yang et al. 2002), thus making very attractive the use of cloud services for such processing purpose.

Mobile devices have increased their computational capacity, with more memory, more processing power, storage, and sensing capabilities. Additionally, it is possible to rent computational resources using the available cloud computing data centers (Varia & Mathew 2014) (Cusumano 2010) (Buyya et al. 2008). This paper describes and compares four cognitive Azure Cloud services. First, Text Analytic service, which provides text analysis that allows detecting the text language, sentiment, entities and key expressions present in the text. Second service, Computer Vision, analyses an image and returns the elements present on it (e.g., celebrities, landmarks, cloths). The third service, Face recognition, whose function is to detect, identify and analyze faces of people in an image. Finally, the video indexer, which allows to identify and classify what is on a video (e.g., people, sentiment, text, clothes, objects, sound). Based on the study performed in this paper the compared cognitive services have their features and others in common. This paper is organized as follows; Section 2 resumes the

related work on the field of cognitive computation. Section 3 describes experimental setup for each service. Section 4 shows the comparison between the studied services. Finally, Section 5 Concludes the work and introduces some future work key points.

Resumed Related Work

Without a doubt, Artificial Intelligence (AI) is an important part of information technology today, and it will be more and more relevant in the future. Developers are using artificial intelligence in the form of services solutions offered by software giants.

Microsoft provides in their AI Platform a set of services and tools that applications can consume. The AI Platform includes services for creating bots; services for machine learning and deep learning; and services for analyzing pictures, real-time videos, and speeches (Del Sole 2018). In the same fields, other software services providers offer very similar services such as Google, Amazon, and IBM.

The access to services is done via APIs. Services are pre-trained and can be directly fed with the users' data to get instantaneous results. Thus, these services do not require machine learning expertise knowledge (Zhang et al. 2010).

Currently, these services APIs can be divided into four big groups:

1. Text Recognition, translation and text analysis (Cimprich et al. 2018);
2. Image recognition and analysis (Browning et al. 2018);
3. Video analysis (Yaseen et al. 2018);
4. Other related services (e.g. face recognition) (Dosaj et al. 2018);

When comparing speech and text processing from the four main cloud service vendors it is possible to find different support for different features. Table 1 enumerates the main features each one of the four main cloud services oriented to text analysis support.

Table 1: Text services comparison

	Amazon	Microsoft	Google	IBM
Speech to text	x	x	x	x
Text to speech	x	x	x	x
Entities extract	x	x	x	x
Key phrase	x	x	x	x
Languages	100+	120	120+	60+
Topics extract	x	x	x	x
Spell check		x		
Autocomplete		x		
Voice verification	x	x		
Intention	x	x	x	x
Metadata extract				x
Relations analysis		x		x
Sentiment	x	x	x	x
Personality				x
Syntax		x	x	x
Tagging		x	x	

Filter content		x	x	
Translation	6	60+	100+	21
Chatboot	x	x	x	x

From the analysis of Table 1, Microsoft cloud service for text recognition and analysis shows to be the most complete, i.e., with more features to offer.

Another cloud service featured by large software vendors is the image analysis service (Chang 2018). Table 2 compares the first image analysis clouds that provide this type of service(s).

Table 2: Image recognition services comparison

	Amazon	**Microsoft**	**Google**	**IBM**
Object detection	x	x	x	x
Scene detection	x	x	x	
Face detection	x	x	x	x
Face recognition	x	x		
Facial analysis	x	x	x	x
Inappropriate content	x	x	x	x
Celebrity recognition	x	x	x	
Text recognition	x	x	x	x
Written text recognition		x	x	
Search similar images			x	x
Logo detection			x	
Landmarks detection		x	x	
Food recognition				x
Dominant colors		x	x	

Based on the analysis of Table 2, Google cloud service, is the one with more features oriented to image analysis. Nevertheless, other services are also very complete.

Similar to text and image, video analysis of different software giants offers different features, except IBM that does not support video analysis. In the Table 3 is a comparison between cloud service providers for video analysis.

Table 3: Video analysis features comparison

	Amazon	**Microsoft**	**Google**
Object detection	x	x	x
Scene detection	x	x	x
Activity detection	x		
Facial recognition	x	x	
Sentiment analysis	x	x	
Inappropriate content	x	x	x

Celebrity detection	x	x	
Text recognition	x	x	
Person tracking	x	x	
Audio transcript		x	x
Speaker indexing		x	
Keyframe extraction		x	
Video translation		9 lang.	
Keyword extraction		x	
Brand recognition		x	
Annotation		x	
Dominant colors			
Real-time analysis	x		

Accordingly, with Table 3, Microsoft cloud is a winner. However, Amazon has the most efficient video analysis APIs as it supports streaming videos. This feature tangibly extends the spectrum of use cases (Li et al. 2018) (Varghese & Buyya2018).

Given all the previously studied related work topics, in this paper is focused on the Microsoft Azure cloud services oriented to text, image, face, and video analytic.

Experimental setup

In this section is introduced each cognitive service and the experimental setup used to compare the four services. For each service, a global description of the steps to set-up the services are given, then the description of the obtained output is enumerated. More forward in this paper, in Section 4, the results are shown, and features are compared.

Text Analytic

To test this service the following text of "Donald Trump" speech was analyzed:

> "Let us choose peace and freedom over domination and defeat. And let us come here to this place to stand for our people and their nations, forever strong, forever sovereign, forever just, and forever thankful for the grace and the goodness and the glory of God."

Then for the analysis of the text, the Azure API was set-up with the following steps:

- Get a subscription key on the azure portal on section "Cognitive Services".
- Use the http request URL:
  https : *//*[*location*].*api.cognitive.microsoft.com*
  */text/analytics/v*2.0*/*[*feature*]. The location can be set to "westeurope".
- Complete the feature of the URL depending on the desired return values; "languages" for the API to detect the language used; "Entities" will return the detected entities in the text;

"KeyPhrases" to return the key-phrases of the sentence; "Sentiment" will return a score of the detected sentiment of the text.

- Use the previous URL for the requests which can also be used to send the text to be analyzed (e.g.: the URL:
  https : *//westeurope.api.cognitive.microsoft.*
  *com/text/analytics/v*2.0*/language* will detect the language of the wanted text).

This service can as well detect text in an image. For that it uses an OCR service. Results are returned in JSON format and include:

- Detected language - returns a score between 0 and 1, the closer to 1, the more certain that the identified language is true.
- Entities - the recognized entities like company logos and celebrity names.
- Key Phrases - the most relevant key phrases in the text.
- Sentiment - Returns a score between 0 and 1 that indicates the sentiment of the text, being 1 a positive sentiment and 0 a negative one.

Face

The face recognition service receives a photo though an API, Figure 1, then Azure Face API processes the photo and return the results in JSON format. This service includes, face detection, find similar faces, group faces accordingly with face similarities and the face identification.

Figure 1: Azure Face API

This service was tested with two photos, Figure 2 and Figure 3.

The face detection includes several services. In this setup, we focus only on face detection. All the others follow the same logic. Then for the detection of faces, the service must be set-up by following the steps:

- Get a subscription on azure portal to face API, on section "IA-Machine Learning". In subscription its necessary choose an endpoint (location) and after that will be assigned the subscription keys.

  Create an HTTP request using the following syntax,
  https://[*location*].*api.cognitive.microsoft.com/face/v*1.0*/detect*[?*returnFaceId*][?*returnFaceLandmarks*][?*returnFaceAttributes*]

Figure 2: Face API test photo 1 **Figure 3: Face API test photo 2**

By default, is only returns the "FaceId" value, the other features are disabled, to obtain this value it is necessary to specify them. To return "faceLandmarks" values its necessary put "returnFaceLandmarks = true", and to return "FaceAttributes" it is necessary put the desired attributes, for example "returnFaceAttributes = age, gender, emotion".

- Put the subscription key on the request header.
- Put the image to detect on a *bytearraycontent*, with the header "application/octetstream".
- Execute the REST API call.

The outputted results include:

- faceId - unique values generated by API to identify detected faces.
- faceRectangle - rectangle coordinates for the face location on image.
- faceLandmarks - landmarks pointing to the important positions of face components.
- faceAttributes - specified visual attributes of a detected faces.

Digitized Image

This service detects objects in images (e.g., computer, piano, suite, animals) and text. This service provides more functionality; besides face detection, it also includes the text analytic among the detection of otherworldly objects.

Figure 4: Digitized image

In Figure 4, is the image used for testing the service. For the objects detection the service must be set-up by following the steps:

- Get a subscription key on the azure portal on section "Cognitive Services".
- Use the http request URL:

https : *//*[*location*].*api.cognitive.microsoft.com/ vision/v*1.0*/analyze*[?*visualFeatures*][*details*] [*language*].

- The location can be set to "westeurope".
- The visual features and details are based in what you want to receive in the output. The "language" is the one that will be used in the returned JSON can be for instance, "en" English (default) or "zh" simplified Chinese.
- Convert the image that will be analyzed in a byte-array. This array will be sent in the http request along with the previous URL.
- The subscription key needs to be sent in the http request header.
- Call the URL request with his header and the API returns a JSON file based on the information of the URL.
- For example, the URL to get a return of the categories and faces of an image it would be: "*https: //westeurope. api.cognitive.microsoft.com/vision/v*2.0*/analyze*? *visualFeatures = Categories,Faces*".

In this case the location was West Europe and the language was default (English).

The outputted results, in JSON format, include:

- Categories – categorizes image content according to categories defined.
- Tags - tags the image with a detailed list of elements related to the image content.
- Description - describes the image content with a complete English sentence based on the detected elements.
- Faces – Identify gender, age and face rectangle.
- ImageType – identify if the image is real, animated, clipart, draw etc.
- Color – indicate the dominant color and accent color.
- Adult – detects if the image is adult or racy content.
- Celebrities (details) – Identifies celebrities returning their names, face rectangle and the confidence (that is that celebrity).
- Landmark (details) – identifies landmarks returning their names and the confidence (that is that landmark).

Video Analytic

The video analytic service from Azure cloud applications (commonly known as Video Indexer) allows for a given uploaded video to detect all the previous services features, for instance: text, sentiment, sound, faces, persons, objects. Furthermore, it allows, other features, such as the creation of subtitles, jump in the video timeline to specific subjects or topics, follow where a person is on the video, detect textual or visual adult content and much more.

The following steps are required for the setup of the video detection service:

- Create an account at the web portal (https://www.videoindexer.ai/) made available by Microsoft, where the user will be able to upload videos and extract/analyze information through the use of a friendly interface.
- Sign-in into the Api-portal (https://api-portal.videoindexer.ai/).
- Subscribe the authorization Product.

- Start using the API services in “operations” through the use of access token (when required), generated by the authorization key, and the SubscriptionKey.

The output results can be viewed, through a web interface or via API, mostly in JSON format, which include the features of:

- Audio Transcription and visual text recognition.
- Automatic Language Detection (9 different languages)
- Caption of the videos(VTT, TTML and SRT).
- Detection of adult content, both visual and textual.
- Face detection.
- Celebrity identification.
- Speaker enumeration and statistics.
- Topic inference.
- Emotion detection (joy, sadness, anger, fear).
- Extraction of Artifacts (“next level of details”).
- Translation of the audio transcript to 54 different languages.
- Search of insights such as spoken words, actions, objects, people.
- Extraction of Artifacts (“next level of details”).
- Audio effects identification (hand claps,speech and silence).

The video used for the purpose of testing how this service can be setup and how it works can be found at the following link, https://www.videoindexer.ai/accounts/5ac76a34b397-41d5-ba1a-2f001891c357/videos/27152aad55/click here.

Comparison Evaluation

In this section the obtained results of the services are resumed and shown based on the input described in Section 3.

Text analytic

The previous results shown are relative to the quote in Section 3.1 where is being analyzed the language, sentiment, entities and key phrases (respectively). In the tests for analytic language detection output, it is possible to see the detected language with the level of certainty (in the case the score is 1.0, so it is certain that the used language is “English”).

Test performed to analytic sentiment, it is important to notice the score of the sentiment detected on the quote Being 1 a positive sentiment and 0 a negative one. In this case was 0.8 this means that the quote is a positive one.

For the detection of the entities present in the quote we can use analyze in Test done to analytic entities, in the results it we can see that the API detected the entity “Glory (religion)” and then it returns the “wikipediaID”, “wikipediaURL” and “bingID” for future searches related to the detected entity.

Finally, the output in tests with the analytic key phrases detection output result shows the key phrases detected on the quote.

Face Detection

The face API was tested with Figure 2, from which the returned result was not conclusive. After executing the face detection, the API does not return any results with the given image. This happens due to the fact that the faces, in image, are too small to detect, less than 36x36 pixels, leading to conclude that the face API is not efficient if the faces in the image are smaller than 36x36 pixels or image have very low quality. After this failed test, Figure 3 was uploaded and tested. This figure includes bigger faces and that make face detection better and more recognition precision. After execution, the Azure face detection on this image, the following result shows a resumed output in JSON with the detected face features.

Tests using Figure 3, the face API show output result having detected six faces (the JSON object shown only contain data from one detected face). For each detected face returned, is possible to observe values of coordinates of face location, FaceRectangle, and the important face components detected, faceLandmarks (e.g.: pupilLeft, pupilRight, noseTip). Also, it is possible observe other values of face attributes:

- Gender - it is the gender of a detected face, male or female.
- Age - is an estimated “visual age” in years.
- Smile - it is a number between 0 and 1 which represents smile intensity.
- Emotion - percentage of confidence for each emotion.
- Hair - this attribute returns three variables, if person is bald in percentage of confidence, if hair it is visible on image and, percentage of confidence for each common colors.
- Facial Hair - return a number between 0 and 1 for three areas: moustache, beard and sideburns. This number increases with the beard size.
- Exposure - It is a face exposure level, and can take 3 values: “GoodExposure”, “OverExposure” or “UnderExposure”.
- Accessories - Returns if detected face contains headwear, glasses or mask. If this attribute is empty, the face does not contain any of these accessories.
- Glasses - If person as wearing glasses, return which type of glasses (“ReadingGlasses”, “Sunglasses”, “SwimmingGoggles”), and if not wearing any, returns “NoGlasses”.
- Makeup - It is compound by two variables, eyeMakeup and lipMakeup, how can be true or false, depending of makeup detected in face.
- headPose - Contains the three angles for face direction (roll, yaw, pitch).

Digitized Image

The digitized service was executed with Figure 4, from which the following output was generated. For the Figure 4, it is possible to find, categories “abstract” and “outdoor” but due to low confidence, and it is possible to know that the API failed to return a trusted category. The description is separated into two topics: “Tags” - all the elements recognized; “Captions” - a brief description of the image with a confidence (between 0-1) based on the elements previously recognized.

Since with Figure 4 results were not the best, to better compare the results from this API and the Face API, Figure 3 was submitted to the digitized image API. For that we will only analyze the results that are more comparable between both APIs.

Tests with Figure 3, output results show that this API identified two of the people present in the image as celebrities presenting their names, the confidence and face rectangles. In the other important and comparable topic is the “faces”. Using the Digitized image, the output show the detection of the six faces presented in the image (only one example is shown because of its size). For each one of the detected faces there are three subtopics: “age” - age of the person based on his face; “gender” - gender of the person based on his face; “facerectangle” - subtopic that returns four positions for the caption of the face.

Now comparing this output result with the Face API result previously explained we can see that there are some similarities: Both API return the face rectangle, the gender and the age of a detected face. But they present some differences:

- Only the Digitized image API can detect and recognize a celebrity. The only way that the Face API can do that is if the face is compared with another face previously saved, in other words, the Face API only can recognize faces if that face was previously saved in the application made by the user.
- The Face API can not only return the face rectangle but also all the face landmarks, attributes and emotions being much more specific about the face analyze.
- Although not shown in this example, the Digitized image can detect text, landmarks and adult content.
- On the other hand, the Face API can compare faces and tell if it is the same person or not and organize many unidentified faces into groups, based on their visual similarity.

Video Analytic

The video analytic service besides the traditional API which returns a JSON file also includes a web-portal which allows the user to manage the output without having to write a single line of code, Figure 5. In this next example, in order to demonstrate the use of the API service we choose to use the “Get Video Artifact” API, that when called on a URL will retrieve insights or information, in format JSON, from a specified subject, in this case emotions that were detected on the video linked above which is located in our account. Test, video analytic output results demonstrate that it is possible to detect that all types of insights were indexed: the time range in the video where emotions were detected, as well as the duration; the dominant emotion detect on that time range and the probability, the dominant emotion is calculated by the fusion of the textual and vocal results, which contain the emotions detected and their probability, when merged they originate the fused results in which is determined the dominant emotion; the text in which the emotion was detected. This is just one of the many features that can be used through the API service. It can also be used to upload videos, extract and search all sorts of information to the developer’s applications, making them more intelligent, by having more discoverable content and engaging videos on their apps.

As we former mentioned Video indexer insights can also be viewed using a web portal. In this portal the information appears in a more engaging and accessible way to the user. In here we can play the video, Figure 5 on the left, and see the insights on the right. This portal can also be used for research of speeches, objects, people or topics, separately or as a group. Video indexing service has been and will suffer multiples updates through the years in order to not only

Figure 5: Web-portal video analytic output

extract information but also personalize, search or publish it. At this moment it can be best described as merger of Analysis Multimedia, Azure Search and Cognitive services being these, Face API, Microsoft Translator, the Digitized Image API and the Personalized Voice Service.

Conclusions and Future work

Text, image, face, and video cognitive recognition cloud services are becoming more accessible to the general public, without the need to acquire expensive hardware. In this paper, we make an overview of three services oriented for text, face, image, and video. The text detection service can also be found on the image and video service. Also, the face detection service is present on the service for the image (objects detection) and video. Table 4, shows a resumed comparison of the studied

Table 4: Different services Azure features comparison

	Text	Image	Face	Video
Text detection	x	x		x
Face detection		x	x	x
Objects detection		x		x
Emotion	x	x	x	x
Adult content	x	x		x
Celebrity Recog.		x		x
Language Recog.	x	x		x
Face comparison			x	x

cloud services. On the first horizontal row are the services, on the first vertical column the features. The "x" marks if each service feature is supported or not. Note that, during our tests, results from one service to the other, using the same input (e.g., same face), results were equivalent. As it is possible to observe from Table 4, different purpose services offer the same features. Also, necessary to refer that the emotion detection, is supported in all services, text, image, face, and video.

As future work, the studied services are going to be compared between different cloud services provides, namely, Amazon, Google, and IBM.

Abstract

Customer service is currently one of the tools for competing companies providing logistics services. The article is devoted to the logistic assessment of customer service provided by companies providing logistic services. The first part of the article focuses on the theoretical aspects in which the authors synthetically (based on a systematic review of the literature) explain the essence and elements of logistic customer service. The second part is devoted to the empirical analysis of the 3 surveyed companies providing logistic services. The article aims to present and evaluate the elements of logistic customer service according to division into pre-trade, transactional and post-trade elements in selected companies providing logistic services. The following companies were selected for the analysis: DHL, UPS, DB Schenker. The choice of these companies was dictated not only by the need to compare individual elements of customer service. It was also checked whether the methods of accepting orders / orders from recipients differ in the surveyed companies, as well as the methods and forms of measuring customer service and communication channels (information flow) between the company and the customer in the analyzed cases. The aim of this article is to present and evaluate the elements of logistic customer service, such as pre-trade, transactional and post-trade elements in selected companies providing logistics services.

Keywords: customer service, logistics customer service, logistics customer service management

Introduction

The saturation of the market with logistics companies means that the determinant of competition is not so much the availability of services, but the provision of them at the highest possible level. The quality of the services offered and the care for the needs and preferences of the client determine the competitive position of modern enterprises. The role of the final recipient and the importance of customer service are becoming increasingly important in business practice. Companies are trying to outdo each other in providing services at the highest level, at the best possible adjustment of the offer to the growing expectations of buyers.

Contemporary organizations are forced to look for new competitive tools that will allow them to stand out on the market and gain new customers. Therefore, in the competitive struggle, customer service, and above all its quality, is becoming more and more important. Biesaga-Słomczewska and Iwańska-Knop explain that this is the company's professionalism manifested in maintaining appropriate standards at every stage of the logistics process. It is about the moment when the customer places an order, up to the final delivery (E. J. Biesaga-Słomczewska, K. Iwańska-Knop). Current customers, when making purchasing decisions, are guided not only by the functionality and features of the product / service, but more and more often they take into account professional and fast service, which provides

Cite this Article as: Iwona WASIELEWSKA-MARSZAŁKOWSKA and Katarzyna SAMEK " Logistic Customer Service on The Example of Selected Logistics Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

them with added value and increases their satisfaction and satisfaction with the purchase. Customer service, therefore, plays an important and indisputable role in this respect, which allows to build trust between the company and the customer, which turns into long-term partnerships.

The dynamics and competitiveness of the modern market makes logistic customer service an important success factor for enterprises operating on the market. Therefore, it is necessary to improve the elements influencing the level of logistic customer service. Taking appropriate actions in this area, and thus preparing and implementing an appropriate logistics strategy for customer service, becomes important from both the survival and development of the company, as well as achieving a sustainable competitive advantage. It is therefore reasonable to research and evaluate the logistic customer service in modern enterprises, taking into account its individual elements. This is particularly important in the logistics supply chain, where customer value, satisfaction and trust are capital that increases the market value of each link in the chain (Maik, 2012).

Methodology

A systematic review of the literature was carried out, the method of non-participant observation was used in the empirical research, and the texts (reports, notes and announcements) of the surveyed companies were analyzed. In the conducted research, the authors used the triangulation technique based on the approach of N. Denzin (Denzin, 1998) and M. W. Lewis (Lewis, 1998) and W. Czakon (Czakon, 2016). The literature review was carried out in 5 stages, i.e. defining the aim of the research, selecting the basic literature, selecting publications, developing a publication database and analyzing the content. Full-text foreign databases such as Emerald Insight, SinceDirect, Scopus®, Springer Nature Journals, Web of Science, Wiley and Polish databases - BazEkon and Ceon were analyzed. The EBSCO Discovery Service tool was used to search for publications. The non-participant observation method was used to conduct qualitative research (in the empirical part), based on the opinion of Z. Kędzior (Kędzior, 2005), M. Stickdorn, ME. Hormess, A. Lawrence, J. Schneider (Stickdorn et al., 2018), and J. Apanowicz (Apanowicz, 2002), treating this method as a method that differs from simple perception in that it is a continuous and purposeful process. Also, the authors share the views of F. Liu and S. Maitlis (Liu, Maitlis 2010), who claim that observation is often used in conjunction with other methods of data collection, at the same time allows the researcher to detailed and dynamically assess situations that cannot be so easily captured by implementing other methods. The observation method became the starting point for text analysis (Czakon, 2016). In the adopted method of text analysis, the data sources were reports, notes and announcements of the surveyed enterprises published on their websites.

Purposive sampling was used, (non-random, non-probabilistic selection): 3 deliberately selected logistics service providers. The selection in the targeted selection of the surveyed enterprises was based on the adopted criteria:

- the first criterion: the geographical scope of the logistics services provided: EU countries and / or North and South America),
- the second criterion: the range of services offered: courier services, logistics operator, customs services)
- the third criterion - the type of transport used in the logistics services provided: minimum road transport.

Conducting the research allowed the authors to invite scientists and practitioners to discuss the recommendations for companies proposed by the authors regarding effective customer service. Moreover, compared to previous research carried out by other scientists with the use of quantitative methods, the adopted methods allowed for an in-depth analysis of the problem and the issues raised.

The following companies were selected for the analysis: DHL, UPS, DB Schenker. The focus was also on checking whether in the surveyed companies due to changes in the manner of customer service, in the methods and forms of measuring customer service and in channels with the customer. In this regard, research questions:

- Are there indicated departments / units dealing with customer service in selected companies?
- How is customer opinion research carried out in the surveyed companies?
- What other solutions in customer service should the company introduce?

Characteristic and Elements of Logistic Customer Service - A General Theoretical Framework

The role of customer service in the activities of enterprises began to be noticed in the 1980s with the development of marketing evolution. It was identified mainly with the possibility of submitting complaints and grievances about the insufficient quality of services or products offered. Due to the changes taking place in the market, organizations began to attribute a different meaning to customer service. It was argued that the market success of an enterprise depends not on the number of submitted customer comments, but on attracting buyers and building long-term relationships with them. It was influenced by customer service provided at the highest level.

In the literature on the subject, there are many definitions relating to customer service, hence it is difficult to provide a universal explanation. When talking about customer service, we mean, first of all, "a whole range of needs that the customer has not identified and defined at a given moment" (Biesaga - Słomczewska, Iwińska - Knop, 2000). The task of the company is to recognize these needs and, if possible, to quickly respond to them. Thus, the level of customer service consists of many factors, such as (Leland, K. Bailey, 1999):

- "knowledge of not only the needs, but also the desires and expectations of customers,
- knowledge supported by experience,
- knowledge of the product and translating its features into the language of benefits,
- seller's involvement".

The modern economy is characterized by high volatility, creating increasingly difficult conditions for functioning. This, in turn, increases the risk of actions taken by the enterprise, and achieving success is much more difficult. A chance for success on the market may be for the company to focus all its activities around the needs of the final buyer as well as to satisfy higher and higher demands. The way to success is the ability to create a distinctive and unprecedented way of satisfying needs by offering a one-of-a-kind product with many benefits. However, simply acquiring a client is not enough, you have to keep him with you. In the concept of relationship marketing, attention is drawn to the fact that the company's success consists not only of the ease of acquiring an increasing number of customers, but most of all the ability to maintain regular and loyal customers (Wilmańska-Sosnowska, 2001). Regardless of whether the customer at the moment considers himself a person worthy of attention or not, he expects the service to take great care and understand his needs. Thus, the level and quality of the service provided are significant here.

The previously presented definitions of customer service can also be applied to logistic customer service, which K. Halicka and S. Święcicka define as "the ability to meet customer requirements and expectations, mainly concerning the place and time of ordered deliveries, using all available forms of logistics activity, including transport, storage, inventory management, information and packaging "(Halicka, Święcicka, 2012). In turn, D. Kempny defines logistic customer service as "a system of solutions that ensures such relations between the time of placing the order and the time in which the product was delivered to the customer, to fully satisfy him and maintain this satisfaction for the longest possible period" (Kempny, 2008).

The importance of customer service in logistics[1] processes and activities is so important that today we refer to the term "customer logistics". It is a process that guarantees a competitive advantage and

[1] The analysis of the literature regarding various interpretations of the essence of logistic customer service included in the literature was outlined in detail in the earlier article entitled *Customer Service in Logistics - a theoretical framework* (Samek, Wasielewska-Marszałkowska, 2020).

additional benefits by managing the supply chain in such a way as to constantly maximize the added value for the final buyer (Kempny 2001). The determinant of logistic customer service is therefore a logistics system that fulfills its role in creating the usefulness of place and time for the product, including customer support after the purchase (Kempny 2001). This in turn determines the level of customer satisfaction regarding time, communication, reliability and convenience of delivery.

Logistic customer service consists of such elements as (Biesaga - Słomczewska, Iwińska - Knop, 2000):

- order fulfillment time,
- service reliability,
- flexibility and completeness of deliveries,
- stock availability,
- ease of placing an order by the customer,
- constant and easy way to obtain information,
- simple forms of documents that must be filled in when placing an order,
- convenient payment terms,
- the quality of the packaging, which has a significant impact on transport and storage.

The high complexity of logistic customer service forces companies to strive to standardize service processes. This is a kind of response of the company to market needs, categorized according to individual customer segments. Accepting and categorizing individual elements of logistic customer service takes place through their positioning and assigning values to individual areas and components from a given area.

All activities related to logistic customer service can be divided into three phases. There are elements in the pre-trade, transactional and post-trade phases (Fig. 1).

ELEMENTS OF THE PRE-TRANSACTION PHASE:	ELEMENTS OF THE TRANSACTION PHASE:	ELEMENTS OF THE POST-TRANSACTION PHASE:
• Written customer service policy. • The client is familiar with the company's policy in the field of customer service. • Sensitive organizational structure. • Flexible delivery system.	• Stock level. • Information management. • Order cycle items. • Speed of shipping handling. • Special shipping operations. • Accuracy of ordering. • Substitute products.	• Installation, assembly, warranty service, changes, adjustments, repairs, spare parts. • Product monitoring in operation. • Customer complaints, complaints, returns. • Temporary availability of a replacement product.

Figure 1: Elements of logistic customer service

Source: La Londe, B. J., & Zinszer, P. H. (1976), Customer service: Meaning and measurement. Chicago, IL: National Council of Physical Distribution Management, p. 281, za: D.M. Labert, J.R. Stock, L.M. Elram, Fundamentaals of Logistics Management, McGrow-Hill, Boston 1998, p. 44, in Ciesielski M. (2006), Logistyka w biznesie, Wyd. PWE, Warszawa, p. 134.

The first phase of logistic customer service - pre-transaction - involves preparing the company for customer service. The elements included in this phase are particularly important because they determine the perception of the company in the market environment, as well as shape the client's needs and affect his overall satisfaction. Certainly, these are activities that require a holistic, non-routine view of the company and therefore the management team is usually responsible for this area (Sułkowski, Morawski 2012). These activities should be established before the customer service standards are launched in the company (Ciesielski, 2006, Kempny, 2001).

The second group of logistic customer service elements consists of the transactional phase elements that relate to the direct contact of the company with buyers. Their proper fulfillment depends mainly on the level of customer satisfaction. Therefore, enterprises are advised to constantly monitor these

elements, look for possible shortcomings and effectively eliminate problems that arise at this stage of customer service.
The last group of customer service elements are post-trade elements, enabling the company to extend contact with the buyer. Nowadays, when enterprises fight among themselves to provide the highest possible customer service, to retain regular and potential buyers, post-transaction elements are gaining in importance (Rutkowski, 2005). Figure 1 contains the elements of logistic customer service indicated for each of the phases.

Regardless of the phase of logistic customer service, the basis of the company's operation and the pillar of effective service is understanding the needs of end buyers. This is a challenge for contemporary organizations. It is helpful to develop an effective, modern and, above all, meeting the market needs of a logistic customer service strategy. And Baraniecka emphasizes that when creating it, organizations should remember about the principles of transparency, honesty and partnership with the client (Baraniecka, 2011). However, practice shows that these measures are not easy to implement. Enterprises struggle mainly with the problem of habits and mentality of employees who are responsible for customer service. The fault is also with the customers themselves, who are by nature opportunistic towards the introduced rules.

Logistics Customer Service – Presentation Selected Results of Empirical Research

Example Logistics Customer Service in DHL[2]

DHL is a leading global provider of logistics services. In 1969, Adrian Dalsey, Larry Hillblom, and Robert Lynn founded DH (Fig. 2). Currently, the company employs 380,000 people, and provides logistics services in over 220 countries (Fig. 3). The company offers a wide range of logistics services, including: courier services, Road Freight (Flexible and reliable. Comprehensive options - pallets, groupage, full and part truck loads), Rail Freight (Secure, reliable and cost effective transportation operating) , Customs (Reduce complexity, delays and penalties with our brokerage and consultancy services.), Transport Solutions (Customized transportation solutions across your value chain.), Integrated Solutions (Comprehensive, bespoke, holistic solutions covering transport, warehousing & management services.), Global Forwardins (Air and Ocean Freight - SeAir - Multimodal Air & Ocean Freight), Road Freight, Rail Freight), Additional Servicec (DHL Cargo Insurance), DHL Supply Chain (World's leading contract logistics provider). DHL provides services for many industries, for example: Automotive, Chemicals, Energy, Engineering & ManufacturingSector, Life Sciences & HealthcareSector, Public Sector e-commerce, Technology and Retail Sector.

[2] Own study, based on information available on the website https://www.dhl.com/en.html, [Retrieved July 12, 2020].

Figure 2: Historic dates at DHL

Figure 3: DHL in numbers

Source: https://www.dhl.com/gb-en/home/about-us/global-network.html [Retrieved July 12, 2020].

In Logistics Customers Service, DHL dedicates for clients a separate tab on the website and subpages of the services provided. Among the pre-transaction items at DHL Website, Vision and actual Strategy company - it covers the most important directions of the company's activities, the need to continue the previously adopted goals is indicated, the main motto "With its" Strategy 2025 - Delivering excellence in a digital world "the Group is laying the foundation to continue its successful growth trajectory beyond the horizon defined by the previous "Strategy 2020". "Deutsche Post DHL Group has never been in better shape. We are convinced that future growth will come from a consistent focus on our profitable core logistics businesses - and digitalization will become the greatest lever," said Frank

Appel, CEO of Deutsche Post DHL Group , during the presentation of "Strategy 2025" in Frankfurt am Main. "We need not reinvent ourselves. We will digitalize ourselves".

The observations show that there is no possibility of finding the organizational structure of the company on the company's website. A clearly defined organizational structure of the company would allow for efficient finding of data for the relevant departments of the organization, including managers managing individual departments.

Analyzing the observed pre-trade elements, such as the flexibility of the delivery system and service management, it was concluded that these elements were briefly and clearly described (both for potential customers and groups of regular service recipients). Among the information included, customers can find aspects related to the services offered, contact the customer service provided on the subpage dedicated to customers. The subpage contains contact details in the native language of the country the customer is looking for, in which country DHL provides logistics services.

Among the pre-transaction elements, it was noticed that the company's website contained information on training courses and instructions, reports in PDF for customers. Customers will also find information on how to search for an expected shipment (Track Your Shipment). Besides, detailed information on customs services (including preparation of customs documentation, terms of delivery INCOTERMS®2010 and INCOTERMS®2020) and answers to frequently asked questions by customers were included.

The transactional elements of customer service in DHL play a key role in the efficient and effective implementation of logistics services. The possibility of monitoring the shipment, the possibility of postponing the delivery date, the choice of an alternative means of transport as well as the convenience of placing orders is particularly important for the customer in this phase. During the observation of the elements of this phase, the authors noted that the designed page for logging in for regular and new customers (Customer Portal Logins) efficiently enables customers to find aspects of interest to the customer, from monitoring the shipment through monitoring "real-time inventory items and order statuses at the warehouse level in entire network, enabling you to transform newly available end-to-end supply chain operations into a competitive advantage. ”

Customer Portal Logins has been divided into sub-chapters in which the customer finds a wide spectrum of possibilities and solutions related to individual customer interests (Fig. 4).

Figure 4: Customer portal in DHL

Source: https://www.dhl.com/global-en/home/login.html [Retrieved July 12, 2020].

Similarly to the elements of the transactional phase, as well as in DHL's post-transaction, the key role is played by a portal specially dedicated to customers, called "Customer portal". If there is a need to file a complaint, change the place of delivery of parcels or order statuses at the warehouse level (SCM), customers can immediately contact the customer service department or verify, file a complaint and solve the problem by logging into the portal.

According to the authors, an important role is played by the subpage "GLOBAL PRESS RELEASES", in which the company, apart from reports and current results of the group (EBIT), informs customers about plans and implemented projects. DHL also dedicates the "Media Center" subpage that has been created, which includes press releases, multimedia materials, a list of press events and a direct link to DHL spokespersons. Besides, customers will also find information on the certificates held by DHL, current messages on the COVID-19 epidemic (COVID-19 UPDATE) containing tips and guidelines relating to the sanitary regime and preventing the spread of the epidemic. This information is updated for both customers and employees of the group.

DHL also uses social media such as Linkedln, Facebook, Twitter, Youtobe and blog. Key information, publications and company reports are posted on social networks.

Undoubtedly, important information for customers are the information published on the DHL Sustainability Report website and information relating to the company's innovation and experience in the implemented innovative solutions tailored to the sectors served.

Example Logistics Customer Service in UPS[3]

UPS was founded in 1907 in Seattle, Washington, is now one of the global courier service providers (CEP), and offers a wide range of services, including: logistics and distribution; transport and freight (air, sea, road, rail); Freight shipped to 195 countries and territories; international trade management

[3] www.ups.com [Retrieved July 12, 2020].

and customs brokerage. As part of special services, the company offers: logistics of service parts; technical repairs and configuration; development and planning of supply chains, management of returns. Key information about the company, including the company's history, facts and figures, cooperation, locations and services offered, can be found on the "About UPS" subpage. The customer can efficiently find the information he is looking for. The strategy, vision, mission and values of the company were communicated to clients on a dedicated "About UPS" subpage (for example: "Our Enterprise Strategy: Create Value, Transform, and Invest to Grow"). The organizational structure of UPS, like that of DHL, has not been indicated on the website.

The results of the study by the authors, including the observation of elements of the pre-trade phase of UPS, indicate that the information for the customer was published transparently. By examining the elements of a flexible customer service system, as well as procedures, instructions and training in the field of customer service, it can be concluded that they are clearly described. On the website, UPS provides the customer with "Service Terms and Conditions" and "Customer Solutions Terms and Conditions". Each customer can use the website to search for the topic of interest, from checking the shipment number to selecting other services offered (for example, a separate "Help and Support Center" page) or by using the "search engine" field. In cases where the client does not find answers to the questions bothering him, he can use the virtual chat platform (Fig. 5). Customers starting their cooperation with UPS can find action steps, guidelines and helpful information on the dedicated "Get Started with UPS" subpage. The authors, after observing the elements of customer service in this phase, distinguished in favor of UPS, the activity of publishing, apart from information in the form of short instructions, an additional solution, such as videos with instructions for customers, including fundamental solutions for the customer, e.g. shipment preparation, shipment tracking, change of delivery etc.

Figure 5: Customer portal and wirtual chat portal in UPS
Source: https://www.ups.com/us/en/Home.page [Retrieved July 12, 2020].

The transactional elements of customer service are closely related to the elements of the pre-transaction phase and indicated on the UPS website and dedicated subpages of Quick Start, Help and Support Center, Customer support. In this phase, time is a very important aspect, which plays a key role for the customer in the provision of services by logistics companies. The elements of the transaction phase observed by the authors correspond to the range of services offered. In each of the services, you can distinguish elements related to Inventory level, Order cycle elements, Substitute products - for example, "contract logistics" service, "supply chain planning and design" (https://www.ups.com/us/en/services/contract -logistics / design-planning.page?) ". The client finds detailed information on information management, including IT technologies and tools, logistics infrastructure as well as aspects related to customs services and supplier management. Elements of this phase, such as: speed of shipping service or operations related to shipping and accuracy of ordering, can be verified by the customer at every stage of the order / order using an individual / institutional login to the customer's account.

In the post-trade phase, a customer who intends to file a complaint can find detailed information regarding the complaint on the subpage: https://www.ups.com/us/en/help-center/claims-support.page? Customers may submit a complaint due to: loss of the parcel, damage or unclaimed parcel on delivery. All information relating to the complaint handling process and the required documentation are provided to customers in the form of information and answers to frequently asked questions.

It is also worth mentioning that to efficiently flow information for customers and acquire new customers, UPS uses social media. Among the social media, USP uses: Facebook, Linkedin, Twitter, Youtobe and UPS Blog. According to the authors, an important role is played by information on the results of sustainable development and corporate social responsibility (CSR) published in the form of reports on a dedicated subpage of the company. The website reads: "UPS is a global leader in logistics, employing more than 495,000 employees and serving 11.5 million customers daily in more than 220 countries and territories. In 2019, we made 5.5 billion calls worldwide, delivering over 21 million packages every day. Sustainability is an integral part of UPS's business strategy and operations[4]".

Example Logistics Customer Service in DB Schenker

The company was founded in 1872 in Vienna by Gottfried Schenker under the name of Schenker & Co. Today, DB Schenker is a leading provider of global logistics services - serving industry and trade in the global exchange of goods using land, air and ocean freight, contract logistics and supply chain management. The company is a logistics leader for the automotive and technology industries, consumer goods, trade fair logistics, special transports and special event logistics. DB Schenker Group is a transnational corporation operating in the TSL industry. It employs approximately 76.1 thousand. employees in about 2,000 branches around the world.

The company cares about customer relations, hence it provides high-quality services tailored to customer expectations. Employees responsible for customer service communicate with customers through all possible channels, e.g. through direct contact via couriers and sales representatives, managerial staff, daily operational support of Customer Service Departments, efficient invoice and complaint handling. Customer satisfaction is the key goal of the company's operations. Organization of regular surveys of clients' opinions on the quality of services with the help of independent research companies. The company publishes the results of the customer satisfaction survey on its website (the results of the survey from 2013 and 2014 are presented in Fig. 6). Additionally, the satisfaction of shipment recipients with the services provided by couriers is measured.

Year	Number of respondents	NPS[5]
2013	272	28%
2014	226	34%

Figure 6: Results of the Customer Satisfaction Survey in 2013-2014

Source: http://2014.dbschenker-csr.pl/ekonomia/relacje-z-klientami#, [Retrieved July 15, 2020].

DB Schenker offers a wide range of logistics services, such as: land transport, air transport, ocean freight, contract logistics, lead logistics and special products. Necessary information about the company, such as the offered products, solutions for various industries, information about the company

[4] https://sustainability.ups.com/media/sustainability-strategy_global-value-chain.pdf [Retrieved July 12, 2020].

[5] Customer satisfaction of DB Schenker Logistics is measured based on the NPS (net promoter score) approach. The survey consists in obtaining an answer to one question regarding the willingness to recommend our services to a friend or friend. Depending on the answer given on a 10-point scale, the respondents are divided into 3 groups of clients: promoters, passive clients and critics. By subtracting the percentage of critics from promoters, we get the net result, i.e. the net promoter score. The survey is carried out using the method of telephone interviews, website: https://www.dbschenker.com, [Retrieved July 15, 2020].

and career, was posted on the company's website. In the "About us" tab, the customer can read the company's description in detail, which includes such information as: company profile, management board of the DB Schenker Group, transport logistic trade fair, strategy, lean and quality, compliance with regulations, history, press releases, customer newsletter, sustainable development, social report, employee volunteering, security, career. The organizational structure of DB Schenker, similarly to that of DHL and UPS, has not been indicated on the website.

The study included the observation of elements of the pre-trade phase of DB Schenker. The results prove that all the information necessary for the client has been posted on the website transparently and understandably. Analyzing the secondary materials for this study, the authors state that the written customer service policy and service management have been clarified, including the data protection rules in dbschenker.com/global, which the customer can read on the website. When reviewing the company's website, it can be noticed that the organization cares for efficient and fast customer service, using an Internet solution for this purpose. The procedure for completing all formalities and specimen documents related to the establishment and implementation of cooperation, the company publishes on its website. The forms include: national land documents, ocean documents, international land documents, aviation documents, railway documents, complaint notification or e-invoice. Also, on the website, the company has a special tab "Connect 4.0" and the possibility of talking to the company's representative via a virtual chat (Fig. 7), thanks to which the customer can make an immediate quote, send an online order, and transparently track the order. In this way, DB Schenker offers trouble-free handling of B2B inland shipments. Regardless of whether the customer needs a truck or other means of transport, connect 4.0 will evaluate the transport in real time and show the estimated delivery time and ensure the transport of the shipment.

Figure 7: "Connect" tab and virtual chat on DB Schenker website

Source: https://connect.dbschenker.com/app/connect/land?step=landing&state=f8a02f06-6075-408a-b37f-fe9cd0719576. [Retrieved July 16, 2020].

Each client can use the website to search for a topic of interest, from reading the company's history to selecting the services offered or using the "search engine" field. After observing the elements of the pre-transaction phase and analyzing secondary data (reports, monitoring, customer service quality books), the authors also highlighted additional activities of DB Schenker in the area of customer service. The organization is focused on cooperation not only with individuals but also on establishing B2B relationships. The website also offers services targeted at specific sectors of the economy, which makes it much easier for potential business partners to choose the right products and logistics solutions. With customer satisfaction in mind, the company has additionally introduced a dedicated application "Drive4Schenker" as part of the DB Schenker Connect 2 Drive service (Fig. 8). Drive4Schenker is an internet exchange platform with offers for full truck loads and part loads. Intelligent search (load size,

location, prices) helps customers find exactly the kind of transport they are looking for. Therefore, it can be concluded that the elements of the pre-transaction phase of customer service at DB Schenker are not only available to customers but also tailored to the needs of individual customers (B2C) and business partners (B2B).

Figure 8: Dedicated mobile application from DB Schenker

Source: https://play.google.com/store/apps/details?id=com.dbschenker.mobile.drive4schenker&hl=pl, [Retrieved July 16, 2020].

Another subject of the observation of logistic customer service at DB Schenker was the elements of the transaction phase. This step looked at aspects such as inventory levels, information management, order cycle items, shipping speed, special shipping operations, ordering accuracy, and substitution products. Summing up, the authors stated that these elements work to the benefit of the examined company. Additionally, thanks to the innovative e-Schenker solution (Fig. 9), the organization efficiently and transparently manages the flow of information, providing customers with the necessary information about the shipment. The application brings together all the company's eServices for international land, ocean, and air transport. Gives customers visibility into all modes of transport - making it easier to manage the supply chain. The wide variety of services of the company include placing orders, advanced shipment tracking, reporting, and many other new logistics solutions.

Figure 9: eSchenker service

Source: https://eschenker.dbschenker.com/app/launch-page/public?language_region=en-US_US, [Retrieved Lipiec 15, 2020].

Elements of the post-trade phase were the last subject of this study at DB Schenker. The following components were taken into account: installation, assembly, warranty service, changes, adjustments, repairs, spare parts, monitoring of the product in operation, customer complaints, complaints, returns. temporary availability of a replacement product. Customers can submit a complaint both using a dedicated form (available on the website) and using the dedicated e-Complaints service. Thanks to it, the entire complaint process is available on-line. All the customer needs to do is log in to e-connect and fill out a short electronic form, and DB Schenker employees will immediately start the complaint handling process. Information in the e-connect system allows for ongoing tracking of the complaint submitted by the customer. He is informed about each change of status by e-mail.

A definite advantage of the company is the implementation of e-Services, thanks to which all elements of customer service can be performed on-line. The company uses social media to reach new customers, and above all for the rapid flow of information. For this purpose, it uses YouTube, Linkedin, and Facebook, where it presents a wide range of multimedia and enters into relationships with customers, sharing logistics solutions with them. Overall, customer service at DB Schenker plays a key role. The company tries to provide clients with the highest quality of all elements included in the pre-trade, transactional, and post-trade phases, which translates into customer satisfaction.

Research summary

The results of the research presented in Figure 10 make it possible to answer the following research questions posed as part of the conducted research.

Elements of the pre-transaction phase	Elements of the transaction phase	Elements of the post-trade phase
• a dedicated subpage with information about the company (key data, facts, mission, vision, range of services offered, geographical locations of branches) • terms of cooperation, legal notices, regulations for the use of services • instructions, presentations, online videos: informing about the preparation of the shipment, location of collection / shipment points • virtual chat • online inquiry questionnaire • search • the most frequently asked question	• ongoing search and monitoring of the shipment, • change of delivery date • dedicated login pages for individual / institutional clients	• dedicated subpage for customers - complaint • necessary documents to consider the complaint • answers to frequently asked questions • use of social media

Figure 10: Customer service elements identified in the surveyed companies
Source: own study based on the results of conducted research.

Are there any departments/units dealing with customer service in selected companies?

All surveyed companies indicated on their websites departments that deal with customer service. Even though there is no organizational structure on the websites of companies, customers can contact the customer service department. You can contact the employees of the companies by phone or e-mail. A dedicated customer service hotline allows you to track the shipment, employees also solve various customer problems. In individual phases of the execution of orders/orders, the customer can also contact using online contact forms or log in to his account. Also, on the company's website, it is possible to ask questions to company representatives using a virtual chat. Unified and tailored to the client's needs interfaces placed on the websites of the surveyed companies allow for quick and trouble-free integration of all business processes, enabling direct customer contact.

How is customer opinion research carried out in the surveyed companies?

The high quality of the services offered in the surveyed enterprises is supported by the care of detailed information on the websites of the companies. Enterprises demonstrate a high level of responsibility and openness to implement changes, innovative solutions in the services offered to the client, publishing CSR, and sustainable development reports. Analyzing the aspect of the method of conducting customer surveys, the authors identified that only one of the surveyed companies publishes reports and results of customer satisfaction surveys. However, information on the form of monitoring customer satisfaction was not provided on the websites of other companies.

What other solutions in customer service should the company introduce?

The authors recommend publishing reports on opinion polls and customer satisfaction surveys as important for implementation in practice by enterprises. It is worthwhile for the organization to research and publish customer reviews in such places. Today, the analysis of opinions in the Internet space is a key source of information that customers reach for before using the services of a given company. The authors, therefore, recommend that logistics companies such as DB Schenker monitor and learn about customer opinions, especially in social networking sites, opinion portals, internet forums, or personal blogs. The analysis of opinions in the virtual space may indicate not only what elements of the offer

require changes, but also what areas of the customer service process should be improved. The organization could also extend the field of customer surveys (CATI and CAWI non-training quantitative surveys) with new online measurement tools that guarantee a quick return of results. Customer satisfaction surveys should be carried out with the use of ready-made tools - such as SurvGo. As a result, the company will receive results in less than 48 hours. Besides, employees will be able to track the progress of the survey in real mode, modify the content of the surveys, and generate automatic reports. On the one hand, reports and information from the conducted research provided to clients on the websites of enterprises mean that enterprises are open to react and improve the services offered, and on the other hand, they will enable the elimination of errors in the process of implementing new services.

Discussion

In this section, the authors refer to the analysis of the research results. Based on our empirical findings and based on a systematic literature review, we propose the following recommendations for companies providing logistics services in the field of logistic customer service:

1. Logistics companies must be aware of the fact that today's customers are more and more demanding and be aware of what they expect from the company. They want not only the correct service but also that companies keep up with the prevailing technological trends. It is about the need to support service activities with dedicated IT systems. It is mainly influenced by people from the Y generation, who currently drive the economy and set market trends. They are a group of highly demanding customers who are familiar with new technologies and who spend a lot of time on the Internet. Companies that want to serve customers from the Y generation, aged 20-30, must adapt customer service so that it is in line with current technological trends and growing market requirements.
2. Effective logistic customer service would not be possible without the support of IT systems. Companies aspiring to be competitive are forced to build relationships with customers based on modern IT tools, call center applications, CRM systems, or e-mail marketing systems. Currently, it is also more and more common to monitor social media in the SaaS model (software as a service).
3. Companies should be aware of the growing role of the customer, therefore periodically (e.g. once a quarter) they should survey their recipients, using the tools offered by social media. The survey questionnaires made available may concern the needs and preferences of customers, as well as their opinions on the services and products offered.
4. Companies that want to improve customer service should use personalized offers and modern service applications dedicated to customers.
5. Another solution recommended by the authors is to present the organizational structure of their enterprises. The published structure will allow clients to get acquainted with the contact persons of individual departments, it will allow them to find out which manager and department for which area they are responsible. Access to the organization chart can also be helpful for potential clients interested in starting a cooperation with the company.

According to the authors, the undertaken research issues and the proposed recommendations invite representatives of science and practice for further discussion in this field. Moreover, the authors, sharing the views of Daugherty et. al. (Daugherty et. Al, 2018) believe that contemporary research on the issues of logistic customer service should also be focused on aspects related to logistics services provided for customers under omnichannel and e-commerce supply chains.

Summary

This article focuses on the development of proposals to improve individual elements of logistic customer service in the surveyed companies, allowing it to be better adapted to the requirements and preferences of customers. The obtained results may, therefore, be useful for enterprises that want to achieve a permanent competitive position by improving the provided customer service. The presented solutions can be used as guidelines aimed at improving individual elements of logistic customer service. They can also be useful for those companies that are starting to operate on the logistics services

market and are looking for good practices in the field of logistic customer service. The results of this study may also be helpful for anyone who wants to use the services of the surveyed companies. The analysis may also bring benefits to potential clients who are considering establishing cooperation with one of the surveyed companies. However, the authors are aware that the effectiveness and efficiency of the customer service used to a large extent depend on the proper recognition of the needs and preferences of customers. As a result of the increasing technological progress, the requirements of current and potential customers are, however, constantly changing. Therefore, in this area, it is necessary to constantly monitor not only the level of customer service provided, but also (if not primarily) to observe market needs

Abstract

The aim of the article is to present a systemic and cybernetic approach which is supplemented by a praxeological theory of human action in the context of creating theoretical framework for the analysis of the issues connected with management sciences. To achieve this goal, the essence of management sciences and the object had to be established with the consideration of the concept of organisation as a specific system capable of action. In the deliberations presented in the article, a systemic analysis of organisation was used for identification of its structure and a cybernetic approach was applied in order to describe control processes that take place in it. Moreover, due to the assumption stating that a constructive element of management is human occurrence in the system, basic praxeological postulates were also accepted which mark a starting point for the analysis of uncertainty issues in management. In the scope of defining concepts, the efforts were made to achieve maximum accurateness through accepting assumptions characteristic to methodology based on analytical philosophy. The result of the research demonstrated in the article was a precise statement of such fundamental concepts as organisation, management, management system, or management function according to a systemic approach. Afterwards, being in possession of an adequate terminological convention, a universal model of organisation in cybernetic terms was shown. In this model, basic elements, flows of information and flows of energy and resources were identified and described. Accepting functional and praxeological character of organisation as a system, the essence and elementary causes of uncertainty in management processes were established. In the article, a concept of management was introduced which uses a systemic approach and a cybernetic modelling for a specific class of systems that include people as elements. These systems in a praxeological sense are systems capable of acting. Accepting praxeological and systemic perspectives together with the principles of cybernetic modelling allowed to perform an original synthesis of knowledge from the scope of management sciences and keep the balance between methodological individualism characteristic to reflexion on human actions and a holistic and multi-perspective perception of the whole which is a basis of a systems theory and engineering. In addition, such a synthesis includes previous research and terminological traditions in the management sciences to the maximum extent.

Keywords: Systemic Approach, Praxeology, Organization, Management, Methodology

Introduction

Present state of management sciences is an intense development caused by the expectations of economic practice. It is definitely a positive phenomenon as it shows a big research potential of this knowledge discipline. What is more, it indicates that the issue, which is taken within its framework, responds to social demand. However, negative results connected with popularity of management issues should not be omitted. The fact is that frequently many authors, who try to stand out on a very competitive market of

"managerial ideas", propose solutions which credibility is highly doubtful (Wooldridge and Micklethwait, 1998). Such a situation is possible because so far management sciences have been at pre-paradigmatic stage in their epistemological development (Gospodarek, 2009 pp. 410). Thus, it is more difficult to control genuineness of theoretical statements in this knowledge discipline in comparison with the natural sciences. Still, it does not change the fact that management issues have common denominators. Undoubtedly, the first is the fact that organisations are a subject of management. The second is the purpose of management, namely maximising the efficiency of those organisations. These two terms i.e. efficiency and organisation were defined in different ways in various management approaches. Considerations on these two terms have changed over the years, because management as a science and practice is embedded in a variety of contexts – historical, legal and cultural, but also in political and economic contexts. Such changeability and evolution in considering these two fundamental terms for management is not a weakness of management sciences, but an act of adaptation abilities to certain conditions and contexts.

An intense development of management sciences and the occurrence of interpenetration of many methods, concepts and ideas in this area have led to the appearance of an approach which integrates different management schools. A traditional integrative approach can be divided into a systemic approach and a situational approach.

A systemic approach is inspired by the ideas of L. Bertalanffy (1968). In the approach, an organisation is treated as a system coupled to the environment, which has its internal structure composed of subsystems that depend on one another. Such a consideration of organisation proposes holism in place of Cartesian approach used by a classic approach to management. It also indicates that optimisation of each part of organisation separately does not necessarily lead to optimisation of the whole. The best example of this can be a bullwhip effect in the supply chain (Lee et all. 1997). Furthermore, in the systemic approach the attention is paid to synergistic effects and a linkage analysis between the system's elements. Currently, the systemic approach is still developed, as evidenced by ideas proposed by Senge (2006). Their popularity, not only in academic community but also among managers, indicates that a systemic paradigm still addresses the needs of management theory and practice.

A situational approach in its essence is similar to a systemic approach. It takes the concept of a system as a starting point; however, it focuses on the fact that each sociotechnical system is an extremely complex system. There can be found a big amount of linkages and dependences between elements in it. A system of this type is a probabilistic system by nature. Therefore, a postulate seems to be reasonable which says that the existence of two identical organisations is not possible. That is why, the specifics and surrounding of a particular organisation should always be included in the choice of management tools and models. The situational approach is distinguished by high flexibility and a lack of dogmatism, while drawing attention to the surrounding where the organisation functions. Due to this fact, the situational approach might be still attractive for contemporary managers.

An integrative approach presented above, which is differentiated into systemic and situational approaches, is a classification proposal put forward by Griffin (2012). It results from traditions in management sciences rather than from substantive grounds of epistemological and terminological character. This is because when analysing the assumptions of a situational approach, it is difficult not to state that it is not of a systemic character. The attention is only switched to a specific context and the environment in which the organisation is functioning. Thus, what seems to be more appropriate and accurate is a systemic approach in management, which can take various research and analytical targeting.
Leaving out terminological inaccuracies and analysing previous output in management sciences, an uncontroversial statement is that systemic thinking is still continued and developed in management. In comparison to other ways of thinking, there is an emphasis on multi-perspective and comprehensive view on management issues in it. Such a research and practical attitude counteracts a tunnel vision thinking and

a research dogmatism. This attitude gives an epistemological impulse for the development of various and new specific research programmes and integration of existing research output that is scattered all over different management schools. In this research, it is important to use a conceptual and theoretical apparatus of a systemic analysis on the one hand and consider the fact that subjects in the organisation systemically understood are real people together with their individualities on the other hand. Otherwise, the systemic approach will lead to technocratic and excessively bureaucratic organisations instead of creativeness and innovativeness.

The essence of management from the systemic perspective

A systemic approach can take various forms depending on the choice of methods and tools that are used in research. In management literature, we can notice such variants of the systemic approach as an analysis based on the model of the complex adaptive system (Choi et al., 2001), an analysis using the concept of network (Ulrich and Probst, 1990; Snehota and Hakansson, 1995), an analysis using a social model of dynamic network (Watts, 2004) or an analysis using a system model of interdependent activities (Zott and Amit, 2010). A methodological pluralism of a systemic analysis leads to the situation that the concept of organisation and the essence of a management process are introduced in different ways. Therefore, in order to study these issues on the ground of the systemic approach, it is necessary to present the accepted research methodology in a clear manner.

Thus, let assume that a basic theoretical construct, which enables an analysis of the reality, is a system understood in the most general sense following Definition 1 (Lin et all., 1990, pp. 52-53).

Definition 1. A system is a set of elements and relations between them.

From a social practice point of view, extremely important are the systems which have set goals and they achieve them through processes leading to transformations of system's inputs into system's outputs. It should be assumed that in the identification or description of these kinds of systems, the following principles need to be respected (Mazur, 1987):

- *rule of accuracy*, which means that the system's goal should be formulated in such a way that there will not be any doubts concerning what elements are included in the system,
- *rule of immutability*, according to which in the course of the analysis it is necessary to stick consequently to the assumptions regarding the fact if any element belongs to the system or not. This rule does not mean the lack of variability in the system. It only says about immutability in establishing the system.
- *rule of separability,* according to which every system can be divided into subsystems; however, such a division must be separate i.e. if one element belongs to one subsystem, then it does not belong to any other subsystem.
- *rule of completeness*, which means that the division of the system into subsystems should be complete. In other words, there cannot be any element that do not belong to any subsystem.
- *rule of functionality* stating that the system and its subsystems ought to be distinguished due to a function they perform. They cannot be differentiated depending on spatial separateness.

When accepting an uncontroversial assumption that an organisation in a material sense is a system and the rules of accuracy, immutability, separability, completeness and functionality apply for its description and identification, we can formulate such conclusions as follows:

- in every organisation, two hierarchically linked subsystems can be distinguished, namely an information and decision subsystem, and an executive subsystem;

- elements included in the executive subsystem and information and decision subsystem always have to be people;
- a hierarchical link of the executive subsystem and information and decision subsystem is kept due to a relation of power in the organisation;
- a superior function of the information and decision subsystem is causing the realisation of goals being postulated by it by an executive system;
- a superior function of the information and decision subsystem can be decomposed on partial functions i.e. planning, organising, motivating, and controlling.

Taking the conclusions demonstrated above into account and accepting praxeological and cybernetic approaches, the concepts of organisation and management can be defined.
If an assumption is made that acting people are a constitutive element of organisation, then organisation is nothing more than a system capable of acting.

Definition 2. Organisation is a system capable of such an acting, in which in the structure of goals and acting resources there is at least one human.

In Definition 2, the concept of acting was used. Acting is understood here in terms of praxeology, and it means an intentional behaviour of a fully aware subject (Mises 2008; Kotarbiński, 2002).

Definition 3. Acting is any intentional and conscious behaviour of a human.

Presenting the concept of acting in such a way indicates that we can talk about organisation only when its elements are people. Thus, organisation is a specific case of a system, in which control processes take place due to people and through them.

Considering the concept of control as causing changes by one system in another one and integrating them with a category of acting, it is possible to define a concept of management.

Definition 4. Management is such control that is realised through the subject's actions, provided that there is at least one human in the structure of subject's goals and means of action.

If we assume that management in organisation has to be carried out by a system responsible for it, then such a system can be called a management system.

Definition 5. Management system of organisation is a system in organisation that comprises an information and decision subsystem and an executive subsystem both of which are capable of acting and hierarchically interdependent with the relation of power.

Each subsystem, mentioned in Definition 5, performs functions adequate for it. As a function, we might understand a set which was differentiated on the grounds of a system's goal and which consists of relatively repeatable events that were caused by the system.

Definition 6. Function of a system is a set, distinguished due to a system's goal, of relatively repeatable events caused by the system.

According to every information and decision subsystem of organisation, functions of this subsystem will be a set of actions targeted at an executive subsystem, which are traditionally called management functions. And these are:

- planning i.e. an action aiming at generating postulated goals,
- organising i.e. allocating and coordinating resources for the best implementation of the plan,
- commanding i.e. leading and motivating people engaged in the implementation of the plan,

- controlling i.e. actions aimed at measurement and assessment of action's results.

Determining management functions identifies and decomposes set managerial actions that are carried out by an information and decision system. It should not be forgotten that a similar functional decomposition can be conducted on an executive system of organisation. In practice, such a decomposition is performed through developing the so-called function-means tree. Identification and analysis of an organisational function-means tree have a fundamental meaning for projecting its organisational structure.

Apart from a functional perspective, an executive system of organisation can also be analysed from the perspective of its complexity criterion. This complexity might refer to subjects that constitute the system, processes which are performed by the system and resources which the system has. These criteria might be the basis for identification of management areas in organisation. Therefore, we can establish the following management areas (Mantura, 2008, p. 568):

- an area being subjectively structured, which can be focused on, for example, workstation management, department management, division management, office management, business management etc.,
- an area being structured in terms of actions, which can be focused on, for example, supply management, sales management, development management, quality management etc.,
- an area being structured in terms of resources, which can be focused on, for example, finance management, human resources management, asset management, product management etc.

In management practice, there are many possibilities for identifying management areas in organisation, because on the grounds of a situation a management area can be distinguished resulting from a combinatorial usage of criteria depicted above. A situational assignation of such an area depends on environmental conditions, potential and internal conditions of organisation. Assignation of management areas causes that they are treated like partial executive subsystems for which management functions are carried out. Such a dependence allows to combine management functions with an organisational structure and a scope of action of the whole organisation.

Cybernetic model of organization

When we adopt a systemic perspective in research concerning management and define management through interaction of an information and decision system on an executive system, we can construct a cybernetic model of organisation in an easy way. Such a model might be a good point in systematising the research issues in management in view of its universality and generality. Generality of cybernetic modelling and its multi-prospectiveness do not exclude other traditions in approaching and determining the essence of management concept (e.g. a resource tradition, an epistemological tradition, a tradition oriented towards management function or a strategic tradition). Due to this feature of a cybernetic modelling, the attempts of building cybernetic models of organisation and management processes have been made for a long time. Classical research in this area was conducted by Stafford Beer (Beer, 1959; Beer, 1970). In his works, he puts forward and develops a thesis that every economic organisation has a required variety, due to a social subsystem, which allows to overcome environmental interference. According to Beer, people are the weakest elements of a system in the routine and repeatable actions on the one hand. However, on the other hand in untypical situations due to possibilities of different behaviours, they can create and initiate flexible and adaptive processes in the whole system. A cybernetic approach to organisation, proposed by Beer, has been continued in many further areas. Attention was paid to the application of the cybernetic approach in the process of taking managerial decisions (Rob, 1984; Quin, 1993). It was also used in analysis of the issues connected with the processes of learning in organisation (Espejo et all., 1996). Cybernetics was also treated as a base for creating methods supporting management (Clemson, 1991). Nowadays, this utility attitude is profoundly continued in management

science. Currently, it is gaining in importance due to popularisation of advanced IT infrastructure of enterprises. Another usage of cybernetic models is the application proposed by Senge in his classic work titled "The fifth discipline" (Senge 2006). His approach is completely different from a mechanical understanding of organisation which is suggested by management science models. There were accusations that management science models omit a human factor in analysis and they treat a human in an instrumental way. Apart from the fact that at a declaratory level, especially in Beer's works, this problem was noticeable; however, in a research practice systemic thinking and cybernetic thinking were based on a mechanistic paradigm in the analysis of social phenomena on the grounds of their strong connections with technique. Innovativeness in Senge's approach is visible mainly in placing an emphasis on a humanistic dimension of management processes. The approach draws attention to the fact that success factors are elements difficult to measure and difficult to model in the quantitative way. Senge noticed that systemic and cybernetic models are intended to help to understand the reality; however, the understanding is of heuristic and qualitative character. Senge does not perceive a system in an ontological way, but he sees it from epistemological and cognitive perspectives as a convenient way to perceive the world. Such a way enables to release from wrong thought patterns, which interfere human rationality and creativity in organisations.

