2014). Daly et al. (2003) mentioned that location has a primary value attribute on the buyer's preference in purchasing residential properties in Australia, UK, and Ireland. Besides, Kauko (2007) stated that location is an important factor to determines the success or failure of the residential housing project. Natasha and Hassan (2015) found that location attributes have a positive relationship and can give a positive impact on the intention to make a property investment. Location was considered as the highest contribution that influences on the housing price (Olanrewaju et al., 2018).

Neighborhood Attributes

The neighborhood is also one of the most important attributes to measure housing affordability. According to Sean and Hong (2014), the neighborhood is defined as an area in which residents live together for the common interest. Previous research by Źróbek et al. (2015) has shown that cleanliness and low crime trends are examples of good neighborhood environments that are important aspects of the purchase of residential properties. The good neighborhood gives a positive impact on housing prices. According to Teck-Hong (2011), a house in a good neighborhood is preferred as households are willing to pay extra for a house of good environmental quality. Thaker and Sakaran (2016) mentioned that the good quality of residential property can be valued by an excellent indoor and outdoor environment. Besides, Thanaraju et al. (2019) mentioned that the safety of the neighborhood is also considered as another important aspect when purchasing a residential property. This is because due to an increase in the trend of crimes such as burglary and snatch. Besides, the security of the neighborhood is very important for the safety level of the residential area since the number of crimes in Malaysia is increasing (Mariadas et al.,2019).

Structural Attributes

Numerous empirical studies have identified structural attributes as influential components of households' in the house-buying decision. According to (Teck-Hong, 2012) structural attributes that can impact home-buying preferences including lot size, the number of bedrooms and bathrooms, and the presence of a garden in a house. Hurtubia et al. (2010) mentioned that the number of bedrooms and bathrooms in a house are important characteristics to be considered when purchasing a residential property. For instance, in Saudi Arabia, private living space such as the number of bedrooms, the size of bedrooms, and the number of bathrooms are considered to be the important factors because it will have a direct relation to the problem of privacy (Opoku and Abdul-Muhmin, 2010). A similar finding by Chia et al. (2016) concluded that private living space is considered to be a key housing attribute because it can be directly related to the issue of privacy. Besides, Sundrani (2018) also mentioned that the number of bedrooms and the size of bedrooms are the most important features to be considered in their homeownership decisions.

Financial Attributes

Financial attributes play important features that the household needs to consider in their homeownership decisions. Besides, financial attributes strongly influence the decision of homebuyers to purchase a residential property (Sean and Hong, 2014; Thaker and Sakaran, 2016). As mentioned by Mariadas et al. (2019), there are several key areas regarding financial consideration such as interest rate, house price, household income, and ability to obtain financing. According to Li et al. (2014) also mentioned that financial factors such as length of the period for the payment, interest rate, amount of monthly payment are the main consideration while choosing a residential property to purchase. Zainon et al. (2017) concluded that financial factor has a positive relationship on housing affordability.

Transport Expenditure

In recent years, there is a new indicator of housing affordability that includes transport expenditure (Sabri et al. 2013; Yusoff et al. 2014). Housing and transportation are the two largest expenses for most households. Besides, housing and transport expenditure show a more complete picture of affordability in the neighborhood. The traditional measure of housing affordability generally focused on housing cost alone, while ignores the transportation cost which incurs a relatively high proportion of income.

Therefore, combining housing and transportation cost offers an expanded view of affordability. Previous research suggested that incorporating transportation costs into housing affordability calculations can reveal a different pattern of affordability, especially in less accessible locations (Dewita et al. 2018). Several studies from European countries provide a similar result of the importance of incorporating transportation costs to reveal more appropriate measures of housing affordability. Transportation expenditure consists of three important variables which are vehicle ownership, vehicle usage, and public transit. Vehicle ownership is determined by the number of the vehicle, monthly payment of the vehicles, and the annual amount of insurance and tax. Vehicle usage is based on the amount of fuel consumption, monthly amount toll, and parking fees, and cost and maintenance of the vehicles. Public transit will be the total amount of monthly expenses on public transit.

Summary of the previous research

Table 2: Summary of previous research on housing affordability

Author	Year	Objective	Independent Variables	Dependent Variable	Conclusion
Rahim and Munaaim	2008	To determine the indicator of housing affordability in Malaysia and variables that affect housing affordability amongst the low-income.	Household income, household expenditure, types of work, level of education, working household, and housing installment.	Housing affordability.	Household income and household expenditure are the main indicators affecting housing affordability.
Bujang et al.	2010	To study the relationship between demographic factors and housing affordability.	Demographic factors such as gender, race, age, marital status, education level, job sector, the status of the job, monthly income, and the number of households.	Housing affordability.	Marital status, number of households, age, education level, and household income have influenced the housing affordability.
Teck-Hong	2011	To examine the impact of neighborhood types on residential property values in Klang Valley	Location, structural and neighborhood characteristics.	Market price.	The neighborhood, structural, and location attributes are statistically significant related to house prices.
Teck-Hong	2012	To determine correct housing attributes required for first-time homebuyers in the urban area.	Location, neighborhood, structural, and social-cultural.	Homeownership.	Location and neighborhood play important attributes in the decision to purchase a house.
Tan and Cheah	2013	To determine the right housing	The locational, neighborhood, structural, and	Homeownership.	The locational and neighborhood have influence

		attributes required by potential first-time homebuyers.	socio-cultural housing attributes.		homeownership preferences by first-time homebuyers.
Eshruq Labin et al.	2014	To develop affordable housing performance indicators (AHPI) for landed houses.	Income ratio, facilities and services, safety and comfort, quality management and grow home.	Affordable housing performance indicators.	Income ratio, facilities and services, safety and comfort, quality management and grow home can be applied as AHPI for landed houses.
Sean and Hong	2014	To determine the key factors that investors before making an investment decision to purchase a residential property.	The locational, neighborhood, structural and financial factors.	The motivation of property investment.	The results revealed that 4 vocational, financial, and structural factors do affect property investors in making their purchases.

Author	Year	Objective	Independent variables	Dependent variable	Conclusion
Salleh et al.	2015	To identify the resident's preferences and influence factors on buying property buyers at the hill area.	Price, location, design, view and ventilation, type of neighborhood, facilities, and amenities in the neighborhood, Feng Shui elements, prestige, luxury, and style.	Property buyer decision.	The most influential factor in buying a property at hillside property was view and ventilation.
Chia et al.	2016	To examine the influence of housing attributes on house purchase intention.	The locational, financial, structural, neighborhood, socio-cultural, and developer brand.	Purchase intention.	Financing, location, structural, neighborhood, and socio-cultural have significant positive relationships with house purchase intention.
Zainon et al.	2017	To identify the determinants affecting the purchase decision among middle-income groups.	Price, design, location, quality, developer's success on the previous project, the number of the project done by the developer, developers' popularity, public facilities, and safety and security.	Purchase decision.	House price is the main consideration in buying the house followed by safety and security and public facilities.
Rameli et. al	2017	To identify the affordability levels and also the socioeconomic factors which affect the homeownership affordability of low-income groups in Kuala Lumpur.	Household income, household expenditures, type of employment, education levels, household sizes, monthly payment for housing, and household savings.	Homeownership affordability.	Household income, household expenditures, and monthly housing payments affect homeownership affordability significantly.

Khan et al.	2017	To evaluates the preferences of first-time homebuyers in buying houses.	Demographic, financial, location, structure, neighborhood, and economy.	Housing ownership.	Economic, financial, and neighborhood have a relationship with housing ownership.
Mariadas et al.	2019	To determine the first home purchase decision among middle-income earners in Selangor.	Finance, location, neighborhood, and structural attributes.	Residential property purchase decision.	Location and structural factors have a negative relationship while financial and neighborhood factors have a positive relationship with a residential property purchase decision.
Salleh et al.	2019	To understand the consistency in purchasing residential properties among homebuyers in Seri Iskandar, Perak.	Location, type of land ownership, neighborhood, concepts and building specifications, financial, developer reputation, and socio-cultural.	Purchase decision.	Respondents place high values on neighborhood variables when deciding to purchase residential properties.
Thanaraju et al.	2019	To evaluate the relationship between the three main factors identified which are financial, location, and neighborhood towards housing preferences of homebuyers.	Financial, location, and neighborhood.	House purchase decision.	Locational factors contribute significantly to the determination of a buyer's preferences when purchasing a house.
Mariadas et al.	2019	To determine the urban residential purchase decision in Klang Valley, Malaysia.	Finance, location, neighborhood, and structural attributes.	Residential purchase decision.	Three factors that influenced the urban residential property purchase decision in Klang Valley are finance, location, and structural.

Methodology

As discussed before, there are a plethora of attributes has been tested concerning their influence on housing affordability. In this study, however, these attributes are proposed to assess and absent in most previous research, especially in the local context.

Conclusion

Housing affordability is a major challenge currently facing by many countries. This paper stressed that housing affordability must be defined and assessed by a wider range of criteria. To determine whether the attributes matter, this paper includes several housing attributes. These include locational, neighborhood, structural and financial attributes of housing. This study also proposed a new factor

Figure 1: A proposed conceptual framework of the

namely transportation expenditure, along with other factors that were adopted from previous studies. These factors are expected to specifically highlight the issue of housing affordability. Finally, based on the review of the literature, a conceptual framework was proposed. This study is expected to identify the factors that influence the affordability issue, particularly involving transportation expenditure.

Acknowledgment

The authors would like to express their sincere appreciation to Universiti Teknologi MARA for granting financial assistance to undertake this study.

Abstract

The article addresses the organizational structure archetype as a solution to a dual problem adopted by the management of an organization at the second "top" level of the organizational hierarchy, i.e., on the one hand, organizational differentiation, and organizational integration on the other. An attempt is then made to define the features of the archetype of medium and large size organizations shaped according to the principle of simplicity. The final part presents the findings regarding the change of the archetype of the organizational structure.

Keywords: Management, Organizational Structure, Archetype, Simplicity

Introduction

It is assumed that the organizational structure is a set of rules ordering the behavior of the organization's participants. They are first introduced officially, but some remain spontaneous and pass the exam in everyday work (Steinmann, Schreyögg, 2001).

The organizational structure, which is an element of every organization, primarily serves the needs of management, in particular:

- defines the division of labor and introduces links between the activities carried out;
- shapes the division of powers and orders the components of the organization hierarchically, assigning them decision-making powers;
- determines the responsibility structure;
- ensures the continuity of the implementation of activities;
- regulates relationships with the environment (Nalepka, Kozina, 2007).

In general, an organizational structure's function is to shape organizational order by structuring the elements and activities of an organization. The process consists in grouping positions into organizational units, creating an organizational hierarchy, defining patterns of mutual influence, and setting the standards of the decision-making and action freedom of organization members (Mreła, 1983)

One of the principles of shaping the organizational structure is simplicity (Ashkenas, 2017), (Ashkenas, Siegel, Spiegiel, 2014), (Bodell, 2016) (Schneider, Hoffman, 2016), (Segall, K, 2016), (Worren, 2016)

emphasized more frequently in literature reports in recent years. The known law of R.W. Ashby, by which all diversity should be balanced by the other, is disputed. As M. Crozier (1993, p. 47) writes, now, "… the effectiveness of responding to the complexity of the environment begins to depend on simplifying structures and procedures. Following the complication of social interdependencies by specializing structures and complicating procedures inevitably ends up getting bogged down in bureaucracy". However, it should be emphasized that it is not about "…negation of the complexity of social systems, but the reflection on the most effective ways of controlling it. Structures and procedures do not adequately respond to this complexity. They lead to stiffening and complications."

The principle of simplicity states that the organizational structure, due to its contextual conditions, should be the simplest possible, i.e., characterized by the least extensive hierarchy possible, and has the lowest degree of specialization, formalization, structuring, and centralization (Hopej-Kamińska et al., 2015). Therefore, the archetype of a structure, i.e., a kind of skeleton on which all organizational rules constituting the structure are based, should also be characterized by the greatest simplicity. Although it is mentioned in the literature on the development of the organization, it is usually indirect. For example, the analysis of different concepts of the life cycle of an organization leads to the conclusion that there are different structural solutions in different phases but within a specific framework.

Their change, in contrast to the small-scale modifications of the existing structural solutions characteristic for subsequent phases, is revolutionary and means the adoption of a new structure in connection with a change in the strategic direction in the face of a profound transformation of the industry (Greiner, 1972), (Steinmann, Schregögg, 2001). Girod and Karim (2017, p. 78) refer to the first type of change as reconfiguration, while the second - restructuring, which is a de facto alteration in the archetype of a structure defining the way "... in which its authorities group resources and coordinate actions". More precisely, it can be assumed that the organizational structure archetype is the solution of a dual problem adopted by the management board at the second "top" level of the organizational hierarchy, i.e., organizational differentiation on the one hand and organizational integration on the other." [**]

The archetype of organizational structure understood in this way contributes to shaping the organizational order, despite minor changes in organizational rules. One can also participate in building the identity of an organization in the sense that the way of organizational differentiation and organizational integration, corresponding to a specific organization, can distinguish it from the competition (Hopej, 2020).

In connection with the above, the following questions arise:

- what should the archetype of a structural solution for medium and large size organizations shaped according to the principle of simplicity be like?
- what are the relationships between the archetype and internal structural solutions of basic organizational units?
- how should the archetype be changed?

The article aims to find answers to them. The attempt to formulate them is based on:

- critical analysis of literature reports, which became the basis for defining the term of both archetype structure and archetypal concept, reflection in basic organizational unit as well as archetype changes
- calculating the simplicity of an archetype using fractal calculus.

[**] The organizational structure archetype should not be equated with its type, because the basic types of structural solutions are usually determined mainly by the organizational differentiation pattern (Steinmann, Schregögg, 2001).