Combining an approach that emphasises the mechanistic perception of organisation on the one hand and a humanistic aspect of management processes on the other hand, we can propose a management model that eliminate too instrumental perception of human in organisation and too strong heuristic and intuitive approach to their role in management processes. Such a synthesis can be made with the use of a cybernetic model of quality management in organisations put forward by Mantura (Mantura, 2008, pp. 566-569). In order to make this model universal, it requires modification, what means that specific elements resulting from its pro-qualitative targeting have to be eliminated. A modified model is presented in Figure 1.

Fig. 1. Cybernetic model of organisation's functioning

In the model demonstrated in Figure 1, management is an action taken by an information and decision system and directed at an executive system. These actions take place thanks to people and through

people, who are elements included in both systems. The information and decision system and the executive system are interconnected in two ways. On the one hand, these are managerial signals which result from the functions of planning, organising, motivating, and controlling. On the other hand, this is information about the executive system's input and output. It is worth to mention that both systems are under the fundamental influence of environment of a particular organisation's functioning. It is a source of supply as well as interference. In the most general sense, the systems can be considered from the viewpoints of micro-environment (competitors, suppliers, customers, public institutions etc.) and macro-environment (economic environment, legal environment, cultural environment, demographic environment etc.).

Influence of the environment on organisation is beyond dispute. However, there is the question whether a reverse interaction i.e. a strong influence of organisation on the environment is possible. In a market situation very similar to a perfect competition, every organisation has an influence on the environment, but it is not capable to change fundamentally the environment's structure. Then, influence on the environment can be brought to the marketing issues and possibly an analysis of the influence on natural environment. It is different when there is a situation similar to a monopoly. In such a case, actions undertaken by this type of organisation affect the structure of the environment in a significant way in many aspects of its functioning, not just in an economic aspect. For instance, a monopolistic situation on the market of social media or Internet search engines might have an impact on elections, fashion or cultural trends. Another example is a dominant role of a big production company in some region. It can influence on a job market, demography or natural environment. Moreover, it can create a specific culture of such a region, which was especially visible in the areas dominated by coal mine companies. The model in Figure 1 predicts the possibility of interaction in two ways i.e. organisation on the environment and vice versa, the environment on organisation. It neither determines nor specifies in any way the size and range of this interaction. These elements are totally dependent on a status and context of functioning of a particular organisation.

Organisations, which function in a relatively stable economic environment of a free-market character oriented towards self-financing and development measured with economic categories, set out an interaction on the market with the use of offered products as a primary objective. These products can take different forms e.g. goods, where a value carrier is of a material character; services, where a value carrier is an action or works in which a value carrier is of informative character. In the model of organisation presented above, products should be treated as an effect of transformations of input into output. Success of the whole organisation depends on the efficiency of this process. The efficiency can be measured in such categories as profit, cost, income and revenue.

The model demonstrated in Figure 1, due to its universality, does not include many aspects like complexity or hierarchism of an information and decision system as well as an executive system. It does not determine complexity of organisation's objectives and people being its elements. This leads to the conclusion that every single time this model should be a subject to operationalisation which takes into account specific conditions of a particular organisation. Such a contextual and specialised approach seems to be consistent with contemporary trends in management, especially in a managerial consulting in which a targeting at activity in specific branches starts to dominate. A saying, according to which knowledge of management principles in isolation from context and specifics of a given branch is everything what a manager or a business consultant needs, is going down in history.

The significance of uncertainty in management processes

The essence of all management functions is to pursue information and decision processes. Thus, managers' role and assignment are to make decisions on the basis of collected and processed information, and then initiate communication processes which result from decisions that had been taken. Hence, it is

safe to agree with Herbert A. Simon's thesis that basically a word "management" can be treated synonymously with decision-making processes in organisations (Simon, 1960). Information and decision processes are initiated on all levels of the organisational structure. Such a phenomenon in many organisations is escalated through participatory and consultative management methods. This means that a boundary between an information and decision system, and an executive system in management systems is contractual and fuzzy. However, it can be noticed that with the higher position in the manager's organisational hierarchy, the significance of initiated information and decision processes at the expense of energy and material processes is increasing. In principle, such a statement is nothing new in management sciences as it is indicated and emphasised in an administrative approach to management (Fayol and Coubrough, 1930).

In managerial practice, we can notice that managerial decisions taken on a higher level of hierarchy are characterised by the fact that they are made in uncertain conditions or risk. On the executive level, frequently decisions are of a routine character. This tendency is being strengthened through the use of work standardisation methods. It is relevant for the efficiency of executive processes' functioning in the aspect of maintaining a stable quality of manufactured goods or provided services.

Apart from a level in organisational hierarchy, a kind of efficiency that is being maximised by a company or organisation has influence on a type of decision to be taken. A company might aim at maximising the static efficiency or dynamic efficiency. Maximising the static efficiency means achieving the best results of the actions on the assumption that the structure of resources and the purposes of the actions are stable. The opposite of this approach is maximising the dynamic efficiency, which assumes achieving the best results of the actions provided that the structure of resources and the purposes of the actions are variable. Maximising the static efficiency leads to the best and economical resource management. In this approach, managers are mainly interested in optimisation of running costs and a permanent improvement of processes in a company. Maximising the dynamic efficiency is related to looking for market opportunities and by its nature it is not focused on operational excellence, but on innovation. Following this approach, a company draws attention to costs to a lesser extent. It is more interested in potential revenue. Differences between static and dynamic efficiencies can be best illustrated by the example of differences between management concepts such as lean management and agile management. The former places emphasis on operational excellence, whereas the latter definitely focuses on searching for market opportunities (Trzcieliński 2016).

Depending on the fact whether a dominant approach is maximising the static efficiency or maximising the dynamic efficiency, the dominant type of decisions that are going to be taken is different. In the case of static efficiency, the emphasis will be put on decision rationality, risk elimination and striving for routinising the decision-making process. Therefore, there will be less decisions in the conditions of risk and uncertainty in comparison with companies oriented towards dynamic efficiency. This results from the fact that achieving dynamic efficiency requires looking for market opportunities and innovation, what in turn implies that managers will have to make decisions which results are unknown or fraught with relatively high risk.

Taking the direction on maximising the dynamic efficiency can significantly increase the level of uncertainty and risk in management. However, it is worth to underline that it does not mean that uncertainty will be eliminated when organisation is oriented towards maximising the static efficiency. A type of efficiency-based orientation might be an important modifier of risk and uncertainty levels in decision-making processes in management, but it is not their direct cause. This is because for a direct cause of risk and uncertainty in management we should consider complexity and dynamics of each management system. It results from the fact that people are subjects and creators of actions in those systems. They get into complicated networks of relationships between one another. Such a state causes the occurrence of a deterministic chaos phenomenon in these types of systems.

A deterministic chaos appears when there is a certain type of arrangement in a particular system, which simulates indeterminism and randomness, but also a high level of vulnerability on initial conditions. The level of uncertainty in these systems can be analysed through the application of differential equations in their descriptions. For economic systems, including management systems, such an approach has plenty of restrictions. On the one hand, they result from calculation problems connected with a possibility of solving a complicated system of differential equations. On the other hand, there are no constant values which describe a human activity (Mises 2000). What is more, even a formal mathematical modelling of a system does not eliminate a problem of vulnerability on initial conditions. This has a significant meaning, because these conditions are a subject to constant changes in management systems as well as in any other social system. It follows that, people performing actions constantly gain new knowledge in the learning process. This way they can change the structure of resources and objectives of succeeding actions at all times.

Despite the influence on initial conditions of a system, an important aspect worth to indicate is that frequently this knowledge is of hidden character, which is difficult to describe verbally. Only subject, who possesses the knowledge, has access to it often in an unconscious way. Hence, a very important conclusion for management is drawn, namely not only a rational analysis has a big impact on the efficiency of managerial decisions, but a manager's intuition has it too. Therefore, a very difficult problem emerges here, which has been repeatedly discussed in practice and theory, and this is whether management is art or possibly it is more like a craft that can be learned.

Conclusion

A systemic approach in management sciences allows to identify organisation as a system and basically show a structure of the system, whereas a cybernetic modelling gives us a possibility to introduce the interdependences between organisation's subsystems and recognise controlling processes which take place in organisations.

When management models are constructed, it is always worth to consider the fact that a social component is a constitutive element of every organisation. It is included in both an information and decision subsystem and an executive subsystem of the organisation. Taking this fact into account comes with the acceptance of organisation as a system capable of acting. This provides the necessity and an opportunity to apply a praxeological approach that supports a systemic analysis and a cybernetic modelling in management sciences.

Integration of the systemic approach and cybernetic knowledge with the praxeological approach enables to define and describe management as a process which is carried out by an information and decision system towards an executive system. This process in management is depicted with the use of classic functions such as planning, organising, motivating, and controlling.

Due to the division of organisation into an executive system and an information and decision system, it is easy to identify basic flows of resources in organisations and transformations that are performed on those resources. Referring economic measures to these processes is nothing more as accomplishment of tasks connected with financial management of the organisation.

An important and interesting element, which requires further analysis, is the matter of uncertainty in management systems. A few pressing issues appear here, namely when there is a possibility to model mathematically such uncertainty in a precise way and whether such a theoretical modelling is allowed and possible. These issues have a fundamental meaning for opportunities and restrictions in the development of operations research and mathematicised theories of decision-making in management. Further research

will be oriented towards examining this issue in the context of accepted in the following article systemic and epistemological assumptions concerning organisation and management sciences.

The Drivers of The Transport Services Exports, Case Study: Romania: A Gravity Model Approach

Anca TAMAS

The Bucharest University of Economic Studies, Romania

anca.tamas@rei.ase.ro

Abstract

Purpose – The aim of this paper is to find out the major drivers of the Romanian transportation services export flows. **Design / Methodology / Approach –** The gravity model and the panel approach were used. The sample includes 12 years and 137 countries. EViews 10 was used for the panel regression, Panel Least Squares Cross section SUR, Panel Least Squares Cross section fixed effects and Robust Least Squares options were considered. The data were collected from World Bank and International Trade Centre databases. **Findings –** The economic size, measured by GDP and the unemployment rate of the receiving country, cultural similarities, like common border and common language, as well as EU membership, have a positive impact on the Romanian transportation services export flows. The geographical distance has a negative, small influence on the transportation exports. The Logistics Performance Index, the Consumer Price Index and the Landlocked of the partner country are not statistically significant. **Practical implications –** The Romanian transportation services exports could increase because the potential exports are greater than the real ones. **Originality / Value -** The paper offers a valuable insight on the Romanian transportation exports. The major drivers of the Romanian transportation export flows are the openness to transport services and the services trade openness of the partner country. **Limitations –** Further research is needed to compare the same services before EU integration. Logistics Performance Index was applied only for years 2007, 2010, 2012, 2014, 2016 and 2018, when the data were available.

Keywords: Gravity Model, Transportation Services Exports

Introduction

Literature Review

Ever since it was introduced by Jan Tinbergen in 1962, the gravity model became the most successful, popular and reliable model to study the trade flows between two countries. The model took its name from the Newton's gravity law: the forces between two particles are positively influenced by their masses and negatively influenced by the square of their distance. The economic translation would be that the trade flows between two countries are positively influenced by the size of their economies and negatively influenced by the distance between them. At first, the model was applied based on this intuitive, simple and even beautiful economic application of the gravity laws, the theoretical foundations were established later on starting with Anderson (1979), Krugman (1980), Bergstrand (1985), Helpman (1987), Deardorff (1998), Baier and Bergstrand (2001), Evenett and Keller (2002), Anderson and van Wincoop (2003), Head (2003), Feenstra (2003), Rose and Spiegel (2004), Brun et al (2005), Martinez-Zarzoso and Suarez-Burguet (2005), Baldwin and Taglioni (2006), Egger (2008), Anderson (2010). Deardorff (1998) considered the gravity model as a fact of life, this is why it fits with all trade models and Head and Mayer (2014) said the gravity model is the workhorse, the toolkit and the cookbook for trade research. So far the researchers of trade flows for goods who used gravity models agreed on some issues: the economic size, measured by GDP or GDP per capita, has a positive impact on the trade flows, while the distance between countries has a

negative impact. As for dummy variables, sharing a common border, a common language or an economic union membership positively influences the trade flows. The controversy persists on the range for the values of the coefficients or on the methodology used and new results come from introducing further determinants of the trade flows.

But when it comes for services trade flows, things are a quite different. The first study referring to services trade flows was the one of Francois (2001), the methodology was further developed by Francois et al (2003), secondly the literature on the services trade flows is scarcer comparing to the one on goods trade flows and it is more controversial as well.

According to Francois (2001), only the GDP of the receiving country influenced the services imports, but Grunfeld and Moxnes (2003) found that the GDP of the importers and the GDP per capita of the exporters matter too. The GDP per capita is an important determinant for the importers and the exporters as well (Walsh, 2006).

According to Grunfeld and Moxnes (2003), the distance between countries has a negative impact on the services trade flows and according to Park (2002), it is significant for all services considered, but Tharakan et al. (2005) found the distance to be insignificant for Indian software services exports. Kimura and Lee (2006) found that the distance is more important for services than it is for goods trade flows, while Lejour and de Paiva Verheijden (2004) found the distance less important for services compared to goods. The distance was not considered a significant determinant for services flows (Walsh, 2006). Geographical distance influence is greater reduced for online services (Alaveras and Martens, 2015) and not so important for air transportation services (Yamaguchi, 2008).

Park (2002) found a common language important for services trade flows, yet Kimura and Lee (2006) disagreed. Kox and Lejour (2005) found that sharing a similar language increases the services trade level. A common language was found as an important determinant for services by Walsh (2006) and by Nordas (2018). Sharing a common language was found important for passenger transportation services (Tsui and Fung (2016).

The membership in a free trade area (FTA) is not significant in the case of services (Grunfeld and Moxnes, 2003) and Kimura and Lee (2006) found FTAs to be positively correlated with the services trade flows. EU membership is not as important for services as it is for goods flows (Walsh, 2006). A FTA with a similar country has a positive impact on the services flows (Nordas, 2018).

According to Walsh (2006), sharing a common border doesn't increase the services trade flows, while Nordas (2018) considered that a common border almost triples the trade.

The comparative advantage of the home country was found to be important for services exports (Alaveras and Martens, 2015).

Transportation services are among the most protected in developed and developing countries as well (Borchert et al, 2012).

The Logistic Performance Index (LPI) created by the World Bank is used as a proxy variable for trade facilitation. The exporter logistics performance seems to be more important than the importer logistics performance (Host et al, 2019).

Remoteness of the receiving country is not significant for transportation services (Covaci and Moldovan, 2015).

All in all, services trade flows are better predicted by the gravity model than the goods trade flows (Kimura and Lee, 2006).

The gravity model has been successful in explaining the international transportation trade (van Bergeijk and Brakman, 2011).

EViews 10 was used in three models, cross section SUR, cross section fixed effects and Robust Least squares.

In the cross-section SUR model, EViews estimates a feasible GLS specification, correcting for heteroskedasticity and contemporaneous correlation.

Robust least squares is reffering to a variety of regression methods designed to be robust or less sensitive, to outliers.

Rose and Spiegel (2004) considered the cross section fixed effects as the best fit.

Romanian transport services exports between 2007 and 2018

When analyzing the Romanian export values in 2018 comparing with the corresponding values in 2007 using the data from International Trade Centre (ITC) and from World Bank, one can see that all exports almost doubled in value (1.99), the services export values are slightly more than double (2.14), while transportation exports almost tripled their value (2.99), that shows the increasing importance of transportation services exports. The share of transportation exports in services exports grew from 20% to 30% and the share of transportation exports in all exports grew from 5% to 10%.

Fig. 1: The evolution of the Romanian transportation export values between 2007 and 2018

Source: International Trade Center, https://www.intracen.org/itc/market-info-tools/trade-statistics/

In the considered period of time, most of the Romanian tranportation exports are to EU countries, from 77% in 2007 to 92% in 2018.

Fig. 2: Romanian transportation exports in 2007-2018

Source: International Trade Center, https://www.intracen.org/itc/market-info-tools/trade-statistics/

Although the number of countries where Romanian transportation exports went to increased from 16 to 56, the top three receiving countries is rather constant.

Table 1: Top three countries for the Romanian transportation exports 2007-2018

2007	2008	2009-2010	2011	2012	2013	2014-2018

Methodology

The aim of this paper is to find the major drivers for the Romanian transportation services exports from 2007 to 2018.

The main research hypotheses are:

H1: The economic size of the partner country has a positive impact on the transportation exports.

H2: The geographical distance between countries has a negative small impact on the transportation export flows.

H3: The major drivers of the Romanian transportation export flows are the openness to transport services and the services trade openness of the partner country.

H4: The unemployment rate and the importance of transport services in the imports for the receiving countries have a positive impact on the transportation export flows.

H5: Sharing a common border, a common language or an EU membership have a positive influence on the transportation exports.

H6: The Consumer Price Index and the fact that the partner country is landlocked negatively influence the transportation export flows.

H7. The comparative advantage for Romania and the Logistic Performance Index for the receiving country positively influence the transportation exports.

The gravity equation is:

$$LNEXPVAL_t = C + c_1LNGDPP_t + c_2LNDIST + c_3LNEXPPRODS_t + c_4LNTSSGDP_t + c_5LNTSIMP_t + c_6LNUNEMP_t + c_7LNCP_t + c_8\ CB + c_9\ CL + c_{10}\ EU + c_{11}\ LL + \varepsilon$$

$LNEXPVAL_t$ is the dependent variable, it means (the logarithm of) the value of the Romanian transport services exports in US dollars. The data were collected from International Trade Centre (ITC). The independent variables were:

$LNGDPP_t$ (the logarithm of) is the GDP of the partner countries, it measures the economic size of the partner countries in year t. Other variables were tested as well, GDPT (the sum of the GDP of Romania and of the partner country), GDPPC (the GDP per capita of the partner country), GDPPCT (the sum of the GDP per capita of Romania and of the partner country), but GDPP proved to have the greatest explanatory power. The data were collected from World Bank database.

$LNEXPPRODS_t$ (the logarithm of) is the export product share of the partner countries in year t, it measures the openness to transport services. The data were collected from World Integrated Trade Solution (WITS).

$LNTSSGDP_t$ (the logarithm of) is the trade services share in the GDP of the partner country in year t, it measures the services trade openness. The data were collected from World Bank database.

$LNTSSIMP_t$ (the logarithm of) is the transport services share in the imports of the partner country in year t, it measures the importance of transport services imports for the receiving countries. The data were collected from World Integrated Trade Solutions (WITS).

$LNUNEMP_t$ (the logarithm of) is the unemployment rate in the partner country in year t, it measures the labour foreign demand. The data were collected from World Bank database.

All the above independent variables are expected to have coefficients with positive signs.

$LNCP_t$ (the logarithm of) is the consumer prices of the partner countries in year t, measuring the purchase power. The data were collected from World Bank database.

LNDIST (the logarithm of) is the geographical distance between the capital cities of Romania and of the partner country, it is considered a proxy for transport costs. The distances were collected using the distance calculator.

LNCP and LNDIST are expected to have negative coefficients.

The dummy dichotomic variables used are:

CB (common border), it takes the value 1 if Romania and the partner country are sharing a common border and 0 otherwise.

CL (common language), it takes the value 1 if Romania and the partner country share a common language and 0 otherwise.

EU (European Union), it takes the value 1 when Romania and the partner country are members of EU and 0 otherwise.

LL (landlocked country), it takes the value 1 if the partner country is landlocked and 0 otherwise.

All the dummy variables, except for LL, are expected to have coefficients with positive signs, while LL is expected to have negative sign.

t is the year and it takes the whole values between 2007 and 2018.

ε is the error term.

The Logistic Performance Index was realized just for the years 2007, 2010, 2012, 2014, 2016, 2018, therefore for these years the H7 hypothesis was tested. In this case, the gravity equation would be:

$$LNEXPVAL_t = C + c_1LNGDPP_t + c_2LNDIST + c_3LNEXPPRODS_t + c_4LNTSSGDP_t + c_5LNTSIMP_t + c_6LNUNEMP_t + c_7LNCP_t + c_8\ CB + c_9\ CL + c_{10}\ EU + c_{11}\ LL + c_{12}LNCOMPADV_t + c_{13}LNLPI_t + \varepsilon$$

Where the new introduced variables will be:

$LNCOMPADV_t$ (the logarithm of) is the comparative advantage for Romania regarding the partner country in year t. The data were collected from World Integrated Trade Solutions (WITS). It is expected to have a positive sign.

$LNLPI_t$ (the logarithm of) is the Logistic Performance Index of the partner country in year t. The data were collected from World Bank database. It is expected to have a positive sign.

t takes the following values: 2007, 2010, 2012, 2014, 2016, 2018.

Using a panel data approach can control the possibility that the unobserved effects might correlate with the regressors (Egger, 2005). Baldwin and Taglioni (2006) recommended using either exports or imports and not the bilateral trade.

The Results

Table 2: The regression results

Coefficients	Panel Least Squares Cross section SUR	Panel Least Squares Cross section fixed effects	Robust Least Squares
C	- 21.91*	- 21.31*	-20.65*
$LNGDPP_t$	1.19*	1.1*	1.09*
LNDIST	- 0,11**	- 0.04***	-0,04*
$LNEXPPRODS_t$	0.98*	1.04*	1.06*
$LNTSSGDP_t$	0.84*	0.99*	0.96*
$LNTSSIMP_t$	0.22***	0.46*	0.41*
$LNUNEMP_t$	0.57*	0.97*	1*
$LNCP_t$	-0.01	-0.15*	-0.12
CB	2.62*	2.42*	2.37*
CL	1.04**	1.4*	1.36*
EU	1.31*	1.3*	1.26*
LL	0.32**	0.12	0.14
R Squared	0.78	0.80	0.69

*Legend: *, **, *** means that the results are statistically significant at 1%, 5%, 10% level*

Source: Author's table based on EViews outputs

All the coefficients have the expected signs, except the ones for LL, which proved to be positive and they are statistically significant, except the ones for LL and LNCP in two models each.

The GDP of the partner country has the expected positive sign, with similar values, slightly over 1.

The geographical distance between countries has a negative influence, though the value is quite low, which is consistent with the statistical results and the fact that between 77% and 92% of the Romanian transportation exports go to EU countries.

Among the most powerful drivers of the transportation exports are the export product share and the share of services trade in the GDP of the partner countries, the coefficients being closed to 1 in all models.

The unemployment rate of the receiving country and the share of the transportation services in the receiving country imports have a significant influence on the transportation export flows, but the coefficients for unemployment rate are twice as the ones for imports share.

The consumer price index has negative signs as expected, but it is statistically significant only in the second model.

Among the dummy variables, the similar culture, the common border and the common language have the expected positive signs and values, the coefficients for sharing a common border over 2 and for sharing a common language over 1.

The EU membership has a positive influence on the transportation export flows, while the Landlocked variable has positive values and it is significant only in the first model.

Table 3: The regression results with LPI

Coefficients	Panel Least Squares Cross section SUR	Panel Least Squares Cross section fixed effects	Robust Least Squares
C	-21.96*	-19.01*	-18.43*
$LNGDPP_t$	1.1*	1.01*	1.008*
LNDIST	-0.05	-0.03	-0.04
$LNEXPPRODS_t$	0.97*	1.02*	1.03*
$LNTSSGDP_t$	0.76*	0.87*	0.87*
$LNTSSIMP_t$	0.43*	0.45*	0.36**
$LNUNEMP_t$	0.77*	0.99*	0.98
$LNCP_t$	-0.007	-0.19*	-0.12
CB	2.88*	2.35*	2.23*
CL	1.12	1.51*	1.46*
EU	1.21*	1.23*	1.20*
LL	0.07	0.04	0.15
$LNCOMPADV_t$	0.03	0.14**	0.14*
LNLPIt	1.23**	0.54	0.33
R squared	0.78	0.80	0.69

*Legend: *, **, *** means that the results are statistically significant at 1%, 5%, 10% level*

Source: Author's table based on EViews outputs

Some differences in the second set of results compared to the first one are to be noticed:

The distance between countries became statistically insignificant, although it has the same negative sign and the similar small values.

The share of services trade in GDP of the partner countries is a bit lower and the share of the transportation services in the imports of the partner country is a bit higher.

The consumer price index in the receiving countries became significant in the second model and Landlocked became statistically insignificant in all models.

For GDP, Export Product Share, Unemployment Rate, Common Border, Common Language, EU membership, the signs are the same and the values are similar with the ones in the first set of results.

For the new tested variables, the comparative advantage has the expected sign and small values and it is statistically significant only for the second and the third model, while Logistic Performance Index of the partner country has the expected sign, it is significant in the first model with a high value and insignificant in the other two models with smaller values.

Based on the coefficients from the gravity equation, the potential transportation exports was competed and compared with the real transportation exports. The results showed that the potential exports are greater than the real ones.

Conclusions

Both the GDP and the GDP per capita of the partner country, as well as the total GDP and the total GDP per capita of Romania and of the partner country were tested, but the best explanatory power was the one of the GDP of the receiving country. The results are similar with the findings of Grunfeld and Moxnes (2003), in contradiction with the results of Walsh (2006) and extending the findings of Francois (2001) for exports as well. Therefore the first research hypothesis is sustained, the greater the economic size of the partner country is, the greater need for transportation it will have, so more opportunities for transportation imports are.

The geographical distance between Romania and the partner country has a negative impact on the Romanian transportation export flows, which is consistent with the fact that most of the Romanian transportation goes to EU countries, therefore the distances are not too large. The results for the significance of the distance are similar to the ones of Park (2002), contradicting the findings of Yamaguchi (2008). The coefficients for distance are much smaller than the ones in the goods flows, in line with the results of Lejour and de Paiva Verheijden (2004) and Walsh (2006). So, the second research hypothesis is sustained for the first set of results and not sustained for the second set of results. Since the first set is a complete panel database, the H2 hypothesis was considered sustained.

The third research hypothesis is confirmed and the major drivers of the Romanian transportation export flows are the openness to transport services and the services trade openness of the partner country.

The fourth research hypothesis is sustained and the unemployment rate of the receiving country is found to be an important predictor of the Romanian transport exports.

The fifth research hypothesis is confirmed. EU membership proved to be a major driver for Romanian transportation exports, thus sustaining the results of Kimura and Lee (2006) and Nordas (2018) and contradicts the results of Walsh (2006). The common border is an important predictor, with the highest value of all variables, once more this confirming the findings of Nordas (2018) and contradicting the ones of Walsh (2006). Sharing a common language is found important for Romanian transportation export flows, in line with the results of Park (2002), Kox and Lejour (2005), Walsh (2006), Tsui and Fung (2016), Nordas (2018) and in contradiction with the ones of Kimura and Lee (2006).

The sixth hypothesis is rejected, although the Consumer Price Index has the expected negative influence, it is not statistically significant in two out of three models. As for the Landlocked dummy variable, it is not statistically significant, nor has the expected negative sign, therefore seen as a measure of remoteness, the results sustain the findings of Covaci and Moldovan (2015).

The last research hypothesis is rejected, although the comparative advantage and the Logistic Performance Index have the expected signs, they are not statistically significant in all models or the values are too small. The results are in contradiction with the findings of Alaveras and Martens (2015) and Host et. al (2019).

As the potential transportation exports are greater than the real transportation exports, there is enough room to improve the exports for these particular kinds of services.

All in all, the gravity model explained very well the Romanian transportation export flows from 2007 to 2018, considering the high values of R squared, confirming the results of van Bergeijk and Brakman (2011).

It seems somehow natural that the results of different empirical studies to be apparently contradictory, because the trade flows are highly sensitive to the specific characteristics of the trade countries.

Abstract

Hardiness is a personality trait that makes individuals stronger, more stable and optimistic in dealing with stress and reduces the negative effects of difficult situations. The purpose of this study is to examine the moderation effect of hardiness on the relationship between job insecurity, perceived organizational support, and organizational justice to organizational commitment. Using data from 338 respondents from six printing industry company, the results showed that job insecurity and perceived organizational support significantly affect organizational commitment, on other hand, organizational commitment was found not influenced by organizational justice. It also found that hardiness significantly moderating job insecurity, perceived organizational, and organizational justice on organizational commitment. This study contributes to further understanding of the role of hardiness in employee's commitment whose companies are facing the challenge of reducing business scale and to managerial of printing industry in order to maintain their employee's organizational commitment better in the business that experiencing a decline. Practical suggestions are provided for managers or organizations who wish to increase employee commitment, and avenues for future research derived from the study's limitations, findings and focus are proposed.

Keywords: job insecurity; perceived organizational support; organizational justice; hardiness; organizational commitment; printing industry.

Introduction

The fourth industrial revolution is destined to have a large impact on work and organization, no longer limited to one industry, but to all industries. At the same time, many jobs will be lost and many people will lose their jobs (Lee, Yun, Pyka, Won, Fodama, Schiuma, Park, Jeon, Park, Jung, Yan, Lee & Zhao, 2018). Digital technology will massively enter all business sectors and will result in a new service and more interaction with customers. Efficiency will play a big role where the physical product will be displaced by digital products. This will cause new industries to emerge and old industries to disappear (Lee & Zhao, 2018). One of the old industry is printing industry, the surviving printing industry companies are fighting against future uncertainty; on how to survive. While printing companies do what they can to survive, their employees suffer its consequences. Compensation and benefits are reduced to cut the company's expenses. Lot of employees are terminated and those who stay, may feel an insecurity that they will be the next target. Talents are avoiding printing industry due to future uncertainty and making this issue harder for printing companies to hire good talents.

Unfortunately, there are limited or similar research about printing industry facing new era of digitalization. The main objective of the present study is to analyze the relationship between job insecurity, perceived organizational support, organizational justice on organizational commitment using hardiness as moderator. The findings of this study can be used by the top management as guidelines to handle their employees.

Cite this Article as: Yohanes PRINCEN and Fanny MARTDIANTY "The Role of Job Insecurity, Perceived Organizational Support, and Organizational Justice on Organizational Commitment using Hardiness as Moderator at the context of Printing Industry" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Moreover, this study will benefit the printing industry in providing better information related with human resources management, objectives and strategies to survive in the current situation.

The paper proceeds as follows. In section 2, literature review related to this research is explored. Then, the methodology is presented in section 3. Result is presented in section 4. In section 5, discussion related to the result is explained. The final section 6 concludes the paper.

Literature Review

Organizational Commitment

Organizational commitment refers to an individual's feelings about the organization as a whole. It is the psychological bond that an employee has with an organization and has been found to be related to goal and value congruence, behavioral investments in the organization, and likelihood to stay with the organization (Joo & Park, 2013). There is distinction between two popular views of commitment, one provided by Porter and his associates and the other is by Becker (Meyer et al., 1990). Meyer (1990) described commitment as the tendency to engage in "consistent line of activity" because of the perceived cost of doing otherwise. Meyer and Allen used the terms of affective commitment and continuance commitment, respectively, to characterize these two views of the construct and noted that, although both views reflect a link between the employee and the organization that decreases the likelihood of turnover, the nature of the link is quite different. Employees with a strong affective commitment remain with the organization because they want to, whereas those with strong continuance commitment remain because they need to.

Job Insecurity

Job insecurity has been defined in various ways. For example, job insecurity has been described as an employees' expectations about continuity in a job situation, concern about the future performance of the job, and a perception of a potential threat to continuity in his or her current job (Sverke et al., 2002). Job insecurity is thought to reflect the degree to which employees perceive their jobs, or important features of their jobs, to be threatened and to which they perceive themselves to be powerless to do anything about it Job insecurity reflects the subjective anticipation of an involuntary event. As such, this anticipation has two components: one that is cognitive (beliefs) and one that is affective (emotional state) (Huang et al., 2010).

Cognitive job insecurity can be defined as the perceived threat to the continuity of one's employment and/or to features of the job, whereas affective job insecurity can be defined as the emotional reactions to the perceived threat to one's job (Huang et al., 2010). Recent research (Jiang & Lavaysee, 2018) proves that affective job insecurity has a stronger influence on attitudes towards job security than cognitive job insecurity. Based on this considerations, this research will use affective job insecurity as discussed in Huang et al., (2010).

Perceived Organizational Support

Perceived organizational support (POS) can be defined as an employee's perception that the organization values his or her work contributions and cares about the employee's well-being and has been shown to have important benefits for employees and employers (Eisenberger et al., 2016). Eisenberger, Huntington, Hutchison, and Sowa (1986) suggested that employees form a general perception concerning the degree to which the organization values their contributions and cares about their well-being. High perceived organizational support (POS) would (a) meet needs for approval, esteem, and social identity and (b) produce the expectation that superior conventional performance and extra role behavior, carried out for the organization, will be recognized and rewarded. On the basis of the norm of reciprocity, POS would

strengthen affective commitment to the organization and increase efforts made on its behalf (Eisenberger et al., 1986).

Organizational Justice

The term organizational justice was first introduced by Greenberg (1987) which represents individual's perceptions and reactions to fairness towards the organization. Justice refers to an action or decision that is morally and ethically right. Justice can be linked to, religion, ethics, equity, and law. Justice or fairness in organizations may include issues associated with perceptions of fairness in pay, equal opportunities for promotion and employee selection processes. Injustice examples maybe of unequal pay for and women doing the same job. Performance reviews conducted by a boss whom the employee had less contact, arbitrary dismissals etc. (Usmani & Jamal, 2013).

Organizational justice includes three dimensions: distributive, procedural and interactional. Distributive justice consists in the perception that the members' outcomes are commensurate with their efforts, contribution and performance. Procedural justice is the result of applying specific normative rules in evaluating whether a process is fair, as representativeness, consistency, bias suppression, accuracy, correctability and ethicality. Beyond the distribution of outcomes or formal processes, injustice perceptions arise when people had faced disrespect form others or the interactional dimension of justice (Rodriguez et al., 2019).

Hardiness

Hardy individuals held a view of the world as meaningful and demonstrated commitment through intention and action, rather than passive involvement in life events. When faced with new experiences, change, or adversity, hardy individuals exhibited feelings of self-reliance, sufficiency, courage, and control instead of dependence or helplessness. The theory of psychological hardiness suggested that change was healthy and stimulated individual development in lieu of presenting a threat to personal well-being and security (Kobasa et al., 1982). The constellation of commitment, control, and challenge altered human awareness of situations; positively affected cognitive appraisal and coping; and had the ability to mitigate and moderate the deleterious influence of stressful life situations (Crosson, 2015).

This study identifies the role of job insecurity, perceived organizational support and organizational justice to organizational commitment while using hardiness as moderator. The interaction effects of moderator are important to examine because they are a commonplace method of investigation in research, which can be rule instead of the exception (Crosson, 2015). Moderator interaction effects are also significant if researcher wants to learn whether relationships between predictor and outcome variables are greater for some individuals than for other individuals (Frazier et al., 2004). Consequently, researcher discovered that the examination of the moderator variable of hardiness was relevant to the study of job insecurity, perceived organizational support and organizational justice to organizational commitment.

There has been much research related printing industry; however, most of past research is when the printing industry is skyrocketing and unfortunately, there are limited research about printing industry when their business is disrupted with technology and their revenues are going down.

The objective to this study is to investigate the relation between relation between job insecurity, perceived organizational support, and organizational justice to organizational commitment and the moderating role of hardiness. It aims to determine whether hardiness plays a significant role between job insecurity, perceived organizational support, and organizational justice to organizational commitment.

Hypotheses 1. Job insecurity has a negative effect on organizational commitment.

Hypotheses 2. Perceived organizational support has a positive effect on organizational commitment.
Hypotheses 3. Organizational justice has a positive effect on organizational commitment.
Hypotheses 4. Hardiness moderates the effect of job insecurity on organizational commitment
Hypotheses 5. Hardiness moderates the effect of perceived organizational support on organizational commitment.
Hypotheses 6. Hardiness moderates the effect of organizational justice on organizational commitment.

Research Methodology

Sample and Procedures

In accordance with the introduction, the printing industry is the one that has the negative impact of the 4.0 industrial revolution. Researchers also conducted pleriminary studies, and found that printing industry employees showed indications of low commitment and high job insecurity. The participants are employees of 6 printing industry which listed a total of 338 employees. Subjects were encouraged to participate in a study about responses to organizational commitment and were informed the objective of the research, to investigate the link between job insecurity, perceived organizational support and organizational justice to organizational commitment with hardiness as moderator. All employees were sent questionnaires with prepaid return envelopes and using google form, respondents were guaranteed anonymity.

Measures

The statement items used in the questionnaire are taken with use a Likert scale where 1 means strongly disagree and 5 means strongly agree. Participation in the study was voluntary and participants were given the opportunity to maintain contact with the researcher in order to follow up the results obtained and to have the possibilities in further follow-up studies.

Job insecurity. This instrument was measured by using 7 items from Huang, Lee, Ashford, Chen & Ren (2010). e.g., “I wish I had more job insecurity in this company”.

Perceived organizational support. This instrument was measured using 8 items from Eisenberger, Cummings, Armeli & Lyncy (1997). e.g., “My organization cares about my opinion”.

Organizational justice. This instrument was measured using 12 items from Castano & Izquirdo (2018). e.g., “The rewards here are fair”.

Organizational commitment. This instrument was measured using 18 items from Meyer, Allen & Smith (1993). e.g., “I would be very happy to spend the rest of my career with this organization”.

Hardiness. This instrument was created to assess the role of hardiness as moderator of the relationship between job insecurity to organizational commitment, perceived organizational to organizational commitment and organizational justice to organizational commitment. This instrument was measured using 15 items from Jimenez, Munoz, Hernadez & Blanco (2014). e.g., “I Involve seriously in what I do, because it is the best way to reach my own goals”

Results

Data analysis was conducted in two stages. Firstly, checking for data entry for reliability of variables using SPSS computer program. Secondly, using AMOS computer program to utilized to run data from questionnaires.

Reliability Analysis

As can be seen in Table. 1 of the instrument used showed adequate indices of internal cosistency evaluated using Average Variance Extrated (AVE) and Construct Reliability (CR). The minimum value of AVE was .519 corresponding to the continuance dimension of organizational commitment and the minimum value of CR was .689 correspong to the job insecurity.

Table 1: Reliability analysis using Average Variance Extrated and Construct Reliability

Variable	Dimension	AVE	CR
Job Insecurity	-	0,632	0,689
Perceived Organizational Support	-	0,609	0,886
Organizational Justice	*Dimensional*	0,648	0,879
	Procedural	0,664	0,854
	Interactional	0,755	0,925
Hardiness	*Commitment*	0,517	0,762
	Challenge	0,484	0,762
	Control	0,465	0,719
Organizational Commitment	*Affective*	0,621	0,907
	Continuance	0,519	0,842
	Normative	0,599	0,899

Analysis of Hypotheses

The result corresponding to the hypotheses are displayed in Table 2. As can be seen in Table. 2, organizational commitment affected negatively by job insecurity (β = -0,085, p.value = 0,022), affected positively by perceived organizational support (β = 0,375, p.value = 0,005), and does not affected by organizational justice (β = -0,058, p.value = 0,691). Meanwhile, hardiness moderates job insecurity, perceived organizational support and organizational justice on organizational commitment.

Table 2: Result of Analysis Hyptoheses

No	Relation	*β*	*p.value*
1	Org. Commitment Job Insecurity	-0,085	0,022
2	Org. Commitment Perceived Org. Support	0,375	0,005
3	Org. Commitment Org. Justice	-0,058	0,691

4	Org. Commitment JI * Ha	0,003	0,001
5	Org. Commitment POS * Ha	0,01	***
6	Org. Commitment OJ * Ha	0,005	0,016

Discussion

The principal objective of this study is was to investigate the relation between job insecurity, perceived organizational support, and organizational justice on organizational commitment and the moderating role of hardiness. Firstly, it should be noted that the first hypotheses proposed in this research was upheld, which refers to the correlation between job insecurity and organizational commitment. The research confirms that people with high job insecurity level will feel insecure about their job and have less commitment. Secondly, the second hypotheses proposed in this research was upheld, which refers to the correlation between perceived organizational support and organizational commitment. The research confirms that people with high perceived organizational support level will show more commitment. Interestingly, it should be noted that the third hyptohses proposed in this research was rejected. The research confirms that organizational justice does not affect organizational commitment. Altough previous research showed organizational justice signifcantlly affect organizational justice positively, researcher also suspect that this condition occurs because of the situation where at the time of this research, printing industry was facing a bad situation, which forced many companies to undertake a massive efficiency strategy that resulted in layoffs in all industrial sectors. In situations like this, still having a job and being committed to the company becomes more important for employees than perceptions of organizational justice.

In terms of fourth, fifth, and sixth hypotheses, the aim was to test whether hardiness affects the relation between job insecurity, perceived organizational support, and organizational justice on organizational commitment. Result obtain confirm that hardiness does have a significant moderating effect between job insecurity, perceived organizational support and organizational justice on organizational commitment at certain level. From these results, two noteworthy conculusion can be drawn. Firstly, the hardiness factor which behaves best as a moderator is perceived organizational support, given that it moderates the relationship between perceived organizational support and organizational justice. This result is greatly relevant to the situation of printing industry as, if means are provided for workers to have greater commitment, for example through the praise or participation in decision making, it is proabel that they will display a greater level of commitment when treated well. Secondly, altough organizational justice does not affect organizational commitment, result showed that hardiness does have a significant moderating effect between organizational justice to organizational commitment. This shows that individuals with higher hardiness are able to maintain commitment to the company when the company does not treating them fairly. This was conveyed by what was delivered by Maddi (2013) that individuals with higher level of hardiness have higher endurance than individuals with lower hardiness, they need more help slumping, difficult and remain in accordance with the results and goals previously set.

Conclusion

In this paper, result showed that job insecurity and percevied organizational support affect organizational commitment, meanwhile organizational justice does not affect organizational commitment. Hardiness plays a moderating role between job insecurity, perceived organizational support, and organizational justice to organizational commitment.

This research is limited to a particular industry company in Indonesia whereas there are more industries in Indonesia. The results of this study cannot be used to explain the role of hardiness moderation on the effect of job insecurity, perceived organizational support, and organizational justice on organizational support in

different industries. For future research, it is recommended to be able to cover more than one industry, this can be used to make comparisons between industries in order to get a better understanding of organizational commitment.

Abstract

The aim of this research is to analyze the determinants of capital structure among manufacturing firms listed on Indonesia Stock Exchange from 2014-2018 with different age and size. The explanatory variables are growth, tangibility, profitability, size, liquidity, and age, meanwhile the dependent variables are total debt ratio and long-term debt ratio. The sample used in this research consists of 88 companies with 264 observation data. The results show that growth, tangibility, profitability, size, liquidity, and age have significant effects on capital structure by using data of all type company sizes or ages. Using a sample of all companies, growth has a significant effect on capital structure. However, growth does not have significant effect among big and old companies. Differences can also be found in other independent variables, particularly size and liquidity with different variations as the companies got older and bigger.

Keywords: liquidity; growth; profitability; capital structure; tangibility; size; age

Introduction

A formalised theory on capital structure began when Modigliani and Miller (1958) argued that under certain restrictive assumptions, the proportion of debt used by a firm is irrelevance to its value, since debt and equity are perfect substitutes. Therefore, the cost of capital used for discounting the expected future cash flows is not affected by the use of debt. These unrealistic assumptions were then relaxed, in which tax and bankruptcy costs are incorporated into the model and there is a trade-off in the effect of using more debt on the value of the firm. Another prominent capital structure theory is the pecking order theory (Myers and Majluf, 1984), which posits that when firms need to finance their projects, they will first attempt to raise debt when internal financing is not sufficient.

As the literature developed, it becomes evident that there is no single theory that can universally explain firms' behaviour when it comes to their capital structure decisions. The effects of some factors on capital structure are not uniform, and these might subject to the moderating effect of other variables. Mateev et al. (2013) showed that various factors have different effects on capital structure among firms with different age and size. Meanwhile, Yildirim et al. (2018) showed that there are differences in determinants of capital structure among sharia-compliant firms and sharia non-compliant firms. Related to these studies, Orlova et al. (2020) argued that capital structure is a complex phenomenon and the choice depends on borrowing access and capacity. Similarly, Ramli et

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

al. (2019) highlighted the importance of leverage as mediating variable in capital structure determination.

Based on the study of Mateev et al. (2013), this study attempts to examine differences in factors affecting capital structure among firms with different age and size in the context of manufacturing firms in Indonesia. We used the model developed by Vo (2017), where growth, tangibility, profitability, size, and liquidity serve as the independent variables, and included age as an additional factor following Ahmad and Aris (2015). Firms in Indonesia are interesting to study since they tended to have lower levels of leverage compared to those in other countries. Gill (2011) shows that in the United States from 2005-2007, manufacturing firms had an average total debt ratio of 55.4% and long-term debt ratio of 32.2%. Similarly, according to Abeywardhana (2016), the total debt ratio and long-term debt ratio of small and medium enterprises (SMEs) in the United Kingdom from 1998-2008 were 56.1% and 16.45, respectively. Meanwhile, Lestari and Irianto (2017) shows that from 2011-2015, the average total debt ratio among firms in Indonesia was only 41.4%. In addition, in terms of debt market, Indonesia was ranked 7th among emerging Asia countries in December 2013. This study only focuses on one industry to avoid biases due to different financial characteristics among companies in different industries.

The following section of this paper discusses some theoretical backgrounds related to capital structure. The section afterwards elaborates in methods used in this study in more details. The fourth section presents the main results and discusses them, by comparing them with some findings in the existing literature. Finally, the last section provides an overall conclusion of this paper.

Literature Review

Capital Structure Definition

There are different conceptualisations of capital structure, as summarised by Kumar (2017). Some only include permanent financing, i.e. long-term debt, preferred stock, and firms' equity, while others equate capital structure with total capital, which includes claims of trade creditor, bank creditor, and bond holders. This last definition is especially relevant when short term financing dominates the right-hand side of the balance sheet, as often found among small firms.

Trade-off Theory

According to trade-off theory, firms need to maintain their debt ratio at moderate levels (Myers, 2001). This is due to the possibility of financial distress when firms use excessive debt. Financial distress refers to all costs associated when firms face bankcruptcy or reorganisation. Firms will thus borrow up to a point where tax shield benefit due to additional debt is equal to financial distress. This theory is based on strong rationality, and is consistent with several observations, such as the relatively low risks of firms with high tangible assets. Firms with higher levels of tangible assets tend to borrow more than those with low levels of tangible assets. However, this theory cannot explain why some big firms with high profitability levels had low levels of debt for years, such as Microsoft and big pharmaceuticals (Myers, 2001).

Pecking Order Theory

Myers and Majluf (1984) analysed firms' assets and growth prospects when additional financing is needed. They assumed a perfect financial market, except that investors do not have a full information on the value of assets or new investment opportunities. Hence, investors did not have the ability to accurately value the securities issued to finance investment activities. They further assumed that managers act based on the interests of firms' owners, and thus they refused to issue undervalued

stocks. Managers will issue stock if the transfer value from old shareholders to the new shareholdres is at least equal to the present value of existing growth opportunities.

On the other hand, firms can issue debt or equity to finance new investment opportunities. Debtholders' claims are prioritised over that of equityholders, and therefore the latter are known as residual claim holders. Debt investors are then less exposed to the risk in valuing firms. Managers who feel that their stock value is undervalued will prioritise debt issuance in the case of external financing needs. Rajan and Zingales (1995) concluded that under the pecking order theory, firms will (1) prefer internal financing; (2) set a targeted payment ratio based on the expected investment opportunities; (3) implement constant dividend policy; and (4) choose first internal financing, followed by low risk debt, high risk debt, and finally equity as their last option.

Size and capital structure

There are different evidence on the role of size in determining capital structure. Rajan and Zingales (1995) found that among firms in most developed countries, the impact of size on leverage is positive. One explanation for this is that bigger firms tend to have lower probability of default and have better diversification strategy. On the other hand, in countries like Germany, size is negatively correlated with leverage. This might be due to a higher probability of liquidation among bigger firms. The costs associated with liquidating these large firms are also large, and thus they are reluctant to increase their leverage (Rajan and Zingales, 1995).

From the risk perspective, Mateev et al. (2013) argued that larger firms are better diversified and rarely experience default; therefore size can be used as a reverse proxy of probability of default. We can then expect size as one variable that can predict the leverage level, with a positive coefficient. Limitations on credit maturity offered by debtholders can explain partly the structure of liability among SMEs. In this context, SMEs use less long term liabilities compared to the larger ones.

Size might also play a role as a moderating variable in the relationship between several factors and debt level, as Mateev et al. (2013) show. They found differences in coefficients' signs among the predictors of leverage, including sales growth, liquidity, size, and asset structure. Moreover, their roles in predicting leverage are more significant among large firms than small firms.

Age and Capital Structure

The impact of age on capital structure has been discussed by previous literature, although not as extensive as the discussions on other variables such as profitability. Age is normally used as an independent variable to predict capital structure. Age can also be seen as a proxy of reputation. Diamond (1989) posited that access to debt market problems will be higher among newly established firms due to their limited or absence of track record. Harris (1991) explained that the longer a firm's history of paying off debt, the higher the reputation ad the lower the interest payment. Hence, it is more optimum for older firms to select safe investment projects, since the odds of assets' liquidation due to the failure of the projects are lower. On the other hand, younger firms with lower reputation choose riskier projects. When they survive, eventually they will turn to relatively safe projects in the longer term. As a result, these firms will experience lower probability of default and cost of debt. In a similar vein, Abor (2008) mentioned that when a firm continues its operation, it shows a sign of sustainability and therefore can increase its debt capacity.

Another stream of literature argues that as a firm gets older, many of its characteristics and behaviour evolved. Kieschnick and Moussawi (2018), for example, showed that governance structures of old firms are different from the younger ones. They documented some differences in the effect of board of director's composition on capital structure among firms with different ages. Mateev et al. (2013) found that the effect of some factors on leverage depend of the age and size of the firm. The

coefficients' signs of sales growth, liquidity, size, and assets' structure are more significant among older firms.

Research Method

This study examines the issue of capital structure among firms with different age and size levels among listed companies in the basic industry and chemicals and consumer goods in Indonesia Stock Exchange from 2014-2018. By focusing on this specific industry, we try to avoid some biases due to different operational cycle and business environment. Table 1 provides a detail on the sample selection procedure.

Table 1: Sample selection procedure

No	Description	N
1	Manufacturing firms listed in 2019	125
2	Firms fulfilling criterion (1) and listed from 2014-2018	99
3	Firms fulfilling criterion (2) and have complete data	93
4	Firms fulfilling criterion (3) with positive book value of equity	88

Fig 1. Conceptual framework

Both major capital structure that have been elaborated in the previous section provide different conclusion on the effect of several variables on leverage, as can be seen in Table 2.

Table 2: Expected coefficients' signs of the independent variables

Variable	Trade-off Theory	Pecking Order Theory
Growth	-	+
Tangible assets	+	-
Profitability	+	-
Size	+	-
Liquidity	+	-
Age	+	-

Trade-off Theory predicts that growth is negatively associated with leverage. Acaravci (2015) summarised that firms with higher growth levels should use more equity financing since firms can avoid underinvestment problems due to potential conflicts with bondholders. On the other hand, according to the Pecking Order Theory, growth has a positive effect on leverage. Firms that are in the development stage often do not have sufficient internal funds to finance their projects (Hossain and Ali, 2012). When this is the case, they will prioritise the use of external debt over external equity.

H1a : Growth has a significant effect on total debt ratio
H1b : Growth has a significant effect on long term debt ratio.
H1c : There are differences in the effect of growth among firms with different age levels
H1d : There are differences in the effect of growth among firms with different size.

Referring to the trade-off theory, tangibility is expected to have a positive correlation with debt proportion. Acaravci (2015) explained that tangible assets have high collateral value, and thus they can help firms to get more debt financing. Meanwhile, Pecking Order Theory predicts that tangibility affects leverage negatively. It is argued in the literature that firms with low tangibility are subject to asymmetric information problems and can lead to a lower equity. On the other hand, when assets tangibility is high, the probability of firms experiencing asymmetric information problem is lower, and thus its equity value will be higher. This leads a situation where it is more beneficial for the firms to have more equity financing (Hossain and Ali, 2012).

H2a : Tangibility has a significant effect on total debt ratio.
H2b : Tangibility has a significant effect on long term total debt ratio.
H2c : There are differences in the effect of tangibility among firms with different age levels.
H2d : There are differences in the effect of tangibility among firms with different size

Vo (2017) showed that following the Pecking Order Theory, firms with higher profitability levels attempt to substitute debt with retained earnings. With these firms' investment levels held constant, the effect of profitability on leverage is expected to be negative. On the other hand, the Trade-off Theory predicts that profitability has a positive effect on leverage. One explanation is that profitable firms are less likely to go bankrupt (Vo, 2017).

H3a : Profitability has a significant effect on total debt ratio.
H3b : Profitability has a significant effect on long term total debt ratio.
H3c : There are differences in the effect of profitability among firms with different age levels.
H3d : There are differences in the effect of profitability among firms with different size

Trade-off Theory predicts that size is positively correlated with debt proportion. Acaravci (2015) argued that larger firms tend to be more diversified and thus can minimise bankruptcy risk. If the risk is smaller, firms will be more eager to finance themselves with debt. Meanwhile, if Pecking Order Theory holds, size has a negative effect on leverage. As elaborated in Hossain and Ali (2012), the problem of asymmetric information is less prevalent in large firms. Asymmetric information can lead to undervalued equity, and discourage managers to issue new equity. When this problem is lower, the equity value will be improved and thus increases the preference for equity financing over debt financing.

H4a : Size has a significant effect on total debt ratio.
H4b : Size has a significant effect on long term total debt ratio.
H4c : There are differences in the effect of size among firms with different age levels.
H4d : There are differences in the effect of size among firms with different size

Referring to the Trade-off Theory, liquidity has a positive and significant effect on debt proportion. A higher liquidity means a better ability in fulfilling short term liabilities, and thus increases the firm's

credibility in repaying its debt (Hossain and Ali, 2012). Meanwhile, Pecking Order Theory suggests a negative relationship between liquidity and leverage. Firms with higher levels of current assets are expected to be able to generate more cash to finance investment projects. Since this theory posits that firms prioritise internal source of financing, the use of debt will be lower (Hossain and Ali, 2012).

H5a : Liquidity has a significant effect on total debt ratio.
H5b : Liquidity has a significant effect on long term total debt ratio.
H5c : There are differences in the effect of liquidity among firms with different age levels.
H5d : There are differences in the effect of liquidity among firms with different size.

Age is expected to have a positive relationship with debt proportion. According to Ahmad and Aris (2015), the older the firm, the greater the access to debt financing since the firm has proven its reputation to debtholders whose main concern is debtor's repayment ability. On the other hand, the Pecking Order Theory associated age negatively with debt proportion. Older firms tend to have higher accumulated retained earnings, which can be used to finance its investment projects. If this theory holds, firms will be discouraged from looking for external financing due to higher costs of fund.

H6a : Age has a significant effect on total debt ratio.
H6b : Age has a significant effect on long term total debt ratio.
H6c : There are differences in the effect of age among firms with different age levels.
H6d : There are differences in the effect of age among firms with different size.

Following Vo (2017) and Ahmad and Aris (2015), in testing the above hypotheses, this research uses the following regression model:

$$CapStructure_{i,t} = CapStructure(-1)_{i,t} + \beta_1 GROWTHi,t + \beta_2 TANG_{i,t} + \beta_3 PROFITi,t + \beta_4 SIZE_{i,t} + \beta_5 LIQUIDITY_{i,t} + \beta_6 AGE_{i,t} + \epsilon_{i,t} \quad (1)$$

The operationalisation of variables used in equation 3.1 is detailed in Table 3.

Table 3: Variables' operationalisation

Variable	Variable operationalisation	Source of definition	Data source
Total Debt Ratio (TDR)	Total Debt/Total Asset	Hossain and Ali (2012)	Bloomberg
Long Term Debt Ratio (LTDR)	Total Long-Term Liabilities/Total Asset	Vo (2017), Mateev et al. (2013)	Bloomberg
Growth (G)	Tobin's Q Ratio	Vo (2017), Mateev et al. (2013)	Bloomberg
Tangible Asset (TAs)	PPE/Total Asset	Vo (2017), Mateev et al. (2013)	Bloomberg
Profitability (P)	Net Profit/Total Asset	Vo (2017), Mateev et al. (2013)	Bloomberg
Size (S)	Ln(Total Asset)	Vo (2017), Mateev et al. (2013)	Bloomberg
Liquidity (L)	Current Asset/Current Liability	Vo (2017), Mateev et al. (2013)	Bloomberg
Age (A)	Ln(Total Asset)	Ahmad and Aris (2015)	Indonesia Stock Exchange

The sample was divided into different groups according to age and size using the median split technique, following Fama and French (1993). Using this technique, firms whose age or size below the median was included in the "low" category sample, while those with age or size above the median belonged to the "high" category sample (Decoster et al., 2011).

In data analysis, this study did not include the outliers, which is defined as observations in the highest 1% and lowest 1%. Panel data regression technique was performed using the Generalised Method of Moment (GMM) estimation. Specifically, the first-difference GMM developed by Arellano and Bond (1991) was used in estimating the model.\

Results and Discussions

Before proceeding with data analysis, we first ensure that there is no multicollinearity problem among the independent variables used in this study. Dohoo (1997) used a coefficient correlation threshold of 0.9 to decide whether multicollinearity persists. The result shown in Table 4 confirms that no multicollinearity found.

Table 4: Multicollinearity test

	Growth	Tangibility	Profitability	Size	Liquidity	Age
Growth	1					
Tangibility	-0.040	1				
Profitability	0.451	-0.203	1			
Size	0.129	0.275	0.175	1		
Liquidity	-0.065	-0.464	0.263	-0.104	1	
Age	0.153	-0.050	0.430	0.114	0.139	1

Table 5 presents the descriptive statistics of our sample, that consists of 440 observations. As total debt ratio and long term debt ratio are the dependent variables in this research, these two deserve further elaborations. Total debt ratio has a mean of 0.217, which means that on average, the total debt of the sample is 21.7% of the total assets. In our sample, there are 15 firms that had no debt in their capital structures. Meanwhile, the average long term debt ratio is relatively low, which is only 0.084. This means that the uses of long term debt among these firms are relatively low. Nevertheless, there is a firm with a long term debt of 52.5% of its total assets. We noted that there were 39 firms that did not use long term debt as part of their financing efforts.

Table 5: Descriptive statistics

Variable	Number of observation	Mean	Standard deviation	Minimum	Maximum
TDR	440	0,217	0,179	0	0,795
LTDR	440	0,084	0,120	0	0,525
Growth	440	2,381	4,189	0,304	37,232
Tangibility	440	0,407	0,193	0,034	0,966
Profitability	440	0,054	0,096	-0,176	0,921
Size	440	37,324	2,305	27,891	41,680
Liquidity	440	2,455	2,116	0,053	15,164
Age	440	3,578	0,419	1,609	4,727

Table 6 presents the regression's results using total debt ratio as the dependent variable, while table 7 shows the results using long term debt ratio as the dependent variable. It should be noted that since we employed GMM, the numbers of observations recorded in the regression models are lower than 440.

Table 6: Regression's result: Debt ratio as the dependent variable

Overall, the results suggest that Pecking Order Theory is the one that can explain capital structure decisions among listed manufacturing firms in Indonesia. We can see this from the relatonships between the independent variables and the dependent variabes. Growth is associated positively with leverage among firms belong to the below-median age and size. They tend to have lower internal financing capabilities compared to older and bigger firms. This finding is in line with those by Titman and Wessels (1988) and Chen (2003).

The negative relationship between tangibility and leverage among small firms when the dependent variable is total debt ratio also supports the Pecking Order Theory. Gaud et al. (2005) argued that firms with low asset tangibilities are subject to asymmetric information problem that can lead to

lower value of equity. In contrast, highly tangible firms are less susceptible to the same problem, and consequently the equity value of these firms will be higher. Issuing new equity becomes more attractive for these highly tangible firms. The result showing the negative relationship between profitability and leverage is in line with the Pecking Order Theory. Hossain and Ali (2012) explained that profitable firms tend to use their own internal finance to fund investment projects rather than looking for external financing. Another finding that is in line with the Pecking Order Theory is the negative relationships between age and leverage. As Ahmad and Aris (2015) argued, the older the firm, the higher the accumulated earnings, and thus firms tend to prioritise this internal funding to finance their investment projects. However, it should be noted that the significance of Age is not confirmed among older and smaller firms.

While most of the regression's results support the Pecking Order Theory, some findings can be justified by the Trade-off Theory. The positive effects of tangibility on leverage in most regressions using different sample are in line with the latter, where firms with larger proportions of physical assets can pledge more collateral in getting more debt (Acaravci, 2015). Firms will take more opportunity of having more debt as long as the tax shield benefit outweighs the financial distress costs.

The positive signs of Size and Liquidity also support the Trade-off Theory, and this is due to the tendency that larger firms are more diversified and have higher abilities in fulfilling their short term debt. These will increase the trust of debtholders in channelling funds to the firms, and lead to increases in debt proportion (Hossain and Ali, 2012). Interestingly, we found that Size is not a significant predictor of capital structure among older and smaller firms, both in the cases of total debt ratio and long term debt ratio as the dependent variables.

We found opposing signs of coefficients of liquidity between the regressions using total debt ratio as the dependent variable and those using long term debt ratio as the dependent variable. The negative effect of liquidity on leverage found when total debt ratio serves as the dependent variable supports the Pecking Order Theory. Hossain and Ali (2012) argued that highly liquid firms are better in cash-generating capacity, which further can be used to finance operational activities. The available emergency funds are also higher among these firms. On the other hand, liquidity has a positive and significant effect on leverage when the dependent variable is long term debt ratio. A higher liquidity signals firms' credibility in repaying their debt (Hossain and Ali, 2012).

Table 7: Dominant theories

Firms characteristics	Dominant theories – Total debt ratio	Dominant theories – long term debt ratio
All	Pecking Order Theory	Trade-off Theory
Age – below median	Pecking Order Theory	Trade-off Theory
Age – above median	Pecking Order Theory	Trade-off Theory
Size – below median	Pecking Order Theory	Trade-off Theory
Size – above median	Pecking Order Theory atau Trade-off Theory	Trade-off Theory

Table 7 summarises the findings and the supporting dominant theories that can explain capital structure behaviour among listed manufacturing firms in Indonesia with different age and size. The conclusions presented in this table are taken based on which theory is supported the most by looking at the relationship between each independent variable and the dependent variable. When total debt ratio is used as dependent variable, Pecking Order Theory dominates in all cases. However, looking into more details, Trade-off Theory has a similar power in explaining capital structure behaviour among large firms. On the other hand, when capital structure is perceived only consisting of long term debt, Trade-off Theory prevails in all firms across age and size levels.

Conclusions

This study aims to examine the determinants of capital structure among firms with different age and size levels. It is found that growth, tangibility, profitability, size, liquidity, and age play significant roles in determining firms' capital structures. While in most cases the effects of these variables on capital structure are consistent, we found differences on the effect of liquidity. In the model with total debt ratio as the dependent variable, liquidity has a significant and negative effect in most cases, leading to a conclusion that Pecking Order Theory can explain capital structure behaviour. On the other hand, with long term debt serves as the dependent variable, the sign of liquidity is positive, indicating that Trade-off Theory prevails. The regression results across age and size levels suggest that age and size matter in moderating the effect of independent variables, particularly Size and Liquidity, on leverage.

Abstract

The same user registers on different social platforms which scatters user data across multiple platforms, these data are incomplete, unreliable, and underutilized. Through the analysis of these cross-platform data, identify different accounts corresponding to the same user's real identity. Linking cross-platform user identities can help build detailed user profiles, recommendation systems and link predictions etc. Our research divides user basic attributes into three types: string attributes, short text attributes and semi-structured attributes, according to the characteristics of different attributes, we study the calculation method of similarity between attributes. In order to improve the effect of user identity recognition, this study selects the optimal machine learning algorithm for user characteristics of different dimensions and completes the learning process by constructing and integrating multiple models. Experimental results show that the integration model based on user profile features has a certain degree of user identity link ability, can effectively integrate multiple categories of attributes between platforms, and improve the accuracy of identity link algorithm. This paper provides a reference for the research on user identification across multiple social networks.