Simplicity of An Organizational Archetype

The ideological scheme of the archetype of a structural solution of a medium or relatively large size organization is illustrated in Figure 1, in which the top management and managers of basic organizational units combine, as it is assumed in fractal calculus, branches with a length corresponding to their autonomy - the shorter the branch, the less autonomy, and vice versa, the longer, the greater the autonomy (Mandelbrot, 1983). Generally speaking, it is the product of two variables:

- horizontal autonomy, resulting from the organizational differentiation pattern adopted at the second "top" level of the hierarchy
- (organizing by function usually results in less autonomy than by objects);
- horizontal autonomy resulting from the dominant instrument of integration. It is greater in the case of integration based on self-agreement or plans and programs than based on the hierarchy (Steinmann, Schreyögg, 2001).

Fig. 1 : Ideological diagram of an archetype of organizational structure

Source: own study

Calculations carried out with the use of fractal calculus prove that the complexity (decrease in simplicity) of the archetype increases as the autonomy of basic organizational units decreases (Hopej, 2020). It means that:

- the most complex archetype is characterized by organizational differentiation by function and organizational integration through a hierarchy,
- the simplest archetype is characterized by differentiation by objects and organizational integration by means of self-agreement, possibly supported with programs and plans having a complementary meaning as an integration instrument (Steinmann, Schregögg, 2001).
- hybrid archetypes, i.e., with differentiation according to functions and objects and with various integration instruments (e.g., by means of hierarchy and self-arrangement simultaneously), are characterized by intermediate complexity (simplicity).

It follows that, if it is possible, basic object-oriented organizational units, the organizational integration of which is primarily based on self-agreement, should be created. Where it cannot be done (e.g., in conditions of poorly diversified activity), functionally oriented units should be set up with the greatest possible responsibility for the function performed. It is related to the limitation of the use of hierarchy as an instrument of organizational integration.

Due to the above, the following question arises: should more smaller or less larger organizational units be established in accordance with the principle of simplicity? Let us also try to answer them using fractal calculus, adopting the following assumptions:

- the measure of complexity is the so-called fractal dimension (Hopej, 2009);
- the autonomy (resultant of vertical and horizontal autonomy) of all basic organizational units is the same;

- the objects of analysis are two archetypes of structural solutions of an organization with the same number of employees (16), but differing in the number of basic organizational units (3 and 5) ***.

The performed calculations (Table 1) show that:

- the greater the number of basic organizational units, the more complex the archetype;
- the greater the autonomy, the simpler the archetype.

Table 1: The simplicity of the archetype of the structure depending on the autonomy of the basic organizational units

Basic autonomy of organizational units (scale 0-1) / Structure archetype	0,75	0,66	0,50
As 3 (complexity)	2,29	2,89	4,58
As 5 (complexity)	2,41	3,03	4,82

Source: based on (Tworek, Hopej, Martan, 2017)

That leads to the conclusion that the simplicity of the organizational structure archetype favors the creation of the smallest number of basic organizational units.

The Archetype and Structural Solutions of Basic Organizational Units

Basic organizational units obviously have their own internal structural solutions, the simplification of which also requires:

- increasing, as far as possible, the scope of decision-making and action freedom of managers of separate organizational units (cells) and their subordinates;
- limiting the number of distinguished organizational units (cells).

***According to these assumptions, one archetype covers 3 basic organizational units, and the other 5. Although the autonomy of all units does not differ, their values may range from 0 ÷ 1 (it was assumed that they are 0.75, 0.66, 0.5). The derivation of the formula for the value of the fractal dimension was presented in the paper (Hopej, Martan, 2009).

In consequence of applying the same guidelines for organizing activities, one can imagine a structure in which the internal structural solutions of basic organizational units are a mirror image of its archetype (Figure 2). [****] Such a structure, however, is a model abstracted from the organizational reality since in management practice structural solutions of basic organizational units usually differ more or less from each other, for example, due to different external and internal conditions (e.g., different qualifications of organization members), or limited rationality of management decisions. Nevertheless, it proves that when actions simplifying the whole organizational rules are consistently implemented, the basic organizational units contain the structural characteristics of the archetype (the archetypal reflection effect). It includes, perhaps even above all, the most significant possible scope of decision-making powers, which is, in a way, a crowning achievement of the simplicity principle, for there is no better way to reduce complexity than to give operating units and their members a great deal of discretion. They can "act in symbiosis with their clients, have a better chance to respond quickly to their expectations, learn from clients, and help them in their learning. Speed of action, mutual understanding, the ability to conduct dialogue, and innovative abilities are essential qualities to achieve true autonomy. Then, the necessity to constantly refer to standard rules is avoided" (Crozier. 1993, p. 50).

Fig. 2: Organizational structure in which the internal solutions of the structures of basic organizational units are a mirror image of its archetype

Source: own study

If the simplification of organizational rules is less consistent, the archetypal reflection effect is less apparent. It is the least visible when, in the opinion of the management of the organization, the principle of simplicity is still adhered to in relation to all organizational rules. That means that the least acceptable activities are implemented to simplify the structure within the autonomy of the basic units. In other words, it occurs when the structural characteristics in all units are correlated, to a slight but

[****] This structure resembles a fractal structure. The main difference lies in the fact that in the presented structural solution, the basic organizational units do not have to be linked by ties of cooperation, but they are present in fractal solutions (Hopej, 2004).

still acceptable degree, with the characteristics of the archetype.Therefore, it can be assumed that there is a continuum of the occurrence of archetypal reflection in basic organizational units (Figure 3). Its extremes are: mirror effect (l) and minimal reflection (m). Moving on the continuum towards the *m* point means increasingly less visible effects of the archetypal reflection, while towards the point l - more and more visible structural solutions of the organization, reflecting the growing simplicity structural solution in the organization.

1 _____ m

Fig. 3: Continuum of the occurrence of the archetypal reflection effect in basic organizational units

Source: own study

The consistency in striving to simplify organizational rules, and thus the appearance of the archetypal reflection effect in basic organizational units, seems to depend to a large extent on the organization members' trust in simplicity, as a directive of efficient operation. It is crucial for perpetuating the emotions related to the elimination of complexity, i.e., the feeling of discomfort from the bureaucratic way of carrying out activities. Therefore, the management of the organization must, among others convince its other members (with their actions, keeping promises, results, etc.) that simplicity has real value in a given organization and is not a mere declaration but one of the basic decision-making criteria. If confidence in simplicity can be built and maintained, the effects of archetypal reflection will be visible throughout the organization.

Changing the Organizational Structure Archetype

It seems that changing the archetype of a structure should be based on at least two assumptions. They are:

- avoiding addiction to organizing,
- non-existence of "good" organization.

The change of the archetype is a profound and large-scale change in the organizational structure and it can be compared to a very serious surgical intervention on a living organism, without anesthesia. Meanwhile, surgeons are, as Malik (2015, p. 211) writes, "… in a much more comfortable position than managers: they can immobilize the patient with anesthesia during the operation. The manager cannot do this. His/Her "patient" sees, feels and watches what is coming, and reacts accordingly. Good surgeons are aware that surgery should not be performed unless necessary. Only when other measures fail do they reach for the knife. Good managers do the same. "They know that while people are adapting to change better and better, they also need, perhaps even above all, stability and peace if they are to operate efficiently. It seems to be forgotten by managers who are addicted to organizing, and who pursue a strategy of continuous transformation of the organization so that "everything is on the move all the time" (Malik. 2015).

It should also be remembered that the change in the structure archetype is rather not conducive to shaping the identity of an organization which, in the light of Stadler and Wäldermann's (2012) research on long-lived companies (the so-called hundred-year-old champions) appears to be a key factor in their survival and success. It does not mean that the archetype should not be changed, because there are such situations that there is no alternative. However, it should be carried out after the best preparation and planning of the process, considering, if possible, the previous states of the structure, as the lack of structural continuity may result in difficulties in maintaining the organization's identity.

The second assumption is that there are no structural solutions without flaws. Each of them has not only its positive sides, but also negative ones. Moreover, they all generate conflicts, emphasize antagonisms between people, create ambiguities, and many other problems. "Moreover, it is very rare to choose a "pure" organizational form. Such forms only exist in textbooks. Existing organizations are practically always a mixture of several "pure" forms; hence they are hybrid creations. It is not something negative, except for management purists" (Malik, 2015, pp. 211-212).

As it is clear from the above considerations, a change in the archetype of a structure means either a change in organizational differentiation or an instrument of organizational integration, or both at the same time. In accordance with the principle of simplicity, it is about a change that increases the autonomy of basic organizational units, so it is, for example, replacing integration by hierarchy, integration by self-agreement, and not increasing the importance of organizational hierarchy in integrating activities. It will also be the creation of a new object-oriented unit next to the functional divisions, not one more product-oriented division, apart from a few existing ones.

Changes of the archetype can be made in either revolutionary or evolutionary ways. In the first case, the top management somewhat shakes up with its structural solution, depriving itself, as Girod and Karim (2017) write, of organizational cholesterol, namely organizational flexibility of operating rules. As mentioned earlier, it is inadvisable that the shocks are carried out too often - the authors cited suggest a period of at least 5 years.

In the other case, the change is introduced gradually, in a manner reminiscent of the surgical operations of a road accident victim, where first his/her life is saved, and subsequent surgical procedures are aimed at reconstructing the upper limbs first, and then the lower limbs. An example may be a change in the archetype of a structural solution of one of the Polish companies in the clothing industry, which consisted in:

- Increasing the autonomy of each of the several factories operating within the production division by locating units dealing with product design and marketing in each of them. Before the change, these activities were carried out in two different divisions supporting the activities of individual plants.
- Introducing, after several months, a divisional structure in place of the functional structures (integrated functional divisions), when favorable circumstances appeared (it was primarily about more efficient implementation of tasks in the conditions of greater decision-making and action freedom of employees).

The right way to do an archetype shift is balancing the pros and cons. Revolutionary change is undoubtedly a greater shock to the organization, but on the other hand it means longer periods of stabilization and favors the use of non-hybrid structural solutions. In turn, evolutionary change means a smaller shock spread over time, but shorter stabilization periods, as well as the possibility of real management actions based on hybrid solutions characterized by greater complexity.

Regardless of whether the archetype change is evolutionary or revolutionary in nature, it cannot be performed in isolation from other aspects of the organization's functioning because, separated from the context, the archetype transformations result in an internal mismatch that can paralyze it. The adjustment of the simplified structure to organizational culture, which is supposed to support a kind of civic community of the organization, seems to be crucial. In general, such a distant culture refers to the extent to which the organization members give themselves to others, and with its dimensions they become suppressed by selfishness and adherence to the norms of decency and good manners (Hopej - Kamińska et al. 2015).

Conclusion

The considerations lead to the following observations and conclusions:

- The organizational structure archetype, shaped in accordance with the principle of simplicity, should be characterized by the greatest possible autonomy of basic organizational units. It is favored by organizational differentiation by object and organizational integration through self-agreement.
- The number of basic organizational units should be possibly small (it is better to create fewer larger units than many smaller ones).
- The so-called archetypal reflection effect occurs in structural solutions of basic organizational units. It is most visible in the case of a mirror image, i.e., when the structural solutions of basic organizational units are a mirror image of the archetype of a structure.

– Changing the archetype can be both evolutionary and revolutionary, but frequent changes resulting from a strategy of continual restructuring is a management error.

Among the issues discussed in this article, some require further research. For example, the effect of the archetypal reflection should be considered more thoroughly, mainly the mechanism of its formation.

Abstract

The main objective of this paper is to analyze the state of the art in research on the use of tone in sustainability reports. We set out to select papers that analyze the existence of bias in the tone of disclosures, specifically in the field of environmental information, in favor of the interests of companies' managers. We carried out a systematic review in the Scopus database and selected 33 articles published between 2000 and 2020. We identified several lines of research that analyze the relationship between tone and the information disclosed in sustainability reports, including one that relates impression management (tone manipulation) to environmental performance. Our work reveals a lack of research on tone in mandatory sustainability reports prepared under the new GRI Standards. By identifying the main lines of research on the topic and the ones with a significant lack of research, this paper contributes to the debate on impression management (tone manipulation) and incremental information in sustainability reports.

Keywords: tone and disclosure, sustainability reporting, tone management, qualitative disclosure, textual analysis.

Introduction

The demand for non-financial information is undoubtedly increasing. In addition to financial information, investors, shareholders, and stakeholders now require companies to provide non-financial reports to help them make decisions on investments and other dealings with companies. For their part, companies are keen to publish non-financial information that will testify to their commitment to environmental and social sustainability.

Given the tendency for environmental disclosures to use qualitative rather than quantitative language, the writers of non-financial reports may be tempted to manage and control readers' impressions, so as to limit criticism by external stakeholders (Talbot and Boiral, 2018), while using concealment and attribution to cast their organization's performance in a favorable light (Merkl-Davies and Brennan, 2007; Grant and Booth, 2009; Talbot and Boiral, 2018), thus increasing the company's legitimacy and enhancing its image (Hopwood, 2009).

Tone and choice of language are therefore key elements in the narrative disclosure of environmental information and must be given proper consideration in any study of textual complexity (Fisher *et al.*, 2019) or of the relationship between disclosure and environmental performance (Cho *et al.*, 2010)—because they can be used to misinform as well as to inform.

In this paper we explore the relevant research to determine the state of the art on the use of tone and choice of language in sustainability reports. To do that, we conduct a systematic review of a sample of 33 research articles, using the methodology and framework developed by (Talbot and Boiral, 2018). Our systematic review covers four streams of research on tone in sustainability reports.

The first stream of research analyses the relationship between tone and companies' environmental performance. In the second stream of research some authors claim that managers have no incentive to manipulate information whilst others argue that companies adopt the GRI methodology to give themselves visibility (legitimacy). The third line of research focuses on the determinants of the tone used by managers in their disclosures. Finally, the fourth stream of research addresses the relationship between tone management and economic performance.

The rest of the paper is organized as follows: section 2 describes the methodology and methodological framework for the systematic literature review. Section 3 sets out the findings of this review, i.e. the state of the art. Section 4 draws the main conclusions.

Methodology

We carried out a systematic literature review on tone in environmental information included in corporate sustainability reports. We applied Grant and Booth's (2009) four-step methodological framework—Search, Appraisal, Synthesis and Analysis[1] (SALSA). By following these four steps, we were able to determine the main lines of research on the topic, the tone-related variables in disclosures, the unexplored strands of thought, and the strands that, to date, have received least attention in the literature.

Search

This phase consisted of collecting the primary data. We used the Scopus database to extract the primary data. We started our search with a wide range of criteria focused on the tone of the information disclosed in sustainability reports:

a. The search was limited by titles, abstracts, and keywords. We chose the following words for the search equation:
    - tone and disclosure;
    - sustainability reporting;
    - tone management;
    - management disclosure;
    - linguistic tone;
    - qualitative disclosure;
    - textual analysis;
    - content analysis;
    - tone volatility.
b. We used a time slot from 2000 to 2020. We checked the papers published in the last two decades to study the evolution of non-financial disclosures and the determinants of that evolution.
c. We selected articles and reviews because the purpose of our systematic review was to examine scientific articles that focus on the subject of our study

From this initial search, we collected 103 articles. We then proceeded to the next stage: appraisal.

Appraisal

Codina (2018) suggests that the next task, after obtaining the initial data set, is to develop an evaluation system which will discard any documents that fall below certain quality standards.

Accordingly, when reviewing the abstracts and conclusions of the collected articles, we checked whether the documents could answer questions such as:

- Is the corporate report that is the subject of the study about sustainability?
- Does the paper analyze the impact of tone on information disclosure?
- Does the paper study the disclosure of environmental information?
- Does the paper analyze whether tone bias in sustainability reports can be linked to the interests of the producers of the reports?
- Does the paper study sustainability reports prepared under the GRI Standards?

We discovered that the scope of our search was too wide, as we found too many articles that did not fit our research objectives. We therefore decided to introduce a second search equation with different criteria for excluding and including articles from the Scopus database. Using these new criteria, we searched for the following terms in title, abstract and keywords:

- tone and disclosure;
- sustainability reporting;
- tone management;
- management disclosure;
- linguistic tone;
- qualitative disclosure;
- textual analysis;
- content analysis;
- tone volatility;
- environmental disclosure;
- GRI;
- Global Reporting Initiative.

We included the terms 'environmental disclosure', 'GRI' and 'Global Reporting Initiative' because they matched our research goals. We wanted to know whether there was any bias in the tone of the environmental information disclosed in sustainability reports and, overall, in sustainability reports prepared in accordance with the GRI Standards.

The study period and the kinds of documents used for this second equation were the same as for the first one.

We obtained 33 articles. We checked the abstract, conclusions and, for some of the papers, other sections of the document to determine whether the information contained in the paper was related to the objective of our study. We also checked some of their bibliographic references. We then moved on to the next stage.

Analysis of the information

We analyzed the selected data set in accordance with Grant and Booth's (2009) framework. To do that, we created a record for each paper, summarizing the main information: goals, methodology used, results, conclusions, and publication date. We compiled a summary of the papers and then proceeded to the next stage.

Synthesis

This synthesis represents the state of the art, which is the aim of a systematic literature review.

Having determined the state of the art, we found four main lines of research analyzing the relationship between tone and information disclosure in corporate reports:

- relationship between tone and environmental performance;
- impression management (tone manipulation) and environmental performance in sustainability reports under the GRI Standards;
- CEO characteristics as a determinant of tone in sustainability reports;
- management tone and economic performance.

Results

The growth in the number of sustainability reports issued by companies can be linked to the pressure from internal and external stakeholders for higher quality in the non-financial information disclosed by firms. This information is intended to give stakeholders (investors, regulators, shareholders, financial analysts, etc.) a deeper knowledge of firms' social and environmental performance (Berthelot *et al.*, 2003; Diouf and Boiral, 2017) to help these stakeholders in their trading and investing decisions (Cho *et al.*, 2010; Boiral, 2013).

Financial markets require sustainability reports to supplement financial information as a basis for risk assessment. Social and environmental investment funds use these reports to evaluate firms' social and environmental behavior (Boiral, 2013).

Nevertheless, some researchers remain critical of sustainability reports, which they say tend to be unrealistic, unaccountable, opaque, poor quality and unreliable, reflecting only the interests of the business (Cho *et al.*, 2010; Moneva *et al.*, 2006; Rodriguez *et al.*, 2015) Sustainability reports, they maintain, are used as marketing tools to enhance corporate image, boost companies' social legitimacy and recruit new shareholders (Deegan *et al.*, 2006; Prado-Lorenzo *et al.*, 2009; Hopwood, 2009; Cho *et al.*, 2012; Diouf and Boiral, 2017; Talbot and Boiral, 2018).

Furthermore, the use of qualitative, rather than quantitative, language in environmental (and social) disclosures allows report writers to manage and influence readers' impressions, so as to limit criticism by external stakeholders (Talbot and Boiral, 2018), while using concealment and attribution to cast their organization's performance in a favorable light (Merkl-Davies and Brennan, 2007; Hopwood, 2009; Talbot and Boiral, 2018), thus increasing the company's legitimacy and enhancing its image (Hopwood, 2009).

Tone and choice of language are therefore key elements of narrative disclosure in any study of textual complexity (Fisher *et al.*, 2019) or of the relationship between disclosure and environmental performance (Cho *et al.*, 2010)—because these elements can be used to misinform as well as to inform.

The role of tone in non-financial disclosures has therefore become a topic of research, in which we identify four main streams; the relationship between tone and companies' environmental performance, impression management (tone manipulation) and environmental performance in sustainability reports, CEO characteristics that determine tone in disclosures and the tone management and economic performance.

Tone and environmental performance

This research stream contains a large number of studies claiming that managers create impression management strategies to help maintain or improve the company's image or reputation and thus bias stakeholders' perception (Cong *et al.*, 2014; Talbot and Boiral, 2018). Managers can also bias stakeholders' perceptions by using concealment or attribution strategies (Merkl-Davies and Brennan, 2007), which involve extensive use of positive keywords and ambiguous, opaque, or evasive language (Cho *et al.*, 2010).

Some studies in this line of research consider the personality, management abilities, age, gender, duality and tenure of the chief executive officer (CEO) as determinants of impression management or tone manipulation (Cong *et al.*, 2014; Buchholz *et al.*, 2018; Liu and Nguyen, 2019; DeBoskey *et al.*, 2019).

Cho *et al.* (2010) analyze the existence of self-serving bias in the language and tone of environmental disclosures and the use of such bias to manipulate stakeholders' perceptions. In their view, the external pressures companies face provide an incentive to adopt a superficial, symbolic approach driven by self-interest rather than by any real concern to improve either transparency or environmental performance.

Cho *et al.*'s (2010) results show that poor environmental performance is significantly and positively related to optimistic language (impression management) and negatively related to certainty.

Based on these results, they conclude that organizations manipulate the presentation of information through choice of language and tone; and that they manipulate disclosure through the quantity, content, and attribution of the information provided.

Arena *et al.* (2015) focus on environmental reports. They look for evidence either of manipulation of stakeholders' perceptions (impression management) or of a genuine willingness to help stakeholders make good investment decisions through transparency and depth of information (incremental information).

Neither Clarkson *et al.* (2008) nor Arena *et al.* (2015) find any evidence of managers' having financial incentives to manage tone in their reports or to mislead stakeholders. On the contrary, these authors find optimistic language to be related to a higher probability of positive future environmental performance, thus confirming the incremental information hypothesis.

They also claim that the relationship between tone and environmental performance varies according to certain characteristics of the board of directors, in particular the board's stakeholder orientation and the existence of a social responsibility committee (CSR) within the board.

Within the research stream on tone management and environmental performance, Rodrigue *et al.* (2015) perform a comparative content analysis of the volume and tone of environmental information in reports prepared by companies and in disclosures by stakeholders (case study). The authors analyze annual reports, sustainability reports, brochures, and press releases between 2005 and 2007.

Rodrigue *et al.* (2015) argue that the differences they find in the volume and tone of environmental disclosures by the company and by stakeholders stem from the different tendency of the disclosed information. Both parties report biased information with the aim of impressing their readers. The disclosed information therefore does not reflect reality but plays a part in constructing, forming, and legitimating the parties' discourses within society.

Diouf and Boiral (2017) analyze stakeholders' perceptions of the quality of sustainability reports. They elicit the perceptions of responsible social investment specialists in Canada and analyze the extent to which those perceptions support the argument that sustainability reports are used as an impression management tool to influence stakeholders' investment decisions.

From their assessment they conclude that companies use sustainability reports to implement impression management strategies rather than to provide incremental information. Companies focus only on positive aspects, while concealing controversies and negative aspects of their performance, so as to influence or distort stakeholders' perceptions.

Impression management (tone manipulation) and environmental performance in sustainability reports under the GRI Standards

It is widely assumed that the information disclosed in sustainability reports is truly transparent and reflects the performance and real impact of the reporting entities' activities. However, the lack of transparency found in some sustainability reports shows them to be a tool for enhancing companies' social and environmental reputation (Deegan *et al.*, 2006) by creating a simulacrum (Boiral, 2013).

The literature shows mixed results on the relationship between environmental performance and the level of disclosure of environmental information. Clarkson *et al.* (2008), for example, report a positive relationship between level of disclosure and environmental performance, whereas Cho *et al.* (2010) and Huang *et al.* (2014) find a negative relationship.

Clarkson *et al.* (2008) find no financial incentive for managers to use the environmental information disclosed in corporate reports in an opportunistic manner. In their view, the stock market is capable of detecting bias in corporate reports and punishes companies that use such bias by lowering their stock price.

According to Clarkson *et al.* (2008), environmental performance is positively related to discretionary disclosure in environmental and social reports and thus also to similar disclosures on corporate websites.

Nonetheless, other studies (Moneva *et al.*, 2006; Boiral, 2013; Talbot and Boiral, 2018) claim that companies adopt the GRI methodology to give themselves visibility (legitimacy), even though their commitment to sustainability remains low.

It is worth noting that disclosures are likely to be more self-interested and to conceal compromising information when companies' environmental legitimacy is questioned. Such disclosures will display tone bias and language manipulation (impression management), regardless of whether the reports are published under the GRI Standards or not.

Talbot y Boiral (2018), Boiral (2013), Cho *et al.* (2010) and Moneva (2006) also analyze the relationship between tone (impression management) and environmental performance, taking a critical stance toward sustainability reports prepared in accordance with the GRI guidelines.

Talbot and Boiral (2018) evaluate the quality of the environmental information disclosed by oil and gas companies and the impression management strategies used to justify or conceal negative aspects of their performance.

Despite the fact that the chosen sustainability reports had high application levels and had been verified by external auditors, the researchers found significant gaps in the measurement of environmental performance. Furthermore, they were surprised by the lack of clear data and the lack of compliance with the GRI guidelines, highlighting the ineffectiveness of the report assurance process.

They also found evidence of the use of impression management to justify results, and strategic omissions and manipulation of figures to hide information.

The authors claim that sustainability reports are used as a legitimacy tool to mitigate social pressure and criticism from stakeholders.

Boiral (2013) performs a content analysis of the sustainability reports and compares the content with sustainability-related events published in the media. The author finds that, contrary to the principles of balance, integrity, and transparency, approximately 90% of the significant negative events were not reported. The fact that only 10% of the negative events were reported supports the theory that sustainability reports are an exercise to camouflage real sustainable development problems.

The use of tone or overly positive, almost narcissistic language contributes to the low credibility of sustainability reports and is consistent with voluntary disclosure theory and legitimacy theory, which predict that companies will use these reports to send positive signals to improve their competitive positioning and social legitimacy. The images used in the reports were found to be predominantly positive, thus failing the GRI criteria of balance and reliability.

CEO characteristics as determinants of tone in sustainability reports

Stakeholders have shown an interest not only in the tone (optimistic, pessimistic, or neutral) of the information disclosed in sustainability reports, but also in CEO characteristics as determinants of tone.

Several studies focus on intrinsic characteristics of the CEO and the impact these characteristics may have on tone in corporate reports. The characteristics of interest include personality (Marquez-Illescas *et al.*, 2018), age, gender (Liu and Nguyen, 2019), duality, experience, and career choice.

Some articles also examine board of directors' characteristics to determine the board's ability to constrain or minimize the use of tone by the CEO (DeBoskey *et al.*, 2019).

Other authors argue that impression management in reporting is strongly related to CEO narcissism (Boiral, 2013; Cong *et al.*, 2014; Buchholz *et al.*, 2018).

DeBoskey *et al.* (2019) investigate whether effective board oversight moderates the strength of the association between CEO power and earnings announcement tone.

The authors assess CEO power across two dimensions—expert power (CEO tenure) and structural power (CEO-chairman duality)—in order to assess the impact of each type of power on disclosures. They also build a model of tone determinants.

The authors conclude that CEO power and board oversight are determinants of tone in disclosures.

Marquez-Illescas *et al.* (2018) test the impact of CEO personality on corporate disclosures. To measure CEO narcissism, the authors use the indirect measurement proposed by (Olsen *et al.*, 2014). After controlling for various tone determinants, their results show that tone in earnings announcements is determined by CEO personality and age.

The positive relationship between narcissistic personality and positive tone in earning announcements proves that narcissistic CEOs tend to reinforce their self-image by applying a positive bias to disclosures. However, egocentricity decreases with CEO age.

The authors' results also show that stock markets react to the tone used by narcissistic CEOs, although the reaction curve is flatter. This suggests that markets take the bias of announcements by narcissistic CEOs into account. Tone can therefore significantly influence a stock's profitability.