Keywords: user identity linkage; social networks; profile features; model ensemble

Introduction

Social network is a virtual community composed of interactions and connections between members of different societies, various social networking platforms have gradually penetrated every aspect of people's life and work, driven by the rapid development of the Internet. Due to the continuous increase

of social network users, various social network platforms begin to refine their respective fields, and people begin to use different social network platforms to meet their various social needs. According to a report released by Global Web Index in 2018, the average Internet user has 8.5 social media accounts. However, the information of users in different social network platforms is rarely Shared and communicated, which makes it difficult to fully depict the persona profile. How to identify the same user on different social media is the key to obtain the complete user information in the social network. Through cross-social network user identity links, users can obtain more complete user profile information, provide users with better services such as preference recommendation and friend recommendation, and also help analyze the migration of users between social media and the development of social media, which has important scientific research value and commercial value. Therefore, user identity links across social networks have become a hot research issue in the field of intelligent information processing and have been reported in international authoritative journals and top conferences in recent years（Zhou et al, 2016; Korula et al, 2014）

In the feature extraction stage, feature extraction is carried out according to user profile features and identity attribute similarity is calculated. In the model construction stage, according to the features extracted in the previous stage, the machine learning model is adopted to train the data set, and the attribute similarity is input into the trained classifier to obtain matching results, and finally the same user of multiple social networks is identified（Shu et al, 2016; Iofciu et al, 2010; Cohen et al, 2003）.Due to the differences of social networks, different user information processing methods are different. Researchers at home and abroad have put forward user feature extraction methods from different perspectives, which can be summarized into three types: Identity link based on user profile, identity link based on user activity record and identity link based on user network structure (see Figure 1). Basic user information refers to the information provided by users that can be collected through public channels, such as user nickname, avatar, region, personal description, gender, age, occupation, educational experience, etc. The user network structure contains information about the nodes and edges of the user in the social network topology（Liu et al, 2014; Shen et al, 2014）. User activity record mainly refers to the text content, time and geographical location of text published by users in the social network platform（Malhotra et al, 2012; Vosecky et al, 2009）. In the three existing approaches, the scale of the user relationship topology is huge, this method has the disadvantages of poor universality and high requirements on the application field, as well as the disadvantages of massive, low quality and multi-noise user activity records. Moreover, due to the increasing attention paid to privacy protection, many user activity information is not open to the outside world. Therefore, it is very difficult to use these two kinds of information to achieve user identity linkage（Motoyama et al, 2009; Korula et al, 2014）.

Fig. 1: User Identity Link Method

In a user's personal page, some basic public information in the user's information is easy to obtain, and the user's basic information data is common in different types of social network platforms. When the user's basic information can be utilized, the accuracy of this method is higher than the other two categories. Therefore, this paper chooses the basic user information commonly owned by social network users as the object to extract the features of identity links. Although the research on identity association based on basic user information has better recognition effect than the other two types of research, there are still some limitations. To fill the gap of previous studies, this paper makes algorithm improvement for the following problems: (1) In previous studies, the extraction method of user's basic attribute characteristics was single （Shu et al, 2017）. One feature extraction method only calculates the similarity of two users in a certain aspect. Applying the extracted features in this one-sided way to the subsequent identity link model will inevitably lead to poor effect, especially the problem of low recall rate. Therefore, it is necessary to apply a variety of similarity computing algorithms in the attributes of each dimension, to mine more comprehensive user similarity information from the limited user basic attribute data. (2) The previous user identity link algorithm is usually only applicable to a limited number of social platforms and is not scalable（Zhong et al, 2018）.Based on the text structure of basic user attribute information, this paper classifies the common user attribute information in social networks into three categories, namely, short string attribute, short text attribute and semi-structured attribute. Based on the idea of classification to calculate the similarity characteristics of attributes, this paper studies the suitable calculation methods on various attributes respectively and improves the applicability and expansibility of the algorithm on the premise of ensuring the calculation accuracy. (3) The previous classification algorithms are rigid and have weak adaptability. The machine learning algorithms used are too single and have poor adaptability to different data types and data sets（Ya, 2019）.Based on the characteristics of different dimensions, this paper adopts the integration model strategy, tries to select the most appropriate machine learning algorithm, and completes the learning task by integrating multiple models.

Related Work

Description of User Identity Link

We abstract the problem between the two social networks, and more social network situations can be extended from this. Set $G^s$and$G^t$for the given two social networks, U^s and U^t are the user sets of the two social networks, $u^s \in U^s$and $u^t \in U^t$are any user taken from two sets of social network users, User identity links across social networks determine whetheru^sandu^t are the same person, the predicate function can be described by the following formula: $F: u^s \times u^t \rightarrow \{0,1\}$, $F(u^s \times u^t) = \begin{cases} 1, \mathrm{u^s and\ u^t\ belong\ to\ the\ same\ natural\ person} \\ 0, \mathrm{u^s and\ u^t\ do\ not\ belong\ to\ the\ same\ natural\ person} \end{cases}$

Extraction Algorithm Based on User Profile Features

User base information in social networks often contains multiple types of attribute information, each of which is different in data format, data content and data characteristics. In order to improve the calculation accuracy of similarity features, this paper divides user's basic attributes into three categories according to text structure: string attribute, short text attribute and semi-structured attribute. According to the characteristics of different attributes, we study the calculation method of similarity among attributes.

Similarity algorithm for string attributes

String attribute refers to a short string in the virtual identity attribute information that cannot be divided or can be simply split for calculation. Among them, the non-separable string attribute is called atomic string attribute; String properties that can be simply split are called composite string properties. The home page URL and username in the user information belong to the combined string attribute in the atomic string attribute, while the URL suffix formed after splitting the URL and the last name and name formed after splitting the username belong to the atomic string attribute. The four commonly used atomic character attribute similarity algorithms are the longest common subsequence similarity algorithm, the longest common subsequence similarity algorithm, the edit distance similarity algorithm and the Jaccard similarity algorithm.

（1）Longest Common Substring. Given two strings, find the longest length of the same substring between them. For example, aaamnpdeff and MnpFFab, their longest common substring is MNP, length 3, and the similarity of two strings is calculated by the longest common substring. The similarity between $string_1$and $string_2$ is shown in Formula 1, cn is the number of comparison frequency, and lcs_i is the character length of the longest common substring.

$$Sim_{LCS} = \frac{\sum_{i=1}^{cn} lcs_i - cn + 1}{|string_1| + |string_2| + \sum_{i=1}^{cn} lcs_i} \qquad \text{（Formula 1）}$$

（2）longest common subsequence. The longest common subsequences of two strings are found, and then the length of two source strings is normalized to generate similarity based on LCS. The calculation method is shown in Formula. Where $|lcs(\mathrm{string_1}, \mathrm{string_2})|$represents the length of the longest common subsequences of $\mathrm{string_1}$ and $\mathrm{string_2}$. $\min(|\mathrm{string_1}|, |\mathrm{string_2}|)$ represents the length of the shorter strings in String1 and String2.

$$Sim_{LCS} = \frac{|lcs(\text{string}_1,\ \text{string}_2)|}{\min(|\text{string}_1|,\ |\text{string}_2|)} \quad \text{（Formula 2）}$$

（3）Levenshtein Distance similarity. The Levenshtein edit distance represents the minimum number of edits from one string to another. The smaller the Levenshtein editing distance between two strings, the higher their similarity. The similarity calculation method is shown in Formula 3.

$$Sim_{Lev} = 1 - \frac{\text{Levenshtein}(\text{string}_1,\ \text{string}_2)}{\max(|\text{string}_1|,\ |\text{string}_2|)} \quad \text{（Formula 3）}$$

（4）Jaccard similarity. The ratio of intersection and union between two strings is used as Jaccard similarity, which is a widely used similarity calculation method. The similarity calculation method is shown in Formula 4.

$$Sim_{\text{Jac}} = \frac{|\text{string}_1 \cap \text{string}_2|}{|\text{string}_1 \cup \text{string}_2|} \quad \text{（Formula 4）}$$

Attribute similarity algorithm for short text

Short text is a common type of content in social networks, generally a text description or description of users in social networks, such as a personal profile and self-introduction in social networks. Compared with the above two types of characteristics, short text type attributes have no fixed structure in format, so the calculation of similarity between attributes is more complex. Users may publish similar or even identical personal descriptions on different platforms, so the following three short-text attribute similarity algorithms are adopted.

（1）Word2vec Cosine Similarity. Word 2VEC is a Word embedding model, this model was proposed by Google company in 2013. Its core idea is a language probability model based on neural network, which uses the context information of words to train the vector representation with fixed dimension for each word in corpus. Word2vec includes two different training models: skip-gram model and CBOW model. In the training process, skip-gram model is the word that predicts its context through a certain word, while CBOW model is the word that predicts its current context through a certain word. After Word2Vec transformation, the cosine similarity between word vectors is calculated, and the cosine similarity between individual description texts is calculated using the cosine similarity.

（2）TF-IDF Cosine Similarity. TF represents the frequency of occurrence of a word in the text, IDF represents the importance of each word. If the number of other texts containing a word is less, the IDF of this word will be larger. The word frequency vector of personal description text is calculated by TF-IDF, and then the cosine similarity between sentence word frequency vectors is calculated as the similarity of personal description text.

$$\text{TF} = \frac{\text{The frequency of a word appears in a document}}{\text{The frequency of all words appears in a document}} \quad \text{（Formula 5）}$$

$$\text{IDF} = \log\left(\frac{\text{The total number of documents}}{\text{Number of documents containing an entry} + 1}\right) \quad \text{（Formula 6）}$$

(3) Word Mover's Distance similarity. Word Mover's Distance is a calculation method of text distance. Based on word embedding of Word2vec, text is represented as a standard word bag vector, word weight is defined, and the minimum cost of text transfer is obtained by minimizing the sum of

word weight transfer quantity and the product of transfer cost between words, to measure text Distance. The smaller the Word Mover's Distance between two sentences, the higher their similarity. Based on this method, the similarity of the personal introduction text can be calculated.

Semi-structured attribute similarity algorithm

Semi-structured attributes refer to the contents filled in by users in a prescribed format on social networking sites, including the work experience and educational background of users in the data set. Compared with the short string attribute, the content of such attribute is longer, and the discrimination effect of the direct calculation comparison on the virtual identity is not obvious, which generally needs to be processed. As the format of these attributes is relatively fixed, the attributes can be further split and sorted according to the format rules, and then calculated for each split item. The Kkuhn-Munkres algorithm is used to calculate the similarity of records. All attribute values of each record are treated as a long string. The string is divided into several substrings by the method of separator word segmentation. We calculate the similarity of each substring by using the maximum weighted matching algorithm of bipartite graph（Hailang et al, 2020）. The details are as follows, comparing two records string_1 and string_2 produces a fully qualified bipartite graph $B = \{V_1 \cup V_2, E, W\}$, the u of each node in V_1 represents substring $\mathrm{u_i}$ of string_1, the v of each node in V_2 represents substring $\mathrm{v_j}$ of string_2, $E = V_1 \times V_2$, the weight W function is defined as the similarity of two substrings, $W(u, v) = Sim(\mathrm{u_i}, \mathrm{v_j})$. $M = \left(V', E'\right)$ is the optimal match for B, $V' \subseteq V_1 \cap V_2$, $E' \subset E$, the semi-structured attribute similarity can be calculated by formula 7, Where m、n represent the number of substrings of string_1 and string_2, respectively.

$$Sim_{km} = \frac{\sum_{e \in E'} W(e)}{max\{m,n\}} \qquad \text{（Formula 7）}$$

Stacking model integration strategy

After completing the calculation of various attribute similarity features, it is necessary to use the classification model to classify the features on this basis. The classifier is the most core part of the model, which is crucial for the selection of the classifier and determines the accuracy of the classification results. The common machine learning classification models include Logistic Regression, Support Vector Machine, Decision Tree, Random Forest, KNN, Boosting, etc. Model Ensemble is an effective method to improve the effect of machine learning, different from traditional machine learning methods, it constructs a model on the training set, and Model Ensemble completes the learning task by constructing and integrating multiple models（Ghanbari et al, 2019）. Figure 2 shows a common model ensemble structure.

Fig. 2: A Common Model Ensemble Structure

Model ensemble mainly includes two stages: building several single models and model integration. A single model is usually obtained by learning the basic learning algorithm on the training set. It is also called a base learner. Model Ensemble uses different learning algorithms to build a single Model and integrates multiple weak models to produce a strong model. Mainstream model ensemble methods include averaging, voting, and learning. Stacking is a more powerful Model fusion method, proposed by Wolpert in 1992. Its basic idea is to integrate the prediction results of several single models through a model, in order to reduce the generalization error of the single model. These single models are called the level 1 model, and the Stacking model is called the level 2 model. Stacking produced single models from the initial training set, integrated the output of the single model as sample characteristics, and produced new training sets by labeling the original sample as new data sample. Then a new model was trained according to the new training set, and finally the sample was predicted with the new model. Algorithm 1 provided the Stacking operation process.

Algorithm 1: Stacking model ensemble algorithm

input：training set D= $\{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$；Single model learning algorithm $\xi_1, \xi_2, \dots, \xi_T$;model ensemble learning algorithm ξ。

1: for t= 1, 2,…,T do
2:$h_t = \xi_1(D)$
3: end for
4:$D' = \emptyset$
5: for i=1, 2,…,m do
6: for t=1, 2,…,T do
7: $Z_{it} = h_t(X_i)$
8: end for
9: $D' = D' \cup ((Z_{i1}, Z_{i2}, \dots, Z_{iT}), y_i)$
10: end for
11. $h'=\xi(D')$
output：H（x）$=h'(h_1(x), h_2(x), \dots, h_T(x)$

In the traditional Stacking model training process, the training set of the secondary model is generated using the primary model. If the first-level model is directly used to predict the initial training set sample to generate the second-level training set, there will be a great risk of overfitting. Therefore, we adopt the way of k fold cross-validation to get the input of the next layer model, k fold cross-validation is the training set into k shares, each time will be one of them as test data sets, another 1 k - data as the training set, using the corresponding training set and testing set for k times training model and predicted

respectively, k forecast result in accordance with the order together, will generate a complete set of the second classifier training set.

Experiments and Evaluation

Data set collection

In order to get the user accounts between different social network links, we take AngleList as collect user attribute information source site, through AngleList user home page URL to access the user access to the home page of Facebook and Linkedin personal public home page URL, filter to select which gives Facebook and Linkedin homepage link is not empty, failure and open access archives information page not AngleLis account, in the end, we got 2,879 Facebook accounts and 3,138 Linkedin accounts, among which, we only connected the user attributes of Facebook and Linkedin, and finally stored the information obtained from the two platforms into the database in a designed format. This paper selects intersecting contents of the two platforms for research, including personal home page URL, username, resume, work experience and educational background, which can be divided into string attribute, text attribute and semi-structured attribute according to data format.

Data pre-processing

Data formats in social platforms are different, so the differences between data formats need to be eliminated to form a unified data format and realize data comparison between different platforms. The string attributes in the collected data include the personal home page URL and the username. All personal home page URLs are uniformly converted into the format of "website domain name/specific string". In order to facilitate the comparison between URLs, the domain name part in the URL is further removed, leaving only the URL suffix. The username can be further split into last name, first name or last name, middle name, first name, etc. For semi-structured attribute processing, entity information can be extracted from HTML text block based on the relatively fixed position of data in the web page. The date of different formats cannot be compared directly, so the format of the date needs to be unified. For the processing of text attribute, the special symbols in the user's short text attribute are mainly processed by replacing the reference entities, English letters are uniformly converted to lower case, and the Numbers and special symbols in the text and short strings are removed.

Experimental Design

A universal feature extraction method is designed for the three attributes of different social networks. Various similarity computing algorithms are used in each dimension attribute to mine more comprehensive user similarity information as far as possible. Four user name feature extraction methods, namely, the longest common subsequences similarity algorithm, the longest common subsequences similarity algorithm, the edit distance similarity algorithm and the Jaccard similarity algorithm, were used to generate the four-dimensional string attribute feature vectors; Three feature extraction methods of Word2vec cosine similarity, TF-IDF cosine similarity and Word Mover's Distance similarity were used to generate 3d feature vectors of the text attribute; The similarity of semi-structured attributes is calculated by using the maximum weighted matching algorithm of bipartite graph, and the feature vector of semi-structured attributes in one dimension is generated. After the training of the basic model, the probability value of the classification result of the best classifier is

taken as the input of the integration classifier of the second model, and the integration model is used for training to establish the fusion model. Finally, the trained integrated model is used to predict, and the final prediction category is obtained. Stacking model of user identification model framework as shown in Figure 3, the model of the first layer with string property, short the semi-structured and attribute similarity as input, select Decision Tree, Logistic Regression, Logistic Regression, SVM, KNN, Random Forest and boosting for a total of six kinds of commonly used machine learning algorithm as the base line model training and testing, 5 fold cross-validation model training, and to make predictions on the test set, select the most effective classifier as the best classifier for the dimension.

Fig. 3: Stacking Model Integration Diagram

Evaluation index

In this paper, standard evaluation indexes are used to evaluate the effect, including Accuracy, Precision, Recall and F1. The calculation formula is as follows, Where, TP represents the correct mapping result that is predicted to be positive represents the correct mapping result with negative prediction represents the error mapping results predicted to be negative; TN represents the result of an error mapping that is predicted to be positive.

$$\text{accuracy} = \frac{\text{TP+TN}}{\text{TP+FN+FP+TN}} \quad \text{（Formula 8）}$$

$$\text{precision} = \frac{\text{TP}}{\text{TP+FP}} \quad \text{（Formula 9）}$$

$$\text{recall} = \frac{\text{TP}}{\text{TP+FN}} \quad \text{（Formula 10）}$$

$$\text{F1} = \frac{2}{1/\text{precision}+1/\text{recall}} \quad \text{（Formula 11）}$$

Result Analysis

Analysis of similarity calculation results

Each similarity algorithm has a good distinguishing effect. The statistical results of similarity calculation for each attribute of users are shown in Table 1. In the experiment, the user's personal homepage URL suffix and the user name are mainly used to verify the string attribute similarity algorithm, the algorithm calculated the URL suffix and user name similarity of the same user with an extremely high value, with the mean value exceeding 0.8, this proves that the URL suffix of the same user's personal home page and user name have a high degree of similarity between different platforms, which is suitable as a key feature to determine whether the same user is the same. In the experiment, the user's work experience and virtual education background were mainly used to verify the semi-structured attribute similarity algorithm. The value of the semi-structured attribute similarity of the same user's virtual identity was significantly lower than that of the string attribute similarity. The user's personal introduction is mainly used to verify the similarity algorithm of the short text. The statistical results are like semi-structured attributes, and the similarity calculation results are lower than those of relatively string attributes.

Table 1: Statistics of attribute similarity of social network platform

Attribute types	Similarity	Mean	Median	Min	Max
String	Home page URL	0.86	1.00	0.00	1.00
	User name	0.92	1.00	0.02	1.00
Short text	Personal introduction	0.38	0.37	0.00	1.00
Semi-structured	Work experience	0.41	0.40	0.00	1.00
	Education background	0.44	0.50	0.00	1.00

Comparison of classification models

For classification model selection in the algorithm, the first to use training samples to train the model, and use test data to test of the trained classifier, evaluating classifier in the performance of the data sets, according to the comprehensive evaluation index to select the dimension of F1 best classifier, under the condition of this experiment data sets, string attribute dimension under the optimal classifier selection for logistic regression algorithm, short text attribute dimension under optimal classifier selection for KNN algorithm, a semi-structured attributes of the decision tree as the best distributor. In order to prove the effectiveness of the model fusion learning classifier, the effect of the best classifier with single dimension features is compared. At the same time, in order to verify whether each dimension feature contributes to the final effect of the ensemble learning classifier, an ensemble learning effect verification experiment is set up in the absence of any dimension feature. The experimental results are shown in Table 2.

Table 2: Effect comparison of classification model

Classifier	ACC	P	R	F1
M1	63.33%	71.90%	49.00%	58.29%
M2	66.40%	70.41%	55.85%	62.29%
M3	54.56%	50.36%	53.33%	51.80%
M1M2	51.84%	47.63%	54.18%	50.69%
M2M3	81.62%	83.66%	83.66%	76.11%
M1M3	73.16%	82.44%	82.44%	58.62%
Stacking Model	84.15%	85.34%	83.76%	85.09%

In Table 2, M1 represents string property of optimal classifier, M2 essay this attribute the best classifier, M3 represents half structural properties of optimal classifier, through integration of machine learning effect after Stacking model has increased significantly, When the integrator classifier lacks a certain attribute of the classifier the outcome of M1 M2, M2 M3, M1 M3 are not as good as those predicted by combining the three single models, the experimental results show the best classifier in each dimension classifier integration can improve effect of algorithm, the experimental results showed that the stacking model had the best effect in recall rate, F1 value and accuracy.

Comparison with other algorithms

In order to verify the effectiveness of the mapping algorithm proposed in this study, we choose the representative user identity link algorithm in recent years to compare with the algorithm proposed in this paper. MOBIUS algorithm was proposed by Reza Zafarani et al in 2013. This algorithm analyzes the implicit characteristics of social network users in the naming mode to identify whether users of different social networks correspond to the same user. The other is a cross-social network user identity identification method based on user nickname proposed by Li YongJun et al. By comparing the naming methods of user nicknames in different social network platforms and analyzing the similarity between nicknames, the algorithm realizes the mapping and matching of virtual identities among Foursquare, Facebook and Twitter. Three algorithms are run on the real data set, and the results of different algorithms are compared and evaluated, the experimental results are shown in Table 4. Since the above two algorithms are only compared for the single attribute of user nickname, and the feature extraction method of the algorithm and the machine learning algorithm are single, the results in this experiment show a general performance. Compared with the other two algorithms, the algorithm in this paper has better performance in many aspects.

Table 5 : Comparison of user identity link algorithms based on user attributes

	ACC	P	R	F1
Stacking Model	84.15%	85.34%	83.76%	85.09%
Li YongJun	82.48%	86.38%	83.16%	84.74%
MOBIUS	80.01%	84.99%	81.90%	83.42%

Conclusion

The rise of various functional social networks has enriched the daily life of users and correspondingly produced large-scale user information. However, fragmented information on multiple platforms cannot fully depict user portraits, which becomes an opportunity for the development of identity link technology. Using the user big data generated by identity association and relying on artificial intelligence technologies such as deep learning to realize accurate characterization of character portraits, it lays a data foundation for the application of discovering social network public opinion, analyzing user behavior characteristics and checking false news, thus providing effective help for group and individual decision-making. In this paper, the text structure characteristics of common user basic information in social platforms are designed and the attribute similarity calculation method is universal to most social networks. Meanwhile, by integrating different machine learning models, this paper improves the effect of user attribute-based identity linking technology by integrating different machine learning models.

There are still some deficiencies in this paper, which need to be further studied :(1) there are many kinds of social network platforms, and some platforms are quite different from each other. The experiment conducted on only two platforms cannot fully explain the universal applicability of the algorithm, so more social platforms should be combined for algorithm verification in the future. (2) The basic attribute information of users will change over time, which is not considered in the study. In the follow-up research, the time dimension should be added to combine with the historical data of identity attributes to further improve the accuracy of the linking algorithm.

Abstract

Airports being a component of the air transport infrastructure make a significant impact on the economy of regions; on the other hand, the airport business performance is largely dependent on the regions' development. The article presents the results of analyzing a trans-regional market of airlift transportation, shows the connection and mutual dependence between the regional airport development strategies and the territory development strategies.

Keywords: airlift transportation market, transregional transport network, airport business, development strategy

Introduction

The transport network makes an important element of a territory's total infrastructure connecting individual regions and ensuring the territorial integrity of a country in general. The access to safe and qualitative transportation services determines the efficiency and growth of production, business, and social sphere. The transport sector and its infrastructure have a significant impact on the development of a territory, not only in the sense of its socio-economic development, but also from the standpoint of ensuring the regional stability and security in crisis situations.

At the same time, the vulnerability of transport sector's economic stability is determined by its interdependence with more than twenty sectors of national economy, as well as with labor, migration, demographics, educational and other social processes of the territories and the country as a whole. The economic analysis of regional airlift transportation is built on the principles of systematology and complexity [Ismagilova, 2016] and is aimed at identifying the reserves for ensuring the robustness of territorial airport networks, both while achieving strategic development goals and when experiencing any negative outer impacts.

Development Trends of the Transregional Airlift Networks

The Southern Urals and adjacent territories (the Republic of Bashkortostan, Orenburgskaya, Chelyabinskaya, Kurganskaya, Sverdlovskaya oblasts (regions)) host large manufacturing, mining, agricultural productions, well-known recreational zones. According to Rosstat (https://www.gks.ru/folder/12781?print=1), as of 01.01.2020, 5.8% of the Russian Federation

population live on the territory that makes up 2.15% of its total territory, the average population density is 22 inhabitants per square kilometer.

The contributions by different types of transport to the total volume of passenger and cargo transportation vary significantly. According to statistics from the Russian Federation Ministry of Transport (https://www.mintrans.ru/documents/7/10301), in 2019, 79.8% of cargo was transported by road, 18.27% - by rail, 1.9% - by sea and inland waterways, 0.02% - by air. As for the passenger transportation: road transport is also in the lead - 88.3%, followed by rail - 10.37%, air - 1.14%, sea and inland waterways - 0.17%. However, in terms of passenger turnover (number of passenger-kilometers), it is the air transport who was in the lead - 56.67%, the railway transport accounted for 23.9%, and the share of automobile transport - 19.28%.

The air transport has the indisputable advantage over all other modes of transport - the air routes are practically unlimited. Besides, the air transport provides a large time gain (due to the high speed of aircraft and the straightening of flight lanes) compared to other modes of transport at medium and especially long distances. According to experts, at distances of more than 1,000 km, the air transport begins dominating in passenger traffic, so it is for a reason that the average distance of one passenger airlift on domestic routes reaches almost 2,000 km, which is 3 times longer than that for the railway transport (long distance passenger transportation). At the same time, the air transport is the first to find itself in the risk zone in case of any unique global-scale crisis situations which happen extremely rare. A pandemic and economic crisis manifestations, as negative synergies, do not change the principles of analysis. To determine the consequences of this influence, one must see the development potential of the industry and territories.

Due to geographical peculiarities of Russia, the air transport plays a special role in ensuring transport accessibility of regions and communities. As economic activity increases, so does the business travel raising demand for speed and convenience that characterize the airlift services, which provides the bulk of passenger traffic and goods and materials supply over long distances.

Airports make the crucial component of the airlift infrastructure. The largest competing airport complexes in the Southern Urals and adjacent territories are:

- State Unitary Enterprise "Airport Orenburg" provides international (customs) transit in the southern direction and communication with the largest transport and logistics hubs in the region and the Russian Federation;
- Orsk Airport (a branch of Orenburg International Airport), as well as State Unitary Enterprise “Airport Orenburg”, provides transit in the southern direction and communication with the largest transport and logistics hubs in the region and the Russian Federation;
- Kurgan Airport provides transit of passengers and cargoes towards Western and Eastern Siberia;
- JSC "International Airport Magnitogorsk" provides transit in the southern direction and communication with the largest transport and logistics hubs in the region and the Russian Federation;
- International airports - transport and logistics hubs: PJSC Airport Koltsovo (the leader in the Ural Federal District); JSC International Airport Ufa; JSC Chelyabinsk Aviation Enterprise.

The airport cargo and passenger traffic statistics allow analyzing the main trends in the development of interregional segment of airlift transportation market. The analysis included:

- the amount of passenger carriage by air;
- the volume of freight traffic through airports.

The dynamics of changes in passenger traffic through competing airports is shown in Table 1:

Table 1: Servicing passengers in competitor airports (departed + arrived), (passengers) (https://www.magnitogorsk.ru/content/ekonomika-i-finansy/upravlenie-ekonomiki-i-investitsiy/glavnaya-8/ekonomika-goroda/strategiya-sotsialno-ekonomicheskogo-razvitiya)

The common trend for changes both in Russia and in the segment under review is the growth of passenger carriage volume. There are some differences in the change dynamics of passenger carriage (Table 2)

Table: 2 Passenger carriage growth rates by competitor airports (based on data in Table 1)

Airport	2015	2016	2017	2018	2019
JSC International Airport Magnitogorsk	77.72%	95.70%	151.32%	121.21%	97.86%
JSC Chelyabinsk Aviation Enterprise	88.19%	96.70%	123.63%	111.62%	104.45%
JSC International Airport Ufa	97.24%	100.17%	121.74%	115.33%	110.35%
PJSC Airport Koltsovo	93.24%	100.88%	125.43%	112.82%	104.68%
State Unitary Enterprise "Airport Orenburg"	95.22%	77.36%	152.82%	106.45%	98.91%
Kurgan Airport	91.78%	86.15%	98.82%	n/a	n/a
Orsk Airport	104.34%	81.17%	40.06%	n/a	n/a
Total by segment	93.43%	97.98%	125.28%	109.84%	105.67%
Total in the RF	101.00%	100.17%	117.02%	110.62%	106.92%

The imposition of sanctions in 2014 resulted in a drop in the traffic via almost all airports under review, with the most affected facility being JSC International Airport Magnitogorsk, the volume of its traffic decreased by 22.28%. In 2016, the traffic decline slowed down, while the two largest airports have begun growing. In 2017, all airports of the segment, except Kurgan and Orsk airports, showed good growth rates supporting the growth rate of the analyzed segment, which exceeded the growth rate of passenger traffic through Russian airports in general. JSC International Airport Magnitogorsk was second in 2017 growth rates. The years 2018-2019 saw a slowdown in growth rates, with most airports maintaining the overall positive growth trend in passenger traffic. In general,

the dynamics of passenger traffic through the segment airports supports the all-Russian dynamics. The distribution of market shares between competitor airports is shown in Table 3.

Table 3: The changing market shares of competitor airports within the "passenger traffic" segment (based on Table 1 data)

Airport	2014	2015	2016	2017	2018	2019
JSC International Airport Magnitogorsk	1.86%	1.55%	1.51%	1.83%	1.98%	1.83%
JSC Chelyabinsk Aviation Enterprise	15.13%	14.28%	14.09%	13.91%	13.85%	13.69%
JSC International Airport Ufa	25.57%	26.61%	27.21%	26.44%	27.21%	28.42%
PJSC Airport Koltsovo	48.54%	48.44%	49.87%	49.93%	50.27%	49.80%
State Unitary Enterprise "Airport Orenburg"	7.17%	7.31%	5.77%	7.04%	6.69%	6.26%
Kurgan Airport	0.88%	0.87%	0.76%	0.60%	n/a	n/a
Orsk Airport	0.84%	0.94%	0.78%	0.25%	n/a	n/a
Segment share in the total RF market	5.84%	5.40%	5.29%	5.66%	5.73%	5.67%

The 2020 data are likely to significantly change the transportation quantitative indicators, but the market structure will most probably remain. The total share of the reviewed segment airports in the passenger carriage through the Russian Federation airports is changing slightly as a percentage fraction. Within the segment under review, there is a significant reduction in the market share of Kurgan and Orsk airports. There were no significant changes in the distribution of market segment among other competing airports throughout the analyzed period. However, in November 2019, a new airport terminal was opened in Chelyabinsk, which made it possible to increase the number of annually served passengers to 2.5 million. Note that launching the new terminal is only a part of the strategy to make Chelyabinsk airport one of the leaders in passenger traffic and route network. This strategy includes, inter alia:

- implementation of the program of co-financing flights from regional and federal budgets. In 2020, it is planned to subsidize flights to such cities as Kazan, Samara, Surgut, Novy Urengoy, Krasnoyarsk, Krasnodar, Mineralnye Vody, Rostov-on-Don, Volgograd, Omsk, Nizhny Novgorod;
- development of high-speed railway access to the airport;
- development of the region's own basic airline and the resource base for it.

It is obvious that prospectively the Chelyabinsk airport's proactive strategy may lead to a reshuffle of market shares in the segment.

The dynamics of air freight traffic differs significantly from the dynamics of passenger traffic (Tables 4 and 5).

Table 4: Cargo transportation through competitor airports (tons) (https://www.magnitogorsk.ru/content/ekonomika-i-finansy/upravlenie-ekonomiki-i-investitsiy/glavnaya-8/ekonomika-goroda/strategiya-sotsialno-ekonomicheskogo-razvitiya)

Airport	2014	2015	2016	2017	2018	2019

Table 5: Rates of changes in cargo transportation through competitor airports (based on Table 4 data)

Airport	2015	2016	2017	2018	2019
JSC International Airport Magnitogorsk	81.98%	104.44%	107.53%	n/a	n/a
JSC Chelyabinsk Aviation Enterprise	76.72%	111.13%	105.96%	106.41%	91.84%
JSC International Airport Ufa	80.39%	115.28%	128.88%	107.76%	94.29%
PJSC Airport Koltsovo	82.77%	109.14%	96.48%	95.27%	93.33%
State Unitary Enterprise "Airport Orenburg"	87.73%	95.86%	125.10%	101.91%	97.30%
Kurgan Airport	99.65%	100.23%	103.64%	n/a	n/a
Orsk Airport	54.37%	76.56%	58.43%	n/a	n/a
through the segment	81.90%	109.12%	102.39%	96.04%	93.50%
total in the RF	87.88%	107.50%	113.75%	92.30%	99.68%

In Russia as a whole, the dynamics of both the freight traffic and its change rate, with regard to the sanctions impact, has an up-and-down nature. Finding the general trend (growth or reduction) requires additional observations and analysis of the relevant performance indicators of competing freight carriers (railway, sea and inland waterways, road transport). According to the statistical data of the State Statistics Committee of Russia (https://www.gks.ru/folder/23455?print=1), the total freight traffic (the amount of transported cargo in ton-kilometers) was distributed among modes of transport as follows: 45.89% of freight traffic fell on railway transport, 47.37% - on pipeline transport (which is not a competitor to the air transport), 4.83% - road vehicles, 1.76% - sea and inland waterways, and only 0.13% - on the airlift. Since the early 2000s, both the total freight traffic, and the freight traffic on railway and road transport have shown an annual increase, albeit insignificant, within 10%. The years 2009 and 2014 have dropped out of the general trend. Freight traffic by the air transport with its up-and-down changes has a general downward trend both in Russia as a whole and in the segment under review. The prospects for fluctuations in the development trends of industries are highly likely in the coming years.

The difference in the growth rates of cargo transportation through the analyzed airports and across the Russian Federation in general has led to a decrease in the market share of the segment as a whole (Table 6).

Table 6: Changes in market shares of competitor airports within the freight traffic segment (based on Table 4 data)

Airport	2014	2015	2016	2017	2018	2019
JSC International Airport Magnitogorsk	1.30%	1.30%	1.24%	1.30%	n/a	n/a
JSC Chelyabinsk Aviation Enterprise	10.42%	9.76%	9.94%	10.28%	11.39%	11.19%
JSC International Airport Ufa	11.73%	11.52%	12.17%	15.31%	17.18%	17.33%
PJSC Airport Koltsovo	70.83%	71.57%	71.59%	67.45%	66.91%	66.79%
State Unitary Enterprise "Airport	3.70%	3.96%	3.48%	4.25%	4.51%	4.69%

Orenburg"						
Kurgan Airport	0.99%	1.21%	1.11%	1.12%	n/a	n/a
Orsk Airport	1.04%	0.69%	0.48%	0.28%	n/a	n/a
Segment share in the entire RF market	4.05%	3.78%	3.83%	3.45%	3.59%	3.37%

Within the segment under consideration, there is a significant reduction in the market share of Airport Orsk, PJSC Airport Koltsovo. No significant changes have been noted in the distribution of the market segment among other competing airports over the entire analyzed period.

Thus, the dynamics of airlift transportation market segment is characterized by the following:
- a growth in passenger traffic parameters, which expands opportunities for the airport business development in general;
- minor changes in the ratio of market shares between competing airports;
- reduction of the segment's total share in the freight traffic market of the Russian Federation as a whole against the background of the general trend for decreasing air freight traffic.

Despite all types of transport being the elements of united transportation infrastructure of the country, certain types of transport compete with each other in the cargo and passenger carriage markets. For the analyzed segment of the airlift transportation market, there also exist certain threats in terms of emerging substitutes – the services replacing airlift transportation.

In September 2019, a new Chelyabinsk-Magnitogorsk high-speed rail route was tested. The total travel time of the test "Lastochka (Russian for swallow)" train from Chelyabinsk to Magnitogorsk was about four hours. The route included two technical stops at Troitsk and Kartaly-1 stations. The speed in some areas during the experiment reached 140 kilometers per hour. In case this route is switched from the test mode to the regular one, this alternative may significantly redistribute the air passenger flows - residents of Magnitogorsk choosing the Chelyabinsk airport.

The spatial development strategies of cities and municipalities are laid along the general strategic priorities of the Russian Federation development and are aimed at increasing the competitiveness of regions (cities, enterprises) (Ismagilova, 2014, https://www.magnitogorsk.ru/content/ekonomika-i-finansy/upravlenie-ekonomiki-i-investitsiy/glavnaya-8/ekonomika-goroda/strategiya-sotsialno-ekonomicheskogo-razvitiya). The strategy of Magnitogorsk urban district (https://www.magnitogorsk.ru/content/ekonomika-i-finansy/upravlenie-ekonomiki-i-investitsiy/glavnaya-8/ekonomika-goroda/strategiya-sotsialno-ekonomicheskogo-razvitiya) provides for an active development of transport infrastructure. In particular, the strategy includes measures that can significantly affect the distribution of airport service consumer flows: implementation of the proposal to arrange regular domestic flights (to be subsidized from the Chelyabinsk regional budget) to the largest transport hubs: Yekaterinburg, Ufa, St. Petersburg; increasing the transport accessibility of the Magnitogorsk interregional agglomeration by rail, in particular:

- development of the proposal to resume the high-speed train "Chelyabinsk - Kartaly - Magnitogorsk";
- promoting the feasibility study for the electrification of Magnitogorsk - Sibai railway line. Assisting in its inclusion to the Strategy for the Development of Railway Transport in the Russian Federation till 2030 and the Development Strategy of the Russian Railways Holding;
- improving the transport connectivity of Magnitogorsk by railway with the largest economic centers: Chelyabinsk, Yekaterinburg, Tyumen, Perm;
- development of road transport infrastructure of interregional and intermunicipal significance;
- assistance in bringing the Chelyabinsk-Magnitogorsk highway to the normative state, formation of roadside service and camping zones;
- reconstruction of the Magnitogorsk - Beloretsk - Ufa highway within the framework of cooperation with the Republic of Bashkortostan;
- formation of the transport corridor "Yekaterinburg - Kyshtym - Miass - Magnitogorsk - Orsk" within the development of cooperation with Sverdlovskaya oblast.

Note that these measures, if successfully implemented, will result, on the one hand, in redistributing the existing structure of transport traffic, but on the other hand, they will contribute to the growth of passenger and freight traffic in the region.

The following conditions will make the basis of competitiveness when choosing travel options by consumers: convenience, comfort, a set of related services, fast communications with transport infrastructure operators, all-round services, including the integration of operators of various transport modes (for example, the purchase of transit travel documents "bus - train - plane" using the "one window" principle, etc.), as well as the price factors.

Results

The analysis results for airport complex enterprises as presented in this article made it possible to demonstrate the peculiarities of this sector businesses, revealing their indicative role in assessing the level of socio-economic development of territories. The role of airports is shown in the integrated development of interregional transport infrastructure. The analysis of dynamic and structural changes in the interregional segment of the air transportation market is an indicator of current trends in the development of territories.

The well-grounded scheme for analyzing the airport complex companies may be used in the development of sectoral strategies for the development of infrastructure of both municipalities and territorial agglomerations. The above analysis of interregional segment of airlift transportation market shows the possibilities for maintaining economic stability during socio-economic bifurcations of polyfactorial negative trends in the current state of the world economy.

Polish *Impact Barometer* as a Tool to Measure Business Contribution to The Achievement of The Sustainability Development Goals

Joanna KRASODOMSKA

Cracow University of Economics, Krakow, Poland

joanna.krasodomska@uek.krakow.pl

Abstract

The important role of business in the realization of the *Agenda 2030* commitments is widely accepted. *Sustainable Development Goals* (SDGs), which are at the heart of the *Agenda*, are nowadays among the key topics in corporate practices and reporting. The paper aims to investigate the situation in Poland as regards the SDGs achievement with a particular focus on companies indicated as the first members of the *Impact Barometer* Programme. The research uses available official NGO's reports, information gathered via SDGs-related website and selected companies' communications. The study findings show that the engagement of the companies operating in Poland in practices and disclosures linked to the SDGs accomplishment has been increasing. However, according to the information currently available, the *Impact Barometer* is used by eight companies, and the identified examples show that corporate disclosure is fragmented and, in some areas, impossible to compare. The paper acknowledges the need for future research in the field of the corporate practice and reporting related to the SDGs and draws attention to the negative *SDGs-washing* phenomena. The results of this study might be useful for researchers, practitioners, and other stakeholders focused on striving for a more sustainable future.

Keywords: SDGs, non-financial reporting, sustainable development, Poland.

Introduction

The United Nations Member States adopted the *Sustainable Development Goals* (SDGs) in 2015 as part of the *2030 Agenda for Sustainable Development* (UN, 2020a). SDGs build on the *Millennium Development Goals* set in 2000 and address global challenges in health, education, social equity and justice, economic security, and environmental issues (Sullivan *et al.*, 2018). The SDGs are not only 17 goals, but also 169 specific targets. Their achievement is monitored and reviewed using a set of global indicators. Member States' governments (UN, 2020a) may also develop their own indicators. At the EU level, a set of 100 indicators has been created and is monitored by the Eurostat to assess the progress towards the SDGs in an EU context (Eurostat, 2020).

Although the SDGs achievement lies within the responsibility of the countries and governments, the business has a critical role in this process. Governments do not have enough resources to provide all the solutions necessary to achieve the SDGs (Sullivan *et al.,* 2017). As Mio *et al.* (2020) argue, businesses' contributions to achieving the SDGs have been already recognized in the literature (see, e.g., Garcia-Sanchez *et al*., 2020; Haffar and Searcy, 2018; Sullivan *et al*., 2018; Wicki and Hansen, 2019), and especially multinational corporations' (MNCs) inputs are seen as essential to the success in pursuing sustainable development.

On the business level, SDGs are linked to corporate social responsibility (CSR), defined as "the responsibility of enterprises for their impacts on society" (European Commission, 2011). Corporate CSR- related activities contribute to the SDGs and provide several advantages to companies (GRI, 2020b). Businesses wishing to treat SDGs as a guideline to modify their business strategies can use dedicated tips and tools, as the *SDG Compass* (GRI, UN Global Compact, WBCSD, 2020). Undoubtedly, the business can play a key role in achieving the SDGs. However, many companies have not traditionally viewed sustainability policies as an essential component of their financial and operational priorities (Sullivan *et al.,* 2017), and the lack of knowledge about the role of business in addressing SDGs

Cite this Article as: Joanna KRASODOMSKA" Polish Impact Barometer as A Tool to Measure Business Contribution to The Achievement of The Sustainability Development Goals" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and its relevance for sustainable development has been highlighted by professionals (Mio *et al*., 2020). There is a general agreement that SDGs are important to our common future. However, despite the initiatives undertaken so far, there is still not enough understanding of what exactly companies' concrete actions should be like (Pwc, 2019).

This paper focuses on the inclusion of the SDGs in corporate practice and reporting in Poland. This particular country has been chosen since a unique tool – *Impact Barometer* has been created here allowing companies to measure their progress in achieving SDGs. The study aims to present the current situation in Poland as regards the SDGs -related corporate practices and reporting with a particular focus on companies which are the first members of the *Impact Barometer* Programme. The study is based on the reports published by the largest NGO in Poland addressing the sustainability concept - Responsible Business Forum (RBF, 2017, 2018, 2019, 2020), as well as on the information posted on the Polish official SDGs-related website and selected companies' communications (reports and websites).

The paper proceeds as follows. The next section presents the SDGs in the business reporting context. After that, the SDGs implementation in Poland is discussed. The following section provides information on the *Impact Barometer* as a tool for SDGs achievement and reporting support. The last section offers conclusions and an indication of future research possibilities.

Corporate non-financial reporting and SDGs

Table 1 presents the 17 SDGs.

Table 1: Sustainable Development Goals

1 No poverty	2 Zero hunger	3 Good health and well-being	4 Quality Education	5 Gender Equality	6 Clean water and sanitation
7 Affordable and clean energy	8 Decent work and economic growth	9 Industry, Innovation and infrastructure	10 Reduced inequalities	11 Sustainable cities and communities	12 Responsible consumption and production
13 Climate action	14 Life below water	15 Life on land	16 Peace, justice and strong institutions	17 Partnership for the goals	**THE GLOBAL GOALS For Sustainable development**

Source: SDSN (2020).

The 12th SDG *Sustainable consumption and production* in its target 12.6 explicitly encourages companies, especially MNCs, to adopt sustainable practices and to integrate sustainability information into their reporting cycle. Indicator 12.6.1 requires data on the number of companies publishing sustainability reports (UNCTAD, 2019). The increase in the reporting on the companies' contributions to the SDGs is significant as it raises SDGs awareness among companies and their stakeholders and facilitates the implementation of good practices.

According to the latest *The Sustainable Development Goals Report* (UN, 2020b), sustainability reporting has been increasingly used by companies to demonstrate their commitment to the *Agenda 2030*, and the quality of disclosures has been improving. Currently, 92% of the world's 250 largest businesses report on sustainability measures, and 74% of these use GRI guidelines to do so. All of the more than 9,500 UN Global Compact participants, the majority of which are small and medium-sized enterprises (SMEs), report annually on their sustainability impacts (GRI, 2020c). Nevertheless, many companies' reports still fail to mention certain critical aspects of environmental, social and governance issues, such as water use, waste and emissions, gender equality, training in anti-corruption issues, and expenditures on employee health and safety (UN, 2020b).

There is no single, uniform methodology for measuring and reporting business progress and impacts on the SDGs. Most companies use reporting standards that predate the SDGs (such as GRI). The complexity and volume of targets under the SDGs also prevent some SMEs from reporting on their contributions to these goals (GRI, UN Global

Compact, 2020). Therefore, several initiatives have been launched to develop an agreed-upon and harmonized set of indicators for consistent and comparable sustainability reporting. One is the *UNCTAD Guidance* (2019) whose objective is to provide practical information on how indicators could be measured in a consistent manner and aligned with the common needs of many different stakeholders of the SDGs agenda.

SDGs are not only an essential practical issue but also a topic of academic research. According to an extensive literature review provided by Mio *et al.* (2020), the SDGs implementation is the most often investigated theme in scientific papers, and it is followed by the interest in the company's role in SDGs achievement or governance and the industry's role in this process. Most of the cited authors (Christ and Burritt, 2019; Isaksson, 2019; Muff *et al*., 2017; Raub and Martin-Rios, 2019; Vandenbrande, 2019) deal with the topic using conceptual and interpretative methodologies, mainly by developing frameworks for SDG implementation. They also mostly discuss or mention all 17 SDGs in their studies. Interestingly, disclosures on the SDGs are not a widespread research problem. As Mio *et al.* (2020) state, apart from Gunawan *et al*. (2020), the literature on SDG disclosure is almost nonexistent.

SDGs in Poland

SDGs in corporate practice

In Poland, the *Agenda 2030* and its objectives are implemented using the *Strategy for Responsible Development* (SRD), adopted by the Council of Ministers in 2017. In achieving SDGs, Poland ranks 16th in the ranking of EU countries (SDSN, 2019) and 23rd out of 166 in the world ranking "SDG Index" (SDSN, 2020). The Polish Main Statistical Office is responsible for monitoring the implementation of SDGs in Poland. According to the UN data for Poland, SDG 1 and 15 are perceived as achieved, major challenges relate to SDGs 7, 13 and 17. The implementation of SDG 12, as well as 2, 5, 9, 10 and 11, pose significant challenges (Sachs *et al*., 2020).

The initiative *Responsible Business in Poland. Good Practices* initiated by the Responsible Business Forum (RBF) allows getting an understanding of the Polish companies' CSR practices. Being referenced in the report issued by the RBF means that a company has proved its CSR engagement by voluntarily subjecting the CSR-related practices to RBF experts for evaluation . The CSR practices included in the report are classified into seven areas according to the ISO 26000 standard (Table 2).

Table 2: Number of good practices of companies operating in Poland according to the ISO26000 areas in 2016-2019

CSR area	2016 N=180	2017 N=177	2018 N=229	2019 N=214
Organizational governance	51	63	83	96
Human rights	27	37	61	74
Labor practices	205	312	417	473
Environment	117	171	235	321
Fair operating practices	45	48	55	73
Consumer issues	63	79	97	95
Community involvement and development	372	480	601	564
Total	**880**	**1,190**	**1,549**	**1,696**

Source: RBF (2017, 2018, 2019, 2020)

Both the number of companies and the number of their CSR-related practices included in the subsequent editions of the report have been growing from year-to-year. In 2020, the total number of submitted practices (new and long-term ones) equals 1,696 and is by 10% higher as compared to the previous year (RBF, 2020). 214 entities reported their engagement in CSR in the last edition (in 2020) and, compared to the 2016 report, their number has increased by 34. As table 2 presents, the highest number of practices relates to the area of community involvement and development and labor practices.

Table 3: Number of SDGs indicated by the companies as linked to their good practices in 2016-2019

	2016	2017	2018	2019
SDG 1	11	47	41	58
SDG 2	17	26	31	31
SDG 3	69	224	317	360
SDG 4	92	332	351	442
SDG 5	9	24	23	74
SDG 6	6	11	18	17
SDG 7	11	18	37	44
SDG 8	29	136	214	336
SDG 9	27	57	91	105
SDG 10	18	61	91	218
SDG 11	38	81	122	186
SDG 12	12	102	175	277
SDG 13	13	41	115	103
SDG 14	1	5	8	14
SDG 15	20	46	73	89
SDG 16	6	18	39	52
SDG 17	6	16	43	53
Total	**385**	**1,245**	**1,789**	**2,459**

Source: RBF (2017, 2018, 2019, 2020)

The same report links corporate good practices with the SDGs. Table 3 presents their number related to each of the 17 SDGs. SDGs 4, 3, and 8 are most often mentioned by companies. The number of references to the SDGs provided by the companies increases with time. The most significant increase in the companies' declared contribution to the implementation of the *Agenda 2030* relates to SDGs 12, 14, 10 and 8.

Sustainability and SDGs reporting in Poland

As far as sustainability reporting is concerned, GRI tool, *SDG Target 12.6/Country-Tracker* allows identifying the number of sustainability reports published in a particular country. In the case of Poland, the *Tracker* shows 44 reports for the publication year 2017 (latest available year), which seems low in comparison to such countries as, e.g., France (189 reports), Germany (176), or Sweden (186). However, the number of GRI reports is higher in Poland than in other Eastern European countries such as, e.g., Romania (8), Slovak Republic (8), or Bulgaria (4) (GRI, 2020a). The introduction of the Directive 2014/95/EU and subsequent changes in the Polish accounting law were important steps towards the increase in the non-financial disclosure volume. Starting from 2018, over 160 large public interest entities (PIEs) were required to provide a non-financial statement in the management commentary or in a separate report.

Some further insights into the sustainability reporting in Poland, with the focus on SDGs, can be gained by analyzing the results of the annual contest for the best sustainability report (*Konkurs Raporty Społeczne*) organized by the RBF and Deloitte (RBF, 2020b). Table 4 presents the winners of the last edition (2019). Five of the recognized reports show direct references to the SDGs. What is more, the title of Kompania Piwowarska's publication (*Sustainable Development Report 2018. Our inputs into the implementation of the Agenda 2030*), explicitly suggests the relation to the UN initiative.

Table 4: The winners of the Best Sustainability Report contest 2019 edition and information on the references to the SDGs in awarded reports

Co. Name	Award type	Direct reference to SDGs
Benefit Systems	Internet users award	Not provided
LPP	WSE award	4, 8, 9 10, 11, 12, 13, 17
Santander Bank Polska	Best Social Report award	3, 4, 5, 8, 9, 11, 13, 17
Grupa Energa	Minister of Investment and Development award	Not provided
Orange Polska	Best integrated report award	1,3, 4, 5, 8, 9, 10, 11, 12, 13, 16, 17
Kompania Piwowarska	Distinction award	3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 16, 17

Source: Benefit systems (2019), LPP (2019), Santander Bank Polska (2019), Grupa Energa (2019), Orange Polska (2019), Kompania Piwowarska S.A (2019).

The *Impact Barometer* and its practical implementation by the first reporters

The *Impact Barometer* is a tool to measure the impact of business on the implementation of the *Agenda 2030* in Poland. It was developed in 2019, and it is available for any company free of charge. The idea of *Impact Barometer* originated from the view that many companies feel overwhelmed by the number and complexity of the *Agenda 2030* indicators and that UN national SDGs are not always adequate for business. In the expert consultation process, six priority SDGs for Polish companies were identified. Then, 30 key indicators were chosen to measure the most important areas of their influence. According to the tool's creators, with a transparent list of indicators, the company can measure its impact, compare the effects with the average values for the Polish business and present the results in its non-financial reporting. The cumulative outcome for all companies will allow monitoring the implementation of the *Agenda 2030* in Poland and identifying on an ongoing basis critical areas of action for achieving targets (GUS, SDG, 2020).

Despite the apparent logic that underlies the *Impact Barometer* development, there might be some criticism involved as well. According to some experts, companies should not focus on only a few SDGs, but assess their impacts in a more comprehensive manner. The research by PwC shows that firms may tend to focus on a small number of SDGs that are most relevant to their business operations or on those to which they already make substantial contributions with no significant efforts (the "easy wins"), such as SDG 8 *Decent work and economic growth*. Some firms might be prone to the "cherry-picking" of the SDGs, and show that they made progress in achieving some SDGs, while neglecting the negative impacts as regards others (MVO Platform, 2018).

Stena Recycling is the first company on the Polish market to use the *Impact Barometer* to report non-financial data. According to the information provided on the official *Impact Barometer* site, seven other companies joined this initiative (Kampania 17 Celów, 2020). Table 5 provides their main characteristics.

Table 5: The *Impact Barometer* initiative: first reporters

Company	No. of employees	Industry	Included in the latest RBF Report	Reference to the *Impact Barometer* in the latest available report
Benefit Systems	532	Activities of sports facilities	Yes	No
BOŚ	1,212	Other finance operation intermediation	Yes	No
Carlsberg Polska	1,300	Wholesale of alcoholic beverages	Yes	No
Carrefour	14,000	Grocery stores	Yes	No
Ergo Hestia	1,800	Life insurance	No	No
PGE	40,000	Electric energy	Yes	Yes
Rossmann	18,404	Retail sale of cosmetics, toiletries and cleaning products	Yes	No
Stena Recycling	541	Recovery and preparation for scrapping, international trade in steel, non-ferrous metals and crude oil; purchase and processing of waste paper and scrap purchase	Yes	Yes

Source: RBF (2020), Stena Recycling (2020), PGE (2020), Benefit systems (2020), BOŚ (2020), Carlsberg Polska (2020), Carrefour (2020), Ergo Hestia (2020), Rossmann (2020)

According to the data included in table 5, the *Impact Barometer* Programme Members are quite a diverse group as regards the size and industry profile. Benefit Systems and Stena Recycling are companies with around 500 employees, while PGE has 40,000 of them. However, despite the low number of employees, Benefit Systems is qualified as a large PIE, and it is required to provide non-financial disclosures under the Directive 2014/95/EU. The company issues a separate non-financial report and uses GRI Standards as a reporting framework.

Only Stena Recycling and PGE present the reference to the *Impact Barometer* in their reports. However, Stena Recycling does not provide values for 18 of the indicators included in the *Impact Barometer* and PGE for 11 of them. Out of 30 indicators, only 9 were disclosed by both companies, and the highest level of comprehensiveness was achieved in relation to SDG 4 and SDG 8 (the same indicators were disclosed by both companies) (Table 6).

Table 6: The *Impact Barometer*: Stena Recycling vs PGE

SDGs and indicators	Stena Recycling	PGE
Goal 3: Ensure healthy lives and promote well-being for all at all ages		
3.1 Average health care expenditure per employee	141.56 PLN	321.23 PLN
Goal 4: Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all		
4.1 Average number of training hours per employee	**4.98**	**9**
4.2 Number of pupils and students covered by the company's activities supporting the education process in relation to the number of employees	Not reported	**45.03**
4.3 Percentage of employees trained in sustainable development	**61.87%**	**6.67 %**
4.4 Percentage of employees involved in sustainable development initiatives	Not reported	**17.86 %**
4.5 Number of people educated about sustainable development in relation to the number of employees	**301,708.32%**	**2,157.77%**
Goal 5: Achieve gender equality and empower all women and girls		
5.1 Percentage of women in managerial positions	**35%**	**23 %**
5.2 Women to men remuneration ratio	Not reported	Not reported
5.3 Difference in admissions of applicants in recruitment processes of women compared to men	Not reported	Not reported
5.4 Percentage of employees trained in countering mobbing, sexual harassment, violence or discrimination	**100%**	**9 %**
5.5 Difference in use of support programs facilitating care of children, senior parents and other dependents by women compared to men	Not reported	Not reported
5.6 Difference in use of parental leave by women compared to men	Not reported	Not reported
Goal 8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all		
8.1 Value added of the company per employee	Not reported	Not reported
8.2 Percentage of employees employed under an employment contract	**97.23%**	**98.12 %**
8.3 Highest to the lowest salary in the company ratio	Not reported	Not reported
8.4 Ratio of low-level employees' remuneration to the minimum wage	Not reported	Not reported
8.5 Employee turnover	**10.57%**	**2.83 %**
8.6 Percentage of persons with disabilities among employees	**1.21%**	**1.51 %**
8.7 Ratio of number of reported violations of the Code of Ethics to the number of employees	Not reported	**0.44 %**
8.8 Percentage of purchases whose suppliers have been verified against CSR criteria	Not reported	**100 %**
Goal 9. Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation		
9.1 Expenditure on innovations in relation to revenue	Not reported	**4.5 %**
9.2 Percentage of expenditure allocated to sustainable solutions as part of expenditure on innovations	Not reported	**97.5 %**
9.3 Number of research projects carried out in cooperation with scientific institutions in the last 3 years	Not reported	**26**
Goal 12. Ensure sustainable consumption and production patterns		
12.1 Material efficiency	Not reported	Not reported
12.2 Energy efficiency	**4.31%**	**10,89 %**
12.3 Percentage of energy from renewable sources	**20.00%**	Not reported
12.4 Greenhouse gas emissions	Not reported	**61,489,339**
12.5 Water efficiency	**7.52%**	Not reported
12.6 Percentage of recycled or reused waste	Not reported	**50.86 %**
12.7 Percentage of raw materials and materials from sustainable sources	Not reported	Not reported

Source: own elaboration based on Stena Recycling (2020), PGE (2010).

Conclusion and indication of future research

There are only 10 years left to the implementation of the *Agenda 2030* goals. 17 SDGs are a call for action to all countries in a global partnership and the business will play a key role in achieving them. With the initiative of this scale and complexity, only joint, true engagement, and uniform reporting will provide an opportunity for a real assessment of progress in the realization of its objectives (Korzeniewska, 2020).

However, apart from the obvious benefits, there are also some challenges involved. After commonly known "green washing" the new term "blue washing" appeared. It is defined as a situation in which firms figuratively drape themselves in the blue UN flag to distract stakeholders from their real, as opposed to cosmetic, poor environmental or human rights records (*New York Times*, 2010). More recent concern is "SDG-washing". The participation in the realization of the SDGs offers opportunities for businesses to demonstrate how they are actively facilitating sustainable development and improve their reputation. Due to this fact, they are keen to map their CSR initiatives to the 17 icons that represent the SDGs with a myriad of colorful infographics on websites and in reports. However, a more thorough analysis of their disclosures shows that they market their positive contribution to some of them and neglect negative impacts on others. According to Nieuwenkamp (2017), focus on the negative impacts on the SDGs is the most urgent and important. Ignoring that undermines the whole collaborative effort.

This study presents a preliminary and descriptive analysis of the Polish companies' actions related to UN SDGs. The findings suggest that, although Poland's situation as regards the progress towards the implementation of the *Agenda 2030* in comparison to other UN Member States might be evaluated positively, further encouragement for business to get involved in SDGs achievement is needed. The number of companies that undertake sustainability practices which are directly linked to the SDGs is growing. Four out of six companies recognized for their outstanding reporting practices included direct references to the SDGs in their reports. However, it should be noted that companies participating in the RBF's initiatives voluntarily submit their practices and reports for evaluation. Therefore, their approaches might not be representative of the problem.

The *Impact Barometer* might be a useful tool for companies even though its implementation does not seem to be at the very advanced stage at the moment. The likely reason is that it has only been a year since the tool was proposed, so its more comprehensive implementation and assessment of the results will be possible in the following years. In the author's opinion, the indicator 4.5 requires more clarification. The numbers like 301,708.32% might be confusing for the report's users without additional explanation. In 2019, 214 companies submitted over 2,400 practices with impacts on SDGs for the RBF evaluation. They seem to be a group of potential new members of the *Impact Barometer* Programme.

Further research is needed as regards the SDGs implementation and reporting by Polish businesses. The first step might be to analyze the reports of about 160 large PIEs, which are mandatorily required to provide non-financial disclosures in Poland, and identify their strategies in this regard. The following research questions seem worth asking:

RQ1. Do these companies provide information on how SDGs are linked to strategy?
RQ2. Do they measure their actual impacts as regards SDGs and report on them or just on activities?
RQ3. Do they only map activities they have already undertaken to the SDGs or evolve their strategies and operations to drive change?
RQ 4. Which NGOs, cause-related organizations, and think tanks do they cooperate with in their journey towards SDGs?
RQ5: How many of them perform "SDG-washing"?
RQ6: Does the *Impact Barometer* deliver the assumed outcomes?
RQ7: Which factors influence the companies' decision to contribute to the achievement of SDGs and join the *Impact Barometer* Programme?

This paper attempts to provide new insights into the SDGs implementation. Despite the limitations involved, it includes information on the unique SDGs implementation tool – *Impact Barometer* and its use by the Polish companies. It also formulates the research questions which indicate the desired direction of the possible future research. The findings of this preliminary study might also be relevant for practice. It seems crucial for the *Impact*

Barometer to be implemented by a large number of companies to achieve its aims. The negative phenomena of "SDG-washing" has to be monitored. The joined collaboration of governmental agencies, NGOs, businesses, and academia members is needed to take action that will contribute to sustainable future. Without a transparent approach to measure progress, the joined efforts might be hard to evaluate and manage effectively.

Acknowledgments

Abstract

Research motivation. This paper is in line with the assumption that the organizational structure of the future will be an adapting hierarchy, and its perfection will be expressed in adapting to nature and human needs. One of them is a chain of command, frequently replaced by the term "scalar chain" or "line of authority". The aim of the study is the theoretical and empirical examination of the influence of the chain of command on different fields in organizations. **Research design/methodology**. This paper uses the methodology of survey research on a representative example of one country (Poland). The data was obtained from a survey on 252 employees of various types of organizations. In the empirical data analysis the Mann–Whitney U test was used. **Main findings and implications**. The authors indicated fifteen fields of an organization which may be affected by the chain of command: attitude to innovation, initiatives, staff morality, decision-taking process, decision-taking process, managers' responses in case of their rating, or of their circumvention, overall performance, employees' performance, employees' wages, employees' commitment, conflicts and stalemates, supervisors' control, superior-subordinate relationship and choice of competitive strategy. However, they were able to empirically confirm the impact on only three of them: initiatives, decision-taking process and employees' wages. Nevertheless, the authors do not advise to resign from the chain of command in organizations. All its advantages stands up for it. They suggest to pay more attention to these three fields in the face of adherence to the idea of the chain of command.

Keywords: chain of command, hierarchy, authority, organization

Introduction

The hierarchy in organizations has not died. Although there are many opposing voices (Lichtarski, 2014). In one of the scenarios it is assumed that a perfect organization will not need an organizational structure at all (Hamel, 2011), in another one – that the organization is fully open and there are no internal boundaries (vertical and horizontal) (Ashkenas, 2002). On the other hand, as Leavitt (2005) argues, all highly flexible structural solutions are inconsistent with human nature, and therefore will not be able to replace traditional hierarchical structures. This paper is in line with the last assumption that the organizational structure of the future will be an adapting hierarchy, and its perfection will be expressed in adapting to nature (*homo hierarchicus*) and human needs. Therefore, it is and will be still justified to study the issues of hierarchical challenges in organizations.

One of them is a chain of command, frequently replaced by the term "scalar chain" or "line of authority". The original proponent of the chain of command was Henri Fayol in one of his 14 management

principles. In the middle of the XX century Fayol stated: "the line of authority is the route followed – via every link in the chain – by all communications which start from or go to the ultimate authority" (Fayol, 1949). According to Crumpton (2013), the chain of command is an element of organizational structure which refers to an organization's hierarchy of reporting relationships. It has an important meaning for all personnel within the organization by determining a line of supervision for providing both direction and guidance and also to troubleshoot and advocate for resources and other needs related to the accomplishment of goals. The chain of command not only establishes accountability, but it also lays out the decision-making power in an organization. It should ensure that every task, job position and department has one person assuming responsibility for performance.

Despite its still valid and significant importance, the problem of the chain of command is insufficiently addressed in contemporary literature. Insufficiently in terms of lacking the complex systematization and practical verification of knowledge. Yes, there were relatively numerous attempts to recognize the impact of the chain of command in organizations. This impact may be positive, constructive (Qian, 1994, Aghion and Tirole, 1997, Kassing, 2009, Syriopoulos and Tsatsaronis, 2012, Oginni et al., 2014, Zydziunaite V. et al., 2015, Sanner and Bunderson, 2018) or negative, destructive (South and Matejka, 1990, Friebel and Raith, 2004, Hart and Moore, 2005, Yoo et al., 2006, Kassing, 2007, Abu Bakar and Mustaffa, 2008, Gaur and Ebrahimi, 2013). However, these attempts are fragmentary and often methodologically not consistent because they either remain purely theoretical or have no statistical validity in the case of empirical research.

The aim of the study is the theoretical and empirical examination of the influence of the chain of command on different fields in organizations. This paper contributes to integration, systematization and empirical confirmation of impact of chain of command. It uses the methodology of literature review and survey research on a representative example of one country (Poland), which can be used in further research across different countries.