In this context, Buchholz *et al.* (2018) assess the relationship between CEO narcissism and the use of an abnormal optimistic tone in financial disclosures. They find that CEO narcissism is positively related to abnormal optimistic tone. The transition within a company from a less optimistic CEO to a more optimistic one is also reflected in the tone of the company's reports, which shift towards abnormal optimism.

The authors also find that narcissistic CEOs are more likely to use abnormal positive tone when their organizations have plans for seasoned equity offerings or R&D investments, with the aim of giving their company more positive visibility and enhancing their own reputation.

Cong *et al.* (2014) examine the rhetoric employed by CEOs to determine CEO leadership and environmental commitment. They conclude that CEOs in companies with poor environmental performance use language in such a way as to highlight positive aspects and hide negative ones and thus legitimize the organization. The authors find a significant negative relationship between the tone used in CEOs' letters and environmental performance. This finding is consistent with legitimacy theory and impression management.

Cong *et al.* (2014) also argue that CEOs use tone as a strategy for environmental initiatives because a positive environmental reputation can improve both company visibility and CEO status.

Along similar lines, Liu and Nguyen (2019) evaluate two types of corporate disclosure, the Management Discussion and Analysis (MD&A) and the CEO letter to shareholders, to distinguish the tone used in each.

Based on a content analysis, they claim that, for the same level of firm performance, the MD&A has a less positive tone than the CEO's letter to shareholders. Furthermore, the MD&A provides incremental information to the financial statements, whereas the language in the CEO letter, influenced predominantly by the level of positive words, is largely inconsistent with current firm performance.

This inconsistency between tone and performance is attributed to overconfident CEOs, who tend to have an overly positive view of their ability. As Buchholz *et al.* (2018) put it, overconfident CEOs underestimate their company's operational risk. Liu & Nguyen (2019), meanwhile, find that the negative tone used by non-overconfident CEOs is consistent with their companies' performance and future risk.

These authors also find that gender affects the tone of CEO letters. Female CEOs use a more neutral tone, i.e. a more equal balance of positive and negative words.

The authors attribute the difference between the tone of the MD&A and that of the CEO letter to the fact that the CEO letter is a voluntary disclosure and is unregulated and unaudited, both in format and in content. CEOs are thus able to use asymmetric information to exercise impression management, overvaluing the positive aspects of company performance and obfuscating the negative ones.

Tone management and economic performance

This research stream can be divided into subgroups focusing on the relationship between the tone of earnings announcements and firm value, economic performance, different types of shareholder decision, stock market reactions, operational risk, litigation, shareholders and, in particular, managers' management capacity (Rogers *et al.*, 2011; Huang *et al.*, 2014; Triki *et al.*, 2015; Luo and Zhou, 2017; Baginski *et al.*, 2018; Bakarich *et al.*, 2019; Campbell *et al.*, 2019).

The above subdivision indicates that tone in earnings announcements is relevant for shareholders and the stock market. As noted by Chen *et al.* (2015), quoted in Luo and Zhou (2017), the reporting of quarterly economic performance is a core task for CEOs. A key factor in managing the tone of these statements is management team capacity (Luo & Zhou, 2017). In other words, tone reflects not only the information about the organization's operational performance provided by the CEO but also the management team's ability to turn organizational resources into earnings.

In their letters to shareholders and earnings releases, CEOs use a biased narrative to explain quantitative data. Neither of these documents is regulated as regards the information it contains. Researchers and scholars have therefore begun to study how these documents are used to manage tone both for incremental information and for impression management.

One of the most cited studies in this field is Huang *et al.* (2014). As qualitative information is used to interpret quantitative information, the authors argue that tone plays a special role in shareholders' appraisals of firm value.

Accordingly, they study whether managers use impression management strategies in earnings releases to misinform users by masking poor financial performance. Their findings suggest that older companies tend not only to have restrictions in their balance sheets but also to use impression management in their disclosures more than younger companies.

Baginski *et al.* (2018) suggest, like Huang *et al.* (2014), that the tone used in earnings announcements is complex and difficult to assimilate, especially for inexpert shareholders, who may be misled by an overoptimistic tone into making risky investments. On the other hand, an overoptimistic tone is likely to arouse mistrust in more expert shareholders, who will distrust any claims that sounds too good to be true.

Rogers *et al.* (2011) analyze the relationship between disclosure tone and shareholder litigation. They conclude that sued firms' earnings announcements are unusually optimistic relative to those of other firms in the same industry with similar economic performance. According to Davis and Tama-Sweet (2012), some CEOs make more optimistic announcements when litigation risk is low. Overly optimistic or biased language or tone is therefore associated with increased litigation risk.

Other studies focus not only on earnings announcements but on different types of corporate disclosure to identify differences in tone. In their study of narrative, Fisher *et al.* (2019) show how the various dimensions of tone vary significantly between different types of narrative. The type of report and the intended audience determine the type of disclosure used. The authors also confirm that tone is a determinant of readability. Like Huang *et al.* (2014), Fisher *et al.* (2019) find that changes in tone are associated with short-term market reactions. In contrast to Huang *et al.* (2014), they do not find that tone is used to obfuscate bad behavior.

In a similar vein, Bakarich *et al.* (2019) analyze how the tone of the reports varies according to the stage of the development cycle the company is at. According to their results, the development cycle stage determines the tone a company uses in its reports.

Triki *et al.* (2015) note that an overly positive tone or strong impression management has a bifurcated (positive and negative) effect on investment decisions. For non-professional investors, an overly optimistic tone has a positive and direct effect on willingness to invest, whereas for professional investors it has a negative indirect effect via reduced disclosure credibility.

Campbell *et al.* (2019) argue that volatility in managers' disclosure tone depends on companies' operational risk and the extent to which managers' disclosures transparently reflect that risk. However,

investors appear to respond as if disclosure tone volatility provides incremental information only about a firm's operating risk.

Concluding Remarks

Tone is an important element in corporate reports because it influences the way stakeholders interpret the disclosed information.

We performed a systematic review of the literature on this topic, from which we drew several lines of research. In general terms, the papers in these lines of research seek to determine whether the tone of discretionary disclosures reflects an impression management strategy that favors the company, or whether the disclosures provide incremental information that is useful to stakeholders. Our review also highlighted the lack of research on tone in environmental disclosures in sustainability reports and on report quality and assurance.

Previous research on the quality and tone of disclosures in sustainability reports under the GRI framework has focused on discretionary (non-mandatory) reports. Analysis of this research reveals that, for some authors, use of the GRI framework favors enhanced disclosure and better environmental performance, whereas for others it favors the use of tone strategies (impression management) to manipulate stakeholders' perceptions.

We did not find any studies that assess the perceived quality of sustainability reports under the new GRI Standards or that consider whether external assurance of sustainability reports is affected by disclosure tone or how such assurance affects investors whose decision making includes an assessment of corporate sustainability performance. Nor did we find any studies undertaken from a stakeholders' perspective.

On the other hand, we must underline the lack of research on how CEO characteristics affect tone in statutory reporting, especially in sustainability reports.

This paper contributes to the debate on impression management (tone manipulation) and the incremental information provided by sustainability reports. It also adds to the understanding of the role of tone in sustainability reports as a tool for financial analysts.

For scholars, the paper provides a basis for experimental studies aimed at analyzing the dominant features of tone in environmental disclosures under the new rules on non-financial reporting. The paper may be also useful to scholars investigating tone management strategies and key indicators of transparency in sustainability reporting, especially in the environmental field. It may serve to clarify the motivation behind firms' social and environmental strategies (e.g. are these strategies led by a desire for legitimation or by a commitment to sustainable development?).

Finally, given the lack of research on mandatory disclosures in sustainability reports, this paper may prompt further inquiry into tone and environmental performance.

Notes

1. Codina (2018) uses the term "systematic literature reviews" to refer to systematic reviews conducted from the healthcare field.

Abstract

The main goal of the research was to answer the question whether the type of production affects the financial efficiency of very small farms. The subjective scope covered very small farms in Poland. The basic source of data were statistics collected as part of the system for collecting and using farm accountancy data - Farm Accountancy Data Network (Polish FADN). Very small farms were identified based on the criterion of their economic size (economic size class: very small, from 4,000 to 8,000 EUR SO). Data for the years 2013-2017 were used for the analysis. The research showed, among others, that regardless of the direction of production, very small farms included in the analysis were characterized by a high significance of fixed assets in the structure of assets, a high degree of self-financing of agricultural activity and a high cost of production. It was also found that units focused on permanent crops had the highest production value and the highest level of costs. In turn, the highest level of agricultural income was characteristic of units focused on field crops, with the entire income coming from operating subsidies. In 2017, financial efficiency in all considered types of very small agricultural holdings decreased in relation to 2013. The lowest financial efficiency in relation to the assets and equity involved was found in non-specialized farms and units focused on the production of herbivorous animals. The obtained results also proved the significant role of external financial support in creating the level of agricultural income of very small farms.

Keywords: very small farm, farm income, ROA, ROE, ROS, FADN, Poland.

Introduction

The agrarian structure in Poland is dominated by small-scale farms. In 2018, according to the data of the Statistics Poland [SP, 2019], there were 1,428.8 thousand farms, of which 53.4% were units with an area of up to 5 ha. The average area of a farm is 11.5 ha, however, 75.4% of farms in the whole group have an area of less than 10 hectares. Statistical data confirm a significant share of small-scale farms in the structure of agriculture in Poland. Agrarian fragmentation in the context of the functioning of this group of entities is the subject of many studies covering, among others, economic, social and environmental aspects (Galluzzo, 2015; Forgacs, 2016; Burkitbayeva and Swinnen, 2018; Veveris and Puzulis, 2018; Żmija and Czekaj 2012; Żmija and Czekaj 2014; Żmija and Szafrańska 2015; Czyżewski and Stępień, 2013; Drygas and Musiał, 2013; Dzun, 2013; Halamska, 2011; Michalska, 2012; Czudec, 2013; Hornowski and Kryszak, 2016; Safa 2005; Van Huylenbroeck *et al.*, 2007; Strzelecka, 2018). The discussion revolves, among others, around the effectiveness of very small farms operation, the scope and amount of agricultural income support, as well as the issue of business registration and its taxation. In the social area, the important role of professional activation

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of rural residents is emphasized, as well as the benefits of cheaper retirement and disability insurance and, as a result, reduced demand for social assistance. It is emphasized that very small farms can be a form of counteracting poverty and social exclusion, supporting the sense of security of rural residents, especially in the context of caring for the elderly and children. In the environmental aspect, small-scale farms contribute to the protection of natural biodiversity and the landscape value of villages, due to, among others, extensive production methods, lower density of livestock and lower use of artificial fertilizers and plant protection products. Finally, small-scale farms can provide the basis for the diversification and multifunctionality of rural areas due to the possibility of using farm assets for non-agricultural purposes.

With regard to farms that sell the results of their agricultural production, one can speak of efficiency as a relation of results to inputs. These entities combine the activities of enterprises and households. The efficiency of agricultural production is dependent on various forms of subsidizing it. Therefore, the question arises whether the type of production conducted affects the financial efficiency of very small farms. We define financial efficiency as the profitability of a very small farm (Kulawik, 2008; Juszczyk, 2019).

The rest of the paper is structured as follows. Next section presents the survey methodology and data sources. Third section presents the results of the study, which consisted of three main stages. First, the production potential of very small farms covered by the study was analyzed and assessed. Next, the effectiveness of using this potential was calculated, taking into account changes in: production, costs and income from the family farm (agricultural income). The importance of operating subsidies in generating this income was also established. In the last stage of research, the financial efficiency of very small farms included in the study was assessed. The following measures were used to establish it: return on assets (ROA), return on equity (ROE) and return on sales (ROS). The last section concludes.

Data Sources and Research Methodology

The main source of data was statistics collected under the system of collecting and using accounting data from farms - *Farm Accountancy Data Network* (Polish FADN). These results are published in cyclical studies of the Institute of Agricultural and Food Economics - National Research Institute (IAFE-NRI). In order to achieve the set goal, the following scope of research was adopted: subjective, temporal and spatial. The subjective scope covers very small farms in Poland that keep agricultural accounting for the needs of the Polish FADN.

In the literature, among the criteria for distinguishing very small farms there are, among others: economic size of a farm (Dzun 2013; Hornowski and Kryszak, 2016; Beluhova-Uzunova et al., 2019) and agricultural area (Żmija and Czekaj 2012; Forgacs, 2016; Burkitbayeva and Swinnen, 2018; Beluhova-Uzunova et al., 2019). Due to the lack of a clear definition of a very small farm[1], in this study a classification criterion of the economic size of a farm was assumed. The *economic size* is determined on the basis of the sum of the Standard Outputs (SO) of all agricultural activities that occur on a given farm and is expressed in EUR (Goraj and Olewnik, 2011). Where Standard Output (SO) is the average value of production of a specific agricultural activity (plant or livestock), which was obtained during 1 year from 1 hectare or 1 animal, in the average production conditions for a given statistical region. The calculation of this parameter takes into account the average values over 5 years (Goraj and Olewnik, 2011).

On this basis, a very small farm was defined as a farm whose economic size does not exceed 8,000 EUR SO (due to the basic source of statistical data that was used in this study, the analysis covered very small farms with an economic size from 4,000 up to 8,000 EUR SO). The adopted assumption is justified due to the subject of the research, as the economic size determines the income potential of a farm and the possibilities of its development (Wilkin, 2013). Total number of very small farms included in the study in particular year is presented in table number 1.