Literature Review

Identification of the influence of chain of command

The arguments proving that the chain of command has an impact on the overall performance of an organization were forced not only by Fayol (1949), but also by South and Matejka (1990), Abu Bakar and Mustaffa (2008) and Hart and Moore (2005). The latter claim that "crisscross" hierarchies, such as the dualistic chain of command, are never optimal. Fayol (1949), as well as Syriopoulos and Tsatsaronis (2012) convince that the clear line of authority implies a faster decision-taking process. Oginni et al. (2014) and Sanner and Bunderson (2018) emphasize that it helps to avoid confusion, conflicts and stalemates. South and Matejka (1990), Abu Bakar and Mustaffa (2008), similarly to Oginni et al. (2014), report that correct superior-subordinate relationships have a major impact on employee commitment to the group and to the core beliefs and practices in the organisation as a whole. Interesting remarks on a positive impact of disturbed by circumvention chain of command are advocated by Kassing (2009). In his research, he finds out that regardless of whether or not employees expressed their concerns to the supervisor initially and directly, there were no accounts in which supervisors did not surface as significant characters. Evidently, employees practice circumvention while reflecting on the chain of command within their organization and the unmistakably cemented role of supervisors in that hierarchy. Thus, according to Kassing (2009), circumvention is a conscientious act that at once usurps and reifies organizational hierarchy.

However, from the few studies reviewed so far, we can also reveal some negative aspects of strict adherence to the scalar chain. The main critique, proposed by Yoo et al. (2006) and Sanner and

Bunderson (2018), refers to barriers of innovative thinking in an organization and slower adaptation to external environmental changes. Yoo et al. (2006) claim that it directly precludes implementation of Porter's differentiation strategy, yet without contradicting at the same time the application of a cost leadership strategy.

The works on constructive impact of the properly functioning chain of command discover its relationship with performance of employees. Such chain induces an increase in subordinates' efforts and wages (Qian, 1994) and their effectiveness (Gaur and Ebrahimi, 2013). Moreover, among positive outcomes for subordinates while breaking the chain of command by circumvention Kassing (2007, 2009) reports: achieving subordinates' goals and compelling supervisory action and corrective action that addressed either workplace conditions or corporate policies and practices that are beneficial to other employees. The increasing initiative or incentive to acquire information is the positive argument for scholars such as Aghion and Tirole (1997).

Simultaneously, the same authors point out that an unclear chain of command, affected by delegating downward to large authority, has its bad side in terms of causing supervisor's loss of control. Kassing (2007) suggests that it can often implicate inadequacies in supervisors' performance or capability. Falconi (1997) advocates that practise encouraging employees to avoid using the chain of command is demoralizing to supervisors, while Brutus et al. (1998), Friebel and Raith (2004) and Kassing (2007) pay attention to possible supervisors' retaliation in relation to the subordinate breaking the chain of command.

Finally, as its component, the chain of command also influences superior-subordinate relationships. Findings in this topic are extremely divided. For example, Kassing (2007) reports that the circumvented chain of command causes superior-subordinate relationship decline, and on the other hand, it may also build compromise, development and understanding in this kind of relationships. Oshagbemi and Gill (2004) come to similar conclusions while reviewing the contentions of different scholars on the impact of the hierarchy on the leadership style. They juxtapose opinions suggesting that properly structured hierarchy can release energy and creativity, rationalise productivity, and actually improve morale with those claiming that it can smother leadership. Abu Bakar and Mustaffa (2008) find out that superior-subordinate communication positively mediate the quality of the superior-subordinate relationship. Thus, it can be said that undisturbed by any communication problems, the chain of command favours maintaining good relations between supervisor and his subordinate.

Identification of fields influenced by chain of command in an organization

An organization is an extremely complex unit and it is difficult to profoundly identify its areas of existence. One of the relatively newest and comprehensive model of an organization was provided by Dauber et al. (2012) and based on the classes organization of theory (Hatch and Cunliffe, 2006). In their concept, which was named the organizational culture model, the authors involved the following areas of an organization (Fink et al. 2012):

• value and belief system: capturing the underlying assumptions of organisational behaviour,

• strategy: representing the overall orientation towards task achievement and impacts on structures and activities of an organisation. Strategies define what should be done,

• structural system: reflecting the manifestation of values and beliefs as norms, rules and regulations. It defines normative patterns of behaviour,

• operations: organisational behaviour and action are the observable manifestation of values, strategies and structures – how things are actually done and can be observed,

• external environment: giving feedback from the market and/or legitimacy as an influential factor on organisational culture.

The authors of this study believe, that their model has worked well for explaining the general fields of an organization. Therefore it has been used for ordering the detailed fields affected by the chain of command (table 1.). On the basis of the literature review the 15 fields of potential influence of scalar chain were identified and then subjected to empirical analysis.

Table 1: Fields of an organization affected by the chain of command on the basis of the literature review

General fields	Detailed fields		Authors
Organizational culture & identity	1.	attitude to innovation	Yoo *et al*., 2006, Sanner and Bunderson, 2018
	2.	initiative	Aghion and Tirole, 1997
	3.	staff morality	South and Matejka, 1990, Falconi, 1997, Zydziunaite V. et al., 2015
Organizational design, structure and process	4.	decision-taking process	Fayol, 1949, Syriopoulos and Tsatsaronis, 2012
	5.	division of tasks between superior and subordinate	Hart and Moore, 2005
Strategic response to organizational (internal) environment	6.	strategic responses of managers to internal environment in case of their rating by subordinates	Brutus *et al*., 1998
	7.	strategic responses of managers to internal environment in case of their circumvention in communication by subordinates	Friebel and Raith, 2004, Kassing, 2007
Organizational behavior and performance	8.	overall performance of organization	Fayol, 1949, South and Matejka, 1990, Abu Bakar and Mustaffa, 2008,
	9.	performance of employees (both supervisors and subordinates)	Oshagbemi and Gill, 2004, Kassing, 2007, Gaur and Ebrahimi, 2013,
	10.	employees' wages	Qian, 1994
	11.	employees' commitment and efforts	Qian, 1994, Abu Bakar and Mustaffa, 2008, Oginni *et al*., 2014
	12.	conflicts and stalemates	Oginni *et al*., 2014, Sanner and Bunderson, 2018
	13.	supervisors' control over resources	Aghion and Tirole, 1997
	14.	superior-subordinate relationship	Kassing, 2007, Abu Bakar and Mustaffa, 2008
Organizational strategy	15.	choice of competitive strategy (between differentiation or cost leadership strategy)	Yoo *et al*., 2006

Methodology

Data Collection

The data was obtained from a survey conducted in Poland on employees of various types of organizations (various companies, offices, social organizations or public utility organizations, etc.). The minimum size of the research sample was set at 240 units according to the calculations below:

$$n = \frac{P(1-P)}{\frac{e^2}{Z^2} + \frac{P(1-P)}{N}}$$

Where:

n – minimum sample size = 240 units

P – fraction size = 90% (it is assumed that hierarchical relationships exist in 90% of the population)

e – maximum error = 5%

Z – for the adopted confidence level α = 99%, this value is approx. 2.58

N – population size = 16,461,000 (this is the number of economically active people in Poland according to the Central Statistical Office data for 2019).

The method of random selection was used. Ultimately, responses from 268 people were collected, however to the analysis below, due to the lack of data, 252 were chosen. The research was conducted using PAPI (paper questionnaires) and CAWI (online questionnaires) in the proportion of 33%:67%, respectively.

Characteristics of the research sample

In terms of age, the research sample is quite diverse. Its largest part (35.1%) are employees aged 36-45. A slightly smaller proportion (30.6%) includes respondents aged 26 to 35 years. The least numerous group (1.1%) are people over 65. In the case of the respondents' education, the differentiation of the research sample is smaller. 62.3% are people with higher education. 28% of the respondents are people with secondary education, and 9.3% – with basic vocational education. Only one person (0.4%) has primary education. The structure of the research sample by gender includes both women and men. The first of these categories accounts for 56% of the research sample, and the second – the remaining 44%.

Diversity of the research sample is also visible in terms of seniority. Most people (34.7%) admitted that their overall professional experience is in the range of 11-20 years. In turn, approx. 19% of the respondents work for 6-10 or 21-30 years. 13.8% of the respondents had the longest work experience (over 30 years). 13,8% of the respondents admitted to relatively short employment – under 5 years.

The majority (76.9%) of the respondents work in economic organizations (eg enterprises, business unions). 10.4% are employed in administrative organizations (state or local government), and 9.3% in public benefit organizations (e.g. hospitals, schools, cultural or scientific institutions). A relatively small

part of the research sample indicated a military or police and social organization as the place of current employment (e.g. a foundation, association, social enterprise, political party, trade union). These groups account for 1.1% and 2.2% of the research sample, respectively.

The largest part (44.4%) is employed in large organizations (over 250 employees). A slightly smaller proportion (25%) work in medium-sized organizations (from 50 to 250 employees). In turn, small (10-49 employees) or micro (less than 10 employees) organizations employ 12.3% and 18.3% of the respondents, respectively.

Organizations of the current employment of respondents in the vast majority (84.7%) have been operating on the market for over 10 years. 9.7% of the surveyed organizations exist over 5 to 10 years. The remaining part (5.6% in total) are relatively young organizations, operating for up to 5 years.

In terms of the scale of activity of the surveyed organizations, the research sample is diverse. Most of them (56.7%) also operate abroad, on international markets. For 22.4%, the activity is limited to the local market. On the other hand, 20.9% sell their products or services in the territory of the country.

From the point of view of the purpose of the research, the question of the type of organizational position was particularly important. 36.9% of the respondents perform managerial functions, i.e. supervise the work of at least one subordinate. Moreover, the work of 88.8% of respondents is supervised by at least one supervisor. This proves that the vast majority of respondents is in some way involved in the existence of hierarchical relationship in their organizations. Inevitably, based on their own experiences, they can share knowledge and feelings about them. It is also worth emphasizing that the research results in this matter confirmed the correctness of the assumptions in calculating the size of the minimum research sample with regard to the size of the fraction.

Data Analysis

To examine the influence on chain of command on the empirical data the Mann–Whitney U test was used. The independent variable was the occurrence of chain of command in an organization. The respondents' declarations were divided into two groups: those having the clear chain of command in their organizations (212 employees), and those who cannot tell, that the clear chain of command is present in their organizations (40 employees). The respondents were asked to evaluate each of the 15 fields identified it table 1. They became dependent variables. The scoring of the respondents' answers was the following: definitely good – 4, rather good – 3, rather bad – 2, definitely bad – 1. The statistical significance of the results was set at the level of $\alpha = 0.05$.

Research Results

The non-parametric analysis of variance with the use of the Mann–Whitney U test recognized statistically significant differentiation between the variances in the following groups – the occurrence of chain of command and: initiative, decision taking process and employees' wages (table 2.).

Table 2: Results of the Mann–Whitney U test

Dependent variables	Z	p	N-yes*	N-no*
attitude to innovation	-1,56750	0,117000	194	38
initiative	-2,08417	0,037145	195	37
staff morality	-1,19444	0,232305	196	35
decision-taking process	-2,62240	0,008732	200	39
division of tasks between superior and subordinate	-0,58130	0,561042	203	37
managers' responses in case of their rating	-1,02416	0,305759	167	35

employees' wages	-2,01325	0,044090	193	37
employees' commitment	0,05958	0,952493	201	37
conflicts and stalemates	-0,36896	0,712156	184	34
supervisors' control	-0,35913	0,719499	203	37
superior-subordinate relationship	-0,28622	0,774707	206	36
choice of competitive strategy	-1,35514	0,175375	187	36

It proves, that there is an empirically verified influence of chain of command in these three fields of an organization. Moreover, looking at the box and whisker plots of these three groups it can be concluded that the absence of chain of command favours the initiatives, decision-taking process and employees' wages. 50% of respondents without clear chain of command gave good (definitely or rather) ratings to the above fields, whereas only 25% of respondents involved in chain of command speaks positively about these fields. The impact of the chain of command on other fields of an organization has not been revealed.

Discussion

Our findings in general might sound quite provoking. In some way they are in contradiction with the findings of the existing literature, because they confirmed the influence of chain of command on only three from identified fifteen fields of an organization. However, it should be underlined that at the same time they did not deny its existence. Moreover, we support claims of Fayol (1949), Qian (1994), Aghion

and Tirole (1997) and Syriopoulos and Tsatsaronis (2012) on the direction of the impact of chain of command on initiatives, decision-taking process and employees' wages in an organization.

Fayol wrote: "the clearer cut the chain of command, the more effective the decision making process" (Fayol, 1949). Similarly claimed Syriopoulos and Tsatsaronis M. (2012): "the unification and integration of the command chain implies a faster decision-taking process". We add that nowadays in the era of employee participation, common access to information and intelligent systems supporting decisions in organizations decentralization should be developed. Rigid adherence to the established chain of command complicates and extends the time of the decision-making process. Even if employees are permitted to, they will refrain from making decisions and, using the idea of the chain of command on purpose, they will transfer this responsibility to their supervisors.

The obtained research results confirmed also the influence of chain of command on initiatives in an organization. It is in line with claims of Aghion and Tirole (1997) who studied, among others, the allocation of formal authority (the right to decide) versus real authority (the effective control over decision) in organizational hierarchy. They discovered that an increase in subordinate's real authority promotes initiative. In fact, increasing subordinate's real authority may be flattening, shortening, declining or even resigning from the chain of command. In our research in organizations where there was not clear occurrence of the chain of command the level of initiative was highly rated. People without close supervision may feel more free, more motivated, and more creative in approaching their tasks. And this, in turn, is conducive to undertaking initiatives of a different nature.

Moreover, our research provided the empirical prove of the influence of chain of command on the employees' wages. Precisely speaking, we discovered that it is better not to be entangled in the existence of the chain of command when somebody wants to achieve higher wages. In his theoretical study Qian (1994) links shortening of the chain of command, on the one hand, to the reduced costs of management staff. However, he also notes that "remaining employees have to be paid with higher efficiency wages to induce them to work, because the effectiveness of monitoring is reduced as the result of the increased span of control". His conclusions are therefore directly related to the results of our research.

Conclusion

This paper follows the approach on the presence of hierarchy in modern companies. We believe that hierarchy tends to be ubiquitous not only in business firms (Ishida, 2015), but also in other types of organizations. In a hierarchy, employees at different hierarchical levels are vertically related: the superior has authority over his subordinates and the subordinate provided information to, and followed instructions from, his superiors (Qian, 1994). This is how the chain of command works in practice.

In our study we contributed to explaining functioning of the chain of command. Precisely, we investigated the impact of chain of command in modern organizations. We integrated an systematized the knowledge on this impact on the basis of the existing literature. We discovered that the consequences of the chain of command actually extend to the entire organization – its culture and identity, structure and processes, relationships with environment, behaviour and performance, and strategy. We indicated fifteen fields of an organization which may be affected by the chain of command. They are the following: attitude to innovation, initiatives, staff morality, decision-taking process, decision-taking process, managers' responses in case of their rating, managers' responses in case of their circumvention, overall performance, employees' performance, employees' wages, employees' commitment, conflicts and stalemates, supervisors' control, superior-subordinate relationship and choice of competitive strategy. However, we were able to empirically confirm the impact on only three of them: initiatives, decision-taking process and employees' wages. Moreover, this impact is rather destructive in its character.

On the basis of the results of our analysis we can suggest some managerial implications. We do not advise to resign from the chain of command in organizations. All its advantages stands up for it. However, we suggest to pay more attention to these three fields in the face of adherence to the idea of the chain of command. For example, we would recommend to enforce the law to make decisions on the particular hierarchy levels instead of shifting responsibility. It significantly shortens the time of the decision-taking process. We also propose the use of incentives, including financial ones, for employees to undertake various pro-development initiatives. This will contribute to an increase in the level of initiative in the organization and, at the same time, better wages for employees.

We are aware of limitations of our research. First of all, although the research sample was representative, it was conducted only in one country – Poland. We intend to extend our research to other regions, and especially in the context of different cultures. Certainly, chains of command will function differently, e.g. in Japanese, American or German companies. We also believe that it takes a more in-depth look at the impact of chain of command on individual areas of the organization. For this, a more interdisciplinary literature review and a thorough operationalization of concepts is necessary, taking into account not only the perception of respondents but also hard, objective data. Besides, we recommend conducting also dynamic analysis. The chain of command could change over time – as every relationships are always dynamic and they don't follow a predetermined pattern of a life cycle (Piwoni-Krzeszowska, 2018). We believe that in the light of our assumptions about the longevity of hierarchies in organizations, this problem deserves further research.

Applying the Kano Model for Analyzing Factors Affecting Patients' Satisfaction

Abstract

In the present society, medical services and processes are developed based on what patients want and expect, therefore creating an attractive quality, by the healthcare providers, has become fundamental. As a result, healthcare providers must anticipate patients' needs, as well as, expectations, by contributing with new service characteristics adjusted to patients' demands, in order to improve their level of satisfaction. The current research aims to explore how the Kano model can be used to identify various patients' needs towards a continuous improvement of the Romanian private healthcare system. The study's findings present that there is a variation in the patients' perceptions related to service quality attributes and so, the service features may be differently organized in Kano's model. The main objective of the research is to use the Kano model that would increase patients' satisfaction, by listening to the voice of the patients, as well as, attaining a competitive advantage on the market for the healthcare providers, by presenting high value-added features.
Due to its open approach, one of the main advantages of the presented framework is represented by its efficiency to integrate in the private healthcare units, tools for better understanding the voice of the customer, like Kano model.

Keywords: Continuous Improvement, Healthcare System, Quality Attributes, Kano Model.

Introduction

In a private clinic, patients become satisfied when the medical service has an attractive quality, when doctors emphasize with them, and when they obtain what they pay for (or even more).

However, the Romanian medical service did not improve as much as patients require. Moreover, the current patients' complaints are almost the same as they were a few years ago, especially at the public healthcare system (Dobrin&Dinulescu, 2019).

Therefore, there are elements and actions that, in a private clinic, represent necessary features (must-have characteristic) and their absence would cause patients' dissatisfaction.

On the opposite side, there are the indifferent characteristics which their absence would be entirely indifferent for the patients (would not have an impact on patients' satisfaction).

However, in a world where quality becomes more and more subjective, is rather hard to identify a certain level of quality that would suit each patient.

Cite this Article as: Ruxandra DINULESCU And Cosmin DOBRIN " Applying the Kano Model for Analyzing Factors Affecting Patients' Satisfaction" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In this case, the best alternative is to use a model that would categorize each characteristic depending on its level of importance for the patients.
Sometimes, the healthcare provider might not know entirely the voice of the patient and so it may prioritize a characteristic before other (when in fact, for the patient, that characteristic does not affect its satisfaction). This is why, surveying patients and then process the answer with the Kano model is a desirable option.

Literature Review

The Kano model was developed by Noriaki Kano, a Japanese consultant, and relates to design characteristics for customer satisfaction (Cohen, 1995).

As mentioned by Hejaili et al. (2009), the model proved its efficiency not only in obtaining the patients' service quality expectations, but also in better understanding the differences that might appear in expectations of patients from different nationalities and cultures.

Furthermore, the Kano model is being constantly endorsed in the healthcare industry, and also recognized as a significant tool in understanding a product or a service lifecycle (Mikulić and Prebežac, 2011).

The Kano model proposes a theoretical and dynamic methodology for perceiving customer needs and perceptions by offering a visual representation of the relationship between the functional performance of quality attributes and the level of satisfaction attained ((Kano et al., 1984; Berger et al., 1993; Robinson, 2009).

Also, Anderson and Sullivan (1993) sustain that service quality represents a pre-requisite of customer satisfaction, which depends on products' and services' performance, as well as whether this performance depends on consumers' expectations.

Generally, the expectations (or customer needs) are segmented into three main categories: basic needs (or dissatisfiers); performance needs (satisfiers) and excitement needs (or delighters), as it can be observed in figure 1:

Fig. 1: Categories of expectations

Source: The author

a) *Must-haves (basic qualities)* – these elements represent a necessary condition or quality that a product or service must include before the customer considers starting a business with that certain company.
When including these elements, they do not necessarily cause customer satisfaction, however their absence will cause dissatisfactions for the customer.
Also, these needs are "unspoken"
Basically, in the customer's opinion, these must-have features must be included.
For example, in a healthcare system, a must-have feature is the cleanliness of the medical cabinets, the good preparation of the doctors, etc, a waiting room for the patients,

b) *Performance attributes* – represent standard characteristics that have the ability to increase or decrease satisfaction based on their degree. In comparison to the above mentioned features, these needs are generally clearly expressed by the patients (spoken). Thus, the better they are met, the more accomplished the patient will feel.
A poor performance of these attributes will lower the patients' satisfaction.
Generally, the performance attributes are directly proportional with the patients' degree of satisfaction (if a service/process performance is high, the patient's satisfaction will increase as well).

Example: waiting time before entering the doctor's cabinet, internet access in the medical healthcare units, modern medical equipment, etc.

c) Excitement needs (attractive needs or satisfiers) – normally, these are unexpected features or characteristics that are meant to impress the patient, even if they are generally "unspoken" needs.
However, the lack of these characteristics does not cause patients' dissatisfaction (Webber, 2007).

Example: free wifi in the hospital, tv in the hospital rooms,

Fig. 2: Kano model

Types of quality

In order to better understand its relationship to competition, Kano divides the notion of quality into four groups:

a) Indifferent quality – the kind of quality that the patient does not consider or appreciate;
b) Expected quality – the quality that the patient expects and requires;
c) One-dimensional quality (performance quality) – the quality that the patient hopes, however, the lack of it does not necessarily makes the patient dissatisfied;
d) Exciting quality – the level of quality that is beyond the patient's expectations; when present, it pleasantly surprises the patient (Besterfield, 1995).

Research Methodology – Case study: A private clinic from Bucharest, Romania

Data Collection

For the present research, a private medical clinic from Bucharest, Romania, was chosen, in order to identify the patients' healthcare needs for improving the quality of the provided services, as well as maintaining the clinic's top medical services.

The private clinic offers a wide range of medical services like cardiology, echography, orthopedics, ophthalmology, pediatrics, psychiatry, etc.

One of the main objectives for creating this research was to identify the patients' needs and requirements that could have an impact on the satisfaction's degree.

The questionnaire was shared, on the field, to a total of 134 patients on a time frame of 1 month (June 2020), out of which only 120 answers were valid (taking into account that some questionnaires had questions without answers, or double answer with the same attribute, etc).

Kano Questionnaire

Before creating our questionnaire, several Kano surveys were considered in order to identify the questions asked regarding the service quality features. Thus being said, the questionnaire was composed of paired questions (functional and dysfunctional) that gathered different information about the quality features. More precisely, the survey covered sets of paired questions, in which every individual set explored a single quality attribute.

Therefore, the operative (functional) form of every question explored how a patient would feel if an attribute were present and the non-operative form (dysfunctional) investigated how a patient would feel if an attribute were missing. In order to bypass the biased results, the questions were presented in a random order.

The questionnaire contained 42 questions on 21 service quality attributes. The patients were allowed to participate in the survey if they met two main criteria: must be at least 20 years old and must have used before the medical services offered by the clinic.

During the Kano questionnaire different attributes were analyzed like medical staffs' empathy, cleanliness, availability of qualified medical staff, provision of adequate information, correct treatment, etc. The answers used were: 1. Like it; 2. Expect it; 3. Don't care; 4. Live with; 5. Dislike.
Also, the Kano evaluation table proposed by Berger et al. (1993) is presented in table 1:

Table 1: Kano evaluation table

		Dysfunctional (X)				
Functional (Y)		**Like**	**Expect It**	**Don't Care**	**Live With**	**Dislike**
Like		Q	A	A	A	P
Expect It		R	Q	I	I	M
Don't Care		R	I	I	I	M
Live With		R	I	I	Q	M
Dislike		R	R	R	R	Q

Source: Matzler & Hinterhuber (1999)

All the attributes are part of one of the following categories of perceived quality as seen in table 2:

Table 2: Kano's attributes

Code	Result
M	Must-Be
P	Perfomance
A	Attractive
I	Indifferent
R	Reverse
Q	Questionable

Source: Adapted from Matzler&Hinterhuber (1999)

The questionable response category includes the number of answers that might have not been precisely understood by the patients.

After that the number of answers from each category for every service quality item is registered in order to settle the final category for each item (attribute).

The next computations included the *category strength* (the estimated value of certain feature and is computed as the percent difference between the highest category and the following highest category), *total strength (*the approximate value of a certain feature built on the amount of answers in attractive, must-be and one-dimensional category)*, better (satisfaction coefficient)* and *worse value (dissatisfaction coefficient)*.

The *better value* is the predicted value of the item to generate satisfaction and is computed as:

$$\text{Better} = (A+P)/(A+P+M+I) \quad (1)$$

Where A, P, M, I – the number of answers in the attractive, performance, must-be and indifferent sections.
The *worse value* represents the approximate value of the feature to generate dissatisfaction if it is not included and is computed as:

Worse = (P+M)/(A+P+M+I) (2)

Results of the Research

Out of a total of 134 questionnaires, only 120 were valid, while 14 questionnaires were excluded due to incomplete answers to Kano quality attribute questions.

The inquiry of the 120 surveys was operated by looking up each pair of answers (both functional as well as dysfunctional) in the interpretation table and after that the results were categorized for each individual attribute.

From the below figure (fig. 3) it can be noticed that the 21 service quality items were classified by the patients as follows:

- 8 service quality as performance attributes (one-dimensional);
- 5 service quality as must-have attributes;
- 6 service quality as attractive attributes;
- 2 service quality as indifferent.

Attribute	Q	M	P	A	I	R	Final category	Category strength (%)	Total strength (%)	Better (%)	Worse (%)
1	0	38	49	24	9	0	P	9.17	92.50	60.83	72.50
2	2	24	51	20	19	4	P	22.50	79.17	62.28	65.79
3	1	18	70	21	10	0	P	40.83	90.83	76.47	73.95
4	0	30	30	36	24	0	A	5.00	80.00	55.00	50.00
5	0	56	18	24	19	3	M	26.67	81.67	35.90	63.25
6	0	28	16	21	54	1	I	21.67	54.17	31.09	36.97
7	0	18	64	26	11	1	P	31.67	90.00	75.63	68.91

20	0	30	26	48	16	0	A	15.00	86.67	61.67	46.67
21	0	27	28	48	17	0	A	16.67	85.83	63.33	45.83

Fig. 3: Evaluation of the items using the Kano technique

Source: Authors' computations based on the questionnaire's answers

Furthermore, also from the figure 3 it can be observed the distribution of the service quality items using the Kano technique.

The next figure (figure 4), representing the better-worse graph, presents the four quadrants of Kano model with the specific categories (attractive, performance, must-have and indifferent).

The results are plotted in a two-dimensional graph, having a maximum value of 1, where the Worse value sets on the X-axis and the value of Better, on Y-axis.

Fig. 4: Two dimensional graph of Better-Worse method

Recommendations

In order to increase the quality of the medical process, from the patients' point of view, the following steps must be followed:

- First of all, based on the results, it is necessary that the medical process has all the *must-haves*; there may be situations when removing attributes from the other two categories might be needed, but not including these mandatory features, might lead to process failure.
- Secondly, we should take into consideration the *attractive* (*satisfiers)* feature in order to see if we can add or improve the quality of the ones we already have. Rising above the competition could be done with the help of these features;
- A good way for increasing patients' satisfaction would be to increase the *performance* attributes within other constraints (like cost);
- Lastly, when the process is improved, *indifferent* attributes could be removed.

Limitations and future directions of the study

Our current research was limited to the application of the Kano model, with the use of a simple questionnaire, for better understanding the voice of the patients. The sample used, as well as the research timeframe were rather small, covering only a part of the patients that visited the private clinic in one month. Mainly there were patients that attended the same departments, so in some cases, the answers might be subjective.

However, to further develop the study, this research will be continued by integrating other methodologies like *Quality function deployment (QFD), SERVQUAL,* or the *analytic hierarchy process (AHP).*

Whilst applying the Kano model permits the healthcare providers to better understand patients' needs, when integrating it with QFD, it helps recognizing trade-offs and translating them into functional service requirements (Chiou and Cheng, 2008; Aghlmand et al., 2010; Nordin and Razak, 2014; Shamshirsaz and Dong, 2014).

By including these tools, a couple of sustainable improvement strategies will be developed.

Conclusions

Nowadays, an important action for the healthcare providers is to include patients in their treatment decisions, as well as exploring the multiple roles that a patient may have, for a better achievement of their expectations.

The fundamental contribution of this study is represented by the implementation of the Kano model in order to obtain various patients' needs correlated with the healthcare service unit, as well as driving the continuous quality improvement of the healthcare services.

This paper presents a systematic methodology for identifying the healthcare requirements, providing information on how to use the Kano model for healthcare services. Thus, for a continuous improvement of the healthcare service quality, the healthcare providers have to identify the changing patients' requirements by implementing analytical processes.

The current study represents still an ongoing research since the continuous improvement process of the healthcare units cannot stop at just discovering the patients' needs.

Thus, for providing quality healthcare services, we believe that a Lean Six Sigma program should be implemented, in order to examine the cause of variations, to create a root-cause analyze, to measure the variation, to improve the processes that present gaps and in the end, to continuously control the improvements achieved.

A Comparative Analysis of Banking Secrecy Rules in Light of AML Rules

Anna V. SHASHKOVA

Full Professor MGIMO-University, Moscow, Russia
a.shashkova@inno.mgimo.ru

Abstract

The aim of the present article is to analyse the position of the Russian Federation and countries such as Spain, the United States and Switzerland concerning banking secrecy rules when executing anti money laundering legislation. We conclude on the necessity of the political establishment to improve Russian law-enforcement in practice as well as the legislation in this area. The banks having received the right to close an account of a legal entity or of an individual unilaterally are able to overdo anti-money laundering and anti-corruption laws. This results in individuals' problems with cash withdrawals and payments on the clearing basis. The authors analyse European practice and problems concerning 'secrecy matters'. Even within Europe the regulatory approaches relating to secrecy differ. Because of the 'secrecy' involving individuals and legal entities, they are deprived of appealing decisions taken by banks and thus restricting their Constitutional rights. The Constitution of the Russian Federation gives general guidelines in respect of human rights and shall be respected by laws and law enforcement practice.

Keywords: Bank Secrecy, Money Laundering, Panama Papers, Troika Laundromat

Introduction

State authorities and agents responsible for the supervisory function, and subsequently the courts, including the Constitutional Court of the Russian Federation are faced with the problem of secrecy in different aspects. This problem must be solved at the highest level with the direct application of the constitutional norms (Balakina, D'Andrea & Masciandaro, 2017; Gheorghe, & Dragomiroiu, 2017; Chilton & Versteeg, 2018).

The Bank of Russia sets requirements for the banks to execute Federal Law No. 115-FZ, dated 7 August, 2001, 'On Combating Legalization (Laundering) of Proceeds from Crime and Financing of Terrorism' too high. Under the threat of revocation of the license for banking activity such requirements simply drive banks into the corner. There is thus a need for the political establishment to act. Recent changes in Russian legislation, e.g. allowing banks to refuse opening of accounts unilaterally, simplified banking activities in Russia.

Such problems of contradiction and interaction of provisions of two laws – the Anti Money Laundering Law and the Law on Banks and Banking Activity – is a subject-matter of the Constitutional Court of the Russian Federation as well as a research in Russia and abroad. Most researches are dedicated to the cases when the law requires disclosure of banking information of a customer notwithstanding the consent of the latter (Croal, 2011; Dal', 1995; Dressel & Tonsakulrungruang, 2018). These situations tend to grow in number because of application of the law. The law does not change, but still more and more restrictive provisions are applied to maintenance of the banking secrecy by the banks themselves.

The aim of the present Article is to identify the problem: the Constitutional right to secrecy, provided under Article 23 of the Constitution of the Russian Federation, is under constant violation. In fact, it is abolished and not applicable in practice by law enforcement bodies as well as professional institutions accountable before the state. Banking institutions being under pressure of withdrawing the

banking license choose to violate rights of their customers instead. Banking customers cannot withdraw banking licences. The maximum they can do is to apply to court (Elliott, 2006; Engibaryan, 2006; Emmenegger, 2017). The situations of cash withdrawal violations have not been studied before. It seems quite simple: legislation provides maximum amounts of cash withdrawal, so if an individual or a company within such admitted amount make a withdrawal, they can conduct withdrawals without any further restrictions. At the same time if they effect multiple withdrawals frequently it can be classified as a suspected transaction under anti money laundering laws. Still there exist situations when a bank denies to give money to an individual in case of a one-time withdrawal. Such situations happen in the Russian Federation where an individual is not limited to s specified sum of cash withdrawals and has never been seriously analysed. (Farquet, 2017; Galbraith, 2007; Gaman-Golutvina, 2010; Gandrud & Hallerberg, 2018).

Definition of Secrecy

Banking secrecy actually refers to a particular type of information that becomes known to a credit institution during the execution of banking activities. Certain other persons are acknowledged with such information as well. Such persons receive the information from credit institutions in the course of its examination and its application (Gololobov, 2014; Golubtsov & Kuznetsova, 2013; Masciandaro & Balakina, 2016).

The banking secrecy is a specific type of commercial secrecy. It consists, first of all, of the secrecy of a bank as an independent subject of economic relations and, secondly, of all commercial secrets of the clients, which the bank is aware of because of contractual relations with the clients.

Types of Banking Information

According to a Russian Professor of Law, Olejnik such problems of banking secrecy need to be considered considering the following general provisions:

- the banking secrecy is a type of legal regimes of information with limited access;
- the banking secrecy regime and regimes of religious, medical, commercial, investigative or judicial secrecy shall be considered as similar;
- the law establishes special regulations that govern banking secrecy (Olejnik, 1999).

Considering the nature of the legal relationships concerning banking secrecy the author distinguishes three kinds of relations:

- relations between the bank and the client;
- relations between the client and the government and
- relations between the government and the bank.

Such relations are governed by a set of rules of the Constitution, legal norms and regulations.

On the one hand, the banking secrecy protects the interests of the client and prohibits third party access to the confidential information of the bank. Such third parties include the state represented by the state agencies (Booysen & Neo, 2017; Tutikhtin, 2018).

On the other hand, legal acts and regulations reinforce the interests of the state, establishing the order of access to the banking secrecy. The author agrees with the opinion of a Russian judge and professor Sarbash that the legislative regulations of the access of the state to confidential information of individuals need to be improved (Sarbash, 1999). The state bodies carrying out public functions represent the state in a particular case.

Banking secrecy is determined by the law, which provides for:

- the legal status of subjects of legal relations concerning using, granting and protecting the information at the disposal the credit institution;
- the content of the information, which is subject to the regime of banking secrecy;

- the conditions and procedure to grant and use the information at the disposal of the credit institution;
- the procedure of legal protection of such information including responsibility for disclosure of such information.

Different legal regimes are applied to the banking information, depending on the content and purpose.

- *Open banking information*. Open banking information shall be provided to unlimited number of persons. Such information is available to anyone who applied to the bank, regardless of the purpose of obtaining such information. Such information may be disseminated through the publication as well. The scope of open banking information is determined by the Russian legislation and by the bank itself. Open banking information, e.g. the annual statements, is subject to publication in specialized official mass media. It shall be reliable, comprehensible not only for professional accountants and submitted timely.
- *Banking information of restricted use*. The dissemination of such information outside the bank is undesirable. It may prejudice the commercial interests of the bank (e.g., the data on the quantity of banking customers, etc.).
- *Closed banking information*. In this case the law is involved. The law generally prohibits the dissemination of such information. Closed banking information protects legitimate interests of the bank's customers. It may be granted to authorized persons only on exceptional basis according to certain rules, the existence of which is covered by the concept of 'providing information'. Such information refers to the banking secrecy itself.

Therefore, one of the sharpest current issues is the problem of compliance by credit institutions with banking secrecy rules while implementing anti-money laundering measures. These problems are of current importance not only in the Russian Federation, but also in the whole world.

Banking Secrecy Legislation in the USA, EU and Switzerland

The United States of America have liberalized its banking laws long ago. The USA simplified the whole approach to the concept of 'banking secrecy' in fact almost abolishing such secrecy. The Bank Secrecy Act 1970 (BSA), which is sometimes referred to as an anti-money laundering law, required financial institutions of the USA to assist the government agencies in detecting money laundering, filing reports on the daily aggregate activity of clients exceeding 10000 USD as well as on tax evasion. Severe penalties in case of non-reporting or non-proper reporting has made no secrecy in client-bank operations for the government agencies (Sykes, 2018).

At the same time Switzerland and several other countries seek to maintain historically established approaches to the organization of secrecy of banking information (Shashkova, 2019; Schumpeter, 1961). The tax evasion scandal in Switzerland of 2008 – 2009 threatened to criminally indict one of Switzerland's largest banks UBS. The scandal revealed the necessity of international cooperation in the area of banking activities, though historically the country tried to keep such matters low profile. Being a home of a significant number of international banks Switzerland has established mature and well-developed regulations of the banking sector. The country remains the world's leading provider of cross-border wealth management services. Data protection and data security are most important issues for private banking in Switzerland.

Most countries of the European Union started to implement transparency of banking deposits and transactions as well. The Finance Ministers of the 15 European Union countries signed a law that would prohibit banks to carry anonymous accounts. The Council Directive 2011/16/EU of 15 February 2011 'On Administrative Cooperation in the Field of Taxation' eliminates the concept of 'banking secrecy' in the matters of interexchange of information on taxation. Another Council Directive amending Directive 2011/16/EU as Regards Mandatory Automatic Exchange of Information in the Field of Taxation provides for interexchange of information on foreign investors. However, it shall be admitted that the liberalization of banking secrecy laws finally leads to customer and cash flow-out.

In the case of cash withdrawals in banks of the European Union, the bank shall complete a special form and notify the relevant state body for financial monitoring about such operation. In case of a significant amount of cash withdrawali, in addition to the traditional form of the notification of the state body for financial monitoring, the bank shall fulfil the form on suspicious transaction operation (Lerer; McGarrigle, 2018). There shall be of course exceptional cases not subject to the legislation on banking secrecy. The problem is in the balance between the compliance with the interests of private clients, based on the constitutional provisions on secrecy and compliance with the interest of state bodies, based on special legislation or even normative acts of the Executive power branch (Shashkova, Verlaine, Kudryashova, 2020). The following question concerning the banking secrecy arises: does the banking secrecy mean that not only the state authorities, but the bank itself does not know the identity of the beneficiary?

In the Russian Federation a number of cases involving the refusal of a bank to allow withdrawal of cash funds by individuals was reported. There is no limit for cash transfers for individuals in Russia. One can buy an apartment in the centre of Moscow paying cash rouble equivalent to USD 10 mln and this will be legal. Companies instead have a cash limit of 100000 RUR (approximately 1400 USD). In case of violation of anti-money laundering rules banks face revocation of a banking license. Within the last 4 years the Bank of Russia revoked more than 350 bank licenses (96 – in 2016, 51 – in 2017, 63 – in 2018, 5 – as of 7 March of the year 2019). Revocations of licenses may be imposed on a bank in case of dealing with 'bad customers', even in case of timely notification the Rosfinmonitoringii on suspicious transactions. That is the reason why banks refuse to withdrawal of cash funds, make the grounds for refusal secret (i.e. not subject to appeal by the customer) and face claims from customers in courts of general jurisdiction and the Constitutional Court of the Russian Federation.

Under the traditional opinion Switzerland has the best legislation on the banking secrecy in Europe. In this country a client can solve their investment objectives through a single bank. Such a bank protects the identity and commercial interests of the client from the rest of the world (Shashkova, 2019).

According to the Swiss legislation the Bank has no right to give out to a foreign state a dossier of clients suspected of tax evasion or of other fiscal crimes. The Swiss law interprets such situation as tax optimization, not tax evasion. Such situation concerns issues when a client 'forgets' to send additional forms of declaration of income from the accounts in foreign banks or 'forgets' to declare the entire amount of income. In this case the clients risk facing only a fine, no other punishment is supposed. A tax offence with the purpose of concealing illegal proceeds using forged papers and documents, entails much more serious consequences, including imprisonment. In fact, such Swiss understanding of the boundaries between the first issue and the second crime are not clear and not respected by all countries. The USA do not accept such Swiss demarcation of the two fiscal crimes. Some other OECD (the Organization for Economic Co-operation and Development) countries do not accept the Swiss point of view either, which result in different approaches to taxation at the international level and harsh criticism of Switzerland's tax policy by foreign governments (Kudryashova, 2019).

The law of the vast majority of countries is subject to changes due to the influence of political forces and processes. In a particular moment it is important to understand which political priorities the government realises. Sometimes such political priorities come into conflict with fundamental human rights. This can be seen in case of counterfeiting legalization of illegal income, money laundering. Most states implementing anti-money laundering procedures have both general legislation concerning rights and freedoms of citizens and specific legislation aimed directly at combating money launderingiii. In the UK, for example, disclosure of information is considered to be contrary to the law in case a person, disclosing such information, simultaneously fulfilled three following conditions:

- such person knows or suspects or has good reasons for knowledge or suspicion that another person is engaged in money laundering;
- the information or other materials on which such knowledge or suspicion or good grounds for such knowledge or suspicion is based, is derived by such person in the course of their professional activities;

- such person has not reported the information properly, as soon as such person received the information or other materials.

However, a person shall not be considered guilty of an offence if such person has good reasons not to provide information or other materials. The same happens in case the person is a professional legal adviser and the person obtains the information or other materials under confidential circumstances[iv].

In certain cases of money laundering the Spanish legislation provides for the possibility of derogation from the principle of the presumption of innocence (Golubtsov & Kuznetsova, 2013). That means that such constitutional conquest as the presumption of innocence loses its power and legality while considering money laundering. The burden of proof is transferred to the person accused of money laundering. At the same time the strict observance of the constitutional rights of such persons is required.

It should be noted that, when it comes to money laundering, especially in the context of the rejection of the presumption of innocence, the issue at hand is only a deliberate lucrative crime. The law establishes the deliberate purpose of the crime. That means that a person must understand that the source of funds or property is illegal while effecting concealment, non-provision of information, acquisition or transfer of such property. The source is not important itself. It can be tax evasion, concealing of the origin of property or injury to third parties[v]. When the action is deliberate the importance is in the orientability of such action: concealment, cover-up or assistance in the laundering of illegal proceeds.

Panama Papers as an Equalizing Factor

Eleven million leaked documents concerning financial and client-attorney information revealed more than 214 thousand offshore entities in 2015 (Schmidt; Myers, 2016). Panama papers showed that the USA received tax and asset information on American assets abroad while not sharing the same kind of information with other countries (Joaristi; Serra; Spezzano, 2018). Such privilege makes it beneficial for both foreign and American clients to hide their assets in the USA, dealing with only American laws and authorities and understanding that information will not be disclosed outside the USA (Swanson, 2016).

Such country as Switzerland was minorly affected by the Papers: some tiny art litigation did not disturb its banking system. The information that among the proprietors of these 214 thousand offshore entities were Swiss banks including HSBC, Credit Suisse and UBS did not make much noise. At the same time tax heavens of Cook Islands linked to New Zealand and Nordea bank of Sweden relations with Panama and British Virgin Islands signalize that official ranking and public information on a country and its banking system may have not much to do with the reality and its hidden resources.

The Russian banking system was not involved in Panama Papers' scandal. Rich friends of the head of the state were mentioned. This information concerns solely different corruption schemes used by Russian nations having close personal relations with Vladimir Putin, which infringes neither the financial system nor the image of people at power inside the country. Russian people are accustomed to distinct types of corruption scandals at the highest level, hence the Papers caused no political and economic effect inside the country.

In March 2019 a new Troika Laundromat investigation conducted by the Organized Crime and Corruption Reporting Project and Novaya Gazeta was based on the part of Panama Papers concerning President Vladimir Putin's old friend and godfather of his oldest daughter Sergei Rolduginvi. He could not explain the source of significant sums of money used by his offshore company in transactions with Russian companies. The Organized Crime and Corruption Reporting Project named Ruben Vardanyan – an owner of the Russian investment bank Troika Dialog – as a facilitator to launder USD 4.6 billion. A number of offshore companies of Ruben Vardanyan also paid fees to the International Economic Forum in Davos, Switzerland.

Revelations of Panama Papers describe more layers than the global financial services show on façade (Cloke; Brown, 2019). The analyses of the Papers showed that up to 10% of global market was managed by only the Panama firm Mossack Fonseca. Such "offshore" sector is outside the formal financial and banking services sector (Hendriksen, 2016). It has its own life and its own regulation, powerful economies and persons use and control it. Concealment of the true owner and bank accounts is performed at a very high level (Gaughan; Javalgi, 2018). Globalization brings business and financial providers of both legitimate and shadow sector of global financial services together. Given the role of national interests the process becomes even more complicated.

Banking Secrecy Problems

Systematic analysis of acts of foreign legislation reveals the following problems:

- Special legislation on anti-money laundering does not provide a clear list of organizations obliged to provide information to the body of financial control. Such entails a non-clear criterion of identification of such legal entities.
- Many countries apply principles of privacy of transactions[vii]. It may also provide a right of a person not to identify them in the transaction.
- Special legislation while using the principle 'Know your customer' provides for two kinds of client authentication: simple and advanced. Since in most cases simple identification is not enough to eliminate money-laundering suspicion, advanced identification shall be required. Such fact automatically results in the application of such advanced identification to the absolute majority of customers. Moreover, when applying a risk-based approach the client is likely to be assessed as having "high risk". Such characteristic affects the client. The client however is deprived of the opportunity to contest such characteristic.

- Lack of clear evaluation criteria leads to the excess of information, and subsequent failure to filter out the information regarding legalization, from the information provided by the organizations in order to avoid sanctions for failure to provide information. Application of sanctions for providing excessive information by the entities cannot eliminate the problem either. The criteria of information to be submitted are not clearly defined, particularly in relation to suspicious transactions.
- Since the information provided to the financial monitoring body has a secret character, no possibility of appeal is provided for the client. To crown it all such information has an evaluation character. This can lead to discrimination in the assessment of a client on grounds of race, appearance or behaviour. All this can result in a direct violation of the natural human rights provided in international documents, e.g. the Universal Declaration of Human Rights[viii].
- It is possible to use the information not only for the purpose of struggling against legalization, but, e.g., for abuse in case such information comes into the hands of unauthorized persons or, worse, criminal hands. The Russian market "Gorbushka"[ix] is a striking example of the above. Other countries also have more or less similar institutions unfortunately.

Currently in Russia there is quite a number of cases where courts clearly recognize violations of constitutional rights of citizens. It is not a single case of judicial practice. The burden of proofs and excuses falls on banks. Banks are forced to introduce some ridiculous limits, as the banks have to follow the law. And one law contradicts the other. No one knows how to implement all these contradictory provisions.

Meanwhile, the institute of banking secrecy is necessary for the effective functioning of the Russian economy. Adverse acquisition risks in the provision of information are still very high in Russia. Adverse acquisition main risks neither lay in the legal vulnerabilities of the assets (which gives skilled aggressors legitimate opportunities on buying controlling stakes) nor in the possibility of the abuse of rights (e.g., suiting a 'victim' with formally legal, but in fact groundless claims). On the contrary, the main risks are:

- illegal seizure of property (e.g., using fake documents) with the support of corrupt employees of all involved in the deal state bodies and courts, which have legal access to banking secrecy;
- a compulsion to convey the property title by personal pressure on the owner (usually under the threat of criminal prosecution).

This is the main reason why Russian, Ukrainian, Kazakh and other businessmen use protective technologies (Gaman-Golutvina, 2010): the fear to fall under the redistribution of property without the possibility of protection of rights in an independent court. In developed countries, e.g. in the United States, the main danger is different: the chance of becoming a victim of a ruinous lawsuit. Every year in the USA thousands of completely frivolous lawsuits are filed with the claims of billions of dollars. In such lawsuits plaintiffs claim millions of dollars for alleged defective goods, 'sexual harassment', 'emotional suffering', 'professional negligence'. A characteristic feature of such claims is that the primary defendants are not persons with a direct relation to the events, which form the basis of the claim, but wealthy companies and citizens related somehow. The aim is to get a legalized extortion 'payment' under the amicable settlement agreements. On this ground the culture in the United States is called 'compensation culture'[x].

According to Russian experts, the loss of 20% of the information consisting in commercial secret, leads to the bankruptcy of the company in 60 cases out of one hundred. Losses from the actions of unscrupulous competitors, using espionage in the financial sector amount to 30% of all damage, which is incurred by banks.

The practice of the Constitutional Court of the Russian Federation on the issue of banking secrecy recognizes violations of constitutional rights of citizens. The protection of information, including banking and professional, is considered by the Constitutional Court as the problem of primary importance, as a necessary constitutional guarantee of the principle of adversarial proceedings laid down in Paragraph 3 of Article 123 of the Constitution.

Conclusion

Globalization provides changes to financial relations and banking regulations. The famous example of Panama Papers shows the necessity for legal regulation of global financial relationships. More effort shall be put on it both nationally and internationally.

Considering all the above one has to acquit the justification to protect the property from the potential effect of such claims. Does banking secrecy provide problems for the state if it seeks to protect the interests of the citizens of this state? Why, once again, we have to oppose the interests of the individual and the system, which consists of such individuals? The answers to such questions are crucial for understanding the development of the constitutional system of the country at issue.

Cash payments are necessary for payment of bribes. Limitations to circulation of cash money in the country make it more difficult to pay them. Though the amount of cash withdrawal limits in a country and corruption perception of such country do not have direct correlation (Figure 1, 2) (e.g., both the United Kingdom and Russia have no limit to cash payments, but Corruption Perception Index in the United Kingdom is 17 times lower than in Russia), still it shall be noted that in countries with strict limitations of cash payments (e.g., Denmark) corruption perception is low as well. For further development Russia shall put restrictions on cash payments of individuals under law and not under practical actions of banks and other regulators.

Fig. 1: Correlation between Limitations to Cash Payments

Fig. 2: Correlation between Limitations to Corruption

All the above makes the authors conclude about the necessity of the political will to improve the legislation of the Russian Federation with the aim of compliance with the provisions of the Constitution. It is also necessary to establish a clear balance between the constitutional rights of the individual and the limit of these rights when carrying out various control activities by public authorities.

Abstract

The paper presents the results of research on improving the methodology of human capital management at enterprises, in particular, personnel efficiency increasing of international company of the oil and gas industry. The aim of the study is to find training methods for effective development of employees of the oil and gas industry for their labor productivity increasing. General scientific methods of analysis, logical generalization and comparison, as well as correlation analysis are used in the research. It is determined that human capital currently remains the most important competitive advantage in oil and gas companies' market. The analysis showed that there are lots of existing methods used by companies for improving of their activity efficiency, but the methods of employees training and development deserve special attention. Within the framework of investigated enterprise, we have obtained the data which indicated that, despite the active use of various off-site methods of employees' training, the company did not provide the economic feasibility of investing in personnel training. Developed complex workplace training methodology, based on coaching approach was introduced and tested and made it possible to obtain labor productivity indicator increasing. It is noted that such an approach is universal and in future it may contribute to strengthening in the relationship between labor productivity and training volume both for managers and workers of various categories of the other enterprises of oil and gas industry.

Keywords: Human Capital, Professional Education, Personnel Training, Coaching, Oil and Gas Companies

Introduction

In the current context, human capital development is of particular importance and becomes indispensable condition for successful functioning of industrial organization and its competitiveness increasing. Strategically oriented professional development of employees plays a crucial role.

Modern manufacturing organizations are forced to function in conditions of uncertainty, volatility and growing competition. In such a case, it is not enough just to be stable for industrial organization. Continuous development is required and it remains a leading factor in of company's competition in the market. At the same time, in this situation, competitive advantages are determined not only by innovative technologies of industrial production, the allocation of production forces and other components, but also by their ability to mobilize and effectively use the available human capital. The

human capital of manufacturing organization is a knowledge holder, generator of ideas for processes and mechanisms improving, the main link in the process of production maintaining and developing, and ensuring source of efficient use of the material resources.

According to the experts, Global Human Capital Trends (2019), today professional development of the human capital plays a significant role. The frantic speed of new equipment and technologies introducing affects the obsolescence of professional skills, and requires constant knowledge extension and additional training of employees.

For Russian economy, oil and gas companies play a critical role, Sopilko et al (2020). Advanced equipment and technologies used by oil and gas companies will determine the development direction of Russia in future, as well as provide and stimulate the functioning of other industries in modern conditions. Therefore, special requirements are placed on learning ability, personal characteristics, and the degree of workers' adaptability in this field. There is a shift in emphasis from organizational costs minimizing to maximizing of human resources implementation. High-risk degree at various positions sets up qualitatively different requirements that are higher than in the other sectors of national economy for qualification level of personnel of oil and gas organizations.

Modern realities and global trends determine the transition of companies to more rational and dynamic management, mainly focused on human capital development. In this regard, a particularly urgent task is to provide certain recommendations for the personnel professional training of industrial company, in particular, of the oil and gas sector.

Current Trends in Human Capital Management

Over the past decade, the HR sphere has been dynamically developing. Approaches to human capital management are rapidly changing. The reports of the world's leading consulting companies reflect the main trends in this field, Global Human Capital Trends (2019). Trends represented in Figure 1 are predominating now.

Fig. 1: Human capital management trends prevailing in the market in 2020
Source: compiled by the authors

High technologies capture the whole world today and the field of HR process management is not an exception, Alekseeva et al (2019), Korneeva et al (2020). However, we believe that such technologies are more effective for mass recruitment and cannot give high results if it is necessary to identify any special, individual competencies of the employee.

It's obviously that according to statistics, the representatives of generation Z (aged 21 to 23 years), Kuryshova et al (2019) have certain values and their ideas about the work and realization of their capabilities. They are very different from generations X and Y who dominate on the labor market today. They are fast, impatient and they want fast growth and results.

For a long time, human capital management focused on standardization and versatility. But now, the

orientation is changing towards individualization. Managers monitor personnel development within the company more closely, they create conditions for flexible career growth, introduce individual bonus packages, etc. That is can be highlighted as the trend of personalization.

Information opportunities also make it possible to work distantly, without being tied to the office. This trend is not entirely new, Sopilko et al (2018), however, this form is relevant during the current coronavirus pandemic in 2020, and can be solidly strengthened in many areas of economy. Such approach provides many benefits, including cost savings.

The employee experience trend is not new, Faggian et al. (2019), and is also currently used by many companies. And although this concept is considered to be quite effective, but, in our opinion, creates certain competencies for employees in relation to a specific company. But such approach will not fully meet the needs of worker, his development and mobility level.

The storytelling trend has emerged because of social media influence on human capital management, Kafidov et al (2017). Various stories are posted on blogs and websites to promote the image of both employees and the company.

The prevailing trend in human capital management is coaching today, Ellinger and Kim (2014). Coaching is a model for the development of so-called mentoring. There are many advantages and disadvantages of this method. On the one hand, experience can be really transmitted, but, on the other hand, it is like an imposition of one's own style and sometimes it might depersonalize staff.

And finally, in the era of “Industry 4.0”, it is impossible to develop something without using of innovative technologies. First of all, such technologies have a vector for labor productivity increasing. So-called “HR innovation laboratories” are being created in many companies nowadays, Zaborova and Markova (2019). Those companies that are engaged in new technologies in HR sphere receive many advantages, because they can work and make marketing researches on customers who have special requests. Human capital management process is becoming faster, more adaptive and innovative.

Within the framework of such trends, it is advisable to note which of them are relevant for the companies of the oil and gas sector of economy. As far back as 2015, KPMG International experts (2015), conducted a study “The Crisis of Qualified Personnel” and identified 5 main strategies that energy companies and enterprises of resources sector can use to overcome the crisis in the long term: human resources planning strategy developing, their maximum and efficient use, more effective management of interaction with third parties that affect enterprise activities, maintaining and increasing of accumulated experience and special knowledge, and its continuity, value proposition reviewing for employees.

The problem of qualified competent workers’ shortage in the oil and gas sector can be successfully solved only if a long-term strategic approach is formed.

Only 7% of the studied enterprises have developed programs for accelerated training for managers, and 44% of them confirmed that they were taking all possible measures to develop this area. When attracting young specialists, enterprises need to keep in mind that the financial component of activity is not the only priority. Many HR representatives of the oil and gas companies admit that their organizations pay little attention to training programs development that are adapted separately for older and younger generations, which differ greatly as in communication as in training style.

Over the past seven years, Deloitte has been conducting international research on trends in the field of personnel management and on difficulties identifying that staff service often face with. We have considered the results of the 2019 polls in Russia. The survey was conducted for 82 companies. Business representatives and HR services respondents were requested to evaluate the importance of such aims and companies’ willingness to work in such conditions. The results of the study are presented

in the Figure 2.

Fig. 2: The main trends in the field of human capital management in 2019 in Russia
Source: compiled from research materials of Global Human Capital Trends 2019, Deloitte

92% of all respondents consider that staff training, experience and leadership development is a top priority in human capital management. It is important to note that each of the business priority topics is observed in the context of large-scale automation and digitalization of the processes related to human capital management.

In the framework of Deloitte's research, industry results in the extractive industry and energy are of interest. According to these studies, in conditions of personnel shortage in these sectors, the emphasis should be made on existing resources and their development. The top 10 most important areas in HR, according to employers in the extractive industry and energy, are presented in Figure 3.

Fig. 3: Comparison of the importance of the main trends in the field of human capital management for extracting and energy enterprises in 2019 in Russia and in the world, %
Source: compiled from research materials of Global Human Capital Trends 2019, Deloitte.

More than 60% of industry representatives around the world noted the importance of organizational transformation of their companies for the growth rate maintaining and competitiveness increasing. 20% of industry representatives in Russia and about 30% in the world switched over to team organizational structure, more than 50% of them reported about a significant increase in business performance due to the activation of cross-functional and digital/virtual teams.

The overwhelming majority of Russian respondents (80%) consider that a key obstacle to the development of new organizational model is a lack of technologies. Foreign industry representatives mention that, first of all, there is a lack of clear understanding of the work principles in cross-functional team conditions among the leaders.

The transition of industry companies to team organizational structure, which implies more intensive interaction within and between departments, is conditioned by the need to ensure higher internal mobility of industrial companies' personnel, which is extremely important in the context of a shortage of qualified personnel in the labor market. Nevertheless, it must be borne in mind that the transition to a team structure involves approach review to career development, motivation and benefits.

Thus, it has been established that the system of professional staff training is crucial for the effective HR management at industrial organizations, for achieving and maintaining of a high level of personnel qualification.

Study of a Problem

The experience of the most successful domestic and foreign companies shows that investing in staff gives quick and high return. So, one monetary equivalent invested in human resources development brings from 3 to 8 monetary equivalent income. Studies devoted to learning and development promoting have shown that at the beginning of the XXI century the growth of the US economy through increase of employees professional training level amounted to 2.1%, it was 0.4% through the population growth, 0.5% due to the due increase in capital. In total, in the United States, increase in the labor force quality ensured 14% increase of real national income, Lee (2019), Agarwal et al. (2019). Researches have also shown that 10% increase in staff training costs gives an increase in labor productivity by 8.5%, while a similar increase in investment gives an increase in productivity by only 3.8%.

In Japan, experts of the Center for Increasing Labor Productivity determined that human resources are the main problem of industry and management and how important is to provide manufacturing and management structures with qualified personnel, Roy (2018). Later, the concept of lifelong education was developed, which has become one of the most effective tools to solve the problems of personnel correspondence to rapidly growing technical potential. The concept assumes that the process of staff professional development becomes permanent.

The training need for managers of the organization is determined both by the requirements of job and/or interests of organization, and by the individual characteristics of employee. Training need, new knowledge acquisition and certain professional skills development are influenced by age, work experience, abilities level and some motivation feature. The need for training may arise in response to current problems and/or may be associated with plans, with future problems of the organization.

Currently, personnel training methods at enterprises are systematic set of actions aimed at certain educational skills and competencies attainment, Kuryshova et al (2019). The choice of personnel training method depends on the specifics of the company's activities, the resources allocated for these purposes, as well as the specific areas of training.

In general, personnel training methods are divided into two groups:

1. Workplace training methods;
2. Off-site training methods.

Each group of teaching methods has its own advantages and disadvantages. So, the main disadvantage

of the off-site training methods (lectures, seminars, brainstorming, case studies, role-playing and business games) is the focus of these training types on the acquisition of theoretical knowledge.
The variety of workplace training methods and analysis of their main characteristics are given in Table 1.

Table 1: key features of workplace training methods

Workplace training method	Parameters			
	Two-way communication	No risks to production	Low financial expenses	High coverage of the number of employees
Briefing	-	+	+	+
Rotation	-	-	-	+
Mentoring	+	+	-	-
Increasing complexity method	-	-	+	+
Procedure instructions usage	+	-	+	+
Industrial training	+	-	+	-
"Secondment"	+	-	-	-
"Action learning"	+	-	+	-
"Shadowing"	+	+	+	-
"Buddying"	+	+	+	-
Coaching	+	+	+	+

Source: compiled by the authors

According to Table 1, it should be noted that the main part of training methods in the workplace has a strong two-way feedback between the mentor and the learner. Such training methods lead to costs minimizing for staff training since the training process takes place on existing educational and material base of the enterprise. However, the effectiveness of such methods as "Mentoring", "Buddying", "Shadowing" directly depends on the professional qualifications of the mentor. And at the same time highly qualified, experienced personnel are always in great shortage so the application of these training methods for a large number of employees is impossible. So, the "coaching" method most closely corresponds to studied parameters and training requirements.

As a result of effectiveness and absolute versatility, coaching approaches that are actively used in the field of human resource management of industrial enterprises, including the oil and gas industry, have recently gained considerable popularity. The coaching model is based on psychological principles that arise during the interaction of leader and subordinate person, as a result of which the employee understands and comprehends his internal capabilities with their further activation, Ellinger and Kim (2014), Kafidov et al (2017). Coaching is also aimed at stereotypical ideas upgrading about the performance of both an individual and the whole team, developing new strategies for the leader's behavior, Kafidov et al (2017). In addition, coaching application makes it possible to increase the qualification level of labor resources, to reduce the risk of qualified personnel loss, to improve employees' responsibility and competence, allowing them to identify and rely on their own deep motivation.

The comprehensive benefits of coaching are aimed at identifying and unlocking the potential of an individual or group of people in the professional field. Coaching can serve as an important tool for managers, as it can allow employees not only to perceive instructions as a guide to action, but also to initiate the thought and creative process of each individual worker, and it will help to increase the competence level of mass professions specialists of industrial enterprises.

The functionality and vectors of coaching are presented in Figure 4.

Fig. 4: Scheme of an extensive integrated coaching system

Source: compiled by the authors

Schematically, the coaching system structure for industrial enterprises can be characterized by interconnected and mutually subordinate blocks (theoretical, managerial and executive or effective), the foundation of which is management efficiency.

Thus, the advantages of coaching approach during staff business training determine the formation of corporate culture based on openness, coherence, actions and goals promptness, trust of the entire team. In an atmosphere of mutual understanding and close cooperation, the "synergy effect" of the leader and the employee is manifested. Joint efforts can help to achieve higher general performance. Each participant of the bundle makes a valuable personal contribution to tasks solving, while individual benefits and do not provide real and long-term success.

However, it should be mentioned that workplace training methods are more practical in nature and help to develop the necessary competencies in specific production conditions. At the same time, such a high practical orientation can impede the development of deep, systematized knowledge of scientific side of studied processes.

Theoretical and experimental studies in the field of professional training for managers of industrial organizations have demonstratively shown that there is no one universal method of training, Hurber et al (2018), Chitsaz et al (2019), Andalib et al (2019). Under the old "social contract", employers were looking for employees who would fill vacancies and perform certain functions. The employer had shown the way, and the task was to follow it. This model has been replaced by the concept that employers invest in staff training and employees become "main value creators" for the company. Value creation is closely related to the identification and key professional qualities using – unique driving forces that can make a company the leader in its sphere or the best in the world. In these new conditions, employers want to stimulate workers to grow professionally, achieve higher work efficiency level and strive to join the "team of creators", which makes the main contribution to creating and adding value. The growing role of intellectual capital in modern companies leads to the need to turn them into a constantly educating organization. Today, top foreign and domestic firms and organizations are personalized systems for the professional competence developing of their personnel, putting into practice the principle of the participation of all specialists in staff training, as well as ordinary managers in self-trainings.

Based on the considered methods of staff training, it is necessary to justify the economic feasibility of using the most promising for effectiveness increasing of industrial enterprises, such as in the oil and gas industry.

Researches and Results

The study of human capital development process, the nature of its components impact on the strategic development of the company was carried out. It was performed for the representatives of various professional groups of employees during some years in production organizations of PJSC Gazprom.

PJSC Gazprom is a global energy company, one of the largest in Russia, with many branches and representative offices abroad. In the opinion of the management, the company's staff is one of the main and most valuable resources of PJSC Gazprom. Therefore, it is of particular interest to analyze the main indicators of the company that characterize its personnel.

The process of gas production and delivery to consumers is an extremely complex and technological. It requires special training of workers, the availability of special knowledge and skills, as well as certain competencies. A main feature of companies in the oil and gas sector is the necessity to achieve accuracy and consistency in the working process of various specialists at each stage of activity.

Labor market monitoring (2018), of the oil and gas industry showed that despite the rather low rates of staff turnover over the past 5 years, every year companies face with a "staff shortage", as well as problems associated with insufficiently high labor productivity. In accordance with the current human resources management policy, PJSC Gazprom plans to solve these problems through the effective usage of human resources potential. Therefore, for several years, special training programs have been implemented using off-site training methods. Cooperation with leading specialized universities helps to carry out preliminary training of future personnel using innovative education technologies for the further implementation in strategic projects.