Table 1: Number of very small farms included in the sample

Year	2013	2014	2015	2016	2017
Number of farms (SY 03)*	640	590	590	650	780

**Note: symbol according to FADN is given in bracket*
Source: Authors' own study based on FADN data: Standard results of Polish FADN agricultural holdings 2013-2017 [Online], IAFE-NRI [15.04.2020] http://fadn.pl/publikacje/szeregi-czasowe/

Temporal scope of the study was 2013-2017, while the spatial scope covered the entire area of the country (Poland). The agricultural type of an agricultural holding, which is defined on the basis of the share of the Standard Output (SO) value from individual agricultural activities in the total SO value of a farm (Floriańczyk, Osuch and Płonka, 2018), was included in the study. The following types of farming were subjected to comparative analysis: a) *field crops* - applies to farms focused primarily on the cultivation of cereals, oilseeds and protein crops for seeds and other field crops, b) *permanent crops* - includes entities that specialize mainly in the cultivation of fruit trees and shrubs, and olives c) *dairy cows* - this type of farming includes units focused on dairy cattle breeding, which is kept mainly for milk production, d) *herbivorous animals* - this group includes farms whose main production direction includes mainly: slaughter cattle, dairy cattle, goats and sheep, and e) *mixed* - this type of farming includes farms that do not meet the requirements for specialist types. The study did not take into account these types of farming: horticultural crops and granivorous animals, due to the fact that the number of entities targeting the above-mentioned types of production in each group did not exceed 15 farms. Thus, in accordance with the principles of disseminating the FADN data, these results could not be published in the Standard Results (Floriańczyk, Osuch and Płonka, 2018). All data presented in the study are the average values for the considered groups of farms.

The following categories of data collected and published in FADN reports were taken into account in the course of this research (Floriańczyk, Osuch and Płonka, 2018): a) *agricultural area* - total area of agricultural land (including land leased for more than one year); b) *total labor inputs* - total human labor inputs (own and hired) as part of the operating activity of a farm, expressed in work units (full-time employees AWU[2]); c) *own labor inputs* - labor input of unpaid persons, mainly family members as part of the operating activity of a farm, expressed in work units (full-time family employees FWU[3]); d) *total assets* - fixed and current assets owned by the farmer; e) *equity* - total assets decreased by the value of total liabilities; f) *total production* - the value of plant and livestock production and other agricultural production generated on the farm; g) *total costs* - all costs related to the operating activity of an agricultural farm and incurred for production in a given accounting year; h) *income from a family farm* - the concept introduced by the FADN - an economic surplus that remains for the farmer to pay for the production factors involved in the farm's operational activity (land, labor and capital) that are his property (Goraj and Olewnik, 2011); i) *subsidies for operating activities* - subsidies for plant and livestock production, subsidies for rural development, subsidies for intermediate consumption, subsidies for the costs of external factors, *decoupled* payments (including single area payment) and other subsidies; j) *farmhouse consumption* - value of production (plant and animal) transferred to the farmer's household; k) *farm use* - value of production (plant and livestock) produced and consumed as part of the farm's operating activity.

The following research methods were used to achieve the assumed goal: a) literature analysis, b) empirical data analysis - using descriptive and comparative methods. The results of the analyzes are presented in tabular and graphic form, c) statistical methods (average, structure indicators, dynamics indicators) and d) profitability indicators.

The production potential and the efficiency of its use as factors shaping the income of very small farms

Table 2 presents data on the production potential of very small farms included in the study. For the purposes of the analysis conducted, factors relating to land, labor and capital were distinguished**.**

Table 2. The production potential of very small farms participating in the FADN system in 2013-2017 - by production direction

Note: calculated based on the following types of data - symbols according to FADN:SE 025, SE 030, SE 020, SE 015, SE 436, SE 441, SE 501
Source: Authors' own study based on FADN data: Standard results of Polish FADN agricultural holdings 2013-2017 [Online], IAFE-NRI [15.04.2020] http://fadn.pl/publikacje/szeregi-czasowe/

Among the very small farms included in the analysis, the entities specialized in field crops were characterized by the highest utilized agricultural area. In the years 2013-2017, these units used an average of 10.12 ha of agricultural land in the production process. It is related to the basic type of

agricultural production conducted on these farms, which requires the involvement of land resources with a larger area in the production process. In turn, the lowest arable land area was characteristic for very small farms focused on permanent crops (on average, 4.36 ha in 2013-2017). When analyzing the production potential related to labor inputs, it was observed that the greatest involvement of the human factor in the production process was characteristic of very small farms specialized in permanent crops (1.47 AWU on average in 2013-2017). Moreover, farms of this type were characterized by a relatively high involvement of external workers in the production process (on average in 2013-2017, almost 25% of the total labor inputs were done by hired workers). For comparison, in the remaining types of very small farms, work was performed mainly by the farm owner and his family members.

The highest value of assets was characterized by units specialized in field crops (ca. 387 thousand PLN on average in 2013-2017) and entities whose main production activity was rearing of herbivorous animals (ca. 372 thousand PLN on average). On the other hand, the lowest value of the discussed category was characteristic for units focused on rearing dairy cows (approximately 269 thousand PLN on average). It was also observed that regardless of the production focus, very small farms included in the analysis were characterized by a high importance of fixed assets in the asset structure. The share of assets involved in the agricultural production process for a period longer than one year accounted for over 90% of total assets (except for the herbivorous animals production type in 2017, when the level of the analyzed indicator was 89.89%). This is due to the fact that fixed production assets (including land, buildings, specialized machinery, technical equipment and others) are necessary for agricultural activity. When considering the production potential related to the capital of very small farms, it was also observed that these units mainly use their own resources to finance agricultural activity. For very small farms included in the study, in the analyzed period, the share of equity in the structure of financing sources fluctuated, on average, around 100%. Only in farms of the field crops type (in 2013-2014) and units focused on permanent crops (in 2014 and 2017), the share of outside capital exceeded 1%. It was also observed that the last of the mentioned groups of very small farms (permanent crops) in the last year included in the analysis increased the involvement of external financing sources (the share of outside capital exceeded 3%).

When analyzing the effectiveness of using the production potential, in the next stage of the research changes in the total production value and total costs in very small farms in Poland were assessed (Fig. 1).

Fig. 1: Total production value and total costs in very small farms in Poland in 2013-2017 - by production focus [thousand PLN]

Source: Authors' own study based on FADN data: Standard results of Polish FADN agricultural holdings 2013-2017 [Online], IAFE-NRI [15.04.2020] http://fadn.pl/publikacje/szeregi-czasowe/

The obtained results showed that the units focused on permanent crops were characterized by the highest production value and the highest level of costs. On the other hand, the lowest average production values were recorded for farms specializing in the rearing of herbivorous animals and dairy cows (in this case except for 2014). It was also established that very small farms are characterized by very high production costs. Moreover, in the case of entities of the granivore type and units with a mixed production profile, in the entire period covered by the analysis, the costs related to agricultural activity exceeded the value of production. Continuing this research thread, the next step was to analyze and evaluate changes in the level of agricultural income and to establish the importance of financial support (in the form of operating subsidies) for the generation of this income (Fig. 2).

Fig. 2: Farm net income and operating subsidies in very small farms in Poland in 2013-2017 - by direction of production [thousand PLN]

Source: Authors' own study based on FADN data: Standard results of Polish FADN agricultural holdings 2013-2017 [Online], IAFE-NRI [15.04.2020] http://fadn.pl/publikacje/szeregi-czasowe/

By analyzing the obtained results, it was found that the highest agricultural income in the entire analyzed period was characteristic of very small farms with field crops as their main direction of production, and this income came entirely from operating subsidies (the ratio of subsidies to income from a family farm in the whole period took values higher than one). Units focused on permanent crops were characterized by the highest ability to generate income as part of operating activities (except for 2014, when the income came entirely from operating subsidies, and half of these subsidies was allocated to financing the costs of agricultural production). In 2013, more than half of the agricultural income of this type of farms was obtained as a result of operating activities, however, since 2015, an increase in the importance of external financial support for generating income for farms of this type has been observed (in the last of the analyzed periods, subsidies accounted for 73% of the discussed category of financial surpluses). Further analyzes showed that the agricultural income of farms focused on breeding herbivores and non-specialized farms in the entire period covered by the analysis came from financial support in the form of operating subsidies. A particularly unfavorable relationship in this respect was recorded among farms focused on breeding herbivores (in 2015 the ratio of subsidies to agricultural income was 3.5, in 2016: 2.7, in 2017: 2.8), which means that the financial results achieved by farms of this type depended entirely on the amount of operating subsidies, moreover, these subsidies were primarily intended to cover the high costs of agricultural activity.

The last stage of the research covered the assessment of financial efficiency of the analyzed group of very small farms. For this purpose, in accordance with the adopted research methodology, the profitability ratios were calculated for: assets, equity and sales in individual types of very small farms (Table 3). Following Wasilewski and Gałecka (2010), Ryś-Jurek (2013) and Hornowski and Kryszak (2016), taking into account the specificity of farms, the farm net income was assumed as the equivalent of net profit in an agricultural holding. According to Ryś-Jurek (2013), the level of sales was calculated as the difference between the value of total production produced in a given year and the value of production transferred to the household and the value of internal consumption.

Table 3: Profitability ratios for very small farms participating in the FADN system in 2013-2017 - by direction of production

Years	Agricultural type:				
	Field crops	Permanent crops	Dairy cows	Herbivorous animals	Mixed
Return on assets ROA [%]					
2013	4.35	3.21	4.68	2.81	2.88
2014	3.20	1.99	4.51	2.44	1.64
2015	3.19	3.34	3.26	1.00	1.89
2016	3.20	3.02	1.77	1.41	2.30
2017	3.02	2.36	3.45	1.28	2.46
Return on equity ROE [%]					
2013	4.40	3.24	4.68	2.82	2.89
2014	3.23	2.01	4.51	2.44	1.65
2015	3.21	3.36	3.26	1.00	1.90
2016	3.21	3.03	1.77	1.41	2.31
2017	3.05	2.44	3.45	1.28	2.47
Return on sales ROS [%]					
2013	51.78	21.82	74.45	43.13	40.64
2014	42.42	17.03	50.33	58.40	27.22
2015	40.70	21.37	47.00	25.89	32.59
2016	42.95	23.51	32.47	30.31	37.22
2017	37.94	21.07	48.65	28.01	38.65

*Note: Profitability indicators where calculated based on the following types of data (symbols according to FADN are given in brackets): Farm net income (SE 420), Total assets (SE 436), Net worth (SE 501), Total output (SE 131), Farmhouse consumption (SE260), Farm use (SE265). Profitability ratios formulas: ROA = (SE420/SE436)*100; ROE=(SE420/SE501)*100; ROS = (SE420/(SE131-SE260-SE265))*100*
Source: Authors' own calculations on FADN data: Standard results of Polish FADN agricultural holdings 2013-2017 [Online], IAFE-NRI [15.04.2020] http://fadn.pl/publikacje/szeregi-czasowe/

Profitability ratios decrease over time in 2013-2017. The exceptions are the ratios obtained in the group of very small farms focused on the rearing of dairy cows in 2017, field farms in 2016, units specializing in permanent crops in 2015, herbivorous animals in 2016 and farms with a mixed production profile in 2015-2017. Moreover, it was established that the highest return ratios were obtained on farms whose main production focus is dairy cows (except for 2016, ROA and ROE in 2015, and ROS in 2014). On the other hand, the lowest financial efficiency in relation to the assets and equity employed was characteristic of non-specialized farms and units focused on breeding herbivores (in 2014 and 2017 it was also entities representing the permanent crop type). On the other hand, the lowest financial efficiency, measured by sales profitability, was characteristic of very small farms whose main production direction was permanent crops.

Conclusions

The aim of the research was the answer the question whether the type of production affects the financial efficiency of very small farms. In the course of the research, an answer to the initially posed research question was obtained. Very small farms vary in terms of their financial efficiency. The production direction affects the profitability of assets and capital. Furthermore, based on the literature

review it was established, that small-scale farms are the dominant form in the agrarian structure of Poland. Due to their characteristic features, they fit into the concept of sustainable agricultural development. They perform significant social, economic and environmental functions.

A significant limitation of our research was the lack of a uniform definition of a very small farm. The classification criterion used in the research is the economic size of the farm, which does not exceed 8 thousand EUR of standard production (average production value of a specific agricultural activity which was obtained during 1 year from 1 hectare or per 1 animal, in average production conditions for a given statistical region). The results of our research showed that the highest area of arable land was characteristic for very small farms specialized in field crops. In the years 2013-2017, these units used an average of 10.12 ha of agricultural land in the production process. They were also characterized by the highest value of assets. The lowest area of arable land was characteristic for very small farms focused on permanent crops (on average 4.36 ha in 2013-2017). It was also found, that regardless of the production direction, very small farms included in the analysis were characterized by a significant importance of fixed assets in their asset structure. The literature stressed that farms in Poland are often over-invested, and they attach more importance to the amount of fixed assets and less to their effective use (Marcysiak and Marcysiak, 2018). Our previous study in the field of very small farms so far prove a negative relationship between the level of agricultural income and the increase in fixed assets expenditure per hectare of agricultural land in the production process (Strzelecka, Zawadzka and Kurdyś-Kujawska, 2019). As emphasized by Grzelak (2014), in the case of small-scale farms, maintaining too many fixed assets may be economically unjustified, as it may lead to ineffective use of resources and generate high costs.

The results of our research also showed that the highest production value and the highest level of costs was characteristic of units focused on permanent crops. The lowest average production values were recorded for farms specializing in rearing herbivores and dairy cows. Moreover, the obtained results indicate that very small farms are characterized by very high production costs. The reason for such a high cost-consumption of production in these farms may be the fact that they do not have modern agricultural machinery and equipment. Therefore, they cannot reduce production costs by replacing human labor with specialized technologies. Moreover, the small scale of agricultural production makes it impossible to reduce unit costs. This results in a lower efficiency of agricultural production compared to larger farms (Strzelecka, Zawadzka and Kurdyś-Kujawska, 2019).

The obtained results also proved that very small farms use their own funds to finance agricultural activities. Only in field crops type units (in 2013-2014) and units focused on permanent crops (in 2014 and 2017) the share of outside capital exceeded 1%. As evidenced by the research results so far, a high degree of self-financing is typical of units in the agricultural sector, especially in the case of very small farms (Hornowski and Kotyza, 2018; Prokop et al., 2019).