In its turn, PJSC Gazprom and its subsidiaries provide educational organizations with assistance in the formation of laboratories and training facilities, educational materials, in student practice organizing, etc. In their turn, educational institutions of higher and secondary vocational education attract managers and employees of the Gazprom Group for teaching.

Also, since 2014, the "The Corporate Continuous Education System (CCES)", Sustainability report

(2018) has been set. It is aimed at employees developing taking into account the increasing requirements of production and labor quality, new technologies introduction and regions expansion where the Gazprom Group operates. Trainings are carried out in educational organizations of PJSC Gazprom, production centers, as well as on the basis of leading Russian universities.

It's known that the personnel effectiveness is primarily determined by the labor productivity indicator (the ratio of the economic result of activities and the number of employees). Despite the fact that employees of the company were under professional retraining at universities in order to improve their qualifications in the period of 2015-2018, the analysis of the financial and economic activities of PJSC Gazprom for the period showed that the indicator of total labor productivity, Gazprom report (2019) did not have a stable tendency to increase from year to year (Figure 5, 6).

Fig. 5: Analysis of labor productivity indicators of employees trained under professional retraining programs in the Gazprom Group

Source: calculated by Gazprom report, 2019

Fig. 6: Relationship between labor productivity and the average number of training hours per employee of PJSC Gazprom

Source: calculated by Gazprom report, 2019

The research of the dependence of the training volume of employees also revealed a weak relationship between the average number of training hours off-site the workplace per one employee of PJSC Gazprom in the main activities and the general labor productivity indicator.

Despite the fact that in 2018 the average number of training hours off-site the workplace per employee were 75.7 hours for workers and 46.3 hours for managers, specialists and other employees, which were significantly lower than in 2017, general productivity had increased by 22%. This fact also confirms the low dependence between indicators.

To confirm these conclusions, correlation analysis of the relationship between off-site training approach and labor productivity indicators of employees was also carried out (Table 2).

Table 2: correlation analysis of the dependence of labor productivity indicator on the volume of the off-site workplace training approach

	Workers, trained	**Managers, trained**
Pearson correlation (r)	0,651	0,887
Dual-sided value*	0,044	0,008

** Correlation is significant at the level 0,05 (dual-sided)*

The correlation analysis between labor productivity and the volume of off-side workplace training, carried out for the period 2015-2018, indicates the presence of a strong correlation between managers who have completed training. However, correlation coefficient value for the workers is 0.651 and is an average indicator, so it may not provide the economic feasibility of the funds invested in training. Significance testing of the linear correlation coefficient based on the Student's t-test did not show a statistical relationship between performance and training volume due to the short time period of the study.

Since 2017, Gazprom has expanded the opportunities for employees to receive education remotely, on the workplace. The study of the dependence of this approach to the employees' professional development and their labor productivity indicator was carried out at Gazprom marketing and trading. Thus, the average number of employees of Gazprom marketing and trading is 495 people (including managers – 206, specialists of various categories – 285, workers – 3). The company is distinguished by a professional and age composition of the personnel. There is a predominance of employees in the age of 30-40 years old.

In 2019, a comprehensive coaching system was tested during the workplace training in Gazprom marketing and trading. The share of specialists and managers who trained was 31.2% of the total staff of the company. Due to the expansion of such training program on the workplace as complex coaching method, the labor productivity indicators of various categories of employees has increased by 10.8% in this company.

Thus, it has been proven that complex coaching approach using contributes to the growth of labor productivity indicators, therefore, comprehensive coaching system can be advisably performed and applied at the other enterprises of PJSC Gazprom.

Conclusion

In the course of research, it was determined that methodology of human resource management improving is an effective direction for potential developing of industrial enterprises now. Human capital continues to be the most important competitive advantage in the market, including the oil and gas companies. Changes in the economy that took place in recent years had radically changed the attitude towards human resources usage and development.

The main methods of professional and personnel training trends are investigated. Their successful implementation is the most important condition for effective professional development. The results of analysis showed that there are variety of methods for activity efficiency improvement but the methods of personnel training and development deserve special attention.

We also analyzed the dependences of some educational methods application on employees' performance at the largest enterprises in the oil and gas industry, PJSC Gazprom. The results of the study made it clear that despite active using of different training approaches off-site the workplace, insufficient increase in workers' productivity was observed, so economic feasibility of investing in company's personnel education was not ensured.

Thus, in order to increase labor productivity indicators at Gazprom marketing and trading, comprehensive coaching method of workplace training was tested. Such complex coaching approach to training at this enterprise in 2019 made it possible to ensure the growth in labor productivity of various categories of employees by 10.8%.

Comprehensive approach to employees training directly at the workplace can further contribute to strengthening in the relationship between the labor productivity indicators and the training volume for both managers and workers of various categories on the other enterprises of oil and gas sector. The advantages of such method are due to the formation of mutual understanding atmosphere and close cooperation between the trainees and the coach, the manifestation of the "synergy effect" between the manager and the employee. So joint efforts can help to achieve a higher total performance. Each member of the team makes a valuable personal contribution to the solution of assigned tasks, since the individual success of employee does not ensure the real and long-term prosperity of the company.

Abstract

The need for marketing tools integrated into interactive communications with users of the global web-based hypermedia system led to the emergence of mobile marketing. The advantages of such communications and upward trends in the wireless telecom industry have resulted in the spread of mobile marketing. To find out how its tools are used in the higher education sector, a survey was conducted among the marketing representatives of Polish and Ukrainian higher education institutions. The authors studied the availability of mobile marketing resources in such institutions to prove the relationship between their mobile and desktop websites and to define the most (and least) common mobile marketing tools in this sector. The study was expected to show no significant differences between Polish and Ukrainian input regarding mobile marketing in higher education and confirm that a website adapted to mobile users in terms of marketing services supports achieving the site's goals.

Keywords: Higher Education Institution, Educational Marketing, Comparative Analysis, Mobile Marketing.

Introduction

The modern world is changing rapidly. Changes in the ways that marketing information is transferred are leading to the emergence of new concepts in marketing. The global intensification of development and the rapid expansion of interactive channels have resulted in the spread of Internet marketing. This has encouraged marketers to look for tools to be integrated into mobile phones, which are increasingly becoming an integral part of personality. Taking into account the needs of mobile Internet users has helped to improve the work of marketing services, especially in terms of attracting new customers and retaining existing ones. In scientific and everyday use, the term "mobile marketing" has started to be used to emphasise the integration of mobile devices into Internet marketing. A. Kaplan (2012) defined this as any marketing activity conducted through a ubiquitous network to which consumers are constantly connected using a personal mobile device. In general, we agree with this interpretation, but consider it expedient to emphasise the dualism of mobile marketing. On the one hand (with regard to information transfer), mobile marketing should be considered as a separate element of marketing activities, involving mobile communications. Modern formats and technologies for information transfer within a cellular network according to L. Kysliuk (2019) include a number of tools: voice information (IVP – Interactive Voice Response), text information (SMS), graphic information (EMS – SmartMessaging), photo and video information (MMS), non-voice interactive communications (WAP, Java), content (themes, images, melodies, slide shows), games and programs, Bluetooth marketing and advertising during the call. On the other hand (with regard to Internet marketing tools), mobile marketing should be considered as a specific marketing activity based on the synergy of mobile and Internet technologies. The main advantages of mobile marketing are: interactivity (receiving feedback in a short time); multimedia (use of text/audio messages along with graphics and video); personalisation (targeted focus on the characteristics and

Cite this Article as: Artur KISIOLEK, Oleh KARYY and Liubov HALKIV "Comparison of Mobile Marketing Tools Used by Higher Education Institutions in Poland And Ukraine" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

needs of a particular consumer); availability during the day (24/7 access to the media channel); audience coverage (simultaneous dissemination of information to a large audience); and profitability (simplicity and affordability of information transfer via mobile devices), etc.

The following factors promote the development of mobile marketing: the number of mobile users is constantly growing; mobile operators are motivated to develop the mobile web; mobile communications are diversifying and becoming more and more common; mobile devices are becoming dominant in remote communications. In 2019, as stated in Grand View Research (2020), the size of the global mobile marketing market was estimated to be 65.06 billion dollars and is expected to increase by 22.9% from 2020 to 2027.

While the importance and prospects of mobile marketing in various fields of human activity have been discussed and proven by both theorists and practitioners, the issues connected with its functioning in the educational environment need further study. The importance of these issues has increased during the coronavirus pandemic. In countries experiencing the pandemic, the established norms have been broken, while wide opportunities for digitalisation have opened up, thus ensuring the further development of educational processes. Educational institutions were forced to quickly master the latest remote access services. Obviously, such communications did not only take place in the educational process, but they also covered all areas of educational management, including the marketing system.

Among educational service providers, higher education institutions outreached schools and preschools in terms of the level of involvement of educational service recipients in their mobile communication processes. This is explained by the nature of higher education students (permanent, active, and progressive mobile users) and the specific character of higher education itself, which serves as a generator and disseminator of new knowledge, a producer and provider of innovations, a driver of economic and social effects, and an environment for innovation and intellectual potential. Therefore, the importance of conducting multifaceted research on the use of mobile marketing in higher education is beyond doubt.

The authors, who represent the scientific community of the higher education sector in Poland and Ukraine, set the goal of analysing the marketing activities of higher education institutions in their countries in order to:

– understand the availability of mobile marketing resources in higher education institutions;
– prove the positive impact of the mobile website on the desktop website strategy of a higher education institution;
– define the most (and least) widespread tools of mobile marketing used by higher education institutions in Ukraine and Poland.

Special focus is given in this article to the evaluation of: similarities in the mobile marketing practices existing in the higher education institutions of Poland and Ukraine, the usage of this new direction of Internet marketing in the higher education sector, the extent of the mobile website's impact on the performance of the higher education institution on the Internet, and the identification of weaknesses in the mobile marketing tools.

Analysis of recent research and publications on mobile marketing in higher education

V. Sharma and M. Berad (2019) as well as D. Rowles (2017) mentioned that mobile marketing is a new concept related to a multi-channel, digital marketing strategy, aiming to reach the target audience on their smartphones and mobile devices via websites, emails, SMS and MMS, social media and apps. This concept has spread throughout the higher education environment.

On the one hand, modern mobile marketing tools are able to meet the growing demand for students to establish deeper, meaningful connections with higher education institutions. But on the other hand, in

the context of a systematic reduction in the number of students and growing competition between higher education institutions, mobile marketing is the fastest and most accessible way to convey desired information to clients (enrolees, students and their parents). In particular, higher education institutions can use it to better show any prospective students the features, opportunities and benefits of student life in their institution. According to VONT (2018) research, 71% of students and 45% of their parents reported that they had viewed the website of a higher education institution on their mobile phone.

In modern conditions, the main potential client for higher education institutions is Generation Z, which is the first mobile and socially conscious population stratum. According to Grand View Research (2020), more than 90% of young people use smartphones to access information or content. Research of J. Fromm and A. Read (2018) shows that Generation Z combines the pragmatism and work ethic of the older generations with the high ideals and digital courage of youth. Accordingly, marketing tools used by higher education institutions to interact with their applicants need to be changed. The approaches used to communicate with the millennial generation do not help to achieve the desired result. For example, Kirk Daulerio and Adrian Serna (2017) have thoroughly studied the issue of supporting Generation Z students enrolled in college through intelligent mobile messaging. Given that the characteristics of this generation include interest in mobile platforms, highly personalised interaction, and instant real-time response, they proposed tools and strategies for higher education institutions to help them in attracting and retaining students.

Over the last decade, marketing strategies for higher education institutions have been rapidly transforming in order to respond to the demands of the new times. Higher education institutions are increasingly looking for new resources, competencies and opportunities to improve their corporate reputation. In his critical analysis of the marketing strategies used by higher education institutions, M. Camilleri (2019) considers mobile marketing to be an effective marketing communication tool in view of the increased competition between the institutions. In this context, Pranati R. T. (2018) has defined the impact of digital marketing tools in the management of educational brands. She notes that higher education institutions must use innovative approaches and special media strategies to improve the effectiveness of their digital marketing. At the same time, V. Sharma and M. Berad (2019) have acknowledged the low level of awareness on the part of business schools regarding the opportunities provided by mobile marketing. Andriani Kusumawati (2018) selected five Indonesian public universities and analysed the various methods of digital marketing they use, including mobile marketing, their effectiveness and the impact they have on students' decision-making processes when choosing a university. João Pedro Esteves Coelhoso (2019) conducted a large study of public higher education institutions in the United Arab Emirates to find out the factors which influenced students' perceptions of the mobile marketing tools used by higher education institutions. In particular, the author identified: risk acceptance, personal commitment, the provision of information, available content, content exchange and perceived value. Ryan De Kock and Lynn A. Futcher (2016), when studying the use of mobile devices in higher education institutions in South Africa, raised another important issue – the cyber security of this process, which is extremely important in today's conditions.

Mobile marketing combined with social media marketing has resulted in an innovative form of marketing known as mobile social media marketing, according to V. Sharma and M. Berad (2019). Therefore, higher education institutions are increasingly integrating or planning to integrate social media apps into their marketing programs. Kuzma and Wright (2013) selected 90 universities in Asia, Africa and Europe in order to investigate the use of social media in enrollment and educational marketing. They emphasise that the use of social media in the marketing and recruitment campaigns of higher education institutions can serve as a catalyst for strategic changes in the education sector as a whole. A similar opinion is shared by Bélanger, Bali and Longden (2014), who studied the social media marketing strategies used by Canadian universities as a tool for institutional branding, recruitment and the engagement of local and international students. Constantinides and Zinck Stagno (2011) identified market segments among prospective students based on the use of social networks and investigated their impact on the students' choice of programs and higher education institutions in the Netherlands.

However, the use of mobile marketing in higher education institutions in different countries differs significantly. For some institutions, it is quite a new experience, while for others it has become common practice. For example, in the United States, higher education institutions continue to implement numerous mobile applications that help in attracting as many students as possible. Mobile marketing strategies in higher education institutions in this country are becoming more personalised and influential. Moreover, according to Modo Labs (2019), US higher education institutions take part in best mobile app competitions in such categories as: the best recruitment and admission, the best app for attracting students, the most innovative app for communication, the best app for using XModule, etc.

Given the high importance and prospects of mobile marketing as a means of educational marketing, there is a need for further in-depth study of the practical aspects of its application in higher education institutions in Ukraine and Poland, in particular.

Materials and Methods

In this study, the authors focused primarily on the marketing activities of higher education institutions in Poland (P) and Ukraine (U). The analytical part, therefore, contains materials from a survey conducted among specialists involved in this type of activity. One questionnaire corresponded to one higher education institution. During the survey, 185 questionnaires were received (Table 1). The respondents comprised representatives of higher education institutions in Poland (66.5%) and Ukraine (33.5%), representing public institutions (52.4%) and private institutions (47.6%).

Table 1: characteristics of the higher education institutions covered by the survey

Country	Number of higher education institutions, total		Share of higher education institutions, %	
	units	%	public	private
Poland	123	66.5	31.7	68.3
Ukraine	62	33.5	93.5	6.5
Total	185	100	52.4	47.6

Source: own development

In this article, the authors will not focus on either a description of the surveyed institutions, or on substantiating the representativeness of the characteristics obtained in the general sample. This part of the research project has already been disclosed. Instead, the authors will present for the first time the results of the analysis of data related to mobile marketing in higher education institutions, in terms of the following three issues: 1) available web resources; 2) the relationship between the general web activity of a higher education institution and its mobile marketing activities; 3) the most (least) common tools of mobile marketing in higher education institutions.

To describe the results of the study, we used the indicator of the population structure (percentage of *i* answers (d_i) among k answer options; $\sum_{i=1}^{k} d_i = 100\%$). The similarity of the structure of responses provided by the respondents from the two countries – Poland (d_i^P) and Ukraine (d_i^U) – was evaluated according to the formula of the coefficient of structural similarity between two objects:

$$P(V) = 1 - \frac{1}{2}\sum_{i=1}^{k}\left|d_i^P - d_i^U\right| . \quad (1)$$

Some questions in the questionnaire have *n* answers, which can be digitised by ordinal points (R_{min} =1, …, $R_{max} = n$). For the generalised estimation of such answers in the form of a positive or negative value, the formula of a centred average has been used:

$$\overline{R_0(V)} = \bar{R} - \frac{R\max + R\min}{2}, \quad (2)$$

where $\bar{R}$ is an average value of ordinal points.

To assess the level of expert agreement regarding the values of these centred averages ($\overline{R_0(r)}$) in some questions in the questionnaire, Spearman's rank correlation coefficient was used:

$$\rho = 1 - \frac{6 \times \sum_{j=1}^{1} d_j^2}{n \times (n^2 - 1)} \quad (3)$$

where d_j is the difference between the ranks of the average centred rank of Poland and Ukraine according to the *j* statement; *n* – the number of statements.

Cramer's conjugation coefficient was used to evaluate the relationships between the two categorical features:

$$C = \sqrt{\frac{\chi^2}{n \times (m_{\min} - 1)}}; \quad (4)$$

where m_{min} is the minimum number of groups by factor (m_x) or resultant (m_y) feature; χ^2 – Pearson's quadratic conjugation:

$$\chi^2 = n\left[\sum_i \sum_j \frac{f_{ij}^2}{f_{i\Sigma} \cdot f_{\Sigma j}} - 1\right] \quad (5)$$

f_{ij} – is the frequency of the characteristic of the *i-th* row (of the *i-th* factor group) on the *j-th* column (*j-th* efficiency groups); $f_{i\Sigma}$ and $f_{\Sigma j}$ – are total frequencies by groups of factor and efficiency characteristics; *n* – is the sample size.

Research Hypotheses

1. There are no significant differences between the answers of the respondents from Poland and Ukraine regarding the available resources, role and tools of mobile marketing in higher education institutions.
2. The availability of a mobile-friendly website adapted as part of marketing services enhances the implementation of important goals of the general web strategy carried out by higher education institutions.

Results

Given the high importance of the various mobile marketing tools used to promote educational products by Ghose (2017), Kotler et al. (2017), Kulinich and Sorokata (2019), Scott (2017), Sznajder (2014), the authors first tried to find out how marketing services use the following tools (j=1,2,3): 1 – mobile site; 2 – responsive web design (RWD); 3 – strategies of mobile marketing activities. The question "Does your higher education institution use the following means of mobile marketing?" has three answer options (i=1,2,3): a) yes; b) no; c) we plan to introduce them within the next 6-12 months. All respondents provided answers to all questions. The calculated percentages of responses from the respondents from Poland (d_{ij}^P) and Ukraine (d_{ij}^U) for each i answer and each j tool are given in Table 2. Based on the values d_{ij}^P and $\overline{d_j}$, and using the formula of the weighted arithmetic mean (weight – the number of respondents in each country), the average percentage of responses in

the two countries (d_{ij}^{U}) was calculated for each j tool. According to the formula of the simple arithmetic mean, the average value of the fraction for each answer variant ($\overline{d_i}$) is determined. Formula (1) was used to calculate the indicator of structural similarity for each of the tools – P(V)j. These values were assigned ranks in ascending order – P (r)j.

Table 2: structure and similarity of the answers of the respondents from Poland and Ukraine regarding the availability of resources used by higher education institutions in their mobile marketing activities

Statement number	Proportion rate, %									P_j	
	yes			no			scheduled for completion within 6-12 months				
	d_{ij}^{P}	d_{ij}^{U}	$\overline{d_{ij}}$	d_{ij}^{P}	d_{ij}^{U}	$\overline{d_{ij}}$	d_{ij}^{P}	d_{ij}^{U}	$\overline{d_{ij}}$	$P(V)_j$	$P(r)_j$
1	53	58	54.7	44	43	43.7	3	0	1.6	0.950	1
2	50	65	55.0	41	36	38.4	10	0	6.6	0.850	3
3	39	45	41.0	60	50	56.6	1	5	2.3	0.900	2
$\overline{d_i}$	47.3	56.0	50.2	48.3	42.7	46.2	4.7	1.7	3.5	x	x

Source: own development

The data in Table 2 allow us to conclude the following. Firstly, there are no significant differences between the answers of the respondents from the two countries (the minimum value of $P(V)_j$ is high (0.850), and the squared coefficient of variation calculated on the basis of three values of P(V)j is 4.5%). The highest level of similarity was observed in response structures regarding the mobile site, while the lowest level was regarding the strategy of mobile marketing activities. Secondly, the marketing services of nearly half of the higher education institutions use all the tools which were analysed. The most common tool was responsive web design (RWD), while the least common was a mobile marketing strategy. In the higher education institutions in Ukraine, the availability of each of the tools is observed more often than in the higher education institutions in Poland. Thirdly, in the near future, Polish higher education institutions plan to use mobile site and responsive web design (RWD) more intensively than those in Ukraine. However, even after the implementation of these plans, Polish higher education institutions will lag behind those in Ukraine in terms of the availability of each of the three tools of mobile marketing separately and all the tools together.

In modern conditions, an effectively functioning web service significantly helps higher education institutions to ensure their mobile marketing strategy is implemented successfully as noticed by Grewal et al. (2016), Prokopenko et al. (2019), Rowles (2017), Tong et al. (2020). Therefore, in the research project, the respondents were also asked to arrange each of the eight goals of a higher education institution's web service according to their level of importance (j=1,…,8): 1 – Promotion of Educational Services; 2 – Creating the Image of the University; 3 – Acquisition of New Students; 4 – Conducting Online Recruitment; 5 – Online Student Service (e.g. Learning Performance, Schedule, Library, Administration); 6 – Interactive Communication with Students; 7 – Online Sales of University Publishers; 8 – Online Sales of Educational Services – e-learning. Respondents rated each goal from the most important (1) to the least important (8). If a certain goal was not considered by the respondent, it was assigned a score of "0". The answers of the respondents from both countries to this question were similar and did not contain any contradictions. On the basis of the received data, the authors grouped the answers into eight groupings based on two features, and made conjugation tables (Table 3). The first grouping feature was assessing the importance of the main objectives of the web service. Based on that, three groups of assessments were formed: high (1-3), medium (4-6), and low (7-8, 0). The second grouping feature was the respondents' statements about whether the marketing services in their institutions have ("yes") or do not have ("no") mobile-friendly web pages. For each

combinational grouping, the authors calculated Cramer's conjugation coefficient by formula (4) and Pearson's quadratic conjugation by formula (5).

Table 3: assessment of the connection between the respondents' answers regarding the availability of a mobile-friendly website as part of the mobile marketing strategy and regarding the importance of the main goals of a higher education institution's web service

The main goals of a higher education institution's website	Availability of a mobile-friendly website	Number of respondents who rated the web service of a higher education institution			Indicators	
		high	medium	low	χ_j^2	C_j
Promotion of Educational Services	Yes	89	11	1	27.7	0.387
	No	45	33	6		
Creating the Image of the University	Yes	85	15	1	62.3	0.580
	No	23	47	14		
Acquisition of New Students	Yes	99	1	1	84.4	0.675
	No	30	33	21		
Conducting Online Recruitment	Yes	74	22	5	86.7	0.684
	No	6	42	36		
Online Student Service	Yes	94	6	1	98.5	0.729
	No	18	55	11		
Interactive Communication with Students	Yes	60	27	14	52.4	0.532
	No	8	62	14		
Online Sales of University Publishers	Yes	46	44	37	37.3	0.449
	No	8	73	4		
Online Sales of Educational Services – e-learning	Yes	37	41	23	32.2	0.417
	No	4	36	44		

Source: own development

The calculated value of Pearson's quadratic conjugacy (χ^2) significantly exceeded the critical value at a materiality level of 0.99 ($\chi^2_{1-0,01}(2=(3-1)\times(2-1)=9,21$). This means that we can speak with 99% confidence about the significance (non-randomness) of the relationship between the features. That is, the respondents from educational institutions whose website is available as part of mobile marketing activities tend to evaluate highly the implementation of all the goals of the higher education institution's general web service. Thus, hypothesis No. 2 is confirmed.

As part of the research project, the respondents were also asked the following question: "What is your opinion on the role of mobile marketing in terms of promoting a higher education institution?" This question has 6 statements (j=1,…,6): 1. Attractive and interesting. 2. It complements other marketing activities. 3. Effective and result-oriented. 4. Promising – its role in marketing activities will grow was created. It should be considered independently of the previous "traditional" activity on the Internet. 6. It is a tool that is still marginally used by higher education institutions. For each statement, one of three answer options was proposed (i=1, 2, 3): a) I agree; b) I do not agree; c) Difficult to say. The majority of respondents chose a positive answer for all statements (Table 4).

The maximum value for the answer "I agree" (98% of respondents in Poland and 95% in Ukraine) was for the statement that mobile marketing complements other marketing activities. As for the minimum share of respondents who chose the answer "I agree", in both countries there were no differences: 11% of respondents in Poland and 24% in Ukraine gave this answer to the statement that

mobile marketing is a tool that is still marginally used by higher education institutions. At the same time, 43% of the representatives of Polish universities and 57% of the representatives of Ukrainian universities could not give their opinion on this statement. Even if they chose "I agree", however, the share of answers about the marginal use of mobile marketing would not exceed the statement about its role as a complement to other marketing activities.

Table 4: structure and similarity of the answers of respondents from Poland and Ukraine regarding the role of mobile marketing in the promotion of higher education institutions

Numbers of statements	Proportion of answers, %									P_j	
	I agree			I do not agree			Difficult to say			$P(V)_j$	$P(r)_j$
	d_{ij}^P	d_{ij}^U	$\overline{d_{ij}}$	d_{ij}^P	d_{ij}^U	$\overline{d_{ij}}$	d_{ij}^P	d_{ij}^U	$\overline{d_{ij}}$		
1	94	87	91.7	1	8	3.3	6	5	5.7	0.925	5
2	98	95	97.0	2	0	1.3	1	5	2.3	0.955	6
3	72	63	69.0	0	10	3.4	28	27	27.7	0.900	3.5
4	92	82	88.6	0	7	2.3	8	11	9.0	0.900	3.5
5	42	50	44.7	37	19	31.0	10	31	17.0	0.815	2
6	11	24	15.4	46	11	34.3	43	57	47.7	0.730	1
$\overline{d_i}$	68.2	66.8	67.7	14.3	9.2	12.6	16.0	22.7	18.2	0.871	x

Source: own development

For the statement "Effective and result-oriented" the share of answers for "Difficult to say" was 28% and 27% respectively, while for the statement "It should be considered independently of the previous "traditional" activity on the Internet" – it was 20% and 31%. The average share of respondents in Ukraine who did not give their opinion for all the statements was 22.7%, which is 5.0 points higher compared to the representatives from Poland. The minimum value of the similarity coefficient for the response structures of the respondents from both countries is high (0.730). The squared coefficient of variation, calculated on the basis of $P(V)_j$, was 8.7%. This testifies, firstly, to the homogeneity of the set of $P(V)_j$ values in the context of the 6 statements under consideration; and, secondly, to a typical average value of the coefficient of structural similarity (0.871).

Covino (2017), Raphaeli et al. (2017), Tseng and Wei (2020) mention, that the choice of a particular mobile marketing tool affects differently the behaviour of the consumers of educational services. They can both increase the investment attractiveness of higher education institutions, according to the researches of Camilleri (2019), Tkach (2015), and open new markets for them, as mention Chukhray and Kulyniak (2015) and Kusumawati (2018), but also negatively present the brand, according to the researches of Kall (2015) and Kvitka S. et al. (2019). In view of this, there was a question in the research project regarding the tools used by higher education institutions during the implementation of marketing activities using mobile devices (j=1,…,11): 1. Text/MMS Messaging. 2. Various Forms of Banner Advertising. 3. Mobile Search 4. Text Links. 5. Social Media Links. 6. Video Advertising. 7. Rich Media Advertising. 8. Dedicated Mobile Applications. 9. Mobile Games. 10. Sponsored Content Services. 11. Product Placement. Each of the tools provided a set of answers from six options: a) not used; b) bad; c) neither good nor bad; d) good; e) very good; f) I do not know. On the basis of the data received during the survey, Table 5 was created. The Polish representatives provided answers for all the statements. However, some respondents from Ukraine did not provide answers regarding eight tools (in Table 5 – the line "available"). Since $\overline{R_0^P(V)}_j$ and $\overline{R_0^U(V)}_j$ were calculated for 11 statements, the authors considered it appropriate to assign them ranks (for Poland – $\overline{R_0^P(r)}_j$, for Ukraine – $\overline{R_0^U(r)}_j$), as well as to assess the degree of correlation between these ranks. To generalise the usage of mobile marketing tools by higher education institutions, we determined the total values

of the average centred points (S $\overline{R_0(V)}_j = \overline{R_0^P(V)}_j + \overline{R_0^U(V)}_j$) for each tool and assigned them ranks (S $\overline{R_0(r)}_j$). The indicators of structural similarity were also calculated and assigned appropriate ranks.

Table 5: characteristics of the answers given by the respondents from Poland and Ukraine regarding the mobile marketing tools of higher education institutions

Indicator	The value of indicators for different tools													$\overline{d_i}$
		1	2	3	4	5		6	7	8	9	10	11

Source: own development

The data in Table 5 make it possible to state the following. Firstly, the top 3 answers given by the respondents from the two countries were: d) good; a) not used; c) neither good nor bad. In general, this indicates the positive attitude of marketing services of higher education institutions to the use of mobile marketing tools. Secondly, the values of the similarity coefficient for the response structures

by the respondents of both countries vary from 0.550 to 0.850. The squared coefficient of variation, calculated on the basis of these values, was 12.6%. This indicates the homogeneity of the set of $P(V)_j$ values for the 11 statements considered in the study, and, consequently, the typical average value of the similarity of structures (0.788) and the absence of significant differences in the opinions of the respondents from the two countries. Thirdly, the value of Spearman's coefficient (r=0.836), which is calculated by formula (3) based on the ranks of the average centred points, exceeds the critical value ($r_{1-0.01}(11)=0.76$). This suggests that the conclusion regarding the high consistency of the expert opinions from both countries should be considered 99% relevant (non-accidental). So, we can say that the experts from both countries evaluated highly the sixth, fourth and second tools, and lowly – the eleventh, first and ninth.

For all the questions considered in this article, no significant differences were found between the answers of the respondents from both countries. This provides grounds for verifying hypothesis No.1.

Conclusion

Mobile marketing has been considered by the authors in terms of it having two roles: as a separate element of marketing activities, one which involves mobile communications, and also as an organised marketing activity based on the synergy of mobile and Internet technologies. The spread of mobile marketing in the field of higher education is primarily due to its students (active mobile Internet users) and the specific nature of its institutions (public institutions of an intellectual and innovative orientation).

The analysis of the responses provided by the representatives of higher education institutions regarding the use of mobile marketing tools, the role of mobile marketing in promoting the institution, the goals of the web service and the mobile marketing tools did not reveal significant contradictions or differences between Poland and Ukraine.

The study of whether marketing services in higher education institutions have their own mobile tools revealed that most of these services have both responsive web design (RWD) and a mobile website. About 40% of higher education marketing services have mobile marketing strategies. These strategies are somewhat more common in Ukrainian higher education institutions.

Combinational grouping of the respondents' answers regarding the importance of each of the main goals of the web service (Promotion of Educational Services; Creating the Image of the University; Acquisition of New Students; Conducting Online Recruitment; Online Student Service; Interactive Communication with Students; Online Sales of University Publishers; Online Sales of Educational Services – e-learning) and the presence/absence of a marketing service mobile-friendly page served as the basis for the analysis of these relationships. It was proved that the representatives of higher education institutions whose marketing services have a mobile website tend to highly evaluate the implementation of all the goals of the university's general web service. 98% of respondents in Poland and 95% in Ukraine agreed that mobile marketing complements other marketing activities.

The research has helped to outline certain reserves for the growing use of mobile marketing tools in higher education institutions at the expense of those tools which are used less often: (Product Placement; Text/MMS Messaging, Mobile Games, Rich Media Advertising, Sponsored Content Services, Dedicated Mobile Applications). The high level of use of tools (Video Advertising, Text Links, Various Forms of Banner Advertising) can serve as a guide for marketers to work effectively in those higher education institutions that do not yet use mobile marketing. There are also opportunities for Polish universities to use the following tools: Mobile Search and Social Media Links. The practice of using these tools was assessed positively by the respondents from Polish higher education institutions. However, they are used less often in Poland than in Ukraine.

Abstract

The formation of a modern market economy presupposes the functioning of a business aimed at increasing the return on invested capital, the implementation of a strategy for improving working conditions and personnel development, cooperation with local authorities, solving environmental problems. The immediate benefits for the company from the introduction of corporate social responsibility are the creation of a stable business environment, reduced operational risks, increased financial performance and sales, increased productivity, reduced costs, market expansion etc.
In Ukraine, the development of corporate social responsibility began with the establishment of a market economy. In the early 90's of 20th century, domestic businessmen began to form an understanding of the need for their participation on a voluntary basis in solving social and environmental problems. Responsible business conduct necessitates the preparation of a public report on the business activity results. Social reporting involves the disclosure of information about both positive and negative results of economic, social, environmental activities of the company. Recently, companies have been preparing not only financial statements but also social statements. Social (non-financial) reporting is becoming an integral part of corporate culture, and the management of corporate social responsibility programs in commercial organizations focused on sustainable development contributes to the balanced social and environmental development of society.
Formation and development of domestic socially responsible business should be based on further development of the fundamental institutional foundations necessary for its effective functioning.

Keywords: corporate social responsibility, company social reporting, socially responsible business

Introduction

The functioning of a modern market economy involves the new paradigm formation – business, classically aimed at increasing the return on investment, begins to implement strategies of working conditions improvement and staff development, cooperation with local authorities, solving

Cite this Article as: Inna Berzhanir, Anatolii Berzhanir, Tetiana Yashchuk, Oleksandr Kirdan And Nataliia Pacheva " Development of Corporate Social Responsibility and Company Social Reporting " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

environmental problems etc. The result of this policy is the investment of funds for the implementation of various social projects in education, health care and environmental protection.
Bukovynska (2010) mentioned that the immediate benefits for the company from the introduction of corporate social responsibility (CSR) are the creation of a stable business environment, reduced operational risks, increased financial performance and sales, increased productivity, reduced costs, market expansion and, consequently, increased market value.

According to the research of Reputation Institute 2019 Global RepTrak [1], the leading role of management factors and corporate citizenship in the formation of corporate reputation remains unchanged and is 15.1% and 14.2%, respectively. The impact of the working conditions factor for the year increased by 0.4% and now is 11.2%. Thus, the total «contribution» of the three CSR factors in creating the company's reputation is 40.5%. It is noteworthy that the importance of these three indicators increases in proportion to the decline in the overall level of the company's reputation.

The factor of responsible and effective participation of CEO in the processes related to corporate social activity is also extremely important. The leaders of all the companies included in the Top 10 ranking of the Reputation Institute are known as responsible top managers, supporters of ethical approaches to doing business and effective social activity.

The 2019 CEO of RepTrak identified factors that have the maximum impact on the formation of a positive image of the Director General. Social responsibility, care for staff and participation in solving environmental problems make up 32% of the reputation of every manager.

In a research study by Hosh and Kershys (2020) indicated that in Ukraine the development of corporate social responsibility began with the establishment of a market economy. In the early 90's of 20th century, domestic businessmen began to form an understanding of the need for their participation on a voluntary basis in solving social and environmental problems. A statistical survey of corporate social responsibility of Ukrainian companies conducted in September 2019 by Pro Bono Club Ukraine showed that an increase in the number of companies with CSR strategies/programs/projects took place in 2015–2016 (Fig. 1).

Fig. 1: Number of Ukrainian companies that have started to implement CSR programs, ea

Source: compiled by the authors

Zinchenko et al (2018) mentioned that the most significant CSR programs for domestic socially responsible business are:

- educational projects (50 companies);
- working conditions and staff development improvement (40);
- green office and other eco-initiatives (35);
- charitable fundraising (35);
- volunteering (arrangement of parks, painting of hospital premises) (31);
- intellectual volunteering (pro bono) (27);

- anti-corruption practices (25);
- development of regions (assistance to regional initiatives) (24).

Responsible business conduct necessitates the preparation of a public report on the business activity results. Social reporting involves the disclosure of information about both positive and negative results of economic, social, environmental activities of the company. Recently, companies have been preparing not only financial statements but also social statements.

Social (non-financial) reporting is becoming an integral part of corporate culture, and the management of corporate social responsibility programs in commercial organizations focused on sustainable development contributes to the balanced social and environmental development of society.

The social report (GRI standard) should reflect the economic, social and environmental policies of the corporation and serve as a tool for managing activities with corporate social responsibility. In each of the three areas, GRI offers a set of quantitative indices. It is based on the concept of sustainable development: the company must find a balance between the needs of today's generation in economic well-being, favorable environment, social welfare and similar needs of future generations.
The development of non-financial reporting is directly related to ensuring the information openness of companies, because today's market economy requires an appropriate level of information support. Large amounts of information operated by the business become a necessary factor in ensuring its competitiveness. In such conditions, the exchange of information is the basis of basic economic processes from production to consumption.

The problem of transparency becomes especially important in terms of conducting socially responsible business, which will not become a reality without transparency of economic decision-making, taking into account the social and environmental consequences for entrepreneurs and society.

By publishing social reports, companies ensure transparency, which, in turn, is one of the factors ensuring their competitive advantage. It has been found that more transparent companies attract investors and have a higher level of capitalization. Every year, the CSR Development Center compiles a transparency index of Ukrainian companies' websites on the basis of an international methodology developed together with Beyond Business (Israel). Thus, in 2017 the structure of the prepared social reports was as follows:

- 1 integrated report (DTEK);
- 1 report in accordance with GRI standards (PJSC «Myronivskyi Khliboproduct»);
- 5 reports in accordance with GRI 4.0 (ArcelorMittal Kryvyi Rih, NJSC Naftogaz Ukraine, SE NEGC Ukrenergo, Lifesell LLC, SE NEGC Energoatom);
- 1 report with GRI 4.0 elements (Nova Poshta LLC);
- 3 unstructured CSR reports (PJSC «Ukrsotsbank», PJSC «Credit Agricole Bank», «SAV-Distribution» LLC);
- 4 general reports of companies with coverage of some elements of CSR Metinvest Holding LLC, PJSC Shakhtar Football Club (Donetsk), PJSC Kyivvodokanal Joint-Stock Company, PJSC Raiffeisen Bank Aval, PJSC Joint-Stock Bank Ukrgasbank).
- 5 reports contain information on the implementation of the Sustainable Development Goals (ArcelorMittal Kryvyi Rih, DTEK, SE NEGC Energoatom, PJSC Myronivskyi Khliboproduct, Nova Poshta LLC).

In 2018, the social reporting of companies that were included in the TOP-100 largest taxpayers in Ukraine in 2017 was assessed according to the State Fiscal Service and the top 10 most transparent companies according to last year's transparency index. Among them: 20 state-owned and 79 private companies, 22 international companies (or their subsidiaries) and 77 national ones (Table 1).

Table 1: Dynamics of leadership in the transparency index of Ukrainian companies (TOP-10)

Source: compiled by the authors

Thus, the nature and extent of corporate responsibility are determined by a system of key institutional factors – the relevance of socially responsible behavior, the CSR conceptualization by the state, providing appropriate institutional conditions for social responsibility, active behavior of stakeholder groups, use of best foreign practices. Formation and development of domestic socially responsible business should be based on further development of the fundamental institutional foundations necessary for its effective functioning.

Abstract

The bank lending to economic entities is one of the factors that play an important role in the development of priority industries, ensuring economic growth and forming the country's competitiveness in the world market. The development of the banks' lending activities is the main element of a strong economic environment and will affect the assurance of the state's independence and realization of its national interests under the conditions of globalization processes. The main role in stimulating the reproduction processes in the economy is played by bank lending as the main source of providing monetary resources for current and investment activities of business entities. However, macroeconomic instability in Ukraine had a negative impact on the development of bank lending, causing a sharp decline in the creditworthiness of borrowers and a significant deterioration in the loan portfolio quality. The banking system in Ukraine has some problems that require improvement and changes in its functioning mechanisms. To develop bank lending and create financial stability, it is necessary to make banking services more qualitative in order to improve their competitiveness; to improve procedures in the banking sector, such as reorganization and liquidation of banks; to encourage commercial banks to lend innovative projects; to increase capital resources of state-owned banks, increase their number and strengthen their role in the financial and credit market in Ukraine. The above measures can contribute to recovery of the national economy and improvement of the overall condition of banking institutions.

Keywords: bank loan, interest rate, bank lending, working capital, borrowed capital.

Introduction

The state of the country's economy largely depends on the adequate functioning of the banking system, and bank lending to economic entities is one of the factors that play an important role in the development of priority industries, ensuring economic growth and forming the country's competitiveness in the world market. The development of the banks' lending activities is the main element of a strong economic environment and will affect the assurance of the state's independence and realization of its national interests under the conditions of globalization processes.

Cite this Article as: Inna Berzhanir, Anatolii Berzhanir, Tetiana Yashchuk, Oleksandr Kirdan And Nataliia Pacheva " Bank Lending Trends in Ukraine" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Sokolova mentioned that an important role in stimulating the reproduction processes in the economy is played by bank lending as the main source of providing monetary resources for current and investment activities of business entities. However, macroeconomic instability in Ukraine had a negative impact on the development of bank lending, causing a sharp decline in the creditworthiness of borrowers and a significant deterioration in the loan portfolio quality.

In 2013–2019 the total volume of credit resources did not increase significantly. Thus, in 2019 it amounted to 827 billion UAH, which is 13.7% more than in 2013 (Fig. 1).

Fig. 1: Dynamics of total volume of credit resources in 2013-2018, billion UAH
[developed according to the official NBU data]

When lending, the size of the interest rate is essential. Average interest rates on loans to borrowers ranged from 4.68% in 2013 to 18.6% in 2019. (Fig. 2).

Fig. 2: Dynamics of average weighted interest rate in 2013-2019,%

The highest level of interest rate was in 2015 and amounted to 21.81%. During 2015–2019, the average weighted interest rate decreased by 3.21% and in 2018 it was 18.6%. This, the credit rates have now decreased and, but for many enterprises, lending remains an expensive tool to attract external funds.

Table 1: Dynamics of volumes of bank credit investments in Ukraine in 2013 2019 (as of January 01.)

Index	2013	2014	2015	2016	2017	2018	2019
Growth rate of loans provided by banks, in % compared to the previous year	98,79	111,78	110,42	95,90	104,23	103,06	107,92
Growth rates of loans granted to economic entities in % compared to the previous year	104,87	114,70	114,86	97,92	107,78	102,04	106,32
Growth rates of loans to individuals in % compared to the previous year	92,63	103,71	106,72	85,10	103,29	108,51	115,27
Ratio of loans granted to economic entities in loans granted by banks,%	74,71	76,67	79,75	81,43	84,21	83,38	82,14
Ratio of loans to individuals in loans granted by banks,%	19,84	18,41	17,79	15,79	15,65	16,47	17,59

Source: [calculated according to the NBU data]

Analysis of Table 1 data shows that in 2013–2019 there was an increase in the volume of loans granted by banks. Thus, in 2019, as compared to March 2013, the growth rate of loans granted by banks was 107.92%. The highest growth rates were in 2014 – 111.78%, and the lowest in 2016 – 95,90%.

In 2019, the growth rate of loans granted to economic entities was 106.32%, which is by 1.45% more than in 2013.

Growth rates of loans to individuals in 2013 were insignificant and amounted to 92,63%. However, during 2014-2019 this index increased by 11.56% and in 2019. It amounted to 115.27%.

In 2013-2019 the volumes of loans granted to economic entities significantly exceed the lending to individuals, which indicates the weakening of the banks' lending to the latter and orientation of the credit policy towards the cooperation with enterprises. It is proved by the growth of loans ratio granted to business entities from 74.71% in 2013 to 82.14% in 2019. Last year the portfolio of hryvnia business loans increased by 2.7% to 478 500 000 000 UAH, although in December it slightly decreased (by 1.5%).
The share of loans to individuals for the analyzed period decreased by 2.25 and in 2019 amounted to 17.59%.

During the analyzed period (Fig. 3), the percentage of general overdue indebtedness on loans increased significantly from 7.7% to 67.92%, which is a negative and threatening phenomenon, as large amounts of problem loans can destabilize the financial condition of banks due to loss of income assets and growth of expenses in reserves to cover losses on bank credit operations. As a result, this will be manifested in the bank efficiency decrease, restraint of lending activity, deterioration of liquidity and solvency of those banks which loan portfolios are overloaded with problem loans.

Fig. 3. The share of overdue indebtedness on loans in the total amount of loans for 2013–2019, %

In a research study by Kornijchuk (2017) indicated that the banking system in Ukraine has some problems that require improvement and changes in its functioning mechanisms. To improve the financial sector and economic growth in Ukraine, it is necessary to create an effective mechanism for improving bank lending policies. To develop bank lending and create financial stability, it is necessary to make banking services more qualitative in order to improve their competitiveness; to improve procedures in the banking sector, such as reorganization and liquidation of banks; to encourage commercial banks to lend innovative projects; to increase capital resources of state-owned banks, increase their number and strengthen their role in the financial and credit market in Ukraine. The above measures can contribute to recovery of the national economy and improvement of the overall condition of banking institutions.

Inclusiveness of Development – A Challenge for A Post-Pandemic Global Economy

Iwona PAWLAS

University of Economics in Katowice, Katowice, Poland
iwona.pawlas@ue.katowice.pl

Abstract

Inclusiveness of development should be a response to exclusion, inequality and injustice in the global economy. The COVID-19 global pandemic strengthened the problem and scale of exclusion. Creating an inclusive post-pandemic global economy would require systemic, organizational and mental changes not only of the society of one or the other country, but of the entire international community. Special circumstances would be necessary for this sort of change, constituting turning points enabling the formation of a new paradigm of development. Author studied, explored and discussed the essence, dimensions and levels of inclusiveness, and then described the factors, instruments, barriers and measures of inclusiveness. Moreover, Author discussed selected studies in the field of inclusiveness undertaken by the authors in recent years and presented selected initiatives launched on international level in order to increase inclusiveness (by the United Nations, Organization for Economic Cooperation and Development, European Bank for Reconstruction and Development and the European Union).

Keywords: inclusiveness, development, global economy, COVID-19 pandemic.

Introduction

The global economy of the 21st century is characterized by huge and still rising inequalities. The increased scale of the problem of exclusion resulted from global financial crisis 2008+, the years of economic instability which followed and – to the greatest extent – the COVID-19 pandemic. Technological changes and development of information and communication technologies did result in higher visibility of the disparities. Technical progress is considered one of the most important factors determining socio-economic development, wealth creation, improvement of living conditions. Digital transformation resulting from technological revolution creates a turning point in regard to the development of the global economy. The significance of digitalization became even greater and more visible at the time of global lockdown in 2020. Radical changes in the conditions of economic activity are observed during the COVID-19 pandemic. Unfortunately, the 2020 pandemic strengthened the problem of inequalities in the global economy. The creation of a fair, more inclusive post-pandemic global economy could be the answer to the existing problem of injustice. The implementation of a new paradigm of inclusiveness of development on a global scale would require not only organizational reconstruction and systemic restructuring, but also considerable mental changes. Radical and global changes and transformations are accompanied by expectations and hopes that the new solutions will help reduce the problem of exclusion in the globalized world economy and the new system will be featured by inclusiveness in each and every dimension and on each and every level. The main problem of this article is inclusiveness of development. The article aims at discussing and presenting inclusiveness of development as a challenge for a post-pandemic global economy. The research tools used in the article included literature studies, analysis and synthesis, comparison and generalization of scientific literature, as well as critical thinking.

The Essence of Inclusiveness

European Bank for Reconstruction and Development (EBRD) defines inclusiveness as „the opening up of economic opportunities to under-served social groups" and it describes an inclusive market economy as an economy which „ensures that anyone regardless of their gender, place of birth, family background, age or other circumstances, over which they have no control, has full and fair access to labor markets, finance and entrepreneurship and, more generally, economic opportunity" (EBRD a).

According to Mączyńska (2019) inclusiveness means „compromising social, economic and ecological targets and – at the same time – optimizing the use of socio-economic potential".

OECD (2019 a) defines inclusive growth as „economic growth, that is distributed fairly across society and creates opportunities for all".

Gupta, Pouw and Ros-Tonen (2015, 546) describe inclusive development as „development that includes marginalized people, sectors and countries in social, political and economic processes for increased human well-being, social and environmental sustainability, and empowerment". Moreover, they claim that inclusive development is „an adaptive learning process, which responds to change and new risks of exclusion and marginalization" (Gupta, Pouw and Ros-Tonen 2015, 546).

OXFAM defines inclusive development as a "pro-poor approach that equally values and incorporates the contributions from all stakeholders—including marginalized groups—in addressing development issues". OXFAM stresses that inclusive development promotes both transparency and accountability. Moreover, it also stimulates cooperation between civil society, governments and private sector actors (OXFAM 2019).

Inclusive wealth is defined as "the aggregate value of all capital assets. Increases in inclusive wealth indicate an improved productive base capable of supporting a higher standard of living in the future. To be truly inclusive, measures of inclusive wealth must include the value of all forms of capital that contribute to human well-being: human capital, manufactured capital, natural capital, and social capital" (Polasky, Bryant, Hawthorne, Johnson, Keeler and Pennington 2015).

According to Mączyńska (2019), inclusive economy is a „system based on the largest possible number of sovereign and equitable participants, connected more closely by ties of partnership and conscious interdependence than hierarchy and subordination in the state-citizen-business-social relations". Mączyńska indicates that contemporary world economy is an economy of surplus – excessive production capabilities, overproduction, excessive consumption, accompanied by excessive burden for natural environment. At the same time, however, despite the above-mentioned market surplus, multilayered and multidimensional exclusion remains a serious problem. Therefore, the creation of a new, pro-inclusive socio-economic system could be a possible solution of the problem of exclusion. Pro-inclusive system could stimulate full use of market potential and – at the same time – it would counteract exclusion on various layers and on various dimensions.

Achieving real inclusiveness of development of the globalized post-pandemic world economy would mean the situation in which each and every entity (citizen, household, company, region, state), and in particular entities and groups discriminated and marginalized in the current development model, had the opportunity to derive the broadly understood benefits of socio-economic and technological progress independently and on the principles of egalitarianism.

Dimensions and Levels of Inclusiveness

Inclusiveness can be considered on various dimensions (layers) and in regard to different levels. The following dimensions (layers) of inclusiveness should be listed (Gupta, Pouw and Ros-Tonen 2015):

social, political, economic, financial, digital, cultural, gender, relational, generational and intergenerational, ecological (environmental), managerial.

Social dimension of inclusiveness (also called social inclusion) is the process aiming at providing equal opportunities for achieving full life potential to all members of a society. Social inclusiveness can be promoted both by economic policy itself, and through activities stimulating equal access to public services, as well as enabling participation in decision making processes (United Nations 2019). Therefore, inclusive society is a society supplied with mechanisms promoting diversity, enabling and stimulating active participation of its citizens in political, economic and social life. Inclusive society offers equal chances no matter social origin, sex, social class, generation, religion, nationality, place of living. Moreover, inclusive society promotes activity of its citizens, and the activity is based on participative processes, and is not forced in any way. The term of social inclusion is very close to social cohesion: the two are somehow built around the concept of social integration. Socially inclusive society is a society in which all groups do have the feeling of belonging, participation, legitimization, appreciation. What is more, socially inclusive society does not have to be demographically homogenous; it can be characterized by heterogeneity and diversity, the diversity which is respected and perceived as a source of higher potential.

Political dimension of inclusiveness relates to the right to participate in political life and political representation of a society. Political inclusion promotes democracy and democratization. It also means the right to express political opinion. On the contrary, political exclusion, i.e. excluding certain groups (minorities and marginalized ones) from political decision taking is considered an essential pro-conflict factor and the one which results in destabilization (Cordenillo 2019). Political inclusiveness and exclusiveness are strictly connected with religious issues and the lack of gender equality. Moreover, to some extent, political exclusiveness relates to migration and migrants' rights; therefore, in a more-narrow meaning political inclusion is defined as the right of migrants to participate in political life and political representation (UNESCO b).

Economic inclusiveness consists in opening economic opportunities for all social groups. Economic dimension of inclusiveness is inclusion into the labor market and in the area of entrepreneurship. Promotion of economically inclusive economy results in a more efficient allocation of human resources. Therefore, economic inclusion constitutes an essential element of the creation of sustainable market economy (EBRD c).

Financial inclusiveness constitutes an important element of economic inclusiveness. Financial inclusion means access of both individuals and enterprises to necessary financial services and products. Access to current account is considered the number one step to financial inclusiveness. A more developed financial inclusion is connected with investment decisions' taking and a more conscious financial risk management (World Bank).

Digital dimension of inclusiveness is strongly connected with an increase of digitalization and development of digital economy. It consists of three dimensions: access to Internet, information and communication technologies (ICT), adoption of ICT and practical implementation and application of ICT (Digital Inclusion Survey). The COVID-19 pandemic proved the significance of digital inclusion and showed effects of digital exclusion in a new light.

The significance of cultural dimension of inclusiveness rises together with increased dynamics and intensity of international ties and interconnections in the world economy. Cultural inclusion requires increased awareness of cultural differences, sensitivity to cultural differences, as well as respect for cultural difference. Culturally inclusive society treats cultural heterogeneity as a chance and opportunity, rather than a threat or barrier. Building and promoting cultural inclusiveness within a society requires cultural competencies that can be defined as a set of values, behaviors, attitudes and practices within an

organization, system, society that enables effective functioning in a multicultural, intercultural environment or at the interface of cultures. Cultural inclusiveness is also about respect for different language, life style, religion, interpersonal behavior. Creating and learning cultural competencies is a long and difficult process, while the creation of culturally inclusive society requires a long-term engagement of local, regional and national entities (Mak, Barker and Anne 2014).

Gender dimension of inclusiveness focuses on promoting gender equality and strengthening the position of women, as well as active participation of women in political, economic, social and cultural life. Unfortunately, still in many societies systems of norms and values are far from gender neutrality; moreover, the status of women, is not equal to that of men, remain a problem in many societies. Gender inclusiveness is therefore essential for women to fully enjoy their human rights (UNESCO a). The COVID-19 pandemic strengthened the negative effects of the lack of gender inclusiveness; therefore, the need for creating increased gender inclusiveness became even greater.

The relational dimension of inclusiveness - is not only (and not exclusively) an attempt to respond to the needs of the most vulnerable and those most experienced by fate, but also to assess the fundamental and structural relations between various social groups and various social actors, which make it difficult to provide long-term social inclusiveness. The relational dimension of inclusiveness entails generational and intergenerational inclusiveness. On the one hand, we observe the exclusivity of the young generation as the rising problem in the 21st century world economy is; on the other hand, we note the exclusion of the growing number of older people. The exclusion of young people (who have had much easier and greater access to the education system than previous generations, and therefore also have a higher level of education) is connected with either unemployment (despite their education) or poverty (despite employment). Thus, from a society's point of view, incomplete use of workforce and skills mismatch are the main challenges from the perspective of relational inclusiveness aimed at the young generation. The aging society, i.e. the demographic implosion and the growing number of older people constitutes another problem of the developed economies of the 21st century. The exclusion of older people partly results from cultural, civilization and technological changes. Due to demographic trends, it is reasonable to increase the socio-occupational inclusion of older (Sobolewska-Poniedziałek 2017). It seems that COVID-19 pandemic has already increased the problem of exclusion of both the young (who lost their jobs) and the older (due to lockdown).

The ecological dimension of inclusiveness is sometimes described as environmental inclusiveness. The importance of this dimension of inclusion is determined by the fact that it is the poorest people who are usually the most dependent on the natural ecosystem, so they are the ones who are most affected by the negative impact of environmental changes both locally and globally, in other words by environmental and/or ecological exclusiveness. Again, the COVID-19 pandemic has enormously strengthened the problem of environmental and/or ecological exclusiveness.

Regional dimension of inclusiveness is particularly important large countries in terms of territory. In such countries, regional development disparities are observed. Peripheral regions are usually less developed, less urbanized. Therefore, their inhabitants do experience barriers in access to education, well paid job places, culture infrastructure. That's why regional exclusion is strongly connected with unequal development opportunities, i.e. it results in economic and/or financial exclusion (EBRD b).
Inclusiveness of management means respecting various dimensions of inclusiveness during the implementation of management processes in institutions, organizations, enterprises. It requires not only knowledge and management skills, but also appropriate interpersonal competences as well as sensitivity and empathy.

Each and every dimension of inclusiveness (described above) can be analyzed and evaluated on various levels, namely: on the level of an enterprise, on local, regional, national, international and – last but not least – global level. It's hard to imagine international and global inclusiveness without achieving a high

level of inclusion of national economies. Creating satisfying national inclusiveness, requires high local, regional and inter-regional inclusiveness. Rising international relations in a global economy of the 21st century, as well as the implementation of the 4th industrial revolution connected with intensive development and common use of information and communication technologies, resulted in the need for stronger actions aiming at reducing barriers for inclusiveness and creating conditions promoting inclusiveness and inclusive development. The coronavirus pandemic widened wealth and income inequalities and indicated the rising need for the promotion of inclusiveness of development on each and every level.

Determinants and Instruments of Inclusiveness. Barriers for Inclusiveness

Due to complexity, multidimensionality and multi-level character of inclusiveness, its determinants, instruments, as well as barriers for inclusiveness of development are diversified.

Determinants of inclusiveness embrace: education, infrastructure, ethics, investment, entrepreneurship, social care. The factors listed above are interrelated and mutually tied up. Creating and strengthening inclusiveness requires respective institutions, structural actions and economic policy settlements. World Economic Forum (WORLD ECONOMIC FORUM 2017, WORLD ECONOMIC FORUM 2018) listed seven pillars of inclusive growth and development:

- Education and skills (access, quality and equity of education);
- Basic services and infrastructure (basic and digital infrastructure, health-related services and infrastructure);
- Corruption and rents (business and political ethics, concentration of rents);
- Financial intermediation of real economy investment (financial system inclusion, intermediation of business investment);
- Asset building and entrepreneurship (small business ownership, home and financial asset ownership);
- Employment and labor compensation (productive employment, wage and non-wage compensation);
- Fiscal transfers (tax code, social protection).

Moreover, the significance of social capital as an essential factor stimulating inclusiveness of development should be underlined. Engagement in the activity of public benefit organizations and institutions, activity for local society, as well as volunteering do promote inclusiveness. Additionally, the creation of pro-inclusive system and promotion of inclusiveness can be achieved thanks to educational and informational actions. Moreover, internationalization, and in particular, contacts with the countries characterized by a higher level of inclusion and inclusiveness, and lower scale of exclusion of various character and different origin, can be treated as pro-inclusive factor.

Instruments stimulating inclusiveness of development embrace regulatory measures, economic and financial measures, as well as managerial measures. Pro-inclusive instruments can be adopted on various levels, beginning with an enterprise level, through local, regional and national levels, up to international and global cooperation. Pro-inclusive instruments can be both active and passive in their character. The application of pro-inclusive instruments should result in reduced exclusion and strengthened inclusion. The list of potential pro-inclusive instruments should include: tax solutions aimed at eliminating tax avoidance and tax fraud, inclusive insurance, microfinance (micro-credits and micro-loans), common education, intensive life-long learning programs, common computer and technological education, inclusive spatial planning, inclusive regional development, promotion of and respect for human rights, higher environmental and ecological standards. These instruments should be used together, due to the fact that none of them used separately can provide a more inclusive growth and development.

Unfortunately, there are many barriers for practical implementation of inclusiveness of development, creating inclusive socio-economic system. It'd be extremely difficult to make full and complete list of the barriers. Some of them, however, should be listed here, namely:

- weaknesses of education systems, including not adequate preparation of both educational institutions of all levels and teaching personnel, as well as lack of continuity of education (especially falling out of education institution too early);
- inefficient and ineffective legal system (both in regard to law making and law enforcement), which results in the exclusion of part of the society (due to complexity of regulations and constant changes of legal regulations);
- poor construction of tax system, which overburdens the weakest entities, while privileged entities (both natural and legal persons) obtain tax reliefs and tax exemptions;
- weaknesses of labor law (the weakest workers, often the least educated ones and – therefore – the least aware of their rights, the worst-paid employees are usually positioned in an asymmetrically worse situation);
- weaknesses of political systems, including lack of democracy in some countries and immature democracy in other countries, usually connected with abuse of power by those in power and lack of rights awareness by part of society;
- various psychological and mental barriers, which make it difficult (or even impossible) to create an inclusive (or at least pro-inclusive) society (e.g. prejudice and superstition regarding nationality, race, religion, culture, sex, age);
- insufficient attitudes and expectations regarding the increase of inclusiveness, both among the representatives of privileged groups and entities, as well as those marginalized and hurt by the binding rules;
- financial barriers, including lack of public funds for the implementation of pro-inclusive instruments, actions and solutions, and lack of the willingness of banks and commercial institutions to offer such pro-exclusive financial instruments;
- generational and intergenerational barriers, the classic generation gap, not only in individualistic sense, but also holistically at both national and international level.

Moreover, one should underline the significance of the 2020 pandemic and global lockdown as a possible new barrier for practical implementation of inclusiveness of development paradigm. The COVID-19 pandemic brought enormous negative economic, financial, social, educational, cultural, psychological and mental effects. It will be extremely difficult to promote inclusiveness in the post-pandemic global environment. On the other hand, however, the significance and importance of inclusiveness of development in the post-pandemic reality will be even greater.

Measuring Inclusiveness

World Economic Forum indicates three key performance indicators regarding inclusiveness, namely (World Economic Forum 2017, World Economic Forum 2018): growth and development indicator, inclusion indicator, intergenerational equity and sustainability indicator. Growth and development indicator is based on four elements, i.e. GDP per capita, employment, labor productivity and healthy life expectancy. Inclusion indicator reflects for elements, namely: median household income, poverty rate, income Gini and wealth Gini. Intergenerational equity and sustainability indicator is the resultant of four elements, i.e.: adjusted net savings, public debt as share of GDP, dependency ratio and carbon intensity of GDP (World Economic Forum 2018).

OECD evaluates inclusiveness with the use of two indicators, i.e.: I. Human well-being and II. Sustainability of well-being over time. When it comes to Current well-being, the following elements are taken into consideration: 1. Quality of life (health status, work-life balance, education and skills, social

connections, civic engagement and governance, environmental quality, personal security, subjective well-being) and 2. Material living conditions (income and wealth, jobs and earnings, housing). Sustainability of well-being over time is assessed in regard to preservation of different kinds of capital, i.e. natural capital, economic capital, human capital and social capital (OECD 2019 b; OECD 2011). The overall objective is to evaluate the chances and opportunities for future well-being through the protection of the four types of capital.

Discussion and Literature Review

Inclusiveness and its lack or shortage (i.e. exclusiveness), inclusive growth and development, as well as inclusive wealth are studied by many researchers worldwide. In-depth studies in the field of inclusiveness of development were undertaken by Gupta and Pouw (2017a), who applied an interdisciplinary approach.

Inclusiveness of an enterprise was studied by Dennis (1997), Desai (2014), Likoko and Kini (2017), as well as Shore, Cleveland and Sanchez (2018), Pilková, Jančovičová and Kovačičová (2016), Kourula, Pisani and Kolk (2017). Dobrea and Podgoreanu (2014) analyzed inclusiveness from a managerial perspective. Relations between inclusiveness and corporate social responsibility was studied by Grover (2014). The significance of leadership for the creation of inclusiveness was diagnosed by Blom and Alvesson (2015), Ye, Wang and Guo (2019), as well as the team consisting of Randela, Galvin, Shore, Holcombe Ehrhart, Chung, Dean and Kedharnath (2018).

The importance of inclusiveness from the perspective of educational systems was analyzed by Arocena, Goransson and Sutz (2015), as well as Jurkowski and Muller (2018).

Berkhout, Bouma, Terzidis and Voors (2018) studied the possibilities of creation and strengthening of local level institutions, so as to promote inclusiveness.

Biswas (2019) focused on inclusiveness of urban policy. Liu, Hu and Jeong (2019) studied the prospects for pro-inclusive development of cities on the example of selected Chinese cities. A city level of inclusiveness was also analyzed by Chu, Anguelovski and Roberts (2017), Hu and Wang (2019) and Esposito De Vita and Oppido (2016).

Inclusiveness of infrastructure projects was evaluated and assessed by Lenferink, Tillema and Arts (2013). Planning of inclusive development of national economies lied in the center of research conducted by Chimhowu, Hulme and Munro (2019), as well as Brand, Boos and Brad (2017). The significance of inclusiveness in the area of governance was analyzed by Karar and Jacobs-Mata (2016), as well as Eizagirre, Rodriguez and Ibarra (2017). Political dimension of inclusiveness was also studied by Ratinem and Lund (2015). Chapman and Shigetomi focused their research on interdependencies between the development of national systemic solutions for inclusive development and predominant life style factor (2018).

Financial dimension of inclusiveness in the context of specific micro-waqf instruments was studied by Mahat, Jaaffar and Rasool (2015). Mostak Ahmed (2016) analyzed financial inclusiveness from the perspective of tax evasion. Financial inclusiveness lied in the center of research conducted by Corrado and Corrado (2017), as well as Frączek (2017).

The importance of social capital and networks for inclusiveness' promotion was studied by Annen (2003). Pansera and Owen (2018) analyzed relations and ties between innovation and inclusive development (2018).

Antonelli and Gehringer (2017) focused on the assessment of relations and dependencies between technological changes and rising income disparities and inequalities. Toms, Verity and Orrell (2019)

analyzed the importance of technological development for increased inclusion of the old. Siddiqi and Collins (2017) evaluated impact of technological changes and new socio-technical solutions on inclusive development.

Gender dimension of inclusiveness was studied by Mansdotter, Lindholm and Lundberg (2006), Koralagama, Gupta and Pouw (2017), as well as Drori, Manos, Santacreu-Vasut, Shenkar and Shoham (2018). Kumar focused on the assessment of the possibilities of creation inclusive green economy (2017). Stiglitz studied prospects for inclusive and sustainable growth of emerging economies (2016). Prospects for inclusive growth of African economies was analyzed by Ngepah (2017), Imbaya, Nthiga, Sitati and Lenaiyasa (2019), as well as Whajah, Bokpin and Kuttu (2019). Mohanty, Gurpur and Beerannavar (2014) focused on inclusive development of South Asia, mostly in the context of human rights.
Inclusiveness of Asia was also evaluated by Aoyagi and Ganelli (2015) and Nath (2014).

Interdependencies between inclusiveness and human rigths lied in the center of research conducted by Arts (2017). Diaz-Sarachaga and Jato-Espino (2019) studied inclusiveness in the context of millennium development goals and their implementation. Kosiedowski (2016) made an attempt to evaluate the implementation of inclusive development concept in Central and Eastern Europe. Inclusiveness of the Polish economy was analyzed by Mączyńska (2014), whose proposals were critically discussed by Miszewski (2016).

Research on exclusive / inclusive wealth was conducted by Ahmad, Derrible and Managi (2018), Halford, Aktouf and Ebrahimi (2008), De Nardii and Fella (2017), Rabiul Islam (2018), Collins, Sellin, de Weck and Clark (2017), Yamaguchi (2014), Halkos, Managi and Tsylika (2018), as well as Engelbrecht (2016). The significance of more inclusive development of service sector was studied by Santana, Cardoso, Ferreira, Montanha, Catapan and Forcellini (2018). Pawlas, Talar, Dziembała and Czech (2020) studied opportunities and challenges for the world economy in terms of inclusiveness.

International organizations actively participated in the promotion of the concept of inclusiveness. United Nations (2000) stressed the need for increased inclusiveness in Millennium Development Goals. Moreover, inclusiveness lied in the center of other UN documents, like e.g. UN Global Sustainable Development Report 2015 (United Nations 2015) or 2030 Agenda for Sustainable Development (United Nations 2016). OECD (2019 a) implemented "Inclusive Growth Project", aiming at analytical and conceptual work in the field of inclusiveness, and establishing public policy options relating to the promotion of inclusiveness of growth and development. EBRD underlined the necessity to achieve higher inclusiveness in EBRD's Transition Report 2016 "Transition for all: equal opportunities in an unequal world" and, later EBRD launched Economic Inclusion Strategy 2017-2021 (EBRD 2017). The central position in EBRD Economic Inclusion Strategy was given to: regions, the young, the old, as well as people with disabilities. EBRD Economic Inclusion Strategy adopted the strategic themes: 1. Access to employment and skills, 2. Entrepreneurship and access to finance, 3. Access to services that enhance economic opportunities. EBRD Economic Inclusion Strategy is based on the assumption of active engagement of private sector in the creation of inclusive market economy. Additionally, it assumes strengthening strategic partnerships on both national and international levels. The European Union also promoted pro-inclusive growth and development. In 2010 the EU adopted Europe 2020 Strategy, which consisted of three priorities, namely: 1. Smart Growth, 2. Sustainable Growth, 3. Inclusive Growth. The Inclusive Growth priority fully corresponded with the concept of inclusiveness. The EU listed three measurable targets within this priority: reducing the number of people living below poverty line by 20 million, increasing employment rate of people aged 20-64 years up to 75%, reducing school drop-out rate to 10% and increasing tertiary education up to 40% by the year 2020. Therefore, education and activity on labor market were considered crucial factors stimulating inclusiveness by the EU (European Commission 2010; European Commission 2019). In 2019 the EU adopted next strategic documents stressing the need for further promotion of inclusiveness: A New Strategic Agenda 2019-2024 (European Council 2019) and Sibiu Declaration (Council of the EU 2019). EU leaders emphasized the vital need to

prevent further deepening of intergenerational, territorial and educational divisions, to ensure equal opportunities and adequate social protection, as well as to develop greater inclusiveness of labor markets and to promote social cohesion.

The COVID-19 pandemic made existing inequalities more visible. Moreover, the coronavirus pandemic further widened inequalities and enormously strengthened disparities on all levels (individual, sectoral, local, regional, national, global). The COVID-19 did hit both the rich and the poor, the young and the old, the highly educated and qualified and those with limited education and qualifications. The COVID-19 crisis is unique and radically different from previous crises. The post-pandemic global economy will be, therefore, radically different from the global world characteristic for 2019. It seems that the first post-pandemic years will bring the global economy featured by even greater inequalities and disparities. The question is, whether, the post-pandemic global economy actors will undertake the necessary efforts to minimize the inequalities and disparities, and to create social inclusiveness, economic and financial inclusiveness, digital, relational, generational and intergenerational inclusiveness, gender inclusiveness, cultural and political inclusiveness. If not, the post-pandemic global world will be characterized by strong and rising exclusiveness of development.

Conclusions

Inclusiveness is a relatively new concept. The process of its shaping and development is under way. Due to rising development disparities and inequalities in the world economy and persistence of instability which followed the global 2008+ crisis, and will (undoubtedly) follow the COVID-19 pandemic crisis inclusive growth, inclusive development, inclusive wealth, and finally construction of inclusive economy and creation of inclusive socio-economic system are considered as essential challenges for global economy in the 21st century. Higher level of inclusiveness could result in considerable benefits, and in particular:

- higher relational, psychological, social, material and environmental wealth;
- increased economic, social and ecological sustainability;
- development, diffusion and practical implementation of knowledge;
- greater control over raw materials in global terms;
- reduced susceptibility and higher resistance of an economy for external influence;
- increased ability to implement desired changes.

In 2020, however, inclusiveness remains – to a great extent – a utopian concept. There are numerous barriers and limitations (political, legal, financial, cultural, mental), which adversely affect the process of creation and practical implementation of inclusiveness and inclusive development in the global economy. They have been enormously strengthened by the COVID-19 pandemic crisis. Lack of inclusiveness results in a number of disadvantages and threats. Lack of inclusiveness is also considered a brake for development, due to the fact that exclusiveness causes limited social capability to use knowledge and assets, moreover exclusiveness results in rising local, regional, national, international and global conflicts.

The need for the creation of higher inclusiveness in a global scale was indicated by international institutions and organizations, including: United Nations, Organization for Economic Cooperation and Development, World Bank, European Bank for Reconstruction and Development, European Union. Therefore, inclusiveness can be treated as a precious development indicator, and at the same time as a difficult and actual development challenge for contemporary world economy. Due to the complexity, multidimensional and multilayered character of exclusiveness which will probably rise in the years to come, it can be considered a global problem for the post-pandemic world economy.

The COVID-19 pandemic is under way. The global economy is experiencing an unprecedented health crisis and socio-economic crisis. COVID-19 is affecting 213 countries and territories around the world; over 27.0 million coronavirus cases and almost 893 thousand coronavirus deaths were reported (as of September 6, 2020) (Worldometer 2020). The COVID-19 pandemic has already influenced individuals, sectors and industries, regions and national economies, as well as the global economy – both directly and indirectly (unprecedented fall in GDP, huge rise in public debt, financial markets and exchange-rates destabilization, worsening labor market situation – reduced employment, rising unemployment, higher rate of inflation, reduced international trade turnover, reduced investment; with entertainment, recreation, tourism, culture, air transportation and travel sector having suffered the most). At present, the number one task is to respond successfully to the COVID-19 pandemic, i.e. to limit the direct and the indirect impact of the coronavirus (to reduce mortality and to limit the depth of socio-economic crisis). The effects and impacts of the COVID-19 pandemic will shape the global economy for decades. The COVID-19 pandemic highlighted important questions regarding the relations between state and market, democracy and centralism, multilateralism and unilateralism, the role of international organizations. Therefore, the architecture of the post-pandemic global economy will have to be reorganized in terms of new coordination mechanisms, new relations between state and private sector, regulation and supervision, freedom and spontaneity, politics and market. The architecture of the post-pandemic global economy will embrace new supply chains and changed consumption models. In all those senses, the world will no longer be what it was. It'll not be possible to simply return to pre-pandemic routine, life-style and economic relations, to return to pre-pandemic normalcy. The COVID-19 pandemic experience, the global economy is going through in 2020, will necessitate changes on all levels and in all dimensions (Juetten 2020; Kołodko 2020; Rapoza 2020; Shih 2020). Additionally, due to the fact that COVID-19 strengthened the disparities and inequalities, creating inclusive post-pandemic global economy ought to be considered a true challenge in the next decades of the 21st century.

The inclusiveness of development requires further study. In subsequent research, it would be necessary to compare the situation in selected economies before the COVID-19 pandemic and in post-pandemic time in order to see the scope of disparities and inequalities. Moreover, further research should include the evaluation of actions and policies undertaken during the COVID-19 pandemic (and especially during the lockdown) by various states. Additional research should focus on changes in the role of international organizations (like the United Nations, World Health Organization, the European Union, the World Bank, the EBRD, the OECD) during the pandemic and in post-pandemic global economy.

Abstract

The article shows the improvement of the mechanism for implementing the investment policy of the region on the example of the Republic of North Ossetia-Alania. The features of the economic and geographical position of the republic and its natural resource potential are revealed. The investment potential and investment risks of the Republic of North Ossetia - Alania are analyzed. The main directions for attracting investments have been determined. The territorial advantages of the region as a whole and in individual areas have been studied. Considered and analyzed investment projects currently being implemented in North Ossetia-Alania. The planned investment projects were considered. The main problems that hinder the systematic increase in the investment attractiveness of the region are identified and the ways of their solution are proposed. The proposed approach can be used in the development of regional investment policy.

Keywords: Methods and Tools, Mechanism, Regional Investment Policy

Introduction

The potential for investment in a specific region is determined by a set of objective prerequisites, which depend on the presence and originality of areas and objects of investment. In addition, an important aspect of the investment potential is the socio-economic situation of the territory, herewith the advantages include the geographical, climatic, demographic and geostrategic components of this process [3, p. 132].

The relevance of the problem under consideration is due to the fact that the regions that have the main competitive advantages in terms of the availability of resources and climatic factors are faced with problems of increasing investment attractiveness.

The republics of the North Caucasus have the broadest potential for the development and promotion of the tourist and recreational complex. In this regard, the Republic of North Ossetia-Alania stands out.

In North Ossetia-Alania, which has absorbed the culture and languages of dozens of peoples living in it, traditional values are being brought to the forefront, which include respect for elders, the promotion of a healthy lifestyle, and the popularization of the cultural heritage of the region. Thus, a large number of centenarians was noted in Caucasus: according to some sources, more than 42 percent of all the inhabitants of the planet whose age has reached one hundred or more years live in this particular region [4, p.22]. Gerontologists scrupulously study the life and living conditions of long-livers of the region, along with such well-known long-lived territories of living as some regions of Italy.

Materials and methods of research

The potential and most probable opportunities for the development of leisure and tourism promotion in North Ossetia-Alania, in our opinion, are:

- natural and climatic conditions, the uniqueness of which was repeatedly emphasized in the directories not only of modern Russia, but also in Soviet times, when tourists massively and in an organized manner arrived in the republic for a spa-vacation and to get acquainted with the amazing nature of the Caucasus;

- the historical and ethnic heritage of the republic, the development of which is on the agenda not only at the republican, but also at the federal level.

- the presence of a significant amount of legally free land, which may contribute to the organization of the construction of hotels of middle and upper class, which is a deficit in the republic. This is noted so far by a few tourists;

- the immediate proximity of resort sites to existing transport arteries and energy infrastructure;

- the accessibility and a high level of education, as well as the abundance of labor resources capable of changing the field of activity.

Significant positive prerequisites for development in the tourism industry should include the presence of mineral water sources on the territory of North Ossetia-Alania, the diversity and useful qualities of which are known not only in Russia but also in the world. They are a favorable factor in the development of the sanatorium-and-health-resort complex of the republic.

Protected areas are also the hallmark of a relatively small republic. Among them territories of federal subordination are allocated, which include the North Ossetian State Nature Reserve, "*Alania*" National Park, and the integrated nature reserve "*Tseisky*". The diversity of the republic's territories includes three hunting reserves and, in total, 216 natural monuments. In total, the area of specially protected natural territories of the republic is 192 011 hectares, which corresponds to 24% of its area.

The republican potential for expanding the tourist and recreational complex involves visiting 1.8 million tourists a year. 9 investment sites in this area today cover such areas as: Mamisonskaya; Vladikavkazskaya; Tamisk-Biragzangskaya; Kora-Ursdonskaya; Digorskaya; Kurtatinskaya; Kazbekskaya; Naro-Zakkinskaya, as well as the Tibskoye mineral water deposit, which is part of the Mamison investment site. All this is a bulwark of the powerful development of the base of the sanatorium component of the republic's recreational complex.

Tamisk field, which is about 10 thousand cubic meters per day proven reserves can serve as a reliable base for the treatment of over 20 thousand people.

Vladikavkaz, Digorskaya, Tseiskaya, Naro-Zakkinskaya, as well as Mamison investment sites are promising areas for the development of the tourist component of the republic's recreational complex. These investment sites are distributed throughout the republic, which in its turn will allow tourists to get acquainted with the multifaceted nature and resource potential of our region, and investments will be evenly distributed across all areas. Each of the destinations is unique and original in its own way and is able to attract large flows of tourists.

The next promising direction for the development of the tourist and recreational complex is the development of agritourism. The basis of this type of tourism is networks of small forms of collective accommodation (guest houses) in the most remote mountain villages. But this type of activity requires support from the state in the form of financial injections, tax benefits and information support. Such a development of agritourism is possible within the framework of the Agritourism Support Fund [7, p. 35].

Discussion

The republican authorities are undoubtedly ready to support the development of projects in the field of agriculture and agritourism, which will be implemented in the mountainous territories of North Ossetia-Alania. Active work in this direction (mountainous areas) includes the development of gardening, sheep breeding, milk processing, the creation of the basis of agritourism.

Dargavsky gorge will become the basis for laying pear orchards with an area of 8 hectares, the allocated grant will allow opening a milk processing workshop in the village of Unal. But this is not limited to the geography of development of similar industries: pilot projects will be implemented in Mozdok and Iraf districts. Another area of development of farm production is Mountain Kartsa, in which there is a lot of undeveloped land, and there is the possibility of creating a whole cooperation of young people united by one useful thing. State support from the republican authorities in this area consists in the issuance of more than 180 million rubles to grants to start-up entrepreneurs - the so-called "Agristartups". And the sum that will be invested in agriculture in this direction will amount to 1 billion rubles until 2024. This must be done for the development of mountainous territories in order to prevent the outflow of the population. Republican authorities should and will create conditions for business development in the mountains, as this is an important area for North Ossetia, where about half of all agricultural land is located in the mountains.

The republican authorities plan to open five tourist routes, covering all gorges and specializing in horseback riding, extreme sports and jeeping. Another of the directions of the territorial development of tourism in the republic may be the ecological type of tourism, the base of which can be the National Park of Alania, founded in 1998 in the Iraf district of North Ossetia-Alania. Its area is 54.926 thousand hectares, on which unique natural, historical and cultural complexes (monuments) of Mountain Digoria, the northern macro slope of the Greater Caucasus, are preserved. They have ecological, historical and cultural value.

The park is given the status of an international ornithological territory, as it is the keeper of many monuments of different eras. Unique in its beauty, a place that freshens the alpine air, seasoned with untouched nature, will become an attractive place for nature lovers from around the world.

These advantages are an important basis in the development and promotion of almost all types of tourism: extreme and skiing, ecological, rural, historical and ethnic, health-improving. These positive aspects are a powerful factor in attracting investment in both the tourism and hotel business of the republic.

The results of the study

The statistics of 2019 shows that over the past New Year holidays, about 1.3 million Russians visited the country's ski resorts, which is 16.7% more compared to the previous period. This suggests that a visit to Russian ski resorts on New Year's holidays confirms the need for further development of the ski infrastructure and the correct determination of the ski industry as one of the most important points of attraction of tourist and investment flow to the region.

Despite the huge potential in the development of the hotel business in the Republic of North Ossetia-Alania, there is a shortage of hotel services and similar accommodation facilities. The data are presented in table 1.

Table 1: The number of hotels

	2015	2016	2017	2018	2019
All inall	9	10	11	14	15

Table 2 reviews the full range of investment potential of the Republic of North Ossetia-Alania.

Table 2. Analysis of the investment potential of the tourism industry of North Ossetia-Alania [8]

Strengths	**Weaknesses**
Natural and climatic conditions that provide prerogatives for organizing business in the field of tourism of various directions, from recreation to treatment and prevention, which meet the standards of Europe and the world.	The unspecified positioning of the republic as a center of tourist and recreational services, providing high-quality rest of the medical and preventive direction.
The presence of investment sites, which in the future can serve for the development of the tourism industry.	Underdeveloped infrastructure for tourism business.
A high probability and possibility of developing the tourism business of the mountain-recreational direction (medical tourism, agritourism).	The target user cannot use the tourism products prepared specifically for him.
	Republic promotion programs are absent.

Source: Compiled by the author.

The characteristic of investment risk in North Ossetia-Alania is the likelihood of loss of investment and income from them. The difference between investment potential and investment risk is that the risk undergoes changes that occur over fairly short time periods. The degree of investment risk is affected by legislative, political, socio-economic, financial, criminal and environmental factors that occur in North Ossetia-Alania.

Recently, the indicators of the republican investment rating are characterized by the indicator 3C2, which means low potential and a high degree of risk. Another 8 regions in the Russian Federation have a similar indicator according to the RAEX Rating Agency: Karachay-Cherkess Republic, Kamchatka Territory, Kabardino-Balkarian Republic, Jewish Autonomous Oblast/Region, Chechen Republic, Republic of Kalmykia, Chukotka Autonomous Okrug/District, Altai Republic.

Ranks of investment risk and investment potential of the Republic of North Ossetia-Alania for the period 2018 -2019 presented in table 3.

Based on the data of table 3, it can be noted that the republic is located at 63 place in the rating of investment attractiveness of the regions of the Russian Federation.

The Republic of North Ossetia-Alania has certain prospects for the development of financial and economic activity, which is the basis for the investment development of the region. One of the promising areas for investors is the development of resort and recreation sphere and tourism.

32 promising investment projects of North Ossetia-Alania united various sectors of the real sector of the economy, from industrial and agricultural production to tourism and the social sphere.

The task that combined the investment projects is to implement the Strategy for the socio-economic development of North Ossetia-Alania until 2030. This document, which has been developing for over a year and a half and adopted in 2020, defines the direction of the region's growth, which consists in highlighting the vectors of further development and developing long-term target programs.

Systematically removing administrative barriers to the development of business and investment, defining dialogue with businessmen and diversifying the forms of state support, North Ossetia-Alania seeks to improve the investment climate. All actions and thoughts are aimed at enclosing potential

investors in an atmosphere of comfort and security, thereby determining that the republic is a favorable territory for life, safe business, professional and career growth.

One of the main projects that the republic has been promoting in federal departments for a year is the Mamison mountain recreation complex project, which meets all international standards for the development of the tourist complex. These are: unique natural beauties and riches of the gorge, the possibility of year-round skiing, numerous healing mineral springs, which allow developing a medical and sanatorium direction. It is assumed that Mamison, which meets international standards, will be launched in 2022. And there are positive trends in financing this project: since Mamison is the "brainchild" of public-private partnership (PPP), then at the meeting of former Prime Minister D.A. Medvedev and the head of the republic V.Z. Bitarov, an agreement was reached on the allocation of a federal share of funds for the implementation of this project.

It should be noted that, according to the legislation, updating of the subject's electric power development programs is annually updated. The programs for 2019-2023 and 2020-2024 are approved. Currently, the Scientific and Technical Center of the Unified Energy System is developing a program for 2021 - 2025.

In the program for 2019-2023, the emphasis was put on commissioning the ZaramagskayaHPP-1 with a capacity of 342 MW and the construction of a high-voltage line 500 kV Nevinnomyssk - Mozdok-2 (Alania) with a length of 265 km. The implementation of these two large-scale projects allowed us to move to a new level of electricity supply in the republic.

The program 2021-2025 will focus on the development projects of the city of Beslan and the resort complex "Mamison". Within the framework of the federal target project "South of Russia" for the power supply of the Mamison mountain recreation complex, the 110/10 kV Mamison substation and the high voltage line 110 kV Mamison - Zaramag with a length of 17 km were commissioned. After updating, previous programs are adjusted. Construction of facilities in accordance with the scheme and program for the development of the electric power industry is carried out at the expense of economic entities and the federal budget.

Despite the high rates of infrastructure development in the republic, they should be developed, since a tendency to decrease in the future is predicted.

The socio-economic development of North Ossetia-Alania indicates that:

- In the republic there are favorable natural resource and unique recreational conditions that are attractive to investors, both domestic and foreign;

- it is necessary to apply modern organizational and economic methods in the work of organizations in the field of construction and to increase the level of investment attractiveness of this industry by reducing the cost of materials, structures, as well as in the direction of training specialists in the construction industry; the cheapening of loans, though, remains the problem;

- the transport industry also requires increasing investment attractiveness in connection with the possible reconstruction of the Vladikavkaz airport;

- information technologies should permeate both the economic and social life of the republic in the future. This will help to introduce best practices in the practice of the republic more quickly;

- state support, both from the republican government and from the federal authorities, should be the basis for the provision of information services, the development of information products;

- reserves to increase the investment attractiveness of the republic of north Ossetia-Alania is concentrated not only in the development of tourism business services.

Attention should be paid to the experience of developing the investment potential of the neighboring republics of the North Caucasus Federal District, whose plans and their implementation can serve as

an example of investing not only in the tourism industry, including agritourism, but also in areas that can bring big dividends in the future. These are:

- construction of a modern fruit storage in the Stavropol Territory. The total project cost is estimated at 4.6 billion rubles;

- construction of a large dairy complex in the Chechen Republic;

- modernization of a mutton plant in the Karachay-Cherkess Republic;

- construction of a plant for the production of pipe fittings in Dagestan;

- construction of a storage for seedlings in the Stavropol Territory. Investments in the project will amount to 400 million rubles;

- construction of a greenhouse complex and the creation of an agricultural park in Ingushetia with a design value of 1 billion rubles.

On the example of successful investment in neighboring regions, in North Ossetia-Alania, one of the objects that will be embodied in 2020 will be the construction of a fruit storage for 2.5 thousand tons. This will be possible at the expense of the “Vladka” company’s own funds. This will be the second stage of the fruit store, in addition, the garden of the Saint-Germain pear variety will be laid. The implementation of this project became possible within the framework of the state program "Development of the North Caucasus Federal District". The republican part of the program began to be implemented as early as 2016 by the Ministry of the Russian Federation for North Caucasus Affairs together with the Ministry of Economic Development of the North Ossetia-Alania and JSC “Investment Development Corporation of the North Ossetia-Alania”.

The plans of the “Vladka” company include the implementation of an investment project that provides for the laying of an intensive apple orchard with an area of 122 hectares, which uses a drip irrigation system. The implementation of this investment project will create more than 30 permanent jobs, the number of seasonal workers attracted can increase to 100 people [8].

LLC “Vladka”, located in the village of Tsrau in North Ossetia, participated in laying the first garden of the enterprise, whose area at that time was 33 hectares. Experts from Italy, North Ossetia, Krasnodar Territory, Rostov Region and Kabardino-Balkaria participated in this process. The planned size of the garden in 2019 was 122 hectares, the yield of which should be 6 thousand tons annually. Varieties of grown apples: *Gala* (red), *Fuji* (violet-red), *Golden* (gold), *RedDelicious* (red), *GrannySmith* (analogue of the "semerenko" - green). Promising summer varieties *SummerFree*, *RedFree* and *Galmack* (red) are also grown.

Conclusions

Summing up the above, I want to say that North Ossetia-Alania, having huge potential for developing investment attractiveness, like other regions, faces a number of problems that are systematically being addressed by the current government of the Republic. Projects are being developed that will help to attract investment in spa and recreation complexes and various types of tourism, including agritourism, extreme tourism and sanatorium and recreation. But despite the huge natural resource potential, the government is not going to get stuck only in this direction. This is evidenced by the intention to build a meat factory in the republic. Investments in construction will amount to 700 million rubles. The creation of such powerful agri-industrial complexes will help to promote the republic in providing itself with high-quality products and their marketing to other regions of Russia, and accordingly, the development of the economy and improving living standards in the region.

Does Investing in IPO's Pay-Off? Evidence from Indian Stock Market

T.Ramesh Chandra Babu Ph.D.

CHRIST University, Bangalore, India
email: aarseebee@gmail.com

Abstract

Purpose: (a) To ascertain the IPO's listing gain or loss and analyse the post IPO's performance. (b) To analyse the impact of IPO subscription ratio, IPO lead manager's (BRLM), sponsor bank's and IPO registrar's reputation on the listing gain or loss. **Design/ Methodology/Approach:** This research paper is based on empirical analysis. All the 16 IPO's listed in the NSE (National Stock Exchange, India) during the year 2019 were considered for the study. The study is based on secondary data. The daily share price and Nifty-50 index value were taken from NSE website (www.nseindia.com) and other relevant data from red-herring prospectus of the respective company. The research / statistical tools used are Event Study, ANOVA, multiple regression, correlation, covariance.**Scope of the study:** The scope of the study is limited to the IPO's listed only in the National Stock Exchange (NSE), India. **Period of study:** The study covers a period from January 2019 to December, 2019. **Limitation of the study:** The study considers only the influence of the external factors on the performance of IPOs. **Findings:** The analysis reveals that 68.75% of the IPO's have given a listing gain and in that only 43.75% of the IPO's have given listing gain more than 10% during the year 2019. The analysis clearly reveals that 68.75% of the IPOs were underpriced and 31.25% of the IPOs were overpriced. The abnormal return of only 56.25% of the IPO's were found to be significant on the listing day. The CAR was positively significant for only 56.25% of the IPO's. The CAAR of all the IPO's listed during the year 2019 was significant only on the first four trading days and the same has gradually disappeared by the end of 30 trading days. The subscription ratio of QIB has very high degree positive influence followed by RII on the listing gain and the subscription ratio of HNI has negative influence on the listing gain. The analysis shows that the Book Running Lead Manager (BRLM), the sponsor banks and the registrar of the IPO issue have no significant influence on the listing gain or loss. **Originality / Value:** This is an original work that analyses the listing gain or loss and the post listing performance of IPO's in India and other factors that might influence the listing gain or loss.

Keywords: IPO Underpricing, IPO performance, listing gains, subscription ratio, event study.

Does investing in IPO's pay-off? Evidence from Indian stock market

Introduction

Initial Public Offering (IPO) refers to the issue of shares by the company directly to the public for the first time. The subsequent issue of shares by the company directly to the public is referred to as Follow on Public Offer (FPO). It is really a tricky decision to put the money in a relatively new company. In IPO investing, there is a chance of getting a significant first day capital gains, or long-term capital gains. On the other hand, there is a chance of incurring a significant first day capital loss, or long-term capital loss.

Usually, a company hires an investment bank to manage an IPO before it goes for a public issue. The under-writers and investment bankers assess the quality of management, future cash flows and returns before arriving at the final offer price and the comparative valuation is done based on the listed peer company.

Cite this Article as: T. Ramesh Chandra Babu "Does Investing in IPO's Pay-Off? Evidence from Indian Stock Market" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The usual anomaly which an investor finds in an IPO issue are (a) underpricing or overpricing (b) information asymmetry (c) agency problem between the investment bank and the issuing firm. IPO underpricing refers to a situation where the listing day closing price is greater than the initial offer price and the overpricing refers to a situation where the listing day closing price is lesser than the initial offer price. An IPO maybe underpriced deliberately or accidentally. Sometimes, an IPO maybe deliberately underpriced to woo the investors or accidentally underpriced when the underwriters underestimated the demand. Information asymmetry refers to the imbalance in the knowledge of information among the investors (and other stakeholders) about the company and its potential growth.

Theories related to the study

The theories closely related with this study are the theories of Under Pricing. The IPO Underpricing theories can be broadly classified into (1) Information Asymmetry theories (2) Institutional theories (3) Ownership and Control theories (4) Behavioral theories.

The theories that support Information Asymmetry theories are: (a) Principal – Agent theory (b) Ex-ante Uncertainty theory (c) Book-Building theory (d) Signaling theory (e) Certification (f) Winner's Curse theory (g) Entrepreneurial Wealth loss theory (h) Partial adjustment theory.

The theories that support Institutional theories are: (a) Law-suit avoidance theory (b) Price Stabilization theory (c) Tax argument theory.

The theories that support Ownership and Control theories are: (a) Entrenchment Managerial Control theory (b) Agency-cost theory.

The theories that support Behavioral theories are: (a) Information cascade theory (b) Investor Sentiment theory (c) Prospect theory.

All the above said theories tried to give explanations as to why the IPO Under-pricing happens and the variations in in the IPO Under-pricing among different firms across different countries. Despite enough evidence of underpricing, all the available research papers show that there are no universal explanations for IPO underpricing.

Review of literature

Miller (1977) first hypothesis was that underwriters set the issue price based on the mean assessment of the investor. The second hypothesis is that the price in the secondary market is determined by the assessment of optimistic investors. Spatt and Srivastava (1991) stated that the under-writers fix the price based on the potential demand and supply equilibrium (market clearing bid price). Benveniste & Spindt (1989) was of the view that the IPO price is based on the intrinsic value. Serman and Titman (2002) stated that the method of pricing (market clearing bid price or intrinsic value) chosen by the underwriter is based on the cost-benefit analysis. Rock (1986), Boone et al (2016) and Chaplinsky et al (2017) proved that the information asymmetry lead to IPO underpricing. Aggarwal et al. (2002) stated that the underpricing is a strategic decision of investment banks Firms to maximize their wealth after the lock-in period of their shares. Loughran and Ritter (2002) explained that underpricing is the outcome of agency problems between the investment bank and the issuing firm.

Chang et al. (2017) gave evidence that agency problems between the investment bank and the issuing firm lead to excessive underpricing in Taiwan's stock market. Baron (1982) revealed that IPO underpricing is the outcome of agency problem between underwriters and issuing firm and the underwriting firm benefits more from the underpricing than from underwriting fees. Ljungqyist (2007) revealed that the underwriters' gain from underpricing exceeds the loss of underwriting fees. Lowry et al. (2017) stated that IPO underpricing can be minimized by minimizing 'information asymmetry' between investors and issuers and by minimizing agency conflicts between underwriters and issuers. Agarwal et al. (2008) measured the retail investor demand using the subscription ratio.

Statement of problem

Initial Public Offerings (IPOs) is considered to be an important source of finance for the business. Past experiences and several previous research works reveal that several IPOs have given a high capital gain on the listing day (underpricing) compared to its performance in the market. The reasons for the underpricing or overpricing can be attributed to internal and external factors of the firm. The usual anomaly which an investor finds in an IPO issue are (a) underpricing or overpricing (b) information asymmetry (c) agency problem between the investment bank and the issuing firm.

This study attempts to analyze and ascertain the IPO's listing day gain or loss as a consequence of underpricing or overpricing of IPO's and explore the influence of external factors on the performance of the IPO's.

Research objectives

1) To ascertain the IPO's listing day gain or loss and analyse the post IPO's performance.
2) To analyse the impact of IPO subscription ratio on the IPO's listing gain or loss.
3) To examine the influence of IPO lead manager's (BRLM), sponsor bank's and registrar's reputation on IPO performance.

Scope of the study

The scope of the study is limited to the IPO's listed only in the National Stock Exchange (NSE), India.

Period of study

The study covers a period from January 2019 to December, 2019.

Methodology

This research paper is based on empirical analysis. All the 16 IPO's listed in the NSE (National Stock Exchange, India) during the year 2019 were considered for the study. The study is based on secondary data. The daily share price and Nifty-50 index value were taken from NSE website (www.nseindia.com) and other relevant data from red-herring prospectus of the respective company.

Research / Statistical Tools

ANOVA, regression, correlation, covariance and Event study (including the following tools):

(1) Actual Return: $R = Ln(P_1/P_0)$
(2) Expected return: $E(R) = \alpha + \beta(R_m)$
(3) Abnormal return: AR = Actual return – Expected return

(4) 't' statistic of Abnormal return = $\frac{AR}{SE_{YX}}$

(5) 't' statistic of CAR = $\frac{CAR}{\sigma_{YX} * \sqrt{n}}$

Where Cumulative Abnormal Return: CAR = $\sum_{t=1}^{n} AR_t$

(6) 't' statistic of CAAR = $\frac{CAAR}{\sigma_{AAR} * \sqrt{n}}$

Where Average Abnormal Return: AAR = $\frac{1}{n}\sum_{i=1}^{n} AAR_i$

Where Cumulative Average Abnormal Return: CAAR = $\sum_{i=1}^{n} AAR_i$

Limitation of the study

The study considers only the influence of the external factors on the performance of IPOs.

Abbreviation:

a) R – Actual Return
b) AR – Abnormal return
c) E(R) - Expected return
d) CAR - Cumulative Abnormal Return
e) AAR - Average Abnormal Return
f) CAAR - Cumulative Average Abnormal Return
g) QIB – Qualified Institutional Buyers
h) HNI – High Net-worth Individuals
i) RII – Retail Individual Investors
j) BRLM - The Book Running Lead Manager

Analysis

The 't' statistics of CAR (cumulative abnormal return) shown in the table-3 reveals that CAR was positively significant for 9 IPO's (56.25%), negatively significant for 4 IPO's (25%) and insignificant for 3 IPO's (18.75%). The table also reveals that all the abnormal return indicated during the first few days (2 to 10 days) has disappeared by the end of 30 trading days.

Table- 4: 't' statistic of CAAR of all the IPO's during the first 30 days post listing performance in the year 2019

The 't' statistics of CAAR (cumulative average abnormal return) of all the IPO's listed during the year 2019 (table:4) reveals that CAAR was significant only on the first four trading days. The table also reveals that all the abnormal return indicated during the first four days has disappeared by the end of 30 trading days.

Hypothesis: 1

H_0: The subscription ratio of QIB, HNI and RII does not have significant influence on the listing gain or loss.

H_1: The subscription ratio of QIB, HNI and RII have significant influence on the listing gain or loss.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.817[a]	.668	.585	22.81389

a. Predictors: (Constant), RII, QIB, HNI

ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	12568.687	3	4189.562	8.050	.003[b]
	Residual	6245.685	12	520.474		
	Total	18814.372	15			

a. Dependent Variable: Listing Gain
b. Predictors: (Constant), RII, QIB, HNI

Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.929	7.997		.116	.909
	QIB	.470	.368	.531	1.278	.225
	HNI	.152	.152	.609	1.003	.336
	RII	-1.135	1.092	-.392	-1.040	.319

a. Dependent Variable: Listing Gain

Coefficient Correlations[a]

Model			RII	QIB	HNI
1	Correlations	RII	1.000	.357	-.769
		QIB	.357	1.000	-.814
		HNI	-.769	-.814	1.000
	Covariances	RII	1.192	.143	-.127
		QIB	.143	.135	-.045
		HNI	-.127	-.045	.023

a. Dependent Variable: Listing Gain

Inference

1) Since the 'p' value of QIB, HNI and RII is greater than 0.05, the null hypothesis is accepted. So, it can be inferred from the coefficient table that none of the factors individually influence the listing gain or loss.

2) But, the R square and the global 'F' test reveals that all the factors jointly influence the listing gain or loss (since the 'p' value of QIB, HNI and RII is greater than 0.05).
3) The beta coefficient reveals that the subscription ratio of QIB has the maximum positive impact on the listing gain and the subscription ratio of RII has the maximum negative impact on the listing gain.
4) The correlation coefficient reveals that the HNI subscription ratio has high degree negative correlation with QIB and RII subscription ratio.

The researcher (myself) was wondering as to why the subscription ratio of QIB, HNI and RII had no significant influence on listing gain or loss. Since the market felt that the issue price of IRCTC was highly underpriced, which has led to enormous listing gain. I removed it and ran the regression. The output revealed a different scenario. Now the subscription ratio of QIB, HNI and RII had significant influence on listing gain or loss. RII (with 2.44 beta and p-value 0.12) and QIB (with 0.634 beta and p-value) positively influenced the listing gain and HNI (with -0.272 beta and p-value of 0.25 negatively influenced the listing gain.

Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig
		B	Std. Error	Beta		
1	(Constant)	-4.936	4.169		-1.184	.2
	QIB	.634	.188	1.061	3.362	.0
	HNI	-.272	.105	-1.631	-2.601	.0
	RII	2.442	.815	1.450	2.997	.0

Hypothesis: 2

H_0: The promoters holding, issue size, issue price and the overall subscription ratio does not have significant influence on the listing gain or loss.

H_1: The promoters holding, issue size, issue price and the overall subscription ratio have significant influence on the listing gain or loss.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.736[a]	.542	.375	28.00289

a. Predictors: (Constant), Issue Price, Promoters Holding, Subscription Ratio, Issue Size

ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	10188.589	4	2547.147	3.248	.055[b]
	Residual	8625.782	11	784.162		
	Total	18814.372	15			

a. Dependent Variable: Listing Gain

b. Predictors: (Constant), Issue Price, Promoters Holding, Subscription Ratio, Issue Size

Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	-9.032	25.768		-.351	.733
	Promoters Holding	.171	.447	.096	.384	.709
	Issue Size	-.002	.011	-.044	-.181	.860
	Subscription Ratio	.498	.174	.686	2.860	.016
	Issue Price	.004	.023	.043	.195	.849

a. Dependent Variable: Listing Gain

Coefficient Correlations[a]

Model			Issue Price	Promoters Holding	Subscription Ratio	Issue Size
1	Correlations	Issue Price	1.000	.059	.003	-.335
		Promoters Holding	.059	1.000	-.511	-.419
		Subscription Ratio	.003	-.511	1.000	.307
		Issue Size	-.335	-.419	.307	1.000
	Covariances	Issue Price	.001	.001	1.176E-005	-8.221E-005
		Promoters Holding	.001	.199	-.040	-.002
		Subscription Ratio	1.176E-005	-.040	.030	.001
		Issue Size	-8.221E-005	-.002	.001	.000

a. Dependent Variable: Listing Gain

Inference:

1) Since the 'p' value of promoters holding, issue size, issue price is greater than 0.05, the null hypothesis is accepted. So, it can be inferred from the coefficient table that all the factors except overall subscription ratio does not influence the listing gain or loss significantly. The global 'F' test confirms the same. Only the overall subscription ratio has significant impact on the listing gain or loss.
2) The R square reveals that only 54.2% of the variation in listing gains or loses is because of the variation in the promoters holding, issue size, issue price and the overall subscription ratio. The remaining 45.8% maybe due to others factors like speculative trading, nature of industry/business, investment in assets, capital structure, cost of capital, management and earning potential (including cash flows) etc.
3) The beta coefficient reveals that only the overall subscription ratio has the maximum positive impact (0.498) on the listing gain, followed by promoters holding (0.171).
4) The correlation coefficient reveals that all the factors have a low degree positive or negative correlation with each another.

Hypothesis: 3

H_0: The Book Running Lead Manager (BRLM) has no significant influence on the listing gain or loss.

H_1: The Book Running Lead Manager (BRLM) has significant influence on the listing gain or loss.

Tests of Between-Subjects Effects

Dependent Variable: LISTGAIN

Source	Type III Sum of Squares	Df	Mean Square	F	Sig.
Corrected Model	18796.070[a]	14	1342.576	73.360	.091
Intercept	6629.083	1	6629.083	362.220	.033
BRLM	18796.070	14	1342.576	73.360	.091
Error	18.301	1	18.301		
Total	24668.534	16			
Corrected Total	18814.372	15			

a. R Squared = .999 (Adjusted R Squared = .985)

Since the 'p' value of BRLM is greater than 0.05, the null hypothesis is accepted. So, it can be inferred from the table that the Book Running Lead Manager (BRLM) has no significant influence on the listing gain or loss.

Hypothesis: 4

H_0: The sponsor banks of the IPO issue have no significant influence on the listing gain or loss.

H_1: The sponsor banks of the IPO issue have significant influence on the listing gain or loss.

Tests of Between-Subjects Effects

Dependent Variable: LISTGAIN

Source	Type III Sum of Squares	Df	Mean Square	F	Sig.
Corrected Model	64.139[a]	1	64.139	.048	.830

Error	18750.233	14	1339.302		
Total	24668.534	16			
Corrected Total	18814.372	15			

a. R Squared = .003 (Adjusted R Squared = -.068)

Since the 'p' value of sponsor banks is greater than 0.05, the null hypothesis is accepted. So, it can be inferred from the table that the sponsor banks have no significant influence on the listing gain or loss.

Hypothesis: 5

H_0: The registrar of the IPO issue has no significant influence on the listing gain or loss.

H_1: The registrar of the IPO issue has significant influence on the listing gain or loss.

Tests of Between-Subjects Effects					
Dependent Variable: LISTGAIN					
Source	Type III Sum of Squares	Df	Mean Square	F	Sig.
Corrected Model	1713.002[a]	3	571.001	.401	.755
Intercept	3056.206	1	3056.206	2.145	.169
Registrar	1713.002	3	571.001	.401	.755
Error	17101.370	12	1425.114		
Total	24668.534	16			
Corrected Total	18814.372	15			
a. R Squared = .091 (Adjusted R Squared = -.136)					

Since the 'p' value of registrar of the IPO issue is greater than 0.05, the null hypothesis is accepted. So, it can be inferred from the table that the sponsor banks have no significant influence on the listing gain or loss.

Conclusion

The analysis reveals that 68.75% of the IPO's have given a listing gain and in that only 43.75% of the IPO's have given listing gain more than 10% during the year 2019 (i.e. 68.75% of the IPOs were underpriced and 31.25% of the IPOs were overpriced). The abnormal return of only 56.25% of the IPO's were found to be significant on the listing day and on the remaining days, all the IPO's abnormal return were not significant. The CAR (cumulative abnormal return) was positively significant for 56.25% of the IPO's, negatively significant for 25% of the IPO's and was completely insignificant for 18.75% of the IPO's. The analysis also reveals that all the abnormal return indicated during the first few days (2 to 10 days) has disappeared by the end of 30 trading days. The CAAR (cumulative average abnormal return) of all the IPO's listed during the year 2019 was significant only on the first four trading days and the same has gradually disappeared by the end of 30 trading days.

The subscription ratio of QIB, HNI and RII had significant influence on listing gain or loss. The subscription ratio of QIB has very high positive influence followed by RII on the listing gain and the subscription ratio of HNI has negative influence on the listing gain. The promoters holding, issue size, issue price does not influence the listing gain or loss significantly. Only the overall subscription ratio has significant impact on the listing gain or loss.

The analysis reveals that only 54.2% of the variation in listing gains or loses is because of the variation in the promoters holding, issue size, issue price and the overall subscription ratio. The remaining 45.8% maybe due to others factors like speculative trading, nature of industry/business, investment in assets, capital structure, cost of capital, management and earning potential (including cash flows) etc. The analysis shows that the Book Running Lead Manager (BRLM), the sponsor banks and the registrar of the IPO issue have no significant influence on the listing gain or loss.

Abstract

The research is aimed to analyze the simplifying ways of getting access to finance by SMEs through such FinTech tool as Blockchain smart lending. The main focus of the paper is to give insight on potential benefits and probable risks of being involved into Blockchain lending as for potential borrowers, namely SMEs, as well as for lenders. The new trend of P2P lending via Blockchain was explored in details and cross-lending platform analysis was conducted regarding identification its potential strengths and weaknesses. Authors revealed that some Blockchain platforms could be controlled by financial or governmental institutions which could be considered as the approach for eliminating risk of mistrusting and probable fraud. Such innovation tools in relation to ensure digital assets, as stablecoins, CDP accounts and MKR tokens were observed. In spite of decentralization nature of Blockchain, it is relevant to establish due diligence procedure and some governmental control because of behavioristic component in relations between lenders, borrowers and platform administrators in order to eradicate possible cases of scam activity.

Keywords: SME, Blockchain, Smart lending, P2P platform

Introduction

It is well-known, that SMEs drive business dynamics at all stages, namely the creation, expansion, contraction and insolvency of firms, and can be considered as the fuel for general economic growth [1]. But SMEs are mainly dependent on financing level, though the issues of their challenges in access to finance should not be underestimated. According to a World Bank Group study [2], SMEs face lack of obtaining bank loans in comparison with large firms. Internal funds, or cash from friends and family, aimed at launching and running their business activities, are among their main financial sources.

Cite this Article as: Alla IVASHCHENKO, Yevheniia POLISHCHUK, Serhii SMERICHEVSKYI And Liubov POPOVA "Enhancing potential of SME Financing through Blockchain Smart Lending" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Taking into consideration World Bank Group study [2], approximately 70% of all micro, small and medium-sized enterprises in emerging markets have limited access to traditional bank credit. This trend is complicated not only by lack of successful credit history and relevant collateral, that SMEs could provide, but also by existent long procedure of bank approval. This procedure consists of a set of bureaucratic processes and complex legal requirements, which the majority of SMEs could not follow. Also, improvement of SMEs' access to finance and finding alternative sources of capital are the key issue regarding dynamical enhancing the role of SMEs in their contribution to GDP and jobs` offering. For solving the mentioned problems of SMEs access to finance it is reasonable to use decentralized ledger technology (DLT), exemplified as Blockchain 2.0, in such cases as P2P lending or smart crypto-lending with the aim to evade from any intermediary service and to reduce commission and interest rates for obtaining the loan. Taking into account the fact that Blockchain is the most secured data storage, in which any transaction, ever executed, could not be altered or removed and any party or authority can influence or control the DLT. These all features make the crypto-lending process via Blockchain more transparent, less risky and cheaper compared to traditional bank one.

DLT based on Ethereum blockchain allows to form global network of lenders, borrowers and financial professionals in such way make the background and infrastructure for crypto-lending, which will be appropriate for credit obtaining by SMEs.

The organization of this paper is as follows. Section 1 is the introduction to the importance of getting finance for SMEs and complexity of such procedures in the conditions of their underfunding. Section 2 outlines relevant opinions and concepts related to potential advantage of Blockchain usage in financial sector, P2P lending and smart contract execution regarding lending transactions. The other section describes methodology for conducting analysis. In the next section, the comparison of traditional and Blockchain lending is thoroughly explained. The following section studies the existent examples of Blockchain application in banking sphere. The further section explores the comparisons of Blockchain lending platforms according to set of criteria as profitability, stablecoins usage, collateral and so on. The features, that are taken into consideration as essentials for proper Blockchain lending platforms performance aimed at keeping safety of collateral and other financial resources, as stablecoin, CDP account and government token MKR are analyzed in the other section. The next section gives insight on possible consideration regulative issues concerning activity of Blockachain lending platforms within developing process of regional smart specialization strategies. Finally, the conclusions are presented, along with the further research directions.

Literature Review

Blockchain use cases in financial sector and potential advantages of its application inti financial services are widely discussed in scientific papers of the prominent researchers.

Ana Reyna (2018) et al underlined such benefits of Blockchain for finance services as transparency, verification system, opportunity to use smart contacts, as time and cost effective method for enterprise running. But along with the mentioned probable gains, a lot of drawbacks should be considered exemplified as lack of governmental and auditing control leading to increasing Blockachain usage for fraudulent and illegal usage; ongoing process of increasing the storage recourse capacity of Blockchain nodes related to the permanent blocks` number growth every 10 minutes; probability of attacks in the network.

Besides, in the paper of Maher Alharby and Aad van Moorsel (2017), the challenges of applying smart contracts and perspectives for its solution are described in details. Codifying, security and privacy issues should be underestimated among the main essential drawbacks due to possible errors of smart contract execution. Authors revealed that failure in any modification and termination of smart contracts could be eliminated through establishing a set of pre-defined rules and standards. The possible eradication of security risks namely as dependency vulnerability in transaction execution or ordering, timestamp and mishandled exception, could be performed by "Oyente" tool usage which was developed by the Decentralized Autonomous Organization (DAO). The mentioned tool is presented by smart

contract security analyzer aimed at elimination possible security hazards. Lack of transaction privacy could lead to limited smart contract users, regarding confidentiality of transactional value, so it useful to apply different encrypcion techniques.

In addition, Loi Luu et al. (2016) in their paper also confirmed the fact that the majority of probable bags regarding smart contract execution could be eradicated by tool Oyente providing pre-deployment mitigation and accurate estimation of gas consumption for contracts in the worst case. According to the mentioned scientists, Oyente usage might help "(1) developers to write better contracts; and (2) users to avoid invoking problematic contracts".

Mohamed Amine Ferrag et al. (2019) mainly paid attention to Blockchain applications in the internet of things (IoT), considering and explaining probable attacks on Blockchain in existent protocols taken into account possible counteractions due to possible attacks. The focus of the research was to develop potential threat models for blockchain aimed at avoiding plausible risks which are typical for distributed network.

Additionally, the work of Michele Marchesi et al. (2018) concerns that the core of successful smart contract execution belongs to Solidity program language which mainly performed on Ethereum Blockchain platform. So, the main results of the article include full modeling for successful implementation of Blockchain business model into traditional entrepreneurship, allowing firms or startups to use their potential advantage, namely BOS (Blockchain oriented software).

Such researchers as Tara Salman & Maede Zolanvari (2019) at their article explored the architecture of Blockchain, distinguishing the main peculiarities of it, exemplified as distributed nature, decentralized consensus, trustless system and cryptographic security. The main attention was paid to public sphere, in which cryptographic technics could be successfully carried out emphasizing the great potential for Blockchain usage in real sector of public security.

Ali Vatankhah Barenji et al. (2019) considered the use case of Blockchain as Peer to Peer (P2P) network, that provide the security into communication between network nodes without intermediation of any central party aimed at coordination and validation of transactions in order to provide cost- and time-efficient methods of its execution.

Tiago M. Fernandez-Carames & Puala Fraga-Lamasi (2019) explored that transactions executed through Blockchain require horizontal and vertical integration in order to provide processes` automatization and ensure communication means for suppliers and clients which could be useful not only in IoT platforms, but in different other spheres as ERP- and MES systems, as well as Blockchain lending. Paper of Kevin Delmolino et al. (2016) examines potential bugs which could occur in smart contract programming in case of smart contracts interaction. The mentioned specific Ethereum mistakes influence on potential Blockchain smart lending, therefore, predicting probable bugs regarding its further elimination.

The analysis, conducted by Fraunhofer-Gesellschaft (2018), gives insight on blockchain applicability in the financial sector, personified as compliance services like creation consolidated accounting register stored in Blockchain database and consortium blockchain for client data. The given application models in blockcahin could lead to higher level of automatization, prevention of double-spending cases, elimination of manipulative risks such as contract backdating, taken into account, reliability of Blockchain, as well as to reduction of review and facilitation encrypted transmission processes via use of smart contracts.

Mildred Chidinma Okoye and Jeremy Clark (2018) presupposed possible ways for risk elimination connected Blockchain lending as monetary instability and counter-party risk which could be presented as follows:

- limitation of currency circulation;
- establishing astute rate or some internal metrics in case of new currency creation;
- cryptocurrency usage as exchange tool and loan basis on stable real currency;
- collateral ensuring by Bitcoin-based solutions or token creation with some value;
- reputation risk in Blockchain could be enhanced by strong credit histories and excluded fake identities;
- providing insurance by credit default swap (CDS) use.

Moody`s report (2018) identifies credit implications via blockchain technology underlining such features as processes acceleration, cost reduction and competitiveness growth.
The essence of smart P2P lending through blockchain regarding probable exclusion of traditional bank services in this case was underlined in the paper of Bhaumik Choksi, Alisha Sawant & Sai Subhasree Pakina (2018). Along with this, authors revealed lack of dependence on currency fluctuations and central authority decisions in Blockchain lending.

Considering the fact of existing a lot of P2P lending platforms, Rainer Lenz (2016) argued that such platforms could be examined as disruptive business models regarding risks related to such type of borrowings. These risks, namely credit, fraud, money laundering, hacking, conflict of interest and operational ones, should not be unestimated and one of the possible solutions for its elimination is to create lending platforms, based on Blockchain.

Taken into account the report of Capgemini Consulting's Digital Transformation Institute (2016), there were selected such use cases of smart contracts in banking as trade finance, mortgage lending and different types of loans, in particular to start-ups and SMEs. Besides, the report claims that widespread adoption of smart contracts will begin in 2020 and save consumers over $500 in fees.

The authors of the paper, concerning the issues of Blockchain crowdlending platform (2017), underlined the main features of Blockchain crowdlending platform as follows: possibility for users to invest small amounts, provision tools for checking project reputation, establishing of platform rules and providing proper due diligence.

In the scientific article of K. Salah et al. (2018), idea of creation Consortium blockchains, formed by a group of organizations, was developed, which could be useful for internal needs of banks.

Pierangelo Rosati and Tilen Čuk (2019) developed the approach underlining the main potential features of lending through blockchain as simplification of decision-making by lenders, risk assessment and credit scoring for all borrowing nodes.

In the paper of Antoniuk Larysa et al. (2017) the essence of digitalization for SME development in the conditions of the Fourth Industrial Revolution is proved by experience of the high-income countries. Such benefits as productivity rate growth, reduction of manual processes, cost- and time-optimization were in the core of the mentioned analysis.

In monetary dialogue (2018) the cryptocurrency in banking sector is considered as potential mean for replacing traditional currency for the majority of services and products providing by banking system, especially in countries with weak monetary policies.

So, potentially, blockchain lending could simplify the procedure for obtaining credit as for bank institutions as well as for borrowers that is beneficial for SME development in the conditions of complicated procedure of access to credit finance, especially in emerging markets.
The main aim of the research is to develop recommendations for practical application of blockchain smart lending for SMEs regarding eliminating risk of their underfunding and increasing their capability into access to crypto-loans.

Research Methods

The research methodology includes quantitative and qualitative methods. Along with quantitative methods, the usage of qualitative methods is appropriate in assessment of surveys of different focus-groups, exemplified as business structures, SMEs in particular, financial institutions, crypto-users, financial facilitators and other stakeholders. This research provides comparative analysis of different types of lending based on the analysis of the main features of traditional bank credit and Blockchain loans considering benefits and potential risks for SMEs. Such methods as empirical research, including critical observation, comparative analysis, dimensional estimations and methods of theoretical research as feasibility analysis and theoretical modeling for applying in modern conditions have been taken in the given paper.

Cross-platform analysis was used to reveal the potential benefits and risks of its application into practice as for lenders as well as for borrowers. This analysis was based on data of reports and KPIs of the mentioned Blockchain lending platforms and was conducted with the aim to identify the most competitive ones from points of profitability, regulation existence, registration complexity on the platform and required collateral.

The content analysis was made by applying Maxqda software which allows to gather and analyze data from various media sources for representing: 1) comparison of traditional and blochchain lending; 2) key features and probable risks of being involved into blockchain crediting; 3) trends of Blockchain lending platforms development and its comparative analysis; 4) essentials of insurance issues in Blockchain lending as to use stablecoins, CDP accounts, etc. Besides, Maxqda software was used to reveal the existence of dependency between the term of obtaining credit resources and interest rate. Such research questions would be answered within this study: how existence of blockchain lending platfoms could simplify SME access to finance? What are the KPI for identification the most appropriate Blockchain lending platform for SME? What is the essence of Blockchain lending, including P2P one? What are the perspectives for regulation activity of such platforms within implementation of regional smart specilization strategy?

General comparison of Blockchain and traditional lending

The essentials for SME development can be considered as availability of loans and other external sources, but in many cases SMEs have risk of not meeting with the bank requirements in order to provide sufficient loan repayment and collateral. Additionally, inability to be competitive and to set required targets could be also among the causes of bank reluctancy in loan issuance to SMEs.

According to 'McKinsey & Company report' [4] such improvements should be made for SMEs in lending sphere as:

Simplification of application submitting by limiting paper confirmation required and automated credit execution through online bank web-sites;

Approval facilitation by credit diversification according to risk type, exemplified as loans with lower risks could be processed automatically and loans with higher risks could be performed under some verification;

Shifting the administrative burden to automatic processing means and focusing on customs support regarding issues of loan obtaining;

Creation of data base, including account, merchant and credit card information, in order to define potential of relevant clients, provide pre-approval if all terms follow to, reduce hand-to-hand application number and provide time-reduction.

Enforcement of all improvements, mentioned for traditional bank system, could be possible through automatic lending execution through DLT, namely Blockchain, which can be presented as Blockchain lending platform. These platforms could become an effective tool for SMEs loan obtaining without any requests for complicated approval process and demand collaterals.

Along with the benefits of Blockchain, namely alternative financing options, this technology provides opportunity to make financial relations between parties which could not provide their financial sources without DLT technology. Though, this process, e.g. peer-to-peer (P2P) based lending via Blockchain, allows potential lenders to make their capital available without interference of any central authority, that could be very beneficial for SMEs activity.

Therefore, such reasons for considering blockchain lending as way for enabling SME potentials could be discussed as:

universality (every participant of decentralized network, which is called nod, has no limited access to it, might perform some operations, but could not delete or remove anything that was added to the blockchain. Though, each nod could only add data to DLT after automatic approval by large number of other nods in the system. But some drawbacks also exist, which influence transparent concept of Blockchain, the anonymity of Blockchain users and sometimes elaborate process of smart contract execution can be underlined among them.

more complex than only cryptocurrency (Ethereum Blockchain is presented by open software program based on the blockchain protocol which allows to create various decentralized applications with the possibilities of practical usage for every stakeholder. So, smart contract execution via Ethereum Blockchain exclude any intermediary participation, when the decentralized application performs review, validation and authentication processes).

- decentralization (Every traditional bank is controlled by central one which in its turn is controlled by government and so on. Blockchain works without any central server control. Proof of validity is confirmed by the existent nods. Every transaction transfers through decentralized servers which allows exclude untrustworthiness).

Blockchain lending could be performed through smart contract execution, characteristics of which are shown at fig. 1.

Fig. 1 gives an analysis of potential benefits of SMEs by using Blockchain smart lending and possible consequences with detailed analysis of new market place for lending as specific platforms divided into centralized and decentralized ones.

But the problems, connected with public skepticism and mistrust towards lending systems performed via DLT, should not be underestimated. Despite this fact, it is business model innovation in which credit score of loan providers is influenced creditworthiness of decentralized network participants, confirming that it can be sustainable by using token-based approach.

Fig. 1: Characteristic features of Blockchain smart lending (formed by authors)

Blockchain use cases in bank lending

However, blockchain lending simplifies the process of credit obtaining, it could lead to total business redefinition, especially, for SMEs. It is especially important in the conditions, when banks are reluctant in getting credits to SMEs due to lack of collateral, proper credit history, profitability level.

For developing countries SMEs more often face to obstacles in access to finance (see table 1), which could be somewhat eliminating by blockchain technology usage.

Table 1: Causes of limited access to credit finance for SMEs

Factor	Explanation
Information asymmetry	exists between potential financial institutions or other bodies, that are ready to lend some money, and business owners
Higher risks	are connected with performing business on the small scale
High transaction costs	commissions of banks and other financial institutions could be too high for SMEs in credit obtaining
Lack of collateral	limited possibility for SMEs to fit the bank requirements in case of providing relevant collateral

According to table 1 such factors as information asymmetry elimination and reduction of transaction cost level could be reached by usage of blockchain lending exemplified as business owner simplification of retrieval potential lender between existing blockchain nodes, which increase transparent level by providing clear conditions for credit obtaining which SMEs could easily identify as are favorable for them or not.

According to one of the leading Blockchain lending platform “WishFinance”, presented by Fintech company from Singapore, declares that Blockchain technology makes each loan transparent and simplifies the securitization process for investors and regulators [3]. In addition, the mentioned platform offers loans for business with fair interest rates based on indicator of net cash-flow and has instant access to POS terminals with data about all financial transaction and participants of local marker aimed at scoring conducting.

As the other example, that confirmed the fact that blockchain lending could be successfully performed, could be considered the British multinational bank Barclays. The mentioned bank established blockchain accelerator within which blockchain-backed credit transactions between Ornua and Seychelles Trading Company established have been performed [5].

Though, implementation of blockchain technology into banking and financial services could be beneficial by creating more responsive and flexible infrastructure. Santander, Spain’s biggest bank, estimates that implementing blockchain technology could save the financial industry up to $ 20 billion per year [7].

But, despite all potential benefits of Blockchain usage into banking services, central banks and official monetary frameworks do not often integrate DLT in the banking, which would lead to creation of new funding forms named blockchain consortiums or syndicates.

Market Analysis of Blockchain Lending Platforms

It is also possible to create syndicated loan market, based on blockchain technology, as the example of which collaboration of Credit Suisse, Symbiont, R3, and Ipreo could be considered [8]. Such international banks as BNP Paribas, BNY Mellon, HSBC, ING, Natixis and State Street initiated the blockchain platform aimed at providing syndicated loans, namely Fusion Lender Comm by Finastra [9].

Characteristic features of Fusion LenderComm include following [10]:
Cooperation between potential lenders and agents (banks) that lead to efficiency improvement, risk and cost optimization, time-efficiency and increasing transparency in syndicated lending;
Data accuracy allows to all parties have immediate access to information connected with all transaction;
Possibility for lenders to choose the agent bank according to their requirements;

Agents reduce all manual actions receiving data base of potential lenders in a syndicated lending that allow to achieve significant cost reduction;

Traders have the possibility to gather all required information for making their decisions smarter.

Other example of lending in financial services could be esteemed the platform Traxia which allows to get money through blockchain technology without any banks [6].

BTCjam [11] was represented by trading platform with services of lending and borrowing using bitcoin. This market place provides its users such gains as high IRR, being intermediary between lenders and borrowers, proper credit verification. From 1th of July 2018 it closed the activity with new loans, but from 2012 to 2016 more than 20,600 of loans were serviced in 122 countries with total value more than 64,000 Bitcoin loaned.

The other lending platform which should be considered is BitBond [12] because of its focus on borrowing to SMEs in Bitcoins. The key competitive elements are observed as follows: transparent pricing (the online calculator for estimating further interest rates and fees), low fees, free-of-charge membership in BitBond, interest rates are from 1 % per month. Till the current moments KPIs could be assessed like more than 165,000 users and 3,200 loans with total value more than 15 mln USD from over 120 countries.

The miscellaneous case of cryptocurrency lending is offered by BTCLend [13], presented by an application for pre-paid subscribers in order to get access to available loans for their account according to the rating based on repayment history based in the mentioned platform. BTC Lend loans also could be used for voice calls, data/Internet and sending SMS. The number of loans is unlimited for subscribers, but in case of negative user balance, e.g. unpaid previous loan, this option is closed till the moment of full credit repayment.

Loanbase [14] was created in Latin America aimed at SME support by providing direct lending to them. The advantages of the mentioned lending platform are cloud-based Big Data integration and real-time credit-scoring, that fostering decision-making about loan disbursement and allows to perform almost immediately.

The successful example of P2P lending performing via Blockchain is BTCPOP [15], which offers Instant Loans, Investment Pools, Collateral Tied Loans, etc. Along with this such services as saving accounts with 5% interest rates, ability to IPO initiation and BTC raise are integrated into platform tool range.

Along with the mentioned Bitcoin lending market place there are a lot of lending platforms with credit distribution in other cryptocurrency like Ethereum, Monero, Litecoin, etc.

For instance, ETHLend [16] is the unique lending platform, in which credit guarantee is presented by the borrower` digital assets, e.g. cryptocurrency. In other words, cryptocurrency act as collateral through smart contract execution. Minimal interest rate is 3 % per annum and possible duration is up to 1 year without any fee.
The other exemplification of Blockchain lending platform is CoinLoan [17], which is licensed as financial institution in Europe that presented as guarantee subject and insurance to fund safety. CoinLoan plays custodian role between potential lenders and borrowers, that allow to choose the most preferable mean of collateral, e.g. fiat money, stablecoins or cryptoassets; the option of loan issuance form in such

case providing high level of security for loan repayment. Unlimited boundaries as global coverage and currency diversity should be also underlined among the advantages of Coin Loan.

Additionaly to the considered platforms, there is a set of centralized and decentralized platforms aimed at providing Blockchain lending.

Platform “SALT-lending” [23] has its own token “Salt” based on Ethereum in order to provide additional collateral regarding interest rate and repayment reduction. This platform is focused on blockchain-backed loans amounted from 5,000 USD each with percentage rate starting from 5,99 per annum on perspective from 3 to 36 months with comparatively high LTV level and without any pre-payment fee. The indirect dependence between interest rate and loan term is explored, which means that with increasing the loan term the interest rate decreases.

Besides, this marketplace provides security and insurance with high level storage system of collateral and multi-signature verification; notification system and mobile application with access to all types of updates, concerning personal accounts and collateral wallets.

BlockFi [24] is akin to Salt because of providing loans in USD, but in addition provide services for management of digital assets via such offers as Bitcoin loans or interest account services or data base of registered lenders and borrowers.

Loans are mainly on short-term perspective (up to 12 months) and interest rates start from 4,5 % to 50 % loan-to-value ratio. The service as cryptocurrency deposit also exists in this platform with interest rate up to 6,2 %.