It was also found that the highest agricultural income was in very small farms whose main direction of production was field crops. This income came entirely from operating subsidies. It also contributed to the achievement of relatively high financial efficiency ratios measured by the return on assets, return on capital and return on sales in the examined group of very small farms. The great importance of operating subsidies in creating agricultural income of very small farms has been confirmed by the results of the research presented in the literature (Kołoszycz, 2017; Hornowski and Kotyza, 2018; Grzelak, 2019).

Further analyses, using profitability indicators, indicate that returns ratios of surveyed units decrease over time in 2013-2017. The exceptions are the ratios obtained in the group of very small farms focused on the rearing of dairy cows in 2017, field crops farms in 2016, units specializing in permanent crops in 2015, herbivorous animals in 2016 and farms with a mixed production profile in 2015-2017. The highest returns ratios were achieved on farms where the main production direction was dairy cows (except for 2016, ROA and ROE in 2015, and ROS in 2014).

The obtained research results contribute to the literature, constituting a thread in the discussion on the financial efficiency of very small farms, as well as practice - the obtained results may be useful source of information for institutions that develop support programs for very small farms. Further research stages should be carried out in order to identify the causes of the declining profitability of very small farms in Poland.

Abstract

The objective of this article is to analyze the generation Y's leadership types preferences. We build upon the presumption that identifying preferences and the effort of satisfying them for a given group of workers, will lead to the enhancement of their work performance. We presume that, apart from higher performance, there will also be a lessening of its fluctuation as well as enhancement of the quality of life perception. The theory section of the article deals with the characteristics of individual generations and with major leadership theories. Research section examines the preferences of the generation Y members in the area of leadership and the subjective rating of the current state of affair in that area. The modified Full Range Leadership Model was chosen as a suitable tool for the analysis. The results of the analysis show that the preferred leadership style is the interviewed sample of respondents from generation Y is transformational leadership. 30% of respondents are dissatisfied with the current leadership style in the company, and the share of satisfaction with their direct superior is higher. The results showed that the way Generation Y is conducted at work is crucial to it; 96% of respondents said that management has a direct influence on their successful retention.

Keywords: Leadership styles, work performance, generation Y, MLQ

Introduction

The goal of this work is to analyze generation Y's leadership preferences and to bring forth suggestions, which could lead to increased generation Y's work team loyalty, increased work performance and enhanced life contentment. To understand this issue, there is the further goal to identify the characteristic traits of individual generations with the focus on generation Y. It is also necessary to identify individual leadership theories and the application of their principles. The aim of this work is also to analyze the millennials' various leadership type preferences in order to find out which one is the preferred one.

In relation to the given goals, this research provides answers to the following questions:

- What is the generation Y's preferred leadership type?
- Are the employees satisfied with the current status of leadership in their workplaces?
- Does the leadership play a role in their loyalty to the company?

Cite this Article as: Jiri KOLENAK, David ULLRICH, Veronika KOLENAKOVA and Daria SEVCIKOVA "Generation Y's Leadership Preferences and Their Influence on Work Performance" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The research will increase the professionalism of leaders in the performance of their work. Professional leadership is not considered as a position, but as the quality of an individual's natural potentials, relating to an inner style that has the potential to follow and gravity and manifests itself in interpersonal contact. Professional leadership is an essential quality for leading people and human systems in today's environment (Ambrozova, 2019).

Generational Management

The goal of this chapter is to understand the generation Y's influence on work sphere in the contemporary world and how effective is their communication ability in the work environment. We will reach this understanding by specifying their characteristic traits. From a sociological point of view, the definition of a generation is as follows: "The term generation, in a sociological sense, describes a group of people growing up in the same time period, who share the lifestyle, thinking, problems and attitudes dictated by that time period. Members of each generation are influenced by the same historical, cultural, socio-economic and political events of the time period and therefore exhibit the same traits. These traits, however cannot be presumed automatically so as not to suppress the individuality of each member." (Kotler, 2007 cited from Heřmanová, 2015) The time frame of one generation is given as the period in which a member of the generation reaches the productivity age and begins to create a new generation. This time frame is usually accepted to be 20-30 years. Related to this, there is the nowadays frequently used term diversity. Currently there are number of scientific and popular articles dealing with the topic of diversity in the gender and ethnographic sense. With the massive entry of generation Y into the work environment, we now also encounter the term generational diversity. This is due to the difference of the generation Y from others in many areas.

It is important to understand the diversity and specifications of individual generations in order to understand their needs, preferences, behavior and decision making. When this is understood, it will be possible to correctly adjust the work environment and to apply effective types of leadership.

Generation Y

The needs and expectations of millennials in the work environment were described in the studies (e.g. Deloitte, 2016) and books (Spiegel, Crampton a Hodge et al.). Generation Y has a strong tendencies to autonomy and independence and prefers freedom and flexibility. These people like to fulfill their tasks in their own time and style (Martin, 2005). They expect an immediate and open feedback and positive evaluation for their effort (Spiegel, 2013). This generation also prefers to be given smaller tasks with tighter deadlines and to work on smaller parts of individual projects. This way their work is the most effective. They welcome the responsibility and the opportunity to show their skills and abilities. They also require enough growth and self-development opportunities, both inside and outside the company (Martin, 2005).

Generation Y grew up in the age of technological boom and information sharing. It is a generation with bigger grasp of technology than any other before it (Spiegel, 2013). Computer and internet use is their second nature and they regularly use modern technologies in their jobs. Greater technology understanding, we observe with millennials, has a positive impact in the form of ability to gather information faster and to utilize the information in their work. However, according to Simon Sinek (2017), a substantial negative impact is the fact that a big part of the generation Y is dependent on the modern technologies, which leads to a lack of concentration, absence of personal social interaction and therefore also to the inability to create and maintain stable and meaningful personal relationships.

Generation Y was actively supported by their parents and led to openly express their opinions and feelings. Thanks to the modern technologies and the internet, the millennials are used to communicate instantly and to make themselves to be heard at all times. They are willing to openly share their thoughts and opinions and they expect the same from the others. At work they are asking not only for the decision to be communicated to them but also the reasons behind these decisions (Spiegel, 2013).

As is shown in the Deloitte research (2016), open and unrestrained communication at work has a direct impact upon the satisfaction of the generation Y with their occupation, as well as on their loyalty to the company and so also on their willingness to stay; 47% of the people interviewed by Deloitte stated they would stay for longer than 5 years in a company allowing and supporting open communication.

A need for feedback, stronger than that of previous generations is another characteristic trait of the generation Y. Tulgan (2009) states that the reason for this is growing up in an environment where they have received a lot of attention and space to openly express themselves. Mentoring and feedback are therefore the tools to communicate with the generation Y effectively and to help them to self-develop. They are quick to apply constructive feedback, which significantly enhances their productivity and performance (Spiegel, 2013).

A feedback provided only once or twice per year at formal meetings is insufficient for generation Y. For more effective work of the millennials, the management needs to be trained in feedback provision and in the skill of these meetings in general (Crampton and Hodge, 2009).

Generation Y grew up in the environment of constant support, care and praise of their parents. This created a safe bubble which shielded them from any negative feelings towards themselves. They often heard that they are unique and that they can reach anything they wish for in this world. Positive style of upbringing like this, leads to a big confidence of this generation and largely influences their faith in their own abilities and knowledge (Spiegel, 2013). Simon Sinek (2017) thinks this to be a major failure of the parenting strategy. As a result of this strategy, millennials, when faced with the real world in their adulthood, suddenly lose the illusion of their uniqueness and exceptionality of their abilities. Sinek (2017) sees this fact as the reason why is generation Y, much more so than other generations, dealing with mental issues such as depression, anxiety and suicidal tendencies.

Flexibility and longing for change are other key attributes of the generation Y. Martin (2005) states that millennials are not only adaptable to change but are actually demanding it. They prefer a work environment, where they can skip from task to task, gain new knowledge, skills, experiences and contacts. If they are not offered enough flexibility, option to work on diverse tasks and in different environments, the millennials tend to get bored fast and they might start looking for new challenges. Thanks to that, they are viewed as unstable and disloyal. Generation Y is the fastest growing segment on the work market, being more than twice as numerous as generation X (Steelcase, 2011). Thanks to this, their work market influence is of a great importance. Because of their specific character traits, described in the previous part of this article, it is important to pay attention to the millennials' preferences regarding their work environment. In the research ran by Deloitte (2016), there were described the following preferences of the millennials, which form criteria for their job search and for their final decision which employer to chose (please note, the wages conditions were not included). The research showed the most important for millennials is the balance between professional and personal life, followed by the opportunity of a career growth. This is followed by flexibility, meaningfulness of the work and availability of professional development programs. Important finding is the fact, that millennials demand for their work to be meaningful, with a positive impact on society. Generation Y feels very low levels of loyalty to the company (Deloitte, 2016). 44% of respondents expect to leave their current job within 2 years.

Generation Y requires work environment with sense of humor and constant challenges (Susan Eisner, 2005). Eisner also states that the main principle of leadership of this generation is an immediate, concrete and constructive feedback. Due to fact that the generation Y prefers an environment which values relationships, they put more importance on the personality traits of their leaders, or managers.

Leadership styles

The basic leadership styles were chosen for the purposes of this research: Transactional, transformational and passive.

Transactional leadership is defined as a relationship based on exchange trade between the leader and the follower, with the goal to trade the valued objective without the intention to reach any higher goal (Burns, 1978). Transactional leader therefore works with the expectation of a reward for fulfilled task and/or a punishment for failure (Awamleh, Evans and Mahate, 2005) and is not motivated to perform above the expectation.

Awamleh, Evans and Mahate define transactional leadership as a style based on an exchange process, within which the leader deals out both rewards and punishments. According to Bass (1985) the transactional leadership is based upon supportive building of relationship between leader and follower, in the sense of establishing expectations, clearly stated responsibility, negotiating rules and giving out rewards for achieving given task. Transactional leadership is based on monitoring and controlling of followers and rewarding desirable behavior (Bass, 1985). Transactional leader gives followers what they want in exchange for what he/she requires. Judge and Piccolo (2004) differentiate between two basic tools for rewarding followers by the transactional leaders – contingency reward. This means the leader states beforehand the expectations (and the reward for success) and the rules for deviations from the goal, which are not in sync with the expectations. Tool for this is a negative stimulation (e.g. a punishment). Transactional leader leads the followers towards reaching his/her expectations and achieving set goals, but not towards exceeding the expectations and extra work effort. According to Bass (1985), the attributes of transactional leadership are:

- Contingency reward
- Management by exception: active and passive

Transformational leadership is a process concentrating on a change of behavior and perception of individual as well as social group. It focuses on satisfying higher needs of the followers. It deals with topics such as emotions, values, ethics, inspiration, long-term goals and strategy. Transformational theory of leadership is currently the most researched theory (Prochazka, 2015) and it is unique in its approach and focus on the highest human needs and on the transformation of the current situation. The first person to introduce the concept of transformational approach to leadership was James MacGregor Burns, in his 1978 book Leadership (Northouse, 2016, p.161). Burns defines the transformational leadership as a process, in which both leaders and followers help each other to achieve a higher level of morale and motivation. The theory of transformational leadership is considered a behavioral theory and it is assumed that transformational behavior can be a learned skill for a leader (Bass, 1990).

Northouse (2006, p.161-p.162) states that the transformational leadership can be used to describe a wide range of leadership styles: From the very specific intention to influence an individual follower, to influencing whole organizations, or even whole cultures. In his other publication “Leadership and Performance beyond Expectations”, Burns further develops his concept of transformational leadership and describes this type of a leader as follows:

- Fair and impartial
- Sets up clear goals
- Has high demands
- Encourages others
- Inspires
- Provides support and appreciation

Factors of transformational leadership (4 I's)

Charisma, Idealized Influence ("II")

Charisma is generally perceived as a very important factor in relation to leadership and was researched by many authors (e.g. Weber, Yukl and others). Transformational leader is a role model and sets an example for the followers. His/her moral and ethical standards are high. The followers perceive such leader as a person with extraordinary abilities, perseverance and determination. The followers admire, respect and trust their leader, which leads to them identifying with his/her goals and values and to the desire to do the right thing (Bass, 1985). As also stated by Yukl (1989, p.260-p.261), charismatic leaders show faith in the abilities of their followers by having high demands, which strengthens the followers' self-awareness and faith in their own abilities. Bass sees charisma as a key component of transformational leadership.

Inspirational Motivation ("IM")

Factor of inspirational motivation describes a leader who has the ability to express his/her vision in such a way, as to motivate and inspire the followers to the vision's achievement (Judge and Piccolo, 2004). Bass (1985) describes the basis of the dimension of the inspirational motivation as leader's ability to apply vision in individual steps and component goals, leading to its fulfillment. He also describes it as the ability to present the application of the vision in such a way, so the followers see the meaning in every performed task and that they understand the way they participate on the vision or the required goal. Many other authors work with the concept of vision and its influence and importance in the business structure. For example Simon Sinek (2017) claims that a vision is the key to the feeling of personal fulfillment and to loyalty and belonging with the company.

Intellectual Stimulation ("IS")

Intellectual stimulation factor specifies the influence of a leader upon the intellectual aspect of the followers. It is a behavior where leader challenges established customs, stimulates followers to see the problem from other perspectives and calls for innovation of thinking and acting.

Individual Consideration ("IC")

Factor of Individual consideration indicates a leader who cares for individual needs of every follower. Leader is often a mentor and coach and one of his/her main expressed behaviors is empathy towards followers and broader surroundings.

Full Range Leadership Model "FRLM"

FRLM has developed from the work of James MacGregor Burns. In 1978 Burns claimed that leadership is either transactional or transformational. Transactional leaders lead by social exchanges, whereas transformational leaders help develop their followers and motivate or inspire them to achieving extraordinary level of success.