Moreover, BlockFi secures its loans by Gemini (trust company in New York), regulated by the New York Department of Financial Services, which increase the reliability of the platform and could be considered as the benefit from potential borrowers` and lenders` point of view.
\
Dharma Lever [25] is decentralized lending platform based on Ethereum presented by special marketplace with set of conditions for lenders and borrowers in order to make the most feasible choice. Dharma platform functions without own token, but works with Ethereum and such stablecoins as DAI and USDC.

The platform, which should be also considered as one of the widespread one, is Compound based on Smart contract execution on Ethereum protocol. Like in previous platform, namely Dharma, users can establish set of conditions as from lending as well as from borrowing side. The level of collateral should exceed borrowing value at rate 150 %.

So, the analysis of existing Blockchain lending platforms confirmed that such marketplaces provide SMEs with unique opportunity to find potential lenders and provide collateral in cryptocurrency ensured by stablecoins.

Essentials of Blockchain smart lending

As it was mentioned, the required block for safe cryptolending is presented by stablecoins which are a cryptocurrency with a stable or constant value over time in order to avoid potential loss in value fluctuations. In many cases, it could be tied in value to a stable fiat currency such as the USD.

But, sometimes, currency backed stablecoins could be used. One of the most widespread examples is Tether [18] which based on value keeping mechanism as every 1 issued or circulated Tether equals 1 USD in the ownership of the Tether organization. So, it means that buy out of Tether is equivalent to 1 USD, in other words, company should have the reserve in 1 USD for every token in circulation.

The potential risk of stablecoin system usage is the lack of decentralization, which is typical for Blockchain and cryptocurrency. It is the responsibility and control of organization, which is in charge of

stablecoin issue. And if reserves are not so reliable as it is required and their value fall down it leads to collapse of their stablecoin supply.

There are other stablecoins backed by traditional fiat currencies, namely USD Coin, TrueUSD, Paxos Standard and Gemini Dollar [19].

Along with the weaknesses of centralized stablecoins, there is potential need to use decentralized ones aimed at exclusion of any human control or interference trough programming execution.

The basis of this stablecoins` type is smart contracts execution, which allows to keep the coin value in constancy. Decentralized stablecoins are not dependent on actions of facilitators, managers, auditors and hold the coin price at steady level relied on smart contract code program functioning.

The most popular decentralized stablecoin, based on Ethereum, is DAI [20], created by organization "MakerDAO". The 3 KPI are the basis of the DAI stability as:

- security (each DAI is backed by different value assets. The diversification of company collateral portfolio allows to guarantee every DAI value by multiplying assets;
- transparency (the information about the collateral backing type for every DAI is easily available and accessed to everyone);
- resiliency (in extreme case, the system is to activate emergency disconnection in order to keep the stable price).

In spite of significant drop in Ethereum price at about 90 % in December 2017 and supply growth of DAI, it has been kept his stable ratio to dollar as 1 DAI equals 1 USD. This statement is confirmed by DAI price and other indicators shown in fig. 2-3.

So, in spite of increasing trend of the circulation of more than 364 mln DAI coins and a lot of DAI holders, the DAI price is determined about 1 USD with maximum value 1,09 USD and minimum 0,95 USD. This trend confirms that no dependence between DAI price and Ethereum price exists despite the fact that DAI is based on Ethereum platform.

Fig. 2. DAI price, USD [21]

Dai Price	$1,01 USD
Dai ROI	1,41%
Market Rank	#34
Market Cap	$369 046 748 USD
24 Hour Volume	$18 996 795 USD
Circulating Supply	364 862 583 DAI
Total Supply	365 392 445 DAI

Fig. 3. DAI statistics [22]

Therefore, the decentralized stablecoins could be reliable collateral in case of Blockchain lending. Besides, for performing Blockchain lending it essential to issue new DAI, made through Collateralized Debt Positions, which are called CDPs. Every borrower could open CDP by blocking Ethereum as pledge and perform DAI withdrawal as debt. The ratio, in which it is possible to borrow, is at a minimum 150 % borrowed DAI in the CDP as Ethereum collateral.

This ratio indicates that for every 1 USD borrowed, user need to have 1,5 USD in Ethereum locked as the subject of pledge. In case of DAI amount repayment, borrower returns the locked Ethereum minus system fee.

So, the scheme of CDP usage does not eliminate the risk of significant price drop of Ethereum, but transparent system allows to check liquidity or state of each CDP.

The other element which is used for decentralized lending is MKR which is assumed as a governance token used for paying system fee in process of CDP repayment, after that MKR token is liquidated. This feature indicates that increased demand for DAI and CDP leads to increase in MKR request and in case of CDP repayment via verse process.

The other option of MKR is to provide sustainability to Blockchain lending system, if the collateral is not sufficient, new MKR tokens are issued and sold automatically in that way reducing their price. Thereby, all the mentioned components of smart blockchain lending could provide safety and reliability of borrowers to lenders and to offer borrowers unique opportunity to provide collateral in cryptocurrency which is almost impossible in traditional bank lending.

Blockchain lending in regional smart specialization

Taken into account the fact, that SMEs in many cases have limited access to finance, especially in obtaining credit resources. So, forming infrastructure for P2P lending availability and establishing regulation for Blockchain lending platforms should become the key priorities in strategies implementation on different levels.

As well known, regional smart specialization is regional result-oriented strategy mostly focusing on innovation and enhancing existing potential of region.

Blockchain-technology could be considered as potential innovation by its integration into financial services that might simplify the procedure of transaction execution, automatization of different processes and providing time- and cost-efficiency. In addition, Blockchain technology open access to P2P lending which is almost impossible in traditional financial services.

Therefore, forming conditions for improving access SMEs to FinTech into services, especially in simplification their access to finance should become one of the main task in action plan for implementation of each regional Smart specialization strategy. This relief could be achieved through development of Blockchain lending infrastructure and its regulation as for CoinLoan and BlockFi.

The regulation of such kind of lending platforms could eliminate potential risks of mistrusting, money laundering and other types of any fraud.

Conclusions

The conducted analysis confirmed the statement that one of the possible solutions for improving procedures of getting finance by SMEs could become Blockchain lending, which exclude all bureaucratic processes of providing almost all company documentation and exploitation diametrically opposite objects as collateral than in traditional lending, exemplified as fiat currency, cryptocurrency, stablecoins, etc.

Blockchain lending platforms with main focus on smart P2P lending could simplify procedure of getting credit by SMEs; offer favorable conditions regarding profitability level, low commission fees and credit termination; give possibility to choose the most appropriate credit variants on the market; stipulate ability to provide collateral in cryptoassets; render possibility to ensure digital assets; have an option of easily seeking potential creditors, etc.

But, apart from potential benefits of getting credit financial resources via smart lending platforms, some potential risks should be observed as lack of governmental regulation in case of fraud and money laundering, probability of scam activity from company-facilitator or administrator of such types of platforms, lack of due diligence for assessment financial condition of these platforms.

Instead, in this context the role of regional policy should not be underestimated in case of establishing some set of rules for regulation platforms` activities for avoiding risks of swindle activities. In this case regional smart specialization should become the tool for elimination the mentioned risk.

So, the following research, concerning issues of widening involvement SMEs in FinTech through getting finance by Blockchain lending, will be developing the methodology of assessing the reliability of such types of platforms in order to eliminate risk of mistrusting and improve underfunding level for SMEs.

The Concept of the Method for Forecasting the Life Cycle Costs of Technical Objects Supporting the Process of Making Purchasing Decisions

Izabela DZIADUCH

Wrocław University of Economics, Wrocław, Poland
izabela.dziaduch@ue.wroc.pl

Abstract

The level of exploitation costs to be covered by the user of a technical object depends, to a great extent, on the accuracy of the investment decisions made. The selection of the optimal investment decision (i.e. the purchase of a technical object) in terms of how much to invest in order to obtain the highest possible savings over the technical object lifetime should be based on the life cycle cost analysis (LCCA), which covers, e.g., the costs related to an object purchase and its exploitation.

The literature on LCC is quite abundant. Articles, monographs, norms and standards present different scopes of this analysis and indicate the industry sectors it is applied in. It should be emphasized, however, that there are still no scientific studies related to LCC estimation considering the variability of exploitation costs of a technical object over time resulting from gradual changes in the object parameters caused by the processes of technical wear, apart from few exceptions. Therefore, the article describes a method aimed at solving the aforementioned problem and becoming a tool facilitating rational purchasing decisions (a buyer will be able to find out the technical object's estimated life cycle cost at the time of its purchase).

The developed method applies econometric modelling, probability distributions and certain elements of descriptive and mathematical statistics. In the method, while estimating cost parameters, the central tendency values and the values of lower and upper quantiles are used, which allows estimating costs in three variants: the expected variant (e.g. modal), the optimistic variant and the pessimistic one.

Keywords: Life cycle cost (LCC), exploitation cost, purchasing decisions.

Introduction

The decisions about purchasing a technical object[1] are usually made based on the investment cost criterion, i.e. its price. Technical objects are characterized by a long lifetime[2], which requires taking into account the total costs incurred for the object maintenance during its lifetime, which include: acquisition costs, exploitation costs and decommissioning costs (McKenzie, 1978; White and Ostwald, 1976). Therefore, it is important that the decisions about purchasing technical objects are preceded by an economic calculation based on which a decision-maker can obtain information whether a given investment in an object purchase is effective (profitable) or not (Dziaduch, 2017).

The subject literature offers many measures estimating cost-effectiveness of an investment. The analysis based on the life cycle cost methodology is a comprehensive measure combining the cost data related to the acquisition, exploitation and decommissioning of a technical object (Legutko, 2004; PKN, 2005; Woropay, 1996). The issue of LCC analysis in the effectiveness assessment of a technical

[1] The term technical object (exploitation object) refers to products serving as a tool for transforming (moving or processing) matter, energy or information. This term is usually used to describe machines, devices and means of transport.
[2] Lifetime (exploitation period) is the period of time from putting a technical object into operation until it reaches the limit state.

object is quite well recognized in the subject literature, yet the problem of estimating its value remains to be solved. It is most difficult to estimate the exploitation costs of a technical object to be incurred by a user during its lifetime. These costs can be broken down into three basic cost categories (Adamkiewicz, 1983; Dietrich et al., 1999; PKN, 2005):

- damage costs including, e.g., costs of restoring the object's serviceability (in other words repair costs, corrective maintenance costs), penalties resulting from the object's unavailability for operation and the loss of revenues caused by the unplanned interruption of operation;
- preventive maintenance costs, which include the costs of performing preventive maintenance services (inspections and the related repairs) and also, if necessary, the loss of revenues resulting from the planned interruption of operation;
- operation costs i.e. the costs incurred in the course of operation (use) of an object, which include e.g. costs of energy consumption (e.g. fuel, diesel), labour costs of employees using the object.

In the existing research studies and publications, the measurement of exploitation costs related to a technical object is based on fixed parameter values, such as, e.g., damage intensity, propellant consumption, duration of preventive maintenance, etc. These parameters, however, do not represent determined values, but random variables. Referring to this problem, the purpose of the article is to develop the concept of a method aimed at forecasting the exploitation period costs taking into account the variability of costs over time, resulting from the gradual changes in the object parameters caused by the technical wear processes.

The proposed method consists of 10 stages. This method applies econometric modelling, probability distributions and certain elements of descriptive and mathematical statistics. The core idea of the method consists in forecasting the exploitation costs on the basis of the central parameter value and the value of its upper and lower quantiles providing the possibility of estimating costs following three variants: the expected (e.g. modal) variant, the optimistic variant and the pessimistic one.

If the purchase price of a technical object is added to the exploitation costs estimated using the developed method, then the total life cycle cost is obtained, which may be taken into account during the purchasing transactions of a technical object. This will allow selecting, from among several competitive technical objects offered by the industry which meet the same technical requirements, the one most economically effective, i.e. the cheapest in the long term perspective.

Related Works

Currently, the subject literature presents several dozen models and methodological approaches referring to estimating individual categories of technical object exploitation costs used in the LCC analysis.

The conducted analysis of the available publications, discussing the LCC analysis, shows that:

- the basic components of operation costs cover the costs of energy consumption (e.g. fuel, diesel) and also the labour costs of employees using the object;
- the average unit parameter values resulting from the analysis of previous years are adopted in the calculation of operation costs (e.g. average cost of energy consumption per time unit, average cost of human labour per unit of time, average purchase price of an energy unit and average energy consumption per time unit);
- operation costs depend on the value of the technical object readiness index (Dhillon, 1996; Kumar et al., 2004);
- operation costs are calculated on an annual basis and next multiplied by the number of years of the object operation or for the entire life cycle of the technical object.

In turn, the literature review addressing cost calculation methods for preventive maintenance in the LCC analysis results in the following observations:

- the basic cost component for performing preventive maintenance is the number of such maintenance processes performed, human labour cost and the cost of consumables and/or spare parts used in the course of planned maintenance;
- different categorizations of preventive maintenance can be identified – first of them take into account the type of element subject to maintenance (e.g. PKN, 2005; Szkoda, 2008), second – the type of activities performed as part of the maintenance process (e.g. Hokstad, 1998), third – the level of preventive maintenance (e.g. Jong-Woon et al., 2009), fourth – the type of activities performed in the course of defined maintenance levels (e.g. Hinow et al., 2008);
- cost accounting is based on average parameter values resulting from the analysis of previous years (e.g. average cost of human labour per preventive maintenance, average cost of consumables and spare parts used to perform preventive maintenance);
- costs of preventive maintenance are calculated on an annual basis and next multiplied by the number of years of the object operation or for the entire life cycle of the technical object expressed in years.

The literature review shows that the authors have developed different methodologies for estimating individual cost components of performing preventive maintenance. For example, the studies: Jong-Woon et al (2009) and Kumar et al (2004), present how to estimate the number of preventive maintenance performed during the lifetime of an exploitation object, Dhillon (2007) describes the method for cost measurement of one hour of maintenance personnel work, whereas Ntuen (1985) offers the formula for calculating costs of logistic support for preventive maintenance.

In turn, the analysis of available publications on estimating the corrective maintenance costs in the LCC analysis shows that:

- the basic component of the costs for restoring an object to its operational serviceability after the occurrence of damage is the number of corrective maintenance, the cost of labour and the cost of spare parts used in performing unplanned maintenance work;
- the analysis of damages and their division is usually not performed,
- the LCC account is based on the average parameter values resulting from the analysis of previous years (e.g. average cost of corrective maintenance personnel work per unit of time (expressed in PLN/hour or PLN/man-hour), average wear cost of spare parts necessary to remove the damage);
- costs of corrective maintenance are calculated on an annual basis and next multiplied by the number of years of the object operation or for the entire life cycle of the technical object

The literature review also shows that the authors have developed different methodologies for estimating individual cost components for removing the damage. The number of observed damages during the technical object exploitation is most often determined based on the overall, constant intensity of the object damages (Dhillon, 2007; Jong-Woon et al., 2009; Jun et al., 2007; Hokstad, 1998; Monteith, 1984; Norsok 1996a; PKN, 2005). The restoration function was used to determine the number of corrective maintenance in the study Kumar et al (2004). In the opinion of Jun et al (2007), when estimating the cost of worn parts during corrective maintenance, the repairability index should be used, which takes the value of 1 – if all damages were removed by replacing the element or 0 – if the corrective maintenance was completed without the need of using spare parts. However, according to Dhillon (1996), the cost of corrective maintenance personnel work should depend on the average downtime of an object caused by damage and the average time till the damage occurrence, which should be described with an appropriate probability distribution. It is worth noting that in some studies the authors, when estimating corrective maintenance costs, do not take into account such cost parameters as labour cost and the cost of spare parts used in the course of performing unplanned maintenance work. The examples of such estimation methods can be found in the studies Frangopol et al (1997), Hinow et al (2008) and Ntuen (1985).

As the literature review shows, only a few studies analysed costs related to the damageability of a technical object, other than the corrective maintenance costs. The analysis of available publications addressing LCC shows that the costs related to damage also include the costs of production losses and the costs of penalties resulting from downtime, as well as the fact that both of these components are frequently identified with the generally understood downtime cost (PKN, 2005; Anders et al., 2005; Hinow et al., 2008; Norsok 1996a, 1996b; Parra et al., 2006; Parra et al., 2009).

The concept of the method for forecasting the exploitation costs of a technical object taking into account the variability of costs over time

As a result of the conducted investigation, followed by collecting and organizing information on life cycle cost estimation, it was proposed to use the calculation procedure consisting of ten stages for the purposes of cost forecasting.

The procedure starts with defining the division structure of an exploitation cost, i.e. the cost categories, cost components and the included parameters. The exploitation cost structure is described by the following correlation:

$KE = \langle K_A, K_{AB}, K_{ABS} \rangle$ (1)

where:

KE- the exploitation cost of an technical object,
K_A- a set of exploitation cost categories,
K_a- a-th exploitation cost category, where $a = 1,2, \dots, \mathrm{A}$,
K_{AB} - a set of components assigned to the set of exploitation cost categories,
K_{ab} - b-th component of a-th exploitation cost category, where $b = 1,2, \dots, B_a$,
K_{ABS} - a set of parameters assigned to the set of components of the exploitation cost category,
K_{abs} - s-th parameter of b-th component of a-th exploitation cost category, where $s = 1,2, \dots, S_{ab}$.

For example: operation cost represents one of the exploitation cost categories, energy consumption cost is one of the operation cost components, whereas the parameters of the above-mentioned component include, among others, energy unit purchase price, energy consumption per unit of time and operating time of a technical object per unit of time.

Stage 2 consists in collecting the data necessary to calculate s- th parameter included in b- th component of a- th exploitation cost category.

Stage 3 consists in defining the same length (span) of time intervals, $\Delta t^1 = \Delta t^2 = \ldots = \Delta t^D$, while $d = 1,2, \dots, D$, where d stands for the time interval number, whereas D represents the number of intervals. The range span is the difference between the upper t_g^d and lower t_d^d time interval value. The range is bounded top, with the upper limit in the given range being the same as the lower limit of the next range.

Stage 4 of the method covers calculating the mean value of s- th parameter included in b- th component of a- th exploitation cost category for d-th time interval:

$$\overline{k_{abs}}^{d} = \frac{\sum_{q=1}^{Q} k_{abs_q}{}^{d}}{Q^d} \quad (2)$$

where:

$\overline{k_{abs}}^{d}$ $\overline{k_{abs}}^{d}$- mean value of s-th parameter included in b-th component of a-th exploitation cost category in d-th time interval,

$k_{abs_q}{}^{d}$ - values of s-th parameter included in b-th component of a-th exploitation cost category collected in d-th time interval, where $k_{abs_q}{}^{d} = k_{ias_1}{}^{d}, k_{abs_2}{}^{d}, \ldots, k_{abs_Q}{}^{d}$,

Q^{d} - number of measurement values of s-th parameter included in b-th component of a-th exploitation cost category collected in d-th time interval.

The estimated mean values of the parameter are assigned at the upper limits of d-th time interval, i.e. t_g^d.

Stage 5 of the method is focused on analysing the correlation occurrence between time - Y and the mean values of s-th parameter included in b-th component of a-th exploitation cost category calculated in d-th time intervals - X. For this purpose, correlation coefficient estimator ρ can be used between the two examined attributes in the population, i.e. correlation coefficient from r sample (Greń, 1982):

$$r = \frac{\sum_{d=1}^{D}\left(x^d - \overline{x}\right)\cdot\left(y^d - \overline{y}\right)}{\sqrt{\sum_{d=1}^{D}\left(x^d - \overline{x}\right)\cdot\sum_{d=1}^{D}\left(y^d - \overline{y}\right)}} \quad (3)$$

where:

x^d - X variable value, i.e. mean values of s-th parameter included in b-th component of a-th exploitation cost category in d-th time interval,

y^d - Y variable value, i.e. time reflected by the upper limit of d-th time interval t_g^d,

$\overline{x}$ - arithmetic mean X variable,

$\overline{y}$ - arithmetic mean of Y variable,

D - number of observations, the same as the number of time intervals.

To verify the significance of the correlation coefficient, the hypothesis that X and Y variables are not correlated should be checked, i.e. null hypothesis $H_0: \rho = 0$, against the alternative hypothesis $H_1: \rho \neq 0$. Student's t-distribution for the predetermined α significance level and for $D - 2$ degrees of freedom shows $t_\propto$ critical value, so that $P\{|t| \geq t_\propto\} = \propto$. If the comparison of t value calculated based on formula (x), i.e.

$$t_{(\propto, n-2)} = \frac{r}{\sqrt{1-r^2}} \cdot \sqrt{D-2} \quad (4)$$

with $t_\propto$ critical value results in $|t| \geq t_\propto$ inequality, then H_0 hypothesis about the absence of correlation between the variables has to be rejected. However, when $|t| < t_\propto$, there are no grounds to reject H_0 hypothesis, that X and Y variables are uncorrelated.

In the case when it is unfounded to reject H_0 hypothesis, the theoretical distribution functions (stage 6) have to fit the mean values of s-th parameter included in b-th component of a-th exploitation cost

category defined for d-th time intervals. For the probability distribution fitting of X variable, any central tendency value should be determined, i.e. the expected value $E(X)$, modal value $M_o(X)$ or median $M_e(X)$ as well as the lower $F(x_q)$ and upper quantile $F(x_{1-q})$.

If there are grounds to reject H_0 hypothesis, the trend line (stage 7a) should fit the mean values of s-th parameter included in b-th component of a-th exploitation cost category defined for d-th intervals.

Stage 7b consists in examining the model compliance with empirical data using R^2 coefficient of determination (Dittman, 2003):

$$R^2 = \frac{\sum_{t=1}^{z}\left(\hat{x}_t - \bar{x}\right)^2}{\sum_{t=1}^{z}\left(x_t - \bar{x}\right)^2} \qquad (5)$$

where:

x_t - cost parameter value in t period,
$\hat{x}_t$- theoretical cost parameter value in t period,
$\bar{x}$- mean value of cost parameter in z time series.

In order to verify the coefficient significance, statistics F should be used to check (Dittman, 2003)::

$$F = \frac{R^2}{1-R^2} \cdot \frac{D-k-1}{k} \qquad (6)$$

where:

D - number of the dependent variable observations (the same as the number of classes),
k - number of predictor variables in the model excluding the variable with the intercept,

which has Fisher-Snedecor F distribution with $k_1 = k$ and $k_2 = D - k - 1$ degrees of freedom, whether the model is inconsistent with the empirical data, i.e. $H_0: R^2 = 0$ null hypothesis against the alternative $H_1: R^2 \neq 0$ hypothesis. If F value is smaller than $F_\propto$ from Fisher-Snedecor F distribution tables for the adopted $\propto$ significance level and also for $k_1 = k$ and $k_2 = D - k - 1$ degrees of freedom, there are no grounds to reject H_0 hypothesis, which means that the coefficient of determination is not significantly different from zero – the model fit to empirical data is far too weak. In this case, such a trend model of the analysed parameter should be found, for which F statistics can show a correlation occurrence between the data (stage 7a).

However, if the coefficient of determination is statistically different from zero, the lower $F(x_q)$ and upper quantile values $F(x_{1-q})$ of s-th parameter of b-th component of a-th exploitation cost category for each Δt time interval should be determined (stage 7c).

Next, in the course of stage 7d, the correlation occurrence between Y time and the defined lower $F(x_q)$ and upper quantile values $F(x_{1-q})$ should be analysed using a correlation coefficient estimator (formula (3)). The hypothesis can be verified using Student's t-distribution with $D - 2$ degrees of freedom. If there are no grounds to reject H_0 hypothesis, the theoretical distribution function has to fit the quantile values of s-th parameter of b-th component of a-th exploitation cost category (stage 7h).

For the fitted probability distribution of X_q variable any central tendency value should be defined. However, if there are grounds to reject H_0 hypothesis, the theoretical distribution functions have to fit the quantile values of s-th parameter of b-th component of a-th exploitation cost category (stage 7e) and the analysis (stage 7f) – using R^2 coefficient of determination (formula (5))– of the developed model compliance with empirical data has to be conducted. The assessment of correlations is performed by testing $H_0: R^2 = 0$ and $H_1: R^2 \neq 0$ hypotheses. The hypothesis can be verified using statistics which has Fisher-Snedecor F distribution with $k_1 = k$ and $k_2 = D - k - 1$ degrees of freedom. If there are grounds to adopt $H_0: R^2 = 0$ null hypothesis, then such a trend model of the analysed parameter such be defined, for which F statistics will determine the correlation occurrence between the data (stage 7e).

In the case when R^2 coefficient of determination is statistically different from zero both in stage 7b and 7f, then in the course of stage 7g the future value of s-th parameter of b-th component of a-th exploitation cost category is determined. This value is obtained by extrapolating the trend function, i.e. by substituting time variable in the model with t moment number or T period for which the forecast is prepared:

- for mean values:

$$x^*_T = f(T) \quad (7)$$

- for $F(x_q)$:

$$x_q{}^*_T = f(T) \quad (8)$$

- for $F(x_{1-q})$:

$$x_{1-q}{}^*_T = f(T) \quad (9)$$

Stage 8 consists in the estimation of cost components. The estimation of cost components is based on analytical expressions defined in the second part of the article or by the researcher. The cost component value estimated for the entire life cycle of T technical object, for which at least one of the parameters remains time dependent is equal to:

$$K_{ab} = \sum_{t=1}^{T} K_{ab_t} \quad (10)$$

Whereas the cost component value for the T entire life cycle of technical object, for which none of the parameters depends on time should be determined based on the following correlation:

$$K_{ab} = K_{ab_{t=1}} \cdot T \quad (11)$$

Stage 9 covers adding up the cost components included in a-th cost category:

$$K_a = \sum_{b=1}^{B_a} K_{ab} \quad (12)$$

Exploitation costs are calculated in stage 10:

$$KE = \sum_{a=1}^{A} K_a \quad (13)$$

Conclusion

The article presents the concept of a life cycle cost forecasting method, which allows capturing the variability of exploitation costs over time arising from the gradually changing object parameters caused by technical wear, based on analysing the occurring correlations between such technical parameters as, e.g., diesel fuel consumption or failure stream and vehicle exploitation time.

The core idea of the method consists in forecasting the exploitation costs on the basis of the central parameter value and the value of its upper and lower quantiles providing the possibility of estimating costs following three variants: the expected (e.g. modal) variant, the optimistic variant and the pessimistic one. The course of the cost curve depends on, e.g.:

- the number of cost categories adopted for the analysis;
- the number of components and cost parameters identified within their framework;
- service life intervals;
- the adopted exploitation time unit;
- the adopted central tendency measure and the confidence interval for the quantile values adopted in the calculations.

The method presented in the article allows, e.g.:

- estimation of exploitation costs in the adapted lifetime period of a technical object;
- comparative analysis of alternative procurement solutions (variants);
- selection of an economically viable object in terms of the lowest total costs (i.e. total purchase costs and exploitation costs).

The carried out literature review on exploitation costs' modelling allowed not only learning about the methods for measuring individual categories of technical object exploitation costs, but, above all, confirming the fact that there is no method which allows determining exploitation costs, taking into account their variability over time resulting from the gradually occurring changes in object parameters caused by the technical wear processes. This article provides a method which solves the above-mentioned problem. In order for this method to be used in practice, its verification is necessary, covering as follows:

- conducting reliability studies of exploitation objects to obtain data of a technical and economic nature;
- entering data into the method and calculating cost forecasts;
- assessing the correctness of the results.

Empirical verification of the method is the next stage of the research work to be carried out by the author of this article.

Abstract

Nowadays, scientists wanting to study a given research phenomenon more and more often use the case study method. Thanks to it, they obtain a comprehensive picture of the studied phenomenon, learn about the economic reality, thus identifying and solving problems faced by enterprises. Additionally, if during the case study, they use other research methods (e.g. individual IDI in-depth interviews), the formulated conclusions are very accurate and much more useful in practice. The aim of the article is to describe and characterize the possibility of using the technique of individual in-depth interviews (IDI) in a case study. The literature review of the issue under study was based on the method of systematic literature review, based on the methodology proposed by Tranfield, Denyer, Smart (Tranfield, Denyer, Smart; 2003). The authors conducted a literature review in three phases, preceded by the determination of the purpose of the study. The first phase included planning the review, the second phase is the proper conduct of the research procedure (this phase consists of five stages) and the last third phase of the preparation of the research report (Tranfield, Denyer, Smart; 2003).

Keywords: individual in-depth interviews, case study

Introduction

Many research methods and tools are used in management sciences. In recent years, however, there has been a clear increase in interest in the case study method. This is evidenced by chapters appearing in many monographs (e.g. David 2006a, Czakon 2006, Yin 2015) as well as scientific articles (e.g. David 2006b, Matejun 2011, Wójcik 2013, Mielcarek 2014). In comparison to the methods of quantitative research, popular method of case study, due to the fact that it provides in-depth analysis of the problem and discussed research issues. S. Sudoł emphasizes that "descriptions of individual cases showing examples of bad management and best solutions or practices allow to provide organizations or managers with proposals for solutions to management problems for their practical application" (Sudoł 2007).

Carrying out a case study is a difficult and long-term process , requiring compliance with methodological rigor. When applying the discussed method , one cannot afford to be fragmented in activities. Only a holistic view of the studied phenomenon enables an objective view and planning of precise actions aimed at the best solution to research problems.

Individual In-Depth Interviews (IDIs) are increasingly used to carry out a detailed case study. IDI research is usually used as a supplement to other research methods - it aims to deepen the knowledge about the studied phenomenon and better observation of the respondent. Therefore, it allows, among others to reach the emotional and motivational patterns of the examined entity.

Cite this Article as: Iwona WASIELEWSKA-MARSZAŁKOWSKA and Katarzyna SAMEK“ Use of Individual In-Depth Interviews (IDI) In Case Studies - Theoretical Background” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

For example, Escher, Brzustewicz (2020) use IDI in a case study undertaking research on sport issues in employee volunteering programs. The combination of different research methods (case study analysis and IDI) in management sciences is not accidental. The literature emphasizes that in the implementation of scientific research it is useful to combine various research methods and techniques (Stanisławski, 2017). Especially with regard to those sciences in which the knowledge of scientists with various research interests and from various scientific disciplines is used. This phenomenon is quite popular, especially in management sciences (Stanisławski, 2017).

The essence of case studies in management sciences

Case study analyzes in management sciences often supplement previous surveys and expert studies. Carrying out such an analysis enables an in-depth exploration of what quantitative research can only suggest. In the literature on management sciences, we can distinguish three goals that case studies serve - theoretical , theory-testing and practical (Fig. 1).

The first goal - theoretical

- enables the development of an existing theory and the explanation of phenomena that have not been explained yet.

The second goal - to test the theory

- it is testing an existing theory - it is mainly about determining the conditions under which a given theory proves itself, but also its falsification.

Third goal - practical

- has a practical and training character. It is mainly used to understand the course of the decision-making process in an organization, carried out under specific conditions.
- this forms the basis for the use of the case study to make managerial decisions in conditions similar to those presented in the case study. This case study is of an application nature.

Figure 1: Case studies objectives

Source: own study based on W. Czakon (ed.), Foundations of research methodology in management sciences, Oficyna a Wolters Kluwer business, Warsaw 2011, pp. 46–54.

The first goal, theoretical, makes it possible to develop the existing theory, provides explanations for hitherto unexplained and unrecognized phenomena, and makes it possible to understand the course of processes over time. The second goal, referred to in the literature as testing the theory. Contrary to the beliefs of verifying, testing a theory consists mainly in its falsification. You cannot prove the truth of the theory by empirical methods. It is justified to investigate, indicate or illustrate the circumstances in which a given theory does not work. The third goal of the case study is aimed at practical implication. Case studies are carried out to achieve this goal, they are illustrative, training and inspiring in nature (Czakon, 2016).

Moreover, some researchers indicate several aspects in which the use of the case study method is justified (Yin, 2014, p. 9-11; Eisenhardt, 1989, p. 547-548):

- there is little knowledge about the phenomenon,
- the available cognitive perspectives seem inappropriate due to insufficient empirical justification,
- available knowledge is marked by contradictions,
- looking for answers to questions like? or why? a given phenomenon occurs,
- the researcher has a very limited ability to control variables (events, circumstances) due to their location in the real context,
- the aim of the process is to study the phenomenon in its real conditions of occurrence (Donajewska, 2016).

It should also be emphasized that in management sciences, due to their close relations with practice, case studies enable the study of real economic phenomena (Grzegorczyk, 2015).

Vissak conducted a comprehensive analysis of the strengths and weaknesses of the application of case studies in management science research, presented in Table 1. A balance of strengths and weaknesses of the case studies (Vissak, 2010 [in:] Donajewska, 2016).

Table 1: Strengths and weaknesses of the case studies

Strengths	Weaknesses
popularity in many scientific disciplines,	underestimated and rarely used as a method of scientific research,
higher response rate than in the case of surveys,	allegation of a low degree of "scientific",
useful for creating a new theory and for criticizing or refining an existing theory,	low acceptability of case study results in prestigious magazines,
enable the explanation of new, complex and dynamic aspects of the organization's activities,	difficulty in interpreting the results,
appropriate to get answers to questions like? and why? concerning the cycle of events in the organization,	high time and labor consumption of research,
enable a holistic view of events and processes in their real context,	unsuitable for researching large groups,
enable the simultaneous conduct of qualitative and quantitative research,	difficulty in defining statistically true generalizations,
high flexibility of the process for the researcher (multiple feedback).	difficulty in obtaining confidential data in organizations - deliberate concealment of information by survey participants,
	the risk of bias and subjectivism of the researcher.

Source: own study based on Vissak (Vissak 2010, p. 379).

There are many definitions of case study analysis in the literature. T. Kaidesoja understands case studies as empirical research in which one or a small number of cases is thoroughly investigated using various data sources (Kaidesoja , 2018). On the other hand, J. Gerring stresses that the case study is probably best understood as an ideal type, not the methodswith hard and fast rules (Gerring, 2004). Schramm emphasizes that the essence of the case study, the main tendency of all its types, is to explain decisions: why they were made, how they were implemented and with what effect (Schramm, 1971). Case studies as a tool for theory generation and testing have provided management field strategy with groundbreaking insights (eg. Penrose, 1960; Chandler, 1962; Pettigrew, 1973; Burgelman, 1983). The case study method is prone to concerns about methodological rigor in terms of validity and plausibility (eg, Campbell, 1975; Miles, 1979; Daft and Lewin, 1990; March et al ., 1991; Yin, 1981).

Case study research is a form of empirical inquiry that investigates a contemporary phenomenon in-depth and within a real-life context, through circumscribing the area of study to a single or to a small number of units (Farquharab, Michelsc, Robsond 2020). Also vase Study research is characterized by the employment of multiple data gathering methods (Zahle, 2018).

Yin, Eisenhardt, (Yin, 1994; Eisenhardt, 1989) indicate that's studio cases are considered the most appropriate as a tool in the critical early stages of new management theory, when the key is tested variables and their relationships.

It should also be noted that the case studies are usually carried out in interaction and practices, who are practitioners cope with real management situations. Hence, case studies represent a methodology that is ideally suited for creating manageable solutions knowledge (Amabile et al., 2001; Leonard-Barton, 1990). Table 2 provides selected definitions case study method indicated in the publication ah different years.

Table 2: Summary of case study definitions

Author	Definition
KM Eisenhardt (1989, p. 534)	"A case study is a research strategy that focuses on understanding the dynamics that exist in specific conditions"
RE Stake (1995, p. Xi)	"Study of the singularity and complexity of a single case, leading to an understanding of its operation in relevant circumstances"
JW Creswell (2007, p. 73)	"A case study study is a qualitative approach where the researcher explores a specific system (case) or multiple specific systems (cases) over time through detailed, in-depth data collection covering multiple sources of information (e.g. observations, interviews, audiovisual material, documents, reports) and reports on the characteristics of the case and related topics "
JF Hair et al. (2007, p. 417)	"It focuses on collecting information about a specific event or activity, often a specific company or industry"
P. Erikkson and A. Kovalainen (2008, p. 303)	"A predominantly qualitative research approach where one or several cases (people, organizations, processes) are examined holistically in their social, economic and cultural contexts"
J. Blatter (2008, p. 68)	"A research approach in which one or several occurrences of a phenomenon are studied in depth"
DR Cooper and PS Schindler (2008, p. 700)	"A methodology that combines individual and (sometimes) group interviews with data analysis and observation, used to understand events and their consequences and processes, emphasizing the full contextual analysis of several events or conditions and their relationships for a single participant, type of pre- experimental research (one - shot case study)"
J. Dui and T. Hak (2008, p. 19)	"A study in which one case (single case study) or several cases (comparative case study) in their real context is selected and the results obtained from these cases are analyzed according to a qualitative approach"
H. Simons (2009, p. 21)	"In-depth study from different perspectives of the complexity and uniqueness of a specific project, policy, institution, program or system in a real context"
M. Saunders , P. Lewis and A. Thronhill (2007, p. 558)	"A research strategy that includes empirical research of a specific contemporary phenomenon in a real context, using multiple data sources"
G. Thomas (2011, p. 513)	"Case studies are analyzes of people, events, decisions, periods, projects, policies, institutions, or other systems that are investigated holistically using one or more methods. The case which is the subject of the research will be an instance of the phenomenon class that provides the analytical framework - the subject - within which the research is conducted and the case is explained and discussed"
E. Babbie (2011, p. 503)	"In-depth study of a single occurrence of a given phenomenon"

Source: M. Ćwiklicki, A. Urbaniak, Case study in management sciences, Publishing House of the University of Economics in Krakow, Krakow 2019, pp . 12-13.

The case study study has several characteristics (Zahle, 2018):

- the object of analysis is a single unit or several such units;
- detailed data that covers various aspects of the unit (s) are collected through multiple data collection methods;
- the end product is an in-depth case study.

The case study method has many advantages. Firstly, the correct conduct of the study using this method allows for an accurate presentation of the studied phenomenon. Secondly, it enables a thorough explanation of the sources of the analyzed situation and the factors influencing it. Third, a case-study study is based on more durable and deeper relationships between the researcher and the studied entity than in the case of quantitative research methods (Matejun, 2011).

It is also credited with disadvantages, such as labor- consumption, low objectivity and cost-effectiveness (Tsey, Lawson, Kinchin, Bainbridge, McCalman, Watkin, Cadet-James, Rossetto,2016). Moreover, the case studies are alleged to lack scientific reliability and the lack

of objective grounds for drawing conclusions. Critics point to the fact that using this method it is not possible to draw conclusions, because the studied units are only part of a larger community (Wójcik, 2013).

The case study uses individual in-depth interviews (IDI). The case study interview follows the delineated line, but it is flexible and allows for modifications (Rubin, Rubin, 2011). This type of interview is called "intensive interview", "in-depth interview" or "casual" (Weiss, 1994).

S. Kaczmarczyk emphasizes that the individual in-depth interviews (ang. (Individual in-Depth Interviews) are direct, personal interviews, which are conducted by professional interviewers with individuals who agreed to be interviewed (respondents). Kaczmarczyk NK Denzin and YS Lincoln present the broad specifics of individual in-depth interviews, according to them, the interviews are "an individual conversation between the moderator and the respondent, during which the issues contained in the scenario, previously agreed with the client, are discussed. Questions are open, and their order and method of asking depend on the moderator the respondent has the opportunity to fully express his feelings, beliefs or explain the motives of the conduct (...). The transcript from the study is the basis for the preparation of a detailed report " (Denzin, Lincoln, 2009). In turn, according to C. Boyce and P. Neale, this interview is qualitative. a technique that involves conducting intensive interviews with an individual among a small group of respondents in order to obtain their personal opinions on specific issues (Boyce, Neale, 2006).

The literature also indicates a number of features that characterize an individual in-depth interview. R. Miński includes these (Miński, 2017):

- direct contact between the interviewer and the interview participant,
- more or less structured interview scenarios,
- open nature of questions,
- recording the answers of the interview participant using e.g. a dictaphone,

An individual in-depth interview has advantages and disadvantages. The advantages most often include providing insightful data, ensuring a friendly atmosphere influencing the freedom of expression of the interview participant, the interview participant's sense of security as a result of direct interaction, the possibility of stimulating the interlocutor to answer and constant monitoring of the information obtained. On the other hand, the shortcomings include, first of all, the need to train interviewers, the requirement to carefully select interview participants, time-consuming and costly (Miński, 2017).

IDI in the Case Study

George Gaskell formulated the metaphor of an in-depth individual interview as "a conversation between two (or more) friends" (Bauer, Gaskell, 2000), which largely reflects the nature of the method itself and says a lot about the role of the researcher and the respondent in the research situation. However, it should be remembered that not every conversation and not every interview meets the methodological requirements of IDI (Bauer, Gaskell, 2000).

Zaharia Rodica Milena, Grundey Dainora, and Stancu Alin (2008) argue that an in-depth interview is a technique designed to elicit a vivid picture of the participant’s perspective on the research topic. During in-depth interviews, the person being interviewed is considered the expert and the interviewer is considered the student. The researcher’s interviewing techniques are motivated by the desire to learn everything the participant can share about the research topic. In depth interview is an effective qualitative method for getting people to talk about their personal feelings, opinions, and experiences. It is also an opportunity to gain insight into how people interpret and order the world.

The literature indicates that Individual in-Depth Interviews (IDI) should be conducted in 5 stages, as shown in Figure 2. In the first stage, **a strategy for selecting IDI participants should be developed**. K. M. Eisenhardt (Eisenhardt, 1989) indicates that the number of cases under study should

be in the range from 4 to 10 (cases) as a number appropriate for the case study, i.e. allowing for scientific conclusions. However, it should be borne in mind that the sample size in any research project will never be large enough to be used for statistical inference.

Figure 2: The steps of the implementation of depth interviews individual (IDI) in a test case (a case study)

Source: The Wallace Foundation, Conducting In-depth Interviews, Workbook E, website: http://www.wallacefoundation.org/knowledge-center/Documents/Workbook-E-Indepth-Interviews.pdf., [Retrieved July 19, 2019].

In the second stage should be **developed ay scenario of individual in-depth interviews** and a questionnaire interview. The selection of such different research tools as emphasized by MQ Patton (Patton, 2002) and SB Merriam (Merriam, 1998) will provide an appropriate answer to the research question and the issue raised in the study. Moreover, J. Gerring points out that case studies are carried out using methods such as individual in-depth interviews with the use of interview questionnaires (Gerring, 2004). Properly constructed scenario depth interview, (Minsk, 2017) consists of three elements:

- the measuring and recording part;
- a part containing information on issues that should be raised with the respondent along with exemplary forms of questions;
- the summary part.

Sometimes the interview scenario is extended with the information part, on which the respondent signs, agreeing to record the interview. The scenario of the individual in-depth interview should meet the following criteria:

1. contain specified topics on which information is sought;
2. not be too restrictive just to maintain the conversation, giving the respondent control over reporting his own experiences;
3. contain questions that evoke extensive (even effusive) answers;
4. contain clearly formulated and neutral questions (not suggestive);
5. contain a logical arrangement of questions (from general to specific).

As part of the third stage of carrying out the analysis of a case study with the use of an individual in - depth interview - **conducting an interview -** the interview should be conducted with direct research participation in the form of open questions addressed to persons representing the enterprise subject to the study. The literature indicates that the average interview time is 60 minutes. , it is stated that it is sufficient time for the respondent to speak freely (Boyce, Neale, 2006) .

Taking into account the fact that in-depth interviews require transcription, the obtained answers should be recorded - recorded on a dictaphone[1].

Steinar Kvale (2010) notes that the very transcription of interviews is not only a way of writing down the spoken word, but also a process of interpretation. Writing is a way of "remembering" to which one can return easily and objectively (Miński, 2017).

Even the best trained researcher is not able at the same time: to lead the interview, take notes and record the exact statements and reactions tested ... ". Interview transcription is one of the key elements of the entire study - it is to provide the researcher with text material necessary for further analysis of the research problem (Miński, 2017).

Transcription is therefore a necessary element, at least in the traditional form of recording interviews, but also causing specific difficulties - especially if it is performed by "subcontractors". Kvale indicates that an important methodological issue is not only the preparation of instructions for transcribers, their selection or training, but also stating in the final report how the transcription was performed (Kvale 2010, p. 157; Miński, 2017).

These activities constitute the fourth stage of the study, i.e. **the transcription of the interview**. The last stage of the research with the use of IDI is **data analysis**. It is important at this stage to check whether the obtained information is complete and meaningful. Moreover, it is necessary to read and listen to the transcripts of interviews many times in order to capture insights relevant to the research.

It is no less important to select information and segregate it, e.g. Miński indicates that the most popular segregation strategies are segregated by questions or segregated by topics (Miński, 2017). Silverman emphasizes that the key to the analysis of qualitative data is the status given by the researcher to the data obtained from the interviews (Silverman, 2007). Therefore, do the data serve the researcher to confirm the assumptions about the subject of the research (context caused by the researcher), or are they the basis for developing a new theory (context not developed by the researcher) (Zahle, 2018) .

Summary and Discussion

In research in the field of management sciences, the use of quantitative methods, which use various statistical tools and are as valuable as qualitative methods, should not be abandoned. Nevertheless, qualitative methods such as case studies using individual in-depth interviews enrich the study. They complement previous quantitative research. Conducting case studies using IDI allows you to explore in depth what quantitative research can only suggest. It may also prove the great universality of the research process, which is the basis for in-depth and reliable drawing conclusions from research.

The use of IDI in case studies is particularly important in the case of enterprise research. In management sciences, qualitative aspects play a fundamental role. Behind every company there is a man, hence learning about his attitudes, behavior and values through qualitative research becomes a necessity. On this basis, drawing conclusions from the implementation of the bubble is much more accurate and reaching into the essence of the issue, which makes it easier to understand. Significant here is the statement of Deniz and Lincoln that "a qualitative researcher (...) is like a patchwork maker (...), he connects, assembles and puts segments of reality together. This process creates and gives psychological and emotional unity - a model - for an interpretive experience" (Deniz, Lincoln 2006).

Soil-saving Agricultural Technologies and State Support for Socially vulnerable segments of the Population in preventing Poverty

Victor F. STUKACH

Doctor of Economics, Professor, Department of Management and Marketing of the Federal State Educational Institution of the Omsk State Agrarian University. Omsk, Russia, in orcid: http://orcid.org/0000-0002-9911 - 6286, Researsher ID: H-1016-2012, vic.econ@mail.ru

Abstract

The article deals with a problem of high political and social significance: providing environmentally friendly food to socially vulnerable categories of the population. This category includes pregnant and nursing women, children, school children, clients of social institutions, and segments of the population whose real incomes are below the subsistence level. The amount of food consumed by this category of population can be 17-20% of the volume in the region. We need land resources that can be used to produce organic food without the use of pesticides with a limited amount of fertilizers.

Goal. To investigate the problem of providing environmentally friendly food to socially unprotected categories of the population. Consider mechanisms for coordinating market, distribution, and informal institutions to provide food to socially vulnerable segments of the population. It is proposed to use state support tools to encourage land users to use soil protection technologies, introduce degraded land into agricultural circulation, and create food aid infrastructure in the regions. It is proposed to use state support tools to ensure the use of soil-protecting agricultural technologies, to create a system of food aid to overcome the poverty of socially vulnerable segments of the population.

Keywords: degraded land, soil protection technologies, state support, poverty prevention, infrastructure of domestic food aid in the region.

Introduction

Due to the special social and political significance, the solution to the problem of the healthy nutrition of socially vulne rable groups is in the area of responsibility of the state. The state, using regulatory methods, have the opportunity to motivate the costs of entrepreneurs and infrastructure organizations in the social sphere and environmental programs within the "Green box Measures" of WTO. This area includes support for socially vulnerable groups and organic farming that related to environmental measures and the use of soils unsuitable for active exploitation; it also includes a system of services of market, distribution and informal institutions to provide for the needy of socially vulnerable groups. This approach has become economically viable for Russia and other countries with a transforming economy that has joined the World Trade Organization. Government support tools can create a mechanism to help farmers who produce on degraded lands.

Food manufacturing largely depends on soil fertility, so they must be healthy and productive. This determines the importance of returning to productive land turnover subject to fatigue, coming from economic activities of entities, as well as the influence of natural phenomena, wind erosion, and water erosion. This situation is typical for many countries and regions (China, Australia, Kazakhstan, Ukraine, in Russia - the Volga region, Siberia, the Caucasus, etc.).

Goal. To investigate the problem of providing environmentally friendly food to socially unprotected categories of the population. Consider mechanisms for coordinating market, distribution, and informal institutions to provide food to socially vulnerable segments of the population. It is proposed to use state support tools to encourage land users to use soil protection technologies, introduce degraded land into agricultural circulation, and create food aid infrastructure in the regions. It is proposed to use state support tools to ensure the use of soil-protecting agricultural technologies, to create a system of food aid to overcome the poverty of socially vulnerable segments of the population.

Methods of Research

Land resources and their condition, the problems of poverty and hunger reduction are the priorities of world social and economic science. In Russia, the problem of proper nutrition in general and for the young generation, in particular, is considered in the context of the health of the nation. In recent decades, large-scale research has been carried out within the framework of the Food and Agriculture Organization (FAO). That confirms the high scientific and practical importance of social protection of the population, the protection of natural factors and the behavioral reactions of the population in need to the state measures.

The FAO report “The State of the World's Land and Water Resources for Food and Agriculture” (SOLAW) notes that although there has been a significant increase in food production over the past 50 years, it has led to degradation of land and water systems on which food production depends [3,6,7,10]. In many cases such achievements in increasing have been linked to management practices.

Literary sources give a sufficient idea of the genesis of processes in the field of agricultural land use. First of all, the loss of soil fertility is associated with the irrational land-use system. A team of scientists from the Russian Academy of Agricultural Sciences (RAAS) prepared a report, based on official sources, that approves that “30 to 40 million hectares of tilth in Russia were withdrawn from land turnover at the beginning of 2008 and now are not used”(G. A. Romanenko, 2008) [1, p. 66].The transformation of land relations has occurred in post-socialist countries. As a result of denationalization and privatization, the forms of land ownership has changed. Then decision-making in the field of technology application was transferred from large state-owned enterprises to a large number of legal entities that owned land.

The decisions of commodity producers regarding the attitude to the used of farmland depend on macro-social factors (that are not controlled by the head of the enterprise; demographic situation); microsocial factors (poverty; the farmer’s desire to make a short - term profit; concern for the survival); public policy. There become relevant studies of informal institutions, identifying the patterns and relationships that affect the specific actions of workers on the use of environmental systems of agriculture in the individual enterprise. It involves identifying factors that go beyond self-preservation in the actions of economic entities. It is necessary to create conditions that shape organizational behavior (so-called “cultural code”) under which it is possible to solve long-term development tasks and, above all, to preserve the environment as the main condition for agricultural production. [4, p.133-142] ,[12]].

An assessment of the feasibility of using degraded land as a resource in the production of environmentally friendly food was maded. The problem of degradation exposed lands is addressed; the macro and micro social factors impacting the decision-making process in soil protection are identified; a comprehensive model for natural factor recovery in production by introducting organic agriculture technology for manufacturing environmentally friendly products. Research methods used in the article: Balance sheet method for agriculture, food production and consumption; written and oral survey. We polled leadership, directors, farmers, businessmen, agro technologists, managers, production managers, field foremen, farm and agriculture machinery operator. The survey had questions on the real-life business life and measures taken; respondents' opinion on the feasibility of

using certain methods and technologies, respondents' awareness of the problem and economic motivation as a result of using methods and technologies, and the social elements of the survey.

After Russia's accession to the World Trade Organization (in 2012), it became necessary to formulate the volumes of state support, taking into account the requirements of the WTO rules. The Concept of measures to support domestic producers and processors of agricultural products was adopted by the Russian Government based on domestic food assistance mechanisms within the "Green box Measures" of WTO. The Concept incorporates the idea of a phased expansion of state guarantees in the field of domestic food aid to the population in need of food products.

Based on domestic food aid mechanisms, the Government of the Russian Federation is implementing a program of "pilot" projects aimed at estimation of efficiency of support measures for domestic producers and processors of agricultural products. The decision was made on the realization in 2013-2015 of "pilot" projects in the republics of Buryatia and Mordovia, Omsk, Saratov and Ulyanovsk regions, in which "pilot" projects for testing the mechanisms of domestic food aid are being implemented. To judge the extent of the World Food Programme (WFP), the calculations were performed for the Omsk region, which is implementing a "pilot" project. The database on the number of people in need was formed [5].

For example, in the Omsk region, according to statistics of 01.01.2014, the population was 1 974 000 people, including 1417 000 in cities and 557 000 people in rural areas. Of the total: 868 000 people are pensioners and veterans of the Great Patriotic War; - 295 000 people are pregnant women, nursing mothers, and children under the age of 3 years; 27 000 people are single mothers (fathers) with children; more than 3 000 people are disabled. Besides, there are more than 1 000 people from large families and low-income families in the region.

According to the regional Ministry of agriculture, the needs of socially vulnerable segments of the population for various types of products are met by local production resources by 78-86%. The needs for bakery products, potatoes, milk and meat are fully met.

The Results

The data of a study carried out by the scientists of the Omsk State Agrarian University within the Russian Foundation for Basic Research grant (RFBR grant). First of all, it was revealed that the decisions of economic entities regarding the attitude to technologies in agriculture, in general, and environmental protection, in particular, are influenced by the conditions. The idea is that up to 80% of farmers in natural and climatic zones with a real risk of loss of fertility due to soil erosion, are concerned about short-term survival and do not care about soil conservation for future generations. About 75% of respondents are not sufficiently informed about the crop rotation system, plant protection, the use of fertilizers and pesticides[4, 5, 9].

The analysis of well-known sources in scientific literature allows us to formulate several regulations that form the attitude to land resources. The main groups of factors are detached. First of all, there are *macro-social factors,* among which - state policy, market conjuncture. *The next factor is "poverty"* - the farmers working in the waste ground use their resources to complete exhaustion; they are concerned about their survival, not about conservation of natural resources. *Microsocial factors* have a decisive influence on the choice of decisions regarding the use of technology. Among microsocial factors are a measure of awareness about the problem and actions taken, access to the information, economic efficiency (profitability), a measure of the acquisition of knowledge and skills regarding the technologies and others that directly affect human behavior, land management.

After identifying the possible points of making efforts to introduce soil protection technologies, the issue of motivation mechanisms for landholders was considered. It can be economic, organizational - legal and educational methods of influence. Among these, the main are state environmental

programs, legislation, economic sanctions, training for staff, educational programs, and activities of state consulting services. In the process of the reform, public authorities need to anticipate the social and economic consequences that directly affect the environment [9].

The dynamic of changing priorities in the range of the economic condition of the enterprise is traced from the level of survival to high profits (tab. 1). Studies have shown that enterprises and individual low-income farmers do not mention the prevention of soil degradation and destruction in the list of priorities.

First of all, farmers take care of their survival in the short-term perspective. And from this, we can deduce that economic entities solve socially significant long-term tasks only when the work is profitable. Moreover, the higher it is, the more the company is interested and able to take care of the environment and the use of soil protection technologies.

Table 1: Priorities of land users depending on the level of profitability of the production

	Priorities of land users depending on the economic performances of the production		
Приоритеты	**High profit**	**Modest profit**	**Low profit (survival level)**
1. Keeping the profitability and growth of agricultural producers			
2. Satisfying the consumer demand for products	1	1	2
3. Satisfying the needs of employees of the enterprise	2	2	3
4. Protection of land from negative processes (soil depletion, degradation, etc.)	3	4	not a priority

The results of this concrete study of the problem of supporting socially vulnerable groups and the eradication of poverty make it possible to mark down the ways to solve it. The main are: providing organic produce to people in need; allocation of land plot for organic production; creating a system of state support for consumers and producers of products; forming of the regional infrastructure of domestic food aid. The mechanism is proposed that motivates land users to conduct organic production, preserve soil fertility, and create service infrastructure, combine market, distribution, and informal institutions to provide goods for needy citizens. This mechanism work with tools of state support within the “Green box” of WTO.

Discussion

Within framework of the study problem, the process of forming a food aid system for disadvantaged groups at the regional level was studied. The research procedures were carried out:

> The number of socially vulnerable groups in the region and their need for food aid were determined;

> Practical measures have been developed to solve the economic and social problems of developing the institutions of the regional infrastructure of domestic food aid;

> The potential use of land, withdrawn from agriculture as a resource for food production, was explained;

> The possibility of creation is investigated and the parameters of the production and logistics center were determined;

> The list of production enterprises, infrastructure organizations included in

the region's food aid system as part of cluster interaction was explored;

> The mechanism for the interaction of the production-logistics center and raw materials suppliers for packaging and processing was developed;

> The project of workflow between production and processing enterprises, trading and payment systems was submitted;

> The assessment of the effectiveness and feasibility of raising the land withdrawn from agriculture for the production of organic food was taken;

> The mechanism for the interaction between production-logistics center and food consumers was developed.

Food aid infrastructure would help to create an institutional environment and infrastructural network that influence the processes of food production and consumption by the population of the region. Adding of missing elements to the infrastructure would attract an additional amount of food resources (up to 15%) using new technologies, reduction in the number of ineffective intermediaries, removing the barriers in the interaction of agents, reduction of raw materials losses. There will be an opportunity to create a stable social procurement for local agricultural producers and processors; to create mechanisms of state support for entrepreneurs implementing projects of domestic food aid, which directly stimulates them to increase production and services. Agricultural organizations and farms would be able to get involved with the distribution network with domestic produced goods.

The social effect consists in the fact that full and high-quality nutrition is provided to children in preschool and educational institutions and to low-income groups of the population; there is the possibility of subsidizing part of the costs for low-income parents.

Conclusion

The study revealed

- The motivation for developing the system of domestic food aid in economies of transition is to overcome the limitations of the WTO on direct state support for producers;
- Environmental technologies in agriculture and soil protection against destruction depends on macroeconomic, microsocial and state policies;
- Poverty in the agriculture carries economic and socio-cultural prerequisites for the development of a negative scenario, keeping the tendency to the destruction of fertility and the quality of the soil layer.

Priorities in the field of state regulation

- Equalization of income differences between farmers who work in undermanaged lands and agents engaged in intensive agriculture; preventing poverty in the agricultural sector using state support tools as part of targeted programs;
- Conducting research in the field of informal institutions, mechanisms for motivating farmers to adopt environmental technologies and use degraded land;

Practical recommendations

- The difference in income of farmers and infrastructure organizations working on unsuitable for intensive technologies land should be covered by targeted state support programs;
- To orient scientific researches to the creation of economically efficient and environmentally friendly technologies;
- To develop a system of retraining of personnel for the private sector and agricultural advisory

services;
- To include information services in work; state monitoring of the conditions of the rental work of farms, financing of soil conservation measures;
- To include pricing policy, subsidies and trade policies in agriculture;
- To control fertilizers and pesticides consumption, soil fertility, groundwater conditions.

Acknowledgment

This work was supported by a research grant from the Russian Foundation for Basic research And the government of the Omsk region of Russia on the topic: "Fundamental processes of forming a system for providing unprotected segments of the population with environmentally friendly food using land withdrawn from agricultural circulation as part of the implementation of the Omsk region development strategy" [No. 18-410-550027]

Abstract

This study focuses on the findings revealed for the age of exploited persons in Romania, specifically through analysing differences by demographic characteristics in relation to the human trafficking phenomenon. The dataset that is modelled and analysed in this study originates from the National Agency against Trafficking in Persons in Romania (ANTIP). Analysis on the selected dataset points out that non-parametric procedures are more suitable. Due to heterogeneity of the age the median is more relevant than the mean thus the results of the Independent-Samples Median Test for variable "Age" across categories show a significant difference across categories for most of the variables, except for Type of residency. Boxplots where significant differences occurred are further presented for the variable "Age" across categories of the variables in order to describe the present variable distributions.

Keywords: exploitation, vulnerability, age, human trafficking, Romania

Introduction

A comprehensive approach to determine the ramifications of the human trafficking starts with determining the victims as supply and later identifying the nature of the labour that the victims ensure. Such view is shared by (Cho, 2015) mentioning the need to address the phenomenon in the view of the four pillars of human trafficking: *Migration*, *Vulnerability, Crime and Policy and Institutional Efforts*

Human trafficking as is demonstrated in the Trafficking in Persons Report (United States Department of State, 2020) remains "a global threat necessitating a global response". Progress in victim identification efforts and significant governments action are mandatory to ensure eliminating all forms of human trafficking.

The trafficking phenomenon is closely related to the poor economic climate in which the victims are struggling in their home country. With the advances in IT communication technologies recruiters gained the means to diversify their methods to carry out illegal activities. Such criminal activities in trafficking spread out diversely from labour workforce exploiting to, child begging exploits, sexual

Cite this Article as: Glăvan Ionela-Roxana, Mirică Andreea And Necula Marian "The Age of Exploited Persons in Romania – Is There A Difference by Sex, Type of Residency, Type of Exploitation, Relationship with The Recruiter or Country of Destination?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

exploitation and international drug commerce. In order to address such a diversified field new adequate laws to combat all the recent forms and means of trafficking are necessary to be implemented.

The urgency to fight against human trafficking is more acute with the recent development of COVID-19 pandemic as its implications magnified the social discrepancies for all the victims. Starting with the fact that traffickers rely on vulnerable profiles in order to exploit them it is of great importance that an economic mitigation should be addressed. In the present context, the lack of jobs and access to medical services increased the number of vulnerable people which in terms created an expanse of the infarctional environment (United States Department of State, 2020).

Age is a relevant factor to address the human trafficking scourge as young victims are predisposed mostly to become later active crime offenders. As Cho (2015) has pointed out crime pillar explains mostly the human trafficking problem and a sense of urgency to adopt criminal justice and crime prevention measures is seen beneficial. In order to reduce the phenomenon complexity of human trafficking a solution approach is one which discourages it is by increasing the penalties for all offenders that exploit children along with the other Policy and Institutional Efforts. Such key observation relies on the fact that children are physically and mentally fragile and do not have the possibilities to anticipate and avoid human trafficking schemes, thus making them a vulnerable group (Gheorghiţă and Vădăstreanu, 2015).

Nevertheless, it is of great urgency to tackle the causes and ensure in Romania the economic means in which such cases are displaced away of the criminal environment, integrated socially and economically, with a proper work opportunity that offers better living condition for the victim in order to avoid re-trafficking or further misbehaviour in the community.

Furthermore, overall regional development policies are equally important because the human trafficking root causes are tied to local or regional underdevelopment issues such as “poverty”, “inequality” and “discrimination” which in terms increase the human security risks (Cho, 2015).

Methodology

Data with regard to the cases of exploited persons in Romania was retrieved from https://data.gov.ro/en/organization/agentia-nationala-impotriva-traficului-de-persoane (accessed 20 Jul. 20). The data contains demographic characteristics for the cases of human trafficking victims identified in 2015-2018. 5 records were deleted from the database as the country of destination is unknown. Next, 15 records were deleted as the type of residency is not available. Then, 35 records were deleted because the relationship with the recruiter is unknown. Considering the country of destination all the countries with under 50 persons were grouped into a new category “other countries”. These countries are: Albania Bahamas Belgium Cyprus Czech Republic Estonia, Finland, Greece, Hungary, Ireland, Libya, Netherlands, Norway, Poland, Portugal, Qatar, Serbia, Sweden, Swiss Confederation, Turkey, United Arab Emirates, USA.

For the purpose of this paper, data will be tested for normality by categories as follows:

- Sex: male, female
- Type of residency: rural areas, urban areas
- Type of exploitation: attempt, begging, labour, other, sexual exploitation, stealing
- Relationship with the recruiter family member, friend, neighbour, procurer, spouse, unknown person
- Country of destination: Austria, Denmark, France, Germany, Italy, Other countries, Romania, Spain, UK.

The Kolmogorov-Smirnov and Shapiro-Wilk tests, as suggested by Lund (2018), using a significance level of 5%. The null hypothesis states that the data is normally distributed. If the data meets the normal distribution assumption the ANOVA test will be performed in order to answer the research question. Otherwise, non-parametric tests will be used.

Results

The age of a person victim of human trafficking ranges between 2 and 75 years with a mean of 22.32 and a median of 18. The standard deviation is 10.6 years, making the variable heterogenous. Tables 1 to 5 present the results for the normality tests of the variable "Age" by each category of the following variables: Sex, Type of residency, Type of exploitation, Country of destination, Relationship with the recruiter. As one can observe, the null hypothesis of normality distribution is rejected. Therefore, non-parametric procedures are more suitable. Moreover, as the age is heterogenous, the median is more relevant than the mean.

a. Lilliefors Significance Correction							

Table 6 presents the results of the Independent-Samples Median Test Results for variable "Age" across categories of the following variables: Sex, Type of residency, Type of exploitation, Country of destination, Relationship with the recruiter. As one can observe, there is a significant difference across categories for most of the variables, except for Type of residency.

Table 6: Independent-Samples Median Test Results for variable "Age" across categories of different variables

Null Hypothesis	Sig	Decision
The medians of Age are the same across categories of Sex.	.000	Reject the null hypothesis.
The medians of Age are the same across categories of Country of destination.	.000	Reject the null hypothesis.
The medians of Age are the same across categories of Relationship with the recruiter.	.000	Reject the null hypothesis.
The medians of Age are the same across categories of Type of exploitation.	.000	Reject the null hypothesis.
The medians of Age are the same across categories of Type of residency.	.664	Retain the null hypothesis.

Figures 1 to 4 display the boxplots for variable "Age" across categories of the variables where significant differences occurred. As one can observe, the median age for men is significantly higher compared to the one for females. Also, females present a median age below 18. With regard to the country of destination, persons exploited in Denmark register the highest median age while those exploited in Romania the lowest. Also, one can observe that the only country where the median age is under 18 is Romania. Considering the relationship between the victim and the recruiter, the lowest median age occurs for the cases where the recruiter is a family member. Moreover, a median age below 18 can be observed for the cases where the recruiter was a procurer. With regard to the type of exploitation, a median age below 18 can be observed for the cases of theft as well as sexual exploitation.

Figure 1: Independent-Samples Median Test for variable "Age" across categories of Sex

Figure 2: Independent-Samples Median Test for variable "Age" across categories of Country of destination

Figure 3 : Independent-Samples Median Test for variable "Age" across categories of Relationship with the recruiter

Figure 4 : Independent-Samples Median Test for variable "Age" across categories of Type of exploitation

Conclusions and Further Research

Among countries in the European Union (EU), Romania ranks at the top in terms of absolute number of victims and absolute numbers by gender (UNODC, 2018). In country with the lowest GDP per capita among EU countries, where nearly 30% of the population lives below the poverty line (Romanian NIS, 2018a) and a quarter of those are aged below 17 years (Romanian NIS, 2018b), the most affected category by human trafficking are children comes as no surprise.

The analysis presented in the paper highlights that nearly 50% of the cases reported in the judiciary system are comprised of individuals below median age equal or less than 18 years, with males are overrepresented. While some of the trafficked persons remain in Romania, the destination of trafficked person is comprised mostly by a cluster of Western and Central European countries, with higher living standards than Romania, where the victim is forced into some form of illegal activity. In terms of the recruiter, this person is usually someone the victim knows or has some form of relation based on trust. In terms of limitations we need to highlight that there are serious concerns of under reporting, mostly regarding the correlation between the case where the victim does not leave the country and the recruiter is part of the family. A topic for further research is the geospatial-temporal model between the number of victims aged below 18 years, the level of economic development or economic inequality at the level of regions, counties and municipalities , number of law enforcers and demographical data, taking into account as dummy variables the data at which different pieces of legislation which target the phenomenon where passed.

In a more general note, trafficking of persons is a very serious issue in Romania and should be pushed higher on the political agenda in order to increase awareness in the general public and take serious actions against it, taken into account the strong evidences from multiple sources.

Abstract

This paper presents an analysis of the differences in the leadership style and links the existing theories with practice. This study will show what kind of leadership styles exist and how they specifically affect the company's performance results. The aim of this paper is examining the leadership style of one company but in different countries, therefore, the answers provided by executive managers are essential, and the sample size is small. Here, the human resource management of a specific large company in two countries is examined. They are different in terms of political and economic aspects. For the needs of comparing the leadership style in one international company based in two different countries (Switzerland and Iran), cultural characteristics need to be determined. For this purpose, Bass & Avolio's MLQ is administered to executives and employees at Buhler AG in Switzerland and its Iran office to measure the leadership style. The result shows, that the cultural dimensions influence the tendency of managers/employees towards transformational/transactional leadership styles in one company but in different countries. According to this research, It is particularly recommended that the leaders in international companies in different environments take cultural aspects more seriously and become more open and supportive of new mindsets and changes, which – in turn – can increase employees' satisfaction and performance in the work environment.

Keywords: Leadership Style, Intercultural Leadership, Culture, External Factors

Introduction

In recent years, companies have had to strengthen their competitiveness due to internationalization so that they can secure their existence on the market. Personnel management is a crucial function of securing long-term competitiveness.

Leadership is one of the essential original fields of action. It describes the process of social influence, in the course of which every company needs to achieve its goals.1 Managers can influence their employees through their leadership behavior in order to achieve the qualitative and quantitative corporate goals. The management style applied is an essential factor for the success of the company.2

In an international environment, the leadership style requires a basic consensus as to the expectations of the manager and the leader. The challenge to the success of international companies is that cultural differences have to be taken into consideration and, accordingly, strategies have to be adapted.3 The increasing importance of intercultural leadership has spurred scholarly interests in this field, which results in the fact that many empirical studies are carried out on it. The research theories offered by Hofstede (1980, 1993), Bass (1981) and Hause (GLOBE study) are some of the most important outcomes of such studies.4

Hofstede has found that there are no universal solutions to the problems of organization and management. Organizations are symbolic. They work according to the way their culture influences their members' thoughts.5

The results of all studies have shown that intercultural management and intercultural leadership are as important as other company's success factors (financial management).

Leadership

In the scholarly literature on the field under discussion, there are various approaches to the term *leadership* as well as various perspectives on it. Some of these definitions are shown below:

- Leadership is seen as a complex phenomenon linked to social relationships among several people.[6]
- Leadership is understood as goal- and result-oriented tool of mutual and activating social influencing for the fulfillment of common tasks in and with a structured work situation.[7]

Human Resources Management

A company aims to maintain long-term successful activity on the market. Therefore, employees are the most valuable asset and play a significant role in the company's success.[8] For this reason, personnel management in the company is of crucial importance. Personnel management can be characterized as an interaction process occurring in the company. In this process, the manager tries to control the actions, thoughts, and feelings of employees in their area of responsibility so that the corporate goals are successfully achieved.

The contributions made by employees, the avoidance and reduction of their undesirable behavior, job satisfaction and the company's improved performance are the most important goals of personnel management. In the area of personnel management, leadership tools, models and theories have been developed so that managers and employees are connected within a specific management situation.

Leadership styles are the most important form of leadership tools, which can be used to describe the manager's behavior.[9]

As this work deals with the comparison of leadership styles in two different countries, in the next section, different types of leadership styles will be explained.

Leadership Style

The leadership style is the way in which the supervisor leads the subordinate employees. It is a simplified model that describes the basic principles of action for the manager.10 There are many types and variations of leadership styles. Scholars are interested not only in the personal characteristics of leaders but also in the effectiveness and efficiency of leadership behavior in certain situations.11 In this context, the American political scientist and historian – Burns (1978) – made a distinction between transactional and transformational leadership. This distinction was further developed by Bernard M. Bass and is also discussed in this study:

- ***Transactional leadership style***

This leadership style is based on an exchange relationship. In this style, the goals of the organization are followed by the employees and they are rewarded for it. The manager is guided by his/her employees' corporate goals, wishes and needs. The work is based on employees' extrinsic motivation.[12]

Transactional leaders are those who approach their followers in order to promise them something and to expect something else. In this way, the manager can influence his/her employees under stress and find quick solutions addressing his/her employees' needs.[13]

Bass & Avolio (1994)[14] divided this leadership style into two components:

- contingent reward: here, managers and employees have mutual expectations of each other, and they agree on a goal for which the employees receive a reward when it is achieved;
- management-by-exception: in this model, employees act independently within a given framework. Managers will intervene in the decision-making process if it is only necessary.

- ***Transformational leadership style***

This style focuses on the manager's function as a role model, which is based on specific goals and motives. The manager pursues these goals, from which identification and personal engagement arise.[15]

The transformational leader recognizes the existing needs of his/her employees and he/she tries to satisfy those needs regarding Maslow's hierarchy of needs in order to engage employees. In this style, the work is based on employees' intrinsic motivation.[16]

Bernard Bass and Bruce Avolio (1994) characterized four basic components of transformational leadership in the following way:[17]

- charisma: the manager gives his/her subordinates a vision and achievable mission. Employees follow the leader because they trust him/her;[18]
- inspiration: the manager demands high performance from his/her employees. The manager pays attention to motivation and emotional appeals which contributes to the increase in the awareness and understanding of goal achievement;[19]
- intercultural simulation: the manager encourages his/her employees so that they can develop their ideas and optimize the opportunities for collaboration;[20]
- appreciation: appreciation is essential in personal development. Employees are treated equally and fairly.[21]

- ***The laissez-fair leadership style***

The word "laissez faire" comes originally from French and means "let's do it". This leadership style is a "non-leadership style".[22] Employees have complete freedom. The manager only passes the requested information on to his/her employees and does not make any management decisions. Besides, the supervisor has little opportunity to structure and control the work. Productivity might be very low here because the feelings of togetherness are missing. Aggressive behavior is often observed in this style.[23]

International Personnel Management

International human resource management, which takes national cultural differences in consideration, is characterized by three research traditions:

- intercultural personnel management focuses on the issue of personnel management in intercultural contexts within a country or in individual countries;
- international comparative human resource management not only focuses on culturally related behavior but also examines differences between human resource management practices in their different institutional environments;
- regarding international personnel management, the circumstances surrounding the emergence of employees abroad need to be examined.[24]

Because intercultural personnel management is the focus of this study, it is examined in more detail.

Intercultural personnel management:

Internationalization and globalization indicate global political, economic and social interdependencies. Since the beginning of globalization, the interconnectedness of the world in the different areas of society has increased. The intensity of competition and innovation on international markets has enormously increased. International management connected with intercultural risks is an essential term for the companies which want to remain on the competitive worldwide market. Intercultural personnel management is related to the type of internationalization strategy, the company's positioning in a foreign cultural environment and management position.[25]

Cultural Contexts

Because the concept of culture is very abstract and its meaning has changed over time, there are different definitions of the concept of culture.

Culture consists of patterns of behavior that are transmitted through symbols. The essential core consists of traditional ideas and their attached values. [26]

- *Culture concept, according to Hofstede*:

Culture is a "mental programming" of behavior. Before something else can be learned, the acquired patterns of thinking, feeling and acting have to be discarded in childhood.[27] Geert Hofstede introduced the concept of "national culture" between 1967 and 1973. In addition, the analysis unit of "national culture" has represented a meaningful unit through its empirical research that covers almost 74 countries. He examined the influence of national culture on organizational culture. His empirical study was done on the basis of the data of the multinational company – IBM. He recorded different values and attitude of employees, taking into consideration, for example, the criteria of the country, profession, gender, and age.[28]

As a result of factor analysis, Hofstede described initially four and later five dimensions which can be used for comparisons of cultures:

- Power Distance Index (PDI): Hofstede regarded power distance as a measurement of how a culture views the power relationship between people. According to the hierarchy of authority, high power distance cultures have higher levels of inequality.

- Uncertainty Avoidance Index (UAI): the term "uncertainty avoidance" comes from the American sociology of organization developed by James G. Marche. Marche and his team discovered how to deal with differences in one way or another in every institution and country. Uncertainty avoidance was defined as the degree to which members of a culture feel threatened by an ambiguous or unknown situation. Weak uncertainty avoidance means short-term planning and thus less stability and structure in life design.

- Individualism *vs* collectivism (IDV): this dimension deals with the relationship between the individual and the group. It has a significant impact on the behavior and structure of groups and cultures. Prevailing cultural values can shape relationships among the family, company and social structures. Societies in which the interest of the individual is greater than the interest of the group are called individualistic and societies in which the focus is on the group are considered collectivist.

- Masculinity *vs* Femininity (MAS): this distinction is based on the fact that men and women take on different emotional and social roles in society. The masculine certainty and selfish aspects such as competitive thinking are the strengths of men.

- Long-Term Orientation *vs* Short-Term Orientation (LTO): the focus of long-term orientation is based on the future while short-term orientation focuses on the present or past. Within the short-term orientation, the tradition as well as current social hierarchy and fulfilling social obligations are valued. Success in cultures with strong long-term orientation and availability *via* a network of personal contacts is influenced by collectivism.[29]

- ***Culture concept and leadership theory according to the GLOBE study***

The GLOBE study defines culture as common motives, values, beliefs, identities and interpretations or the meanings of essential events that result from the shared experiences of the members of collectives.[30] The GLOBE (The Global Leadership and Organization Behavior Effectiveness Research Program) study was initiated by Robert House at Pennsylvania University in 1991. He identified the attributes of a successful leader and leadership differences between cultures. The research aimed to develop an empirical study based on the theory. 62 countries are involved in this study and nine social and organizational cultural dimensions. Six leadership dimensions have been developed:

- cultural dimensions: in order to differentiate various societies and organizations, nine cultural dimensions were developed:

a) uncertainty avoidance: this dimension originally refers to Hofstede's dimension "uncertainty avoidance";[31]

b) power distance: this dimension shows the acceptance of the unequal distribution of power and has its origin in Hofstede's research;[32]

c) institutional collectivism: this shows the strengthening of collective resource distribution and collective trade;

d) group collectivism: this dimension demonstrates how far individuals have loyalty, pride and solidarity in culture and how they express them to their family or company;

e) gender equality: this determines the reduction in gender inequality. The origin of this dimension is Hofstede's "masculinity/femininity" criterion;

f) certainty: this dimension describes a culture member's specific confrontational-aggressive relationship behavior towards others;

g) future orientation: this dimension expresses the future-oriented behavior of individuals, such as planning activities and investment in the future;[33]

h) performance orientation: the "performance orientation" dimension determines how strongly a culture encourages and rewards its members for top performance and performance improvement;[34]

i) human orientation: this dimension illustrates how far a culture rewards fair, sincere, selfless, and compassionate behavior;[35]

- The influence of culture on implicit leadership theories: one of the central questions of the GLOBE study refers to this topic: Which specific characteristics of the leader generally lead to effective leadership and which of these characteristics are related to cultural peculiarities. Therefore, six global leadership dimensions have been summarized in the following way:

a) charismatic/value-based leadership: this leadership style is defined as the ability that leads to the motivation and inspiration of others as well as to high-performance expectations;

b) team-oriented leadership: this leadership style focuses on effective team-building and the implementation of shared goals among team members;

c) participatory leadership: this style can be defined as the degree to which the organization's employees feel involved in executives' decision-making and implementation;

d) human-oriented leadership: human-oriented leadership refers to supportive, considerate, and generous leadership;

e) autonomous leadership: this leadership style refers to independent and individualistic leadership traits;

f) self-protective leadership: this type of leadership focuses on ensuring the safety and security of individuals and groups through status improvement.[36]

Research Method

In this research, two groups of companies are studied – Bühler AG in Switzerland and in Iran. Bühler Holding AG is an international Swiss family company based in Uzwil which specializes in process engineering, especially in the field of production technology. Bühler AG was founded on February 10, 1860, and it operates in over 140 countries, with a global payroll of 10,640. In 2016, the company generated sales revenues of CHF 2,45 billion.[37]

In this part, an employee survey is done at Bühler AG with its headquarters in Switzerland and its branch in Iran. Thanks to the results of this survey, the management structure of the company and the expectations of the employees in terms of leadership behavior can be determined. Bass & Avolio's MLQ was administered to executives and employees at Bühler AG in Switzerland and its Iran office to measure the leadership style, the results of this behavior and the expectations of employees in a company in two different environments.

The MLQ is based on the evaluation of leadership behavior. Seven facets of leadership are recorded in the questionnaire in the MLQ, which can be assigned to three overriding factors.

Transformational leadership is represented by the following scales: charisma, inspiration, spiritual stimulation and appreciation. Transactional leadership applies the following two criteria: contingent reward and management-by-exception. The last factor is laissez-faire leadership which is related to avoiding leadership.

The questionnaires contain 21 questions. Gender, age, and education were also given in the questionnaires. Bass's leadership questionnaire was redrafted and, as a result, a questionnaire was structured based on employee expectations. In the leadership questionnaire, each item could be rated on a Likert scale from 0 to 4 (0: never; 1: rarely; 2: sometimes; 3: often; 4: always).The Likert scale for evaluating the answers provided by employees in the questionnaires is as follows: 0: strongly disagree; 1: disagree; 2: undecided; 3: agree; 4: strongly agree.

Since in this research, the leadership style will be examined, the answers provided by executive managers are essential, and the sample size is small.

Data

Bass & Avolio's MLQ was emailed to a total of 53 executives and employees at Bühler AG in Switzerland and its branch in Iran. An anonymous written survey was carried out. The response rate was around 90%. In other words, a total of 48 people answered the questions. The questionnaire was completed by 12 executives in Switzerland, 12 executives in Iran and 12 employees in Switzerland and 12 employees in Iran.

- Gender: the gender of the managers surveyed in Switzerland and Iran was distributed in the following way: 1/12 female, 11/12 male in Switzerland and 4/12 female, 8/12 male in Iran. The proportion of the employees in Switzerland is as follows: 7/12 male, 5/12 female and in Iran: 6/12 female, 6/12 male.

- Age: the age of the Iranian employees ranges from 27-40 while the range of the age of the Swiss employees is from 26 to49. What was also considered is the average older age of the Iranian executives in comparison to those from Switzerland.

- Education: the education of most of the respondents was related to engineering and technology (62.25% on average) and management/MBA (22.25% on average) in both countries.

Research Results

- *Executive manager – Switzerland*

The alpha coefficients of each scale show different reliabilities in the result of the Swiss executives, whereby factor 3 (intellectual stimulation) and factor 1 (idealized influence) have the highest reliabilities and "management by exception" and "laisser faire" have clearly lower values. Statistically, the results of the factors with $\alpha<0.5$ cannot be used. The following table shows that the Cronbach's alpha of the transformational scale of 0.824 can be described as good. The reliability measure for the transactional scale is 0.566 and is rather weak. The low-reliability measure of laissez-faire leadership with 0.281 can also be classified as weak.

Table 1: Reliability of the data collected on leadership styles among the Swiss executives

Leadership style	Number	Standard deviation	Standard error	Variance	Cronbach's alpha
Transformational	12	4.71	1.977	22.20	0.824
Transactional	6	2.89	1.908	8.38	0.566
Laissez-faire	3	1.30	1.104	1.69	0.281

Source: Author's own study.

- *Executive manager – Iran*

In the course of calculating the Cronbach's alpha from individual management dimensions (transformational, transactional, laissez-fair), the results show a relatively high rate of transformational and transactional leadership.

Table 2: Reliability of the data collected on leadership styles among the Iranian executives.

Leadership Style	Number	Standard deviation	Standard error	Variance	Cronbach's alpha
Transformational	12	3.75	2.746	14.08	0.465
Transactional	6	3.70	1.703	13.71	0.789
Laissez-faire	3	1.73	1.877	3.00	-0.174

Source: Author's own study.

- *Comparison of leadership styles between executives in Switzerland and Iran*

The following figure shows the comparison of the correlations of leadership styles between Swiss and Iranian executive managers:

Chart. 1: Comparison of leadership styles between the executives in Switzerland and Iran.

Source: Author's own study

What should be noted when comparing the correlations of leadership dimensions between executives in Switzerland and Iran is the high relationship between transactional leadership and laissez-faire among Swiss executives although they are significantly weaker among Iranian executives. The same degree of correlation holds between transformational leadership and laissez-faire among executives from both countries.

- ***Employees in Switzerland***

In the table below, Cronbach's alpha has been calculated from the expected leadership styles. With α>0.7, the results of the expected transformational and transactional leadership styles are highly reliable.

Table 3: Reliability of the data collected on expected leadership styles among the Swiss employees.

Leadership Style	Number	Standard deviation	Standard error	Variance	Cronbach's alpha
Transformational	12	5.24	2.378	27.45	0.794
Transactional	6	3.96	2.034	15.71	0.737
Laissez-faire	3	1.43	1.145	2.06	0.364

Source: Author's own study.

- ***Employees – Iran***

For the Iranian employees, "laissez-faire" shows high internal consistency (α=0.507) in contrast to the Swiss employees and even to the Swiss/Iranian managers. In general, poor reliability could be caused by some factors, for instance, by the fact that the Swiss/Iranian employees have difficulty articulating socially undesirable behaviors. The reliability of the expected transformational leadership is particularly good with a value of α=0.886.

Tab 3: Reliability of the data collected on expected leadership styles among the Iranian employees.

Leadership style	Number	Standard deviation	Standard error	Variance	Cronbach's alpha
Transformational	12	6.10	2.061	37.27	0.886
Transactional	6	1.81	1.844	3.27	-0.039
Laissez-faire	3	2.61	1.832	6.81	0.507

Source: Author's own study.

- ***Comparison of expected leadership styles between employees in Switzerland and Iran***

As shown in the following chart, the expected leadership styles of the employees in transformational and transactional leadership in Iran are almost identical while the employees in Switzerland tend to be transformational leaders.

Chart. 2: Comparison of expected leadership styles between the employees in Switzerland and Iran.

Source: Author's own study.

The employees' expectations of laissez-fair leadership in both countries are low. However, it is interestingly higher in Iran than in Switzerland.

Hypothesis Testing

In this section, the results of the main hypotheses are introduced and summarized:

Hypothesis 1: Hofstede's cultural dimensions influence the tendency of managers/employees towards transformational/transactional leadership styles.

According to Hofstede's research into cultural differences, it was expected that the majority of the Swiss executives and employees would prefer to use the transformational leadership style while the Iranians tend to lean towards the transactional leadership style. This hypothesis can be confirmed, considering the Swiss employees and managers. The Iranian leaders also behave as it was expected and show a tendency towards the transactional leadership style. However, the Iranian employees consider transformational leadership to be an effective leadership style, which contrasts with Hofstede's cultural norms in Iran.

H2: According to Beukman's findings, there is a relationship between Hofstede's cultural dimensions (masculinity, individualism, avoidance of uncertainty and short-term orientation) and transformational leadership factors.

This hypothesis could be formulated through the information obtained on the basis of Hofstede's cultural dimensions about Iran and Switzerland, together with the information about the relationship of these cultural elements with individual transformational leadership factors.

Based on the data collected, the executives in Iran are very conservative and resistant to change or innovation, which, according to Hofstede, was to be naturally expected. Hofstede found that Iran has a high uncertainty avoidance society. Besides, such societies are resistant to innovations, changes and new ways of thinking. The results show that the employees are more open to change and expect managers to evaluate their new ways of thinking and innovations positively. In other words, this hypothesis cannot be confirmed regarding the connection between high uncertainty avoidance and low intellectual stimulation among the Iranian executives, in contrast to the Iranian employees.

Another point is the striking difference in the tendency towards "individualized consideration" among the Iranian employees and managers. A possible explanation for this difference is the masculinity/femininity (Hofstede's cultural dimensions) of Iranian society. According to Hofstede, Iran has a more feminine society. Nevertheless, many Iranian executives are dominated by masculine characteristics such as execution ability, independence and competition as well as insensitivity to feelings, which is not to be expected in Iran. The Iranian employees have feminine values, which has already been explained by Hofstede. It can be used to confirm the relationship between femininity and a high level of individualized consideration among the Iranian employees although this relationship cannot be confirmed (but not rejected) among the Iranian executives.

In contrast to the other two cultural dimensions, high collectivist mentality causes a high level of inspirational motivation among all Iranian respondents (managers and employees). Obviously, it was to be expected because, in a collectivist society, people like to pursue a common goal and work together to achieve it. For this purpose, the managers ensure that a vision is offered and focus on the importance of cooperation and the success of the team. However, this hypothesis could not be confirmed by either the Swiss executives or the Swiss employees.

Hypothesis 3: According to Gaspar's/Lowe's/Patterson's studies, the following (r) correlations are valid:

H3.1: Contingent reward *vs* transformational leadership style: $0.3<r<0.5$

H3.2: Management-by-exception *vs* transformational leadership style: $r\approx0$

H3.3: Laissez-faire *vs* transformational leadership style: $-0.0<r<-1.0$

The three empirical studies (Gaspar, 1992; Lowe, Koeck, & Sivasubramaniam, 1996; Patterson, Fuller, Kester, & Stringer, 1995) suggested that transformational MLQ scales correlate very positively with one another (0.50-0.80), whereby 0.3 correlate -0.5 with contingent-reward, close to zero with management-by-expectation and negatively with laissez-faire. However, this claim cannot be fully confirmed in this work. For example, except for the Iranian employees, a positive correlation between the transformational leadership style and the laissez-faire scale can be found in all other respondents. This positive correlation is particularly high (0.62) among the Swiss employees. "Management-by-exception" correlates more or less with the transformational leadership style as expected. The same is valid for "contingent reward", except for the Iranian employees.

Summary

This study aimed to determine whether there is a difference between Iranian and Swiss leadership styles at Bühler AG. Besides, the expectations of the employees regarding their superiors were examined. The data collected showed that there is a high degree of agreement between the opinions of the Swiss employees and managers. However, the Swiss employees prefer their superiors to intervene in the decision-making processes more often than they actually do.

In contrast, the majority of the Iranian executives focus on transactional leadership and apply the transformational leadership style to a smaller degree, which is against the expectations of their employees. It is particularly recommended that the Iranian leaders take intellectual stimulation more seriously and become more open and supportive to new mindsets and changes, which – in turn – can increase employees' satisfaction and performance in the work environment.

Abstract

Assessment of the effectiveness of health systems has been an issue for a number of European countries for years. The aim of the present study is to evaluate and compare the functioning of the Polish healthcare system with the systems of the selected Baltic countries taking into account the opinion of the patients, as well as objective factors. Evaluate the effectiveness of health systems over the years 2012-2018 was made by comparing the Euro Health Consumer Index (EHCI) and using the methods of numerical taxonomy. The Polish health care system is one of the least effective systems in Europe. The results of the analysis allow us to conclude that the state and the organization remains similar to the so-called systems of the former Eastern European countries. Failures of the Polish system are the issue of patients' rights and the implementation of modern forms of patient care or prevention.

Keywords: Euro Health Consumer Index, numerical taxonomy, health systems management, effectiveness

Introduction

Health systems are extremely complex mechanisms, the operation of which is determined by the functioning of many institutions and organizations. But it combines them into a single system and a common overarching goal is to meet the health needs of society. Regardless of the country, each health system is characterized by the diversity of its stakeholders. Among them are public institutions, commercial organizations, public associations and finally individual recipients. The multiplicity of goals and interests to pursue, together with the mass character of the recipient's health benefits, force the entire system to need very precise and clear formulation of its functions and objectives (World Health Organization, 2000) and thus - conscious and responsible management.

A multitude of models, according to which health systems in the world work today (Bielecki and Nieszporska, 2019), as well as the complexity of the areas within which they can be considered (Bielecki and Nieszporska, 2017), give reason to believe that there is no universal way of managing them. However, at the end of the twentieth century, health systems of many countries were faced with a relatively uniform need to implement new ways of management (Frączkiewicz-Wronka, (ed.), 2010). This involved a significant increase in costs (common to many countries) resulting not only from the rapid development of medical technology, but also from changes in the age structure of populations (Van Eenoo et al., 2016; Jakovljević, 2017; Botrugno, 2018), increased health consciousness of societies, as well as an increase in spending on education and prevention (Taylor, 2016). There has been the implementation of innovative methods and techniques, and among them is New Public Management. It's primary purpose is to adapt to the public sector ideas, methods and techniques used in the private sector (Lubińska, (ed.), 2009) through the disaggregation of units in the

Challenges in Managing the Polish Health System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

public sector, a higher level of competitiveness in the public sector, clear standards and metrics to measure the effectiveness and greater emphasis on monitoring results (Woodin, 2011).

Common to almost all European countries, these challenges have resulted in diverse reactions, resulting in different and even radically different states of their health systems (Wilkens, Ovhed and Strandberg, 2012). While for example in the Nordic countries, the system has reached a kind of stability and the Scandinavian welfare states have public health care systems which have universal coverage and traditionally low influence of private insurance and private provisioning (Hofmann, 2013), the Polish system still suffers from underfunding, low availability of services, organizational issues and legal issues (Nieszporska, 2017). Therefore, the process of the management system in Poland should be supported by tools and methods allowing for continuous monitoring and supervision, indicators and metrics that allow you to assess the extent to which the intended objectives are met and laying out new strategies.

Given the above, the working assumption saying that in order to make appropriate management decisions in health care, you need to continuously monitor patients opinions about it, as well as to analyse the variables indicating the therapeutic activity of entities.

Accordingly to the Euro Consumer Health Index in selected countries of the Baltic Sea, taxonomic methods were used to evaluate the functioning of the health systems of these countries. These two methods of a health systems evaluation were chosen to compare the grading of health systems completely independent from patients' point of view with beneficiary's assessment.

Materials and Methods

Methods for Measuring the Performance of Health Systems

The primary and most important goal of any health system is to ensure public health at the highest possible level, in accordance with the applicable standards in the world. The achievement of such a goal is determined around the world on the basis of well-known and collected quantitative data such as life expectancy at birth, deaths, mortality rates of infants and other age groups, indicators of maternal mortality, causes of death, metrics representing the lifestyle of society (including: percentage of smokers, alcohol consumption, rates of overweight and obesity), immunization rates, the number of mental disorders. Research conducted in Poland and analysis of the health system seem to be largely based on data related to the above variables, while in the world, in practice there are a number of other methods (Zweifel, Breyer and Kofmann, 2009). Contemporary management of health systems requires the tools to monitor the achievement of goals. These metrics are called performance indicators (performance measures) (Kozierkiewicz, 2013). According to the WHO (Smith, Mossialos and Papanicolas, 2008), their main role is to improve the quality of decisions made by patients, providers and managers (Dymyt and Dymyt, 2018).

These metrics allow an assessment of the efficiency of the entire system at a national, regional level, as well as in individual institutions. They contribute to the determining and adjusting of goals to the realities of the system, conducive to assessing the capabilities of the system, communicating with stakeholders in the system, assigning responsibility to individual occupational groups, contributing to improving the quality of services, allowing you to track progress, provide stakeholders with information about the state of the system and the progress in achieving the objectives (Lichiello and Turnock /Consultant/, 2010). Among the areas affected are:

- health of the population (measured e.g. via: life expectancy, years of life lost, the metric DALY),
- health outcomes units (measured using the measurement condition of the patient, such as, for example EQ-5D, SF-36),
- Clinical quality and appropriateness of medical care (determined e.g. using measures of health status, postoperative mortality rates, incidence of blood pressure measurement),

- reaction of the system demand for benefits (e.g. reflected. by measuring the patient satisfaction),
- equality of access to services (e.g. determined by means of measures of usability, availability index),
- productivity of the system (represented by the measures: cost-effectiveness, efficiency technical and allocative).

Generally speaking, these metrics allow the measurement of the effectiveness of the strategy of health systems checked by practitioners and creators of public health services in many countries, but also managers of other public and private sector organizations. On the basis of exactly the same type of measurement in different countries, many initiatives were established among them (Kozierkiewicz, 2013):

- *Health for All in 2000* (WHO);
- *Health systems performance in 2000* (WHO);
- *Performance Assessment Tool for Quality Improvement in Hospitals* (WHO Denmark);
- *European Community Health Indicators* (The European Commission);
- *Australia's National Health Performance Committee's Framework* (Australia);
- *Canadian Institute for Health Information's Performance Framework* (Canada);
- *The National Indicator Project* (Denmark);
- *Netherlands National Health Care Report* (Netherlands);
- *NHS High-Level Performance Framework* (United Kingdom).

Determination of performance indicators systems, requires the use of multiple methods of measurement, indicators, analytical techniques and various methods of data collection and processing due to the large variety of areas analysed.

In the presented paper, the Euro Health Consumer Index and numerical taxonomy were used to evaluate the health systems in selected countries of the Baltic Sea basin.

Euro Health Consumer Index (EHCI) is one of the most interesting indicators for an assessment of health systems in different countries, due to the fact that its systems are evaluated from the perspective of the consumer health benefits. Universally it seems to be the fact that health systems are primarily for the patient and they have been created for him. However, nowadays the burden of analysis and critical reflection on the state system is rather transferred to an economic dimension; yet look at the eyes of the patient and just get an opinion from his perspective which is of greater importance.

EHCI beginnings date back to 2004, in which the report was published the Swedish Health Consumer Index. The comparison was made in 21 countries based on 12 indicators. These focused on creating health policies in different countries, the choices made by beneficiaries, the level of service and access to information. Over the years, measures have been changing. At the beginning of its existence, it focused on: infant mortality, cancer survival and the treatment of stroke and heart disease. Today we are enriched with data on access to information, quality of service, mobility funding benefits under the directives of cross-border, and e-health, as well as the introduction of more stringent data such as 30-day case fatality for heart infarction and stroke.

1. patients' rights and information,
2. accessibility (waiting times for treatment)
3. outcomes,
4. Range and reach of services provided,
5. prevention,
6. pharmaceuticals.

48 indicators derived from 6 groups of subjects included in the evaluation as well as COPD and mortality indicator, connected in one synthetic Euro Consumer Health Index, which value belongs to the range (0-1000); the highest value is the best estimate of the health system of the country.

Numerical taxonomy is also the method to evaluate and compare the health systems in selected countries. It enables to ranked the systems, and therefore rated them on the basis of the so-called of synthetic qualities of which one works best (taking into account the few selected features). In a second step, numerical taxonomy lets to assess a similarity of the systems using the method of clusters, according to which states are divided into groups and each of them included similar countries and these different assigned to other clusters. To analyse the similarities and differences in the functioning of health systems in some countries, cluster analysis can be carried out according to the so-called Ward method. It is a method binding, which seeks to minimize the sum of squares of any two clusters and to link objects (countries), so that the resulting clusters intragroup variance of characteristics of the objects is as low as possible. Each object is treated and analysed with this method, initially as a single cluster to the next stages of the study to reduce the number of groups thus formed by combining pre-existing in the so-called 'group of higher order'. The whole process ends with the creation of a single cluster, which includes all the analysed objects.

Results

Euro Health Consumer Index (EHCI) in the Countries of the Baltic Sea Region

There are many tools that can estimate the state of the health care system that are not popular in Poland. However, in accordance with the opinion of some Polish experts "due to vastness of international experience and resources held in Poland, the data allow us to conclude that the creation of assessment tools of the system, in particular assessing the state of health of services is possible" (Kozierkiewicz, 2013). However, an important factor in the creation of such a system is de-politicization of the health sector and entrusting the role of the organization and management of the sector such organizations, to ensure the political neutrality. The Polish model of health care, however, assumes that the system should be the idea of the concept of public health service financed by taxation of society. Under this assumption, one of the primary roles of system management belongs to the state. It is obvious that the role of each country's attention to social welfare in the context of health, "but the specific ability of interest groups to obtain influence can lead to seizure of regulatory processes" (Getzen, 2000), then the state ceases to place the welfare of society in the first place, realizing the interests of the ruling political groups.

However, EHCI is an international project, that also allows Poland to perform analysis. An important highlight is the fact that the counted metrics in EHCI are specific to how consumers of health care are served by systems of European countries. Taking countries of the Baltic Sea basin into account there are differences in terms of their health policies, systems and organizational structure, which does not mean that health activities have no common trends. As assumed, for example, ScanBalt® FMBA - Northern Europe's Leading Accelerator for Inter-regional Cooperation, the vision of cooperation between the countries of this region is realistic and it can create *a globally leading macro-region within health economy and biotechnology based innovation* (https://scanbalt.org/). Currently Denmark, Finland, Sweden, Germany, Netherlands and Norway, stand out in this group overall biotechnology innovation and are well placed in ScanBalt among other nations. A separate group is The East Baltic ScanBalt countries, Estonia, Lithuania, Poland and Latvia. Interestingly, the level of development of ScanBalt countries and their rank in the rankings ScanBalt® FMBA is to a large extent the level of assessment of health systems by patients within the EHCI. The lowest positions in the group of those countries when it comes to the value of the EHCI is occupied Estonia, Lithuania, Poland and Latvia (Figure 1).

Fig. 1: The Euro Health Consumer Index for the period 2012-2018 in selected countries

Source: Björnberg and Yung, 2019

In the years 2012-2018 the average value of the index in these countries amounted to 687, 593, 552, 563 (own calculations based on reports). The report's authors see their lowest position in the Polish caused by negligence, abuse of management and poor organization of the system and in Lithuania and Latvia in the financial crisis (Björnberg and Yung, 2019).

In the group of the "800 Club", those countries for which the EHCI exceeded the value of 800, during the years 2012-2018 were Denmark, Finland, Germany and Norway. The country with the best result in the audited period, the health system, in the opinion of consumers was Norway with an average index of 835 points. And although, as the report emphasizes, Norwegian patients complained about waiting times, the first place in the rankings provides the sub-discipline Prevention (Björnberg and Yung, 2019). The countries with the highest index values stand out in the areas of health, which represent sub-disciplines: e-Health, Outcomes, Range and Reach of Services Provided and Patients' Rights and Information.

Ranking of Health Systems Using Numerical Taxonomy Methods

A quoted measure of the efficiency of the health systems but cannot be the sole determinant of the evaluation of a system. Many factors not included in the EHCI reports have no significant impact on the functioning of health systems, many of them cannot be assessed by the patient (even if as a result of ignorance of the consumer benefits, or ignorance of some of the data variables), and many have a subjective character. Therefore, each ranking of a health care system should be enriched with an objective and independent opinion from the patient and analysis of demographic and economic factors that characterize the country, as well as reflecting the structure and resources of the health system.

Complementing the above, the following variables characterizing the eight health systems (in the countries: Denmark, Estonia, Finland, Germany, Latvia, Lithuania, Poland, Sweden) for the years 2016-2018 were collected and analysed:

X1 - the number of doctors involved in the total population,
X2 - the share of the number of nurses in the total population,
X3 - the share of the number of midwives in the total population
X4 - the number of hospital beds per capita,

X5 - the average length of stay in the hospital.
X6 - the share of people over 65 years of age in the total population,
X7 - public expenditure on health care in US dollars (USD) per 1 capita Purchasing Power Parity.

The above variables were chosen because they describe the complete situation of analysing systems and data which are relatively common for all countries.

Organizing health systems in selected countries began the normalization of attributes, using quotient mapping (Malina, 2004). As a measure of the distance we adopted the Euclidean distance (Panek, 2009) and that the best method, which gives results characterized by the greatest value of the directional variance (Kolenda, 2006). Then the weights were determined, while the method and anti-template were used to use the method based on orthogonal projection, in which the value of the third quartile for the nth-trait was adopted as the standard, and the anti-standard the value of the first quartile for the nth-trait. After calculations, the synthetic feature values were determined for each country and year under analysis (Table 1).

As is evident from the calculations, taking into account the seven noted above variables in each of the analysed years, Germany and Sweden occupied the first places in the ranking. The last two places were Estonia and Lithuania, and Poland consistently recognized as the third from the end.

Table 1: Values of characteristics of synthetic

Years Countries	2016	2017	2018
Denmark	2.35	2.36	2.34
Estonia	1.78	1.78	1.80
Finland	2.64	2.56	2.62
Germany	3.16	3.21	3.20
Latvia	1.52	1.51	1.54
Lithuania	2.02	2.02	2.04
Poland	2.03	2.02	2.07
Sweden	2.85	2.79	2.76

Source: Own calculations on the basis OECD 2020

The results shows the grouping mostly in graphical form by using the so-called Call or Dendrite tree (dendrogram). Dendrites present the sequential clusters of increasingly higher orders with specific binding distances, by indicating the similarities and differences between the objects studied from the point of view of the considered characteristics.

The results of analysis of the functioning of health systems in selected countries is presented in Figure 2, Figure 3 and Figure 4, which shows that the greatest similarity due to the characteristics studied showed Lithuania and Estonia. The distance between the regions in terms of the variables studied were the smallest group. One group with Lithuania and Estonia include binding at approx. 1.15 also Latvia and Poland. This leads to the conclusion that the past and the historical conditions of the functioning of these countries, as well as the so-called common Siemaszko model, according to which health systems were managed in those countries continue to make them similar and seem to have a continuous effect on the quality of their health systems. Quite different from European countries which form a group from behind the former Iron Curtain and so include Germany, Sweden, Finland and Denmark.

Fig. 2: Dendrogram for selected countries in 2016

Source: Own calculations with using Statistica 13.3

Fig. 3: Dendrogram for selected countries in 2017

Source: Own calculations with using Statistica 13.3

The analysis can also draw the conclusion that created and depicted in figs. 2-4 the group focused countries with similar levels of wealth and financial resources provided for health care. This confirms that GDP is the main determinant of health expenditure (Akca, Sonmez and Yilmaz, 2017; Strzelecka 2016) and describes the level of the health capacity of the system (Rabiej, 2017).

Conclusion

The smooth functioning of health systems in each country is a specific priority. This is due to the importance and great significance for the public health system – the parental entity of each of the sectors of the national economy. Decision making in health care, effective management and goal setting sector, it therefore appears one of the key conditions is not only the effectiveness of the systems themselves (Bui et al., 2015), but also the existence of healthy societies.

Taken in the development of analysis of the health system in Poland compared to other countries it had two objectives. The first is reflected consumers' opinion of benefits and thus identify critical points for patients of the functioning of the system. The second is to focus on the evaluation of health systems using objective factors affecting the operation of the Polish system and the systems of neighbouring countries.

Therefore, bearing in mind the opinions of Polish consumers of health services, as well as the relationships between them are independent of the factors characterizing the health systems in the countries bordering the Baltic Sea, it should be clearly stated that Poland is in such comparisons on one of the last places. The study indicates that one of the reasons for this may be the political past of our country, which still makes the Polish system similar to the system in Lithuania, Latvia and Estonia. Common to these countries is a model of human behaviour and functioning system of hierarchy of values so devalued and even distorted in the second half of the twentieth century it brought with it a multitude of already existing consequences in areas such as medical ethics, and a mutual doctor-patient relationship.

Polish similarity to Latvia, Lithuania and Estonia in terms of the functioning of health systems in them is also associated with a similar level of current expenditure on health. On average, they are in these countries 6.44% of GDP, which is in large differences in terms of expenditure with Germany, Sweden, Finland and Denmark, which account for an average of 10.38% of GDP. Underfunding of the health sector entails reforms so as to avoid financial instability in health care and thus contribute to increase investment in health care (Strzelecka, 2014).

Much of the quantitative data presented by OECD (OECD, 2020) such as life expectancy at birth, deaths, mortality rates of infants, indicators of maternal mortality, metrics representing the lifestyle of society (number of smokers, alcohol consumption) are also comparable for Poland, Latvia, Lithuania and Estonia. Maybe they also affect the similarity of the health systems in these countries.

Polish creators for health policy or health care managers this is an important signal of continuous years of lack of patient satisfaction with the functioning of the sector. According to reports, in Poland there continues:

- a competitive insurance market,
- characterized by extremely low public spending on the sector,
- is heavily politicized health system,
- does not keep up with demand for the services of an aging population,
- no patient organizations, which would affect the shape of the system,
- It characterized by a very low level telecare.
- There is no implemented patient information systems at all levels of health care,
- It does not guarantee their patients equal and universal access to medical services (Universal access to health care means that everyone has access to quality health services they need, without the risk grapple with financial difficulties associated with covering the cost of treatment. (World Health Organization, 2013)).

Practice and experience of neighbouring countries shows that it is well known from management practice, that if top management starts focussing on things other than producing the best products or services, the quality of products/services declines (Björnberg, 2017), which clearly sets out the directions of change in the management of Polish health system.

Abstract

An increasing housing price in Perak has made it difficult for homebuyers to own affordable housing. Housing affordability ensures that housing provided is affordable for every income group, especially the low and middle-income groups. It has brought the government and housing developers to take close the issue of housing affordability by supplying public low-cost housing schemes. The traditional measurement of housing affordability is by using the percentage of household income spent on housing. The important cost that is usually ignored in measuring housing affordability is transportation costs. Housing and transportation are the two largest expenses for most households. This paper aims to determine the factors affecting housing affordability by including transportation expenditures. A total of 65 questionnaires were distributed to the homebuyers in Perak Tengah. Multiple linear regression was conducted and the results revealed that locational, neighborhood, structural, and financial were significant factors influence housing affordability. It also showed that including transportation expenditure into the calculation of housing affordability can reveal true housing affordability measurement.

Keywords: Housing affordability, locational, neighborhood, structural, financial, transportation expenditure.

Introduction

Affordability concerns to make housing affordable for every household however it is not meant focused only on the low prices but concerns about the quality of the house. The government is responsible for providing housing for low-income households, but private sectors have concentrated on the high-end house due to a significant increase in house and land prices. To deliver affordable and quality housing, it is important to clarify what are the main factors that influence people to buy houses such as housing prices and location. Housing affordability is a crucial issue over the last decade since the continuous increase in property prices due to economic rapid growth. This is because the house price is the main consideration when to decide to own a house. Housing prices within an urban area in Malaysia are becoming severely unaffordable as compared to housing in rural areas. Housing prices are highly dependent on location since there is a relation to the role of location in the housing market. The location also has become the main consideration when purchasing a residential property, in particular, the distance between the residential neighborhood and employment centers. Housing is not truly affordable if located in an accessible area with high transportation costs. This is because of the transportation costs are highly associated with the selection of residential location.

A significant number of previous research on housing affordability has been focused on housing costs and household income. Recently, there is a new indicator of housing affordability which includes transportation expenditure (Yusoff et al., 2014). This is because housing and transportation are the two largest expenses for most households. Previous housing affordability studies generally ignore the dimensions of transportation cost even though there is a strong influence on household expenditure (Mattingly and Morrissey, 2014). However, in research by Dewita et al. (2018) mentioned that incorporating transportation costs into housing affordability measurements reveal a different pattern of affordability. There has been little research to investigate how the combination of housing and transportation costs can impact housing affordability measurements. Therefore, this study seeks to measure housing affordability by considering not only the cost of housing but the condition and location efficiency by measuring transportation costs.

Literature Review

Housing affordability

Recently, researchers have changed from the traditional way of defining the measurement of housing affordability and wider the perspective of concept. Research in the USA suggests that housing that may be considered affordable in terms of price of the house is related to annual household income, however, transportation costs are often underestimated or ignore (Mulliner and Maliene, 2012). The research stated that the interaction between housing and transportation cost provides a more meaningful measure of housing affordability. Affordability is the ability of the person in providing something that usually referred to the ability in financial terms. The various definition and concepts of housing affordability give different approaches to measure housing affordability such as price to income ratio, residual income, and purchase and repayment affordability (Gan and Hill, 2009). Purchase affordability is considering whether the ability of the household to borrow enough funds to purchase a house. Repayment affordability is considering the burden on the household to pay the mortgage while income affordability is referred to the measurement of the ratio of house prices to the income of the purchaser. Besides, housing affordability is defined condition of when people have the potential to save a certain portion of income to buy the house and as well as other consumption (Mostafa et al. , 2006). In Malaysia, housing affordability is denoted as the rent-to-income ratio or house price-to-income ratio known as income affordability. The median multiple is a common measurement suggested by the World Bank and the United Nations which rates of affordability of housing by dividing the median house price and annual median household income. Affordability is rated on a scale of 0 to 5, as shown in Table 1. Housing markets are rated as affordable at or below 3 times the median multiple, moderately unaffordable at or below 4 times median multiple, seriously unaffordable at or below 5 times median multiple, and above 5 times rated as severely unaffordable (Suhaida *et al.*, 2011).

Table 1: Categories of housing affordability

Rating	Median multiple
Severely unaffordable	5.1 & above
Seriously unaffordable	4.1 to 5.0
Moderately unaffordable	3.1 to 4.0
Affordable	3.0 & below

Sources: The International Demographia (2006-2011)

Housing Attributes

Housing preferences will be determined by a set of various attributes of housing households (Tan and Cheah, 2013). Housing attributes have been shown in previous research as major factors influencing housing affordability such as structural, location, and neighborhood of housing.

Location attributes are highly related to the area or place where the housing is located whether an urban area or rural area. The distance is considered as the main factor that affects the buyer's preference in decision making such as distance to the workplace, schools, shops, and other facilities (Sean and Hong, 2014). Daly et al. (2003) mentioned that location has a primary value attribute on the buyer's preference in purchasing residential properties in Australia, UK, and Ireland. Besides, Kauko (2007) stated that location is an important factor to determines the success or failure of the residential housing project. Natasha and Hassan (2015) found that location attributes have a positive relationship and can give a positive impact on the intention to make a property investment. Location was considered as the highest contribution that influences on the housing price (Olanrewaju et al., 2018).

The neighborhood is also one of the most important attributes to measure housing affordability. According to Sean and Hong (2014), the neighborhood is defined as an area in which residents live together for the common interest. Previous research by Zrobek *et al.* (2015)has shown that cleanliness and low crime trends are examples of good neighborhood environments that are important aspects of the purchase of residential properties. The good neighborhood gives a positive impact on housing prices. According to Teck-Hong (2011), a house in a good neighborhood is preferred as households are willing to pay extra for a house of good environmental quality. Thaker and Sakaran (2016) mentioned that the good quality of residential property can be valued by an excellent indoor and outdoor environment. Besides, Thanaraju et al. (2019) mentioned that the safety of the neighborhood is also considered as another important aspect when purchasing a residential property. This is because due to an increase in the trend of crimes such as burglary and snatch. Besides, the security of the neighborhood is very important for the safety level of the residential area since the number of crimes in Malaysia is increasing (Mariadas et al.,2019).

Numerous empirical studies have identified structural attributes as influential components of households' in the house-buying decision. According to (Teck-Hong, 2012) structural attributes that can impact home-buying preferences including lot size, the number of bedrooms and bathrooms, and the presence of a garden in a house. Hurtubia et al. (2010) mentioned that the number of bedrooms and bathrooms in a house are important characteristics to be considered when purchasing a residential property. For instance, in Saudi Arabia, private living space such as the number of bedrooms, the size of bedrooms, and the number of bathrooms are considered to be the important factors because it will have a direct relation to the problem of privacy (Opoku and Abdul-Muhmin, 2010). A similar finding by Chia et al. (2016) concluded that private living space is considered to be a key housing attribute because it can be directly related to the issue of privacy. Besides, Sundrani (2018) also mentioned that the number of bedrooms and the size of bedrooms are the most important features to be considered in their homeownership decisions.

Financial attributes play important features that the household needs to consider in their homeownership decisions. Besides, financial attributes strongly influence the decision of homebuyers to purchase a residential property (Sean and Hong, 2014; Thaker and Sakaran, 2016). As mentioned by Mariadas et al. (2019), there are several key areas regarding financial consideration such as interest rate, house price, household income, and ability to obtain financing. According to Li et al. (2014) also mentioned that financial factors such as length of the period for the payment, interest rate, amount of monthly payment are the main consideration while choosing a residential property to purchase. Zainon et al. (2017) concluded that financial factor has a positive relationship on housing affordability.

Transport Expenditure

In recent years, there is a new indicator of housing affordability that includes transport expenditure (Sabri et al. 2013; Yusoff et al. 2014). Housing and transportation are the two largest expenses for most households. Besides, housing and transport expenditure show a more complete picture of affordability in the neighborhood. The traditional measure of housing affordability generally focused on housing cost alone, while ignores the transportation cost which incurs a relatively high proportion of income. Therefore, combining housing and transportation cost offers an expanded view of affordability. Previous research suggested that incorporating transportation costs into housing affordability calculations can reveal a different pattern of affordability, especially in less accessible locations

(Dewita et al. 2018). Several studies from European countries provide a similar result of the importance of incorporating transportation costs to reveal more appropriate measures of housing affordability. Transportation expenditure consists of three important variables which are vehicle ownership, vehicle usage, and public transit. Vehicle ownership is determined by the number of the vehicle, monthly payment of the vehicles, and the annual amount of insurance and tax. Vehicle usage is based on the amount of fuel consumption, monthly amount toll, and parking fees, and cost and maintenance of the vehicles. Public transit will be the total amount of monthly expenses on public transit.

Methodology

Quantitative research was utilized in this study whereby 68 questionnaires were distributed to respondents and 65 questionnaires which were answered without error were collected to be analyzed. The area for questionnaire distribution focused on Perak Tengah among home buyers between 20 to 59 years old. The data obtained were analyzed through the Statistical Package for Social Science (SPSS) software.

Conceptual Framework

In this present study, five independent variables (location, neighborhood, structural, financial, and transportation expenditure) and one dependent variable (housing affordability) were examined. The conceptual framework for this study was shown in Figure 1 shows the interrelationships between independent variables and the dependent variable.

Figure 1: Conceptual framework

Variables used in the study

The measure of housing attributes, as defined by locational, neighborhood, structural, and financial housing attributes. Six locational housing attributes were considered in this study; access to shopping facilities (Shopping), public transport facilities (Transport), health care facilities (Health care), leisure facilities (Leisure), to school (School), and the workplace (Workplace). Neighborhood attributes

included in the study were the level of neighborhood crime rate (Crime), gated neighborhood (Gated), neighborhood cleanliness (Cleanliness), neighborhood pollution (Pollution), and green surrounding neighborhood (Green). The size of a living area (Living), size of the kitchen (Kitchen), number of bathrooms (Bathroom), number of bedrooms (Bedroom), eco-friendly home (Eco), and built-up area (Built-up) were included to indicate structural attributes of the housing. Lastly, four financial housing attributes included in this study, namely price of the house (Price), amount of monthly repayment (Repayment), amount of interest rate (Interest), and duration of loan repayment (Duration). Transportation expenditure is divided into three variables which were vehicle ownership, vehicle usage, and public transit. Vehicle ownership is determined by the number of the vehicle, monthly payment of the vehicles, and the annual amount of insurance and tax. Vehicle usage is based on the amount of fuel consumption, monthly amount toll, and parking fees, and cost and maintenance of the vehicles. Public transit will be the total amount of monthly expenses on public transit. The definition of independent variables used in the study is shown in Table 2.

Table 2: Definition of independent variables in the study

	Variables	Definition
Locational attributes	Shopping	1 if access to shopping facilities is the main consideration when purchasing a house, 0 otherwise.
	Transport	1 if access to public transport facilities is the main consideration when purchasing a house, 0 otherwise.
	Health care	1 if access to health care facilities is the main consideration when purchasing a house, 0 otherwise.
	Leisure	1 if access to leisure facilities is the main consideration when purchasing a house, 0 otherwise.
	School	1 if the access to school is the main consideration when purchasing a house, 0 otherwise.
	Workplace	1 if access to the workplace is the main consideration when purchasing a house, 0 otherwise.
Neighborhood attributes	Crime	1 if the level of crime rate in the neighborhood is the main consideration when purchasing a house, 0 otherwise.
	Gated	1 if the presence of a gated neighborhood is the main consideration when purchasing a house, 0 otherwise.
	Cleanliness	1 if the cleanliness of the neighborhood is the main consideration when purchasing a house, 0 otherwise.
	Pollution	1 if the level of pollution in the neighborhood is the main consideration when purchasing a house, 0 otherwise.
	Green	1 if the green surrounding of the neighborhood is the main consideration when purchasing a house, 0 otherwise.
Structural attributes	Living	1 if the size of the living area is the main consideration when purchasing a house, 0 otherwise.
	Kitchen	1 if the size of the kitchen is the main consideration when purchasing a house, 0 otherwise.
	Bathroom	1 if the number of the bathroom is the main consideration when purchasing a house, 0 otherwise.
	Bedroom	1 if the number of the bedroom is the main consideration when purchasing a house, 0 otherwise.
	Eco	1 if an eco-friendly home is the main consideration when purchasing a house, 0 otherwise.
	Built-up	1 if the built-up area of the house is the main consideration when purchasing a house, 0 otherwise.
Financial attributes	Price	1 if the price of a house is the main consideration when purchasing a house, 0 otherwise.

	Repayment	1 if the amount of monthly repayment is the main consideration when purchasing a house, 0 otherwise.
	Interest	1 if the amount of interest rate of the loan is the main consideration when purchasing a house, 0 otherwise.
	Duration	1 if the duration of loan repayment is the main consideration when purchasing a house, 0 otherwise.
Transportation expenditures	Vehicle ownership	Number of vehicles
		Monthly payment of the vehicles
		The annual amount of insurance and tax
	Vehicle usage	The annual cost of fuel
		The monthly amount of toll
		The monthly amount of parking fees
		The annual cost of maintenance
	Public transit	Amount of monthly expenses on public transport

Levels of Housing Affordability

The median multiple is a common measurement suggested by the World Bank and the United Nations which rates of affordability of housing by dividing the median house price and annual median household income. The affordability levels are categorized by four which are affordable, moderately unaffordable, seriously unaffordable, and severely unaffordable. The household is classified as affordable if the median multiple is lower than 3.0 while the household is classified as moderately unaffordable if the median multiple is between 3.1 to 4.0, seriously unaffordable if the median multiple is between 4.1 to 5.0 and severely unaffordable if the median multiple is higher than 5.1.

Results and Discussions

Table 3 shows the demographic profile of the respondent. The questionnaire was completed by 65 respondents. Out of 65 respondents, 47 were females (72.3%) and the remaining 18 were males (27.7%) thus female respondents were slightly higher than male respondents. In terms of age, 33.8% of the respondents were in the age of 20-29, followed by the age of 30-39 (30.8%), the age of 50-59 (20.0%), and the age of 40-49 (15.4%), respectively. The majority of the respondents were married with 66.2% while single with 32.3% and widowed with 1.5%. There was a total of 43.1% were have master's degree qualification followed by a bachelor's degree with 29.2% and diploma qualification with 15.4%. The public sector was the overwhelming majority of the respondents at 53.8%, followed far behind by private with 30.8% and self-employed with 13.8%. Most of the respondents were the owner of the house (52.3%), several are a tenant (27.7%) and a few stayed at family homes or home share. 33.8% of respondents stayed at a single storey terrace followed by a double storey terrace with 27.7% and stayed at an apartment or flat with 16.9%.

Table 3: Profile of respondent

Variables	Frequency	Percentage
Gender		
Male	18	27.7
Female	47	72.3
Age		
20-29	22	33.8
30-39	20	30.8
40-49	10	15.4
50-59	13	20.0
Marital status		
Married	43	66.2

Single	21	32.3
Widowed	1	1.5
Education level		
SPM	5	7.7
Diploma	10	15.4
Bachelor Degree	19	29.2
Master's Degree	28	43.1
Doctor of Philosophy	3	4.6
Sector of employment		
Private	20	30.8
Public	35	53.8
Self-employed	9	13.8
Unemployed	1	1.5
Occupied status		
Owner	34	52.3
Tenant	18	27.7
Family home/share	13	20.0
Type of house		
Single storey terrace	22	33.8
Double storey terrace	18	27.7
Semi detached	5	7.7
Bungalow	4	6.2
Condominium/Service residence	2	3.1
Flat/Apartment	11	16.9
Others	3	4.6

Regression Analysis

There were two equations presented in regression analysis. The first equation is solely based on the effect of housing attributes on housing affordability without taking into consideration transportation expenditure, whereas the second equations include transportation expenditure into the model. As shown in Table 4, the first and second equations explained about 77% and 80% of the variation in housing affordability, respectively.

The results from both equations revealed that the access to shopping facilities and school were negatively significant to the housing affordability. Additionally, access to public transport, leisure facilities, and workplace were positively significant to the housing affordability. However, the health care facilities was insignificant to the housing affordability. It showed that homebuyers in the study excluded health care facilities in determining the factors affecting housing affordability.

Since the crime rate in Malaysia increased significantly, thus homebuyers were slightly more concerned about their neighborhood condition. Based on estimation results concluded the level of crime rate, gated neighborhood, level of cleanliness, and green surroundings in the neighborhood were statistically significant and positively associated with housing affordability. This result consistent with the findings of (Teck-Hong, 2012) mentioned that neighborhood security is an important aspect when purchasing a house. Lastly, the level of pollution is not significant to the housing affordability in the first equation but positively significant after considering transportation expenditure in the equation.

For structural housing attributes, the size of the kitchen and the number of bedrooms were statistically significant and negative relationship to the housing affordability in both equations. This result is similar to Opoku and Abdul-Muhmin (2010), private living space such as the number of bedrooms is the main consideration when purchasing a residential property. Besides, the number of bathrooms and built-up areas of the house were positively statistically significant towards housing affordability. Nevertheless,

the size of the living area and eco-friendly home were no significant relationship with housing affordability. It indicates that the size of the living area and eco-friendly home were not the main consideration when purchasing an affordable house.

Furthermore, homebuyers more preferred houses that have good financial attributes. It shows that house prices, monthly repayment, interest rate, and duration of the loan were statistically significant to housing affordability. There was a positive relationship between monthly repayment and duration of loans with housing affordability in both equations. The finding is consistent with Mariadas et al., (2019a) that shows financial attributes considered as the important factors to the housing affordability.

After considering transportation expenditures to the model, the model is statistically significant. It shows that there was a significant relationship between housing attributes and transportation expenditures towards housing affordability. Additionally, the amount of insurance and tax and the annual fuel consumption was statistically significant to the housing affordability and negatively associated. The monthly payment, cost of the toll, cost of parking fees, maintenance, and public transport were no significant relationship with housing affordability.

Conclusions

There are appeared to be different for the current and previous conceptual measurement of housing affordability due to exclusion of transportation expenditure. This study also relevant to the housing developers because it provides information for improving the housing delivery system by including transportation expenditure. To ensure the success of affordable housing schemes, developers should be sensitive to homebuyers' interest by determining the factors related to homeownership priorities. The result of this study showed that variables associated with locational attributes such as access to shopping, public transport, leisure, school, and workplace were found to be significant to housing affordability. Homebuyers are not only paying attention to the quality of housing but they are also concerned about the good and safe environment. Homebuyers would prefer gated communities and guarded neighborhood. Besides, the financial factor is found to be an important consideration when purchasing a residential property. It shows that homebuyers are more concerned about the house price, the interest rate, amount of monthly payment, and the duration of the loan when purchasing an affordable house. Transportation expenditures such as the amount of insurance and tax and consumption of fuel were statistically significant to the housing affordability. Given the significant factors of transportation expenditure, local and state governments are encouraged to consider transportation expenditures when planning for affordable housing. This paper supported the argument that incorporating transportation costs into affordability measures reveal true housing affordability. Thus, the transportation expenditure should be a part of the definition of affordable housing as it influences household expenditure.

Abstract

Housing affordability has been a major concern issue as the house price has increased significantly. Owning a house is significantly known as one of the major goals and reflects a single investment of a lifetime. Affordable housing is not mainly focused only on house prices, but it also includes the quality and amenities of the house. There are many indicators to measure housing affordability in Malaysia such as locational, neighborhood, structural, and financial attributes. However, the traditional measure of the affordability of housing has generally ignored the cost of transportation that incur a relatively high proportion of income. Therefore, this study aims to measure housing affordability by considering not only the cost of housing but the condition and location efficiency by measuring transportation costs. It is because combining transportation costs on the measure of housing affordability calculation can reveal a different pattern of affordability.

Keywords: Housing affordability, locational, neighborhood, structural, financial, transportation expenditure.

Introduction

Home has been recognized as one of the essential needs and significant component in the urban economy. Additionally, owning a house is one of a major goal and represents a single investment of a lifetime. It acts as a shelter to support household living. Besides, the need for housing is the main priority for the citizens to ensure their ongoing lives. However, one of the biggest problems lower-income Malaysian households face today is finding affordable, secure, and appropriate housing since housing within an urban area is more expensive as compared to housing in a rural area. Thus, the housing ownership should consider factors such as the financial capability of the buyers, development cost, and selling price.

Malaysians are facing problems in housing ownership since the house price has increased significantly. Besides, housing prices in the urban area in Malaysia are becoming severely unaffordable recently. The high rate of urban growth due to migration, increase in population size, and income level was significantly contributed to the housing market. The change in housing markets was due to increasing

in demand and fluctuating price that affects the housing affordability. Housing affordability is not a new issue and it has taken over the global attention. Besides, housing affordability becoming one of the most critical development issues and considerable challenges especially for low incomes households. In most of the world including Hong Kong, Japan, Australia, Ireland, Nigeria, Indonesia, Singapore are facing the problem of housing is unaffordable. An affordable housing issue becomes the main focus on managing the growth of housing prices and reducing the effects of the housing issue.

A significant number of previous researches on housing affordability has been focused on housing costs and household income. Thus, a need for a broad and better understanding of housing affordability rather than simple measures based on housing expenditure and household income which cannot deal with issues such as housing conditions, location, and access to quality. Mulliner and Maliene (2012) criticized that pre-existing affordability literature focused on house prices rather than the condition, location, and neighborhood characteristics of the housing. Therefore, this study seeks to measure housing affordability by considering not only the cost of housing but the condition and location efficiency by measuring transportation costs.

Literature Review

Concept of housing affordability

In many countries, housing affordability has become the main considerable attention for several years. Affordability is the ability of the person in providing something that usually referred to the ability in financial terms. Housing affordability can be defined in three different ways (Gan and Hill, 2009); purchase affordability, repayment affordability, and income affordability. Purchase affordability is considering whether the ability of the household to borrow enough funds to purchase a house. Repayment affordability is considering the burden on the household to pay the mortgage while income affordability is referred to the measurement of the ratio of house prices to the income of the purchaser. Besides, housing affordability is defined condition of when people have the potential to save a certain portion of income to buy the house and as well as other consumption (Mostafa et al. , 2006). In Malaysia, housing affordability is denoted as the rent-to-income ratio or house price-to-income ratio known as income affordability. The median multiple is a common measurement suggested by the World Bank and the United Nations which rates of affordability of housing by dividing the median house price and annual median household income. Affordability is rated on a scale of 0 to 5, as shown in Table 1.

Table 1: Categories of housing affordability

Rating	Median multiple
Severely unaffordable	5.1 & above
Seriously unaffordable	4.1 to 5.0
Moderately unaffordable	3.1 to 4.0
Affordable	3.0 & below

Sources: The International Demographia (2006-2011)

Housing markets are rated as affordable at or below 3 times the median multiple, moderately unaffordable at or below 4 times median multiple, seriously unaffordable at or below 5 times median multiple, and above 5 times rated as severely unaffordable (Suhaida *et al.*, 2011).

Locational Attributes

Location attributes are highly related to the site or place where the housing is located whether an urban area or rural area. The distance is considered as the main factor that affects the buyer's preference in decision making such as distance to the workplace, schools, shops, and other facilities (Sean and Hong,