FRLM is a tool frequently used to measure transformational, transactional and passive leadership. Below is shown a model which differs from the original one in grouping of the individual components and in the identification of passive approach to leadership. The original model contained the above described 4 attributes of transformational leadership "4 I's". In this new model, the component of Idealized Influence (charisma) was divided by Burns into two new components: Idealized Influence (attributes) and Idealized Influence (behavior). The attributes component focuses on description of leader's traits and the behavior component focuses on his/her actual behavior and acting. This brings it up to "5 I's". The original model includes the laissez-faire concept, but in the new model this system is changed to passive leadership category which became a synthesis of the laissez-faire concept and passive ruling of deviations (originally part of the transactional leadership). This change was made to more accurately diversify individual leadership styles (Bass, 2000).

Research Methodology and Results Interpretation

Multifactor Leadership Questionnaire (MLQ) is the tool used to collect the data. It consists of 36 research questions, whereas 4 questions were assigned to each of the attributes of leadership styles (e.g. CR, IIA, MBEP, etc.). A unipolar Likert scale was used to measure and analyze the data (from 0=Never to 4=Very often, if not always).

Participants of the research were individuals from Europe, working for global companies in the industrial area. The research was performed using a questionnaire sent to the individual groups. The total amount of respondents included in the research was N=44.

Research questions were developed based on the available version of MLQ5X-Short questionnaire, which is widely used tool for measurement in the area of Full Range Leadership Model. In its original state, this tool serves as means to a leader's self-assessment. To use this tool for the research project with the goal to find the respondents' preferences and to find the required ideal state, the individual statements were modified; instead of statement "I …" the statement "My ideal leader …" was used (for example, instead of statement "I prefer the good of the group over my own interests", a new statement was used: "My ideal leader prefers the good of the group over his/her own interest"). To each dimension of transformational, transactional and passive leadership is assigned one statement. The respondents rate the statement using the unipolar Likert scale.

As a measuring tool, the original model Likert scale was used (0=Never, 1=Rarely, 2=Sometimes, 3=Often, 4=Very often, if not always). For research of the questions in rating of the current state, the Likert scale of agreement was used (strongly disagree, disagree, neutral, agree, strongly agree).

Demographics of the researched group

More than half of respondents are men (61.4%) and the biggest part of respondents are in the age group 32-38 years old (54%). Most of the respondents have master's degree (61.4%). Almost half (45.5%) of employees are with a company for 2-5 years. In the second place there are two same size groups of respondents, being with a company 6-10 years and 16-20 years (18.2% both). Most of the respondents (43.2%) work in a Sales Management department as Account managers, or Sales engineers. Second biggest group consists of Project management department employees (25%).

Leadership style preferences

After collection and export of data corresponding to the age range of generation Y (as already stated, data of respondents above 39 years of age were removed from the analysis), average values were calculated for every individual component of leadership (Idealized Influence (Attributes), Idealized Influence (Behavior), Inspirational Motivation, Intellectual Stimulation, Individual Consideration, Contingency Reward, Management by exception: Active, Management by exception: Passive, laissez-faire). Next, the average values were calculated for individual leadership styles (transformational, transactional and passive).

Analysis showed that the most preferred style is transformational (3.26), then transactional (2.60) and the least preferred is the passive style (0.95). In individual components, the first place went to components of transactional leadership: Inspirational Motivation (3.24), followed by Idealized Influence (Attributes) (3.34). Third place is divided between two components reaching the same average (3.28): Idealized Influence (Behavior) of the transformational leadership and Contingency Reward of the transactional leadership.

Respondents' average scores of leadership preferences:

Transformational leadership	
Idealized Influence (Attributes) (IIA)	3.34
Idealized Influence (Behavior) (IIB)	3.28
Inspirational Motivation (IM)	3.42
Intellectual Stimulation (IS)	3.15
Individual Consideration (IC)	3.11
3.26	

Transactional leadership	
Contingency Reward (CR)	Management by exception: Active (MBEA)
3.28	1.91
2.60	

Passive leadership	
Management by exception: Passive (MBEP)	Laissez-Faire (LF)
1.49	0.41
0.95	

Source: self-processed

Influence of age and gender

Analysis of age, divided into sub-groups 19-25 years, 26-31 years, 32-38 years, shows score assigned to individual leadership style progressively decreasing with higher age. The exception is the passive leadership which, compared to other groups, scored the highest with the oldest group (1.04). Results show that the transformational leadership style is preferred by the youngest segment of respondents. According to analysis, the gender plays only a small role in the leadership style preference for transformational leadership (the score difference is 0.05) and for passive leadership (the score difference is 0.01). Only for the transactional leadership, we can see more significant difference; men's preference score is higher (2.71) than women's (2.41).

Satisfaction with the current state

Statement that the current leader satisfies the respondent's preference - 11% strongly disagree and 9% disagree. Strongly agree 14% and agree 32% of respondents. After summation of individual polarities of the scale (strongly agree + agree vs. strongly disagree + disagree), we find that total of 20% of respondents rate their current leader as unsatisfactory to their preferences and 46% as satisfactory. 34% chose the neutral rating. With the statement that leadership style in the company transforms to respondents' satisfaction, strongly disagree 5% and agree 25% of respondents. 32% of respondents agree, and no one chose the strongly agree option. After summation, the result is 30% of respondents rate the transformation of leadership in their company as unsatisfactory to their preferences and 32% as satisfactory. 38% of respondents chose the neutral option.

Respondent's loyalty to the organization

The goal of this part is to find out, whether is the leadership style a significant factor in deciding to stay with the company. Another goal is to find out how big a portion of respondents are thinking about leaving the company in near future (within 2 years). With the statement that leadership style plays role in respondent's staying with the company, 2% disagree and no one strongly disagrees. 55% of respondents agree and 18% strongly agree. After summation we get the result that for 30% of respondents the leadership style plays role in their loyalty to company. For 2% it doesn't play role. 2% of respondents chose the neutral option.

Ideal leader's preferred traits

The goal of this question is to find out whether characteristic traits of generation Y correspond with the traits the millennials expect to see in their preferred leader. We are also trying to establish, whether the typical traits and requirements of millennials we introduced in the theoretical part, are preferred by them in their leaders. In the question: "Name any leadership traits you consider the most important for your leader to have", respondents were asked to name the most preferred leaders'traits. It was an open question without pre-defined options and respondents could chose up to three arbitrary traits. Analysis of the quantity of words showed, that the most important traits correspond with the typical traits of the millennials, stated in the theoretical section (below chart shows the first 6 positions).

1.	Open communication	17
2.	Mentoring	11
3.	Trust	7
4.	Feedback	4
5.	Honesty	3
6.	Vision	3

Discussion

The results show a significant tendency towards the transformational leadership amongst members of generation Y, working in global corporations in the industry area. The only other significant rating was given to Contingency Reward, which is the transformational leadership's logical addition. Transformational leadership is preferred as a whole because there were no significant differences found between its individual components. More detailed age division rating of generation Y showed stronger preference for transformational leadership in the 19-25 years category.

Men prefer transactional leadership more than women. This can be explained by the fact that men are more competitive.

Questions about satisfaction with the current state of leadership show almost equal division between positive, neutral and negative ratings of this factor.

Significant conclusion is that applied leadership style is an important parameter in deciding whether employees stay with the organization long-term. It can also often be the reason for them leaving the company.

Likewise, a significant conclusion is that amongst preferred ideal leader's traits is namely the ability to communicate openly, the ability to help the employees grow using mentoring and credibility.

In the next phases of research of this problematic, it will be appropriate to do a broader qualitative research, not only with generation Y but also with their colleagues from generation X. Broader context and focusing on both generations, Y and X, and their differences (if any) is the next necessary step for understanding ties of the employees to their leader and to each other. This will lead to a better collaboration and satisfaction. Researching the relation of preferred leadership styles and personal parameters of individual respondents is the next big research opportunity. Their understanding of themselves, how do they work, their perception and their motivation for quality performance, is the primary step for further development.

Results of the research are well applicable in the area of education and training of ambitious individuals or of people with the responsibility to lead. Very useful is also discussion of this topic in

the workplace and, ideally, cooperation of the leader and his/her team. Co-activities of leader and followers may lead to the improvement of interpersonal relationships in the work environment.

Summary and Conclusion

The goal of this study was to analyze preferences of generation Y in the area of leadership and to offer suggestions leading to work performance increase and to higher loyalty of this generation to the work team.

The theoretical part introduces personality traits of generation Y and their contrast with other generations. Principal values are vision, honesty and open communication. Members of this generation require to feel challenged by demanding tasks, coached and mentored. Next were introduced basic approaches to leadership.

Next goal of the study was to analyze current state of generation Y members, who are working in a global industrial corporation. Also to analyze their satisfaction with the leadership style utilized by their direct superior as well as satisfaction with the company on the whole. Aim of this work was also to analyze generation Y's leadership style preferences and to find out which leadership style is the most suitable for them. A modified version of Full Range Leadership Model was chosen as an appropriate tool for the analysis. The results of the analysis showed the transformational leadership is the preferred style of the generation Y. Significant fact is also the result, that full 34% are considering leaving their companies within 2 years. 30% is unsatisfied with the current leadership style in the company, but the degree of satisfaction with their direct superior is higher. Results show that the way the generation Y is being led is fundamental for them. 96% of respondents stated that the leadership has a direct impact on whether they will stay in their current jobs, or not.

Predicative Functions of Financial Literacy and Consumer Culture in Achieving Sustainable Development

Vladimir A. CHERNOV

Nizhny Novgorod, Russia
E-mail address: Chernovva@rambler.ru

Abstract

The author suggests one of the ways to achieve sustainable development in the economic, environmental and social spheres in the form of a complex that includes improving the culture of thinking, the level of rational consumption, and financial literacy of the population in the behavioral economy. The author recommends that projects aimed at improving financial literacy in the higher education system should be supplemented with training in predicative thinking, value orientations, and consumer culture. The author considers these categories as the fundamental foundations of economic culture and financial literacy, which are necessary for achieving sustainable development.

Keywords: Behavioral Economics, financial literacy, higher education, culture of thinking, rational consumption, culture of consumption, sustainable development, cognitive abilities, paternalism, dialectics

Introduction

The economy of many countries around the world is currently experiencing difficulties, which are compounded by the COVID-19 pandemic. Achieving sustainable development requires even greater efforts. The UN General Assembly Declaration of 25.09.2015 States: "We are determined to achieve sustainable development in its three components-economic, social and environmental-in a balanced and integrated manner»1 . The methodology for determining the degree of stable growth in sustainable development is proposed in the framework of the Global Reporting Initiative (GRI) and Dow Jones Sustainability (DJS). This system provides indicators that assess the organization's performance by economic, social and environmental components.

To achieve sustainable development, it is not enough to activate enterprises in activities aimed at preserving natural resources, protecting the environment, as well as increasing corporate social responsibility. Active participation of citizens is required. The hypothesis of the study is that citizens can make the greatest contribution to the conservation of natural resources by increasing the culture of consumption in conjunction with financial literacy.

The UN General Assembly Resolution proposes to protect the planet from degradation, including through the introduction of rational consumption and production models and the rational use of its natural resources2. The purpose of the study is to reveal the relationship between consumer culture, thinking culture, value orientations, financial literacy and their role in achieving sustainable development, as well as to develop recommendations for improving educational projects to improve financial literacy, economic culture in the behavioral economy in order to increase the culture of consumption and achieve sustainable development.

Research base steel curricula that provide entry level knowledge, skills that are necessary to establish the competence defined by the study plans of higher educational institutions. The work programs of the following disciplines were studied: Philosophy; Sociology; Psychology and pedagogy; life Safety; Legal bases of nature management and environmental protection; Mathematics, etc. Were used the normative, methodological and practical materials of the project of Moscow state University named M. V. Lomonosov, of the Ministry of Finance of the Russian Federation, the world Bank for improving economic culture, as well as research results and achievements of other scientists in this field. The research methodology is based on a dialectical approach, an inductive-deductive method, and a descriptive analysis of the causal relationships between the content of the educational environment and behavioral Economics.

The Sequence and Conditions for The Achievement of Financial Literacy

How can we achieve the most rational consumption? Can we count on the fact that citizens in large numbers to choose a preferences of an «inner rational agent' and those of the future over the present»? This requires a high level of self-control and self-discipline. The level of possession of such qualities depends on upbringing, starting from childhood. Is known, that people who delayed gratification longer as a child were academically more successful and socially more competent as grown adult individuals. Economists measure self-control mostly by means of present bias, which can be defined as not being able to resist instant gratification over a future and larger reward. The term "present-bias" has been used to refer several seemingly similar behavioral biases such as impatience, procrastination, self-control problems, etc.. It is "present-bias" that are the predominant factor that do not allow us to count on the willingness of the masses to sacrifice the preferences of the present in favor of the preferences of the future. Кроме этого the human mind has a limitation in assimilating the information often referred to as 'bounded Rationality', which also leads to deviations from rational human behavior.

What is the role of the state in improving behavioral Economics? Is it applicable for this purpose paternalistic government policies, aimed at changing an individual's behavior in the present so as to improve that individual's well-being in the future? This policy leads to contradictions between the freedom and welfare of citizens, between ends paternalism and means paternalism and indicate that the tacitly assumed existence of a trade-off between well-being and autonomy is either meaningless or illusory.

Nevertheless, the state cannot completely refrain from contributing to the improvement of the behavioral economy and the economic culture of its citizens. At the same time, this sector of sustainable development requires not prohibited measures, but constructive participation of the state in the formation of a culture of consumption through financial (tax), industrial, and legal policies, not encouraging, but regulating fiscal policy degradation-parasitic consumption. The instruments of such regulation are considered in the sources (Alan, 2019; Alberto, 2010; Michelle, Jeffrey, Joel, 2019; Scott et al., 2019].

It is also necessary to find the means that most contribute to resolving the contradictions between citizens ' preferences for the future and the present in the behavioral economy. In this regard, the goals of rationalization of consumption are achievable through the internal interests of the individual. Citizens, as a rule, are interested in preserving their own funds, reducing financial losses, expenses that are not caused by natural needs, do not promote health, a healthy lifestyle, spiritual and aesthetic needs of a person, and so on. Such irrational expenses are caused by the influence of thoughtless emotions, cognitive errors; sophisticated influence of neuromarketing with insufficient corporate social responsibility. Irrational behavior is not in the interests of citizens, as it leads to financial losses, infringement of rights, increase in excessive, irrational expenditures, financial losses, unjustified destruction of natural resources with a negative impact on the environment to the detriment of sustainable development of society. People who are not interested in unjustified losses of their own funds can exclude irrational actions by increasing the culture of consumption.

The basis of the culture of consumption is that the development of production of products, works and services should serve to meet the natural needs of people while preventing irrational, unjustified spending, waste of personal finances of citizens and the destruction of natural resources, littering the planet.

The **quality of consumption** is determined by the degree of its utility for society and its sustainable development.The culture of consumption affects the health of each person and society as a whole, the family budget and financial literacy, which depends on the consumer's preferences when choosing purchases. Irrational consumption leads to the destruction of natural resources, environmental pollution, and destruction of the biosphere.

And so increasing the culture of consumption is becoming more and more relevant, primarily in the interests of the individual and society. Culture, in turn, requires knowledge and rational thinking. Such qualities are achieved by education and upbringing.

Customers who receive education will get benefits, which will make it easier for them to achieve satisfaction. Customer learning focuses on providing skills in the use of information according to their needs. This is necessary because without the provision of adequate skills in the use of information, the activities carried out by marketers are not optimal; thus, customer learning can be used as one of the marketing strategies.

In neuromarketing in behavioral Economics, it is necessary to distinguish natural human needs from degradation-parasitic consumption that damages spiritual and moral values with negative legal, financial, somatic, physiological, and environmental consequences to the detriment of sustainable development. Financial literacy is required for awareness of needs. It is important that when responding to decoy effect in marketing techniques, the consumer is able to recognize signs of food quality and safety.

The Relationship Between the Culture of Thinking, Financial Literacy and Consumer Culture

Thus, training in rational spending of citizens ' funds is associated with economic culture, consumer culture, and, in particular, with increasing financial literacy. To do this, as part of the joint participation of Lobachevsky State University of Nizhny Novgorod (UNN) in the project of Lomonosov Moscow State University (MSU), the Ministry of Finance of the Russian Federation, the world Bank1 to increase economic culture, we proposed to Supplement the program with the theme of increasing consumer culture. For this purpose, the universal competence "Able to make informed economic decisions in various areas of life" developed within the framework of the Federal network methodological center project was used in terms of indicators of financial literacy among graduates of educational programs for preparing bachelors in non-economic areas and specialties.

The results of financial literacy training include knowledge of the basics of economic agents ' behavior: theoretical principles of rational choice (maximizing utility) and observed deviations from rational behavior (limited rationality, behavioral effects and systematic errors associated with them); consumer culture and neuromarketing: financial, legal, ethical, somatic, physiological, environmental consequences, the ability to critically assess the relationship between consumer culture and sustainable development; assess individual risks associated with economic activity and the use of personal financial management tools, as well as the risks of becoming a victim of fraud; in neuromarketing in behavioral Economics, distinguish natural human needs from degradation-parasitic consumption to the detriment of spiritual and moral values with negative legal, financial, somatic, physiological, environmental consequences, to the detriment of sustainable development.

[1] Faculty of Economics of Lomonosov Moscow state University and projects to improve financial literacy of the population of the Russian Federation. Financial literacy in universities. Federal network methodological center. URL: https://fingramota.econ.msu.ru/about/ (date of access 04.08.2020).

Here is one example of a sophisticated advertising company on an Internet page that advertises a specific product. Moreover, there may be several different pages that offer to try the same product for 10 rubles, 100 rubles, 1,000 rubles, and so on.each of them provides inexpensive contextual advertising. Then it is estimated which page more people will go to. Based on this, a decision is made on what price is best to set. This marketing technique is based on the lack of financial literacy of the population, on their false preferences, cognitive and behavioral biases, and low culture of thinking.

False values, false egos, false ambitions, in social attitudes, stereotypes, habits, emotions, and irrational thinking are often formed when a person is evaluated not by his moral qualities and benefits to society, but by the level of material superiority. It is on such principles that an immoral economy is built, on the one hand, when commercial interest prevails over corporate social responsibility. In this case, the business in the pursuit of profit ignores the needs and health of the consumer, manipulates his consciousness and subconsciousness, infringes on the rights, with characteristic crimes, corruption and other illegal phenomena.

On the other hand, a consumer with false value orientations "strengthens" their position in society by demonstrating a level of material superiority. Therefore, he seeks to buy and display more expensive goods and more of them, based not on natural needs, but from the desire to surpass others by demonstrating his achievements in material consumption, following a false ego, false ambitions. Thus, from the natural needs of the society moves to the degradation-parasitic consumption. This leads to an increase in irrational spending not only of the personal budget, but also of natural resources and increased environmental pollution, destruction of the biosphere.

Such a consumer is more easily subjected to manipulation, unfair marketing techniques, material tricks that use his material preferences, false ambitions, false ego, self-conceit, greed, unwillingness to work conscientiously, a tendency to immoral acts, corruption and crime, the desire to assert themselves and increase their authority through material superiority, to satisfy false ambitions, false ego. Manipulation of the conscious and subconscious mind is based on false values and false ambitions, greed and greed, and a tendency to corruption, when the more a person consumes, the more he considers himself worthy and authoritative in society. These shortcomings of a not fully enlightened worldview with false value orientations demoralize the consciousness and are one of the main factors in the decline of economic culture.

An insufficiently enlightened person is more likely to spend resources (material, labor, and financial) on false values and thus be manipulated, make cognitive mistakes, make irrational actions, and make false choices under the influence of sophisticated neuromarketing influences. A morally stable person with genuine value orientations, in contrast to a demoralized person, is more conscious and rational in choosing priorities and spending resources, which is due to the culture of thinking.

And so, the quality of consumption depends on the value orientations and culture of thinking, which is determined by the degree of utility for society and its sustainable development in the economic, social and environmental spheres.

To avoid such negative consequences, it is needed to be able to choose the right value orientations, possess a complex system of thinking based on the possession of dialectical logic and the ability to apply it when justifying and making decisions in various areas of life.

Individual differences in people's cognitive abilities are mediated by intelligence and working memory. These properties of the human brain are directly related to the individual's ability to formulate task structures when faced with economic choice scenarios. However, research in problem structure formulation shows that intelligence is the only predictor of behavior based on economic choice scenarios, without any effect of working memory.

To increase the level of intelligence and achieve these competencies, there is not enough knowledge in the field of Finance. As a result interdisciplinary elements (in particular from psychology) began to be incorporated into behavioral theories of finance, in attempts to understand the process of decision-

making under risk. Psychology is not enough to develop rational thinking. Are necessary: comprehension of philosophical foundations, social value orientations; moral education, spiritual aspirations; dialectical logic that forms predicative thinking on the basis of a complex, systematic approach, of cause-and-effect relationships, identifying the essence of ongoing processes, the ability to identify and comprehend established relationships between essence and phenomenon, form and content, part and whole, cause and effect, absolute and relative truth. It will require the ability to apply knowledge taking into account the place, time and circumstances, the use of induction and deduction; the ability to identify contradictions and find ways to resolve them; understanding of evolutionary processes with the transition of quantity to quality; knowledge of the fundamental laws of market interaction in their unity and contradictions, etc. Only in such a comprehensive education, cognitive abilities will be most complete in understanding financial literacy.

Cognitive ability is one of the fundamental factors in explaining financial literacy. Experimental evidence supporting the key role of cognitive ability in financial literacy acquisition. We find that individuals with higher cognitive abilities are more financially literate.

Conclusion

With the development of the culture of thinking in society, consumer demands in the socio-cultural sphere increase, leading to aesthetic, moral, intellectual, and spiritual satisfaction, which do not entail the expenditure of natural resources and environmental pollution. In General, with the development of a culture of thinking, the share of values that contribute to economic culture and sustainable development increases in human consumption. For example, studies of the relationship between religion and economic or financial decision-making showed that the influence of reminders of religious topics on time preferences for Finance reduced the percentage of “present-bias” by 10.4%.

Another example is when, during the great recession from 2005 to 2014, spending on beauty products increased among women aged 18-40. The increase occurred regardless of marital or employment status. We find evidence to support the claim that the lipstick effect is caused by a substitution away from spending on women's clothes. According to the U.S. census Bureau, between 2007 and 2010, real median household income declined by about 7.2% (from $ 59,500 to $ 55,500 in 2017). This example shows that young women in a period of declining income, saving money on such categories of expenses as food in restaurants, jewelry and clothing, direct them to buy more cosmetics. This means that in difficult times, the needs for aesthetic appearance for them were stronger than their property needs.

It also seems natural that education and increasing the culture of consumption contribute to the development of a taste for values in the socio-cultural sphere. As this trend develops, expenditures that lead to the destruction of natural resources will be replaced by expenditures on cultural consumption, activating the production of cultural values, preserving the environment, and promoting sustainable development.

And so, the increasing level of education in curriculum competencies leading to improvement of culture of thinking, the culture of consumption will contribute to the financial literacy of the population, growth of economic culture, preservation of environment, sustainable development.

To implement these conclusions, we have given recommendations for a comprehensive increase in the culture of thinking, the level of rational consumption, and financial literacy of the population in the behavioral economy by means of education and upbringing. Projects aimed at improving financial literacy in the higher education system are proposed to be supplemented with training in predicative thinking, value orientations, and consumer culture. These categories are considered as the fundamental foundations of economic culture and financial literacy, which are necessary for achieving sustainable development.

Abstract

Tactile marketing is a relatively poorly explored area of sensory marketing. The research that has been conducted so far in this area concentrates primarily on utilising the touch sense while selling material products. Researchers have predominantly focused on hands, which are the receivers of sensor stimuli. The authors of the present paper consider tactile stimuli that come from a number of various sources and appeal to several, diverse parts of human body. The objective of the paper is to present, based on own research, tactile preferences of consumers aged 15-23 in the aspect of their presence inside various types of commercial and service facilities. The research was conducted on the sample of 430 persons. Majority of young consumers prefer sufficient free space where they can move freely. Their remaining tactile preferences are as follows: walls covered with natural wood or paints put on plaster; floors made of natural wood, ceramic tiles, and also covered with carpets; soft floor coverings in the form of carpets, carpeting, rugs; bed places neither excessively firm nor excessively soft; seats covered with fabric or natural leather upholstery – soft or neither soft nor firm; objects that can be touched – rounded with soft surface.

Keywords: tactile marketing, tactile preferences, young consumers

Introduction

Tactile marketing is presently in its initial stage of development. It constitutes one of the elements of sensory marketing, whose aim is to appeal to all the five human senses: sight sense, sound sense, smell sense, taste sense and touch sense. As B. Hulten, N. Broweus and M. Gijk (2009) stress „the human senses have long been ignored in marketing, despite our awareness of their great significance". The research conducted in 13 countries demonstrate that as much as 99 percent of all brand communication concentrates on two senses – sight and sound (Martin Lindstrom 2005). However, sales can be increased not only through appealing to the sight sense, sound sense or smell sense, but also by engaging the touch sense (Brenda Soars 2009).

According to J. Peck (2010), despite its omnipresence touch sense has not been studied in marketing. This situation has not changed significantly over the years. The ones who miss out on this are manufacturers and sellers, as the touch experiences play an important role in the consumption of services and commodities.

Tactile marketing we define as influencing customers' sense of touch when customers purchase and use products and services in order to increase their satisfaction, which is conducive to achieving business goals. A satisfied customer returns to the company and makes purchases again. Moreover, according to the world's best seller, Joe Girard (2019), a satisfied customer spreads good opinion about the company to at least 250 people from his surroundings. As a result, the number of customers, sales volume, revenues and profits increase.

Cite this Article as: Arnold PABIAN And Aleksander PABIAN " Physical Contact with Material Objects - Sensory Marketing Perspective" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In tactile marketing the primary focus of researchers is making use of the touch sense while selling material products (goods). Moreover, the research in the area of touch sense generally concentrate on the active seeking and perception by the hands (Joann Peck, 2010). Furthermore, researchers usually analyse single sources of tactile stimuli and their perception. However, the observations of the authors of the present paper show that during their presence inside facilities of various types, including the service ones, customers are subjected to the influence of a number of tactile stimuli, which are received not only by hands, but also other body parts. In such cases a significantly wider range of diversified stimuli determines tactile comfort or discomfort of customers. The touch experience is individual in its nature and as a result it involves different needs of individuals regarding touching brands and products in order to create a certain perception about them (A.V. Citrin, D.E. Stern, E.R. Spangenberg, M.J. Clark 2003) (J. Peck, T. Childers 2003). This means that touch experiences may differ in particular age groups and also with relation to gender.

The main area of interest for the authors of the present paper are poorly recognised tactile preferences of young consumers related to their presence inside various types of commercial and service facilities (shops, restaurants, cafes, hostels, youth hostels and others). Furnishing of such facilities is a source of tactile stimuli, which appeal to various parts of human body. The research conducted by the authors includes tactile stimuli received by feet, buttocks and thighs, front and rear part of the torso, hands. The authors have considered in their research various elements of interior furnishing that people have or may have touch experience with. Sensations that follow such a contact decide about tactile comfort or discomfort, which affects general satisfaction or dissatisfaction concerning the presence in the facility.

In order to satisfy touch needs and requirements of youngsters appropriately it is necessary to identify their preferences in this respect. The paper presents the results of the research that aimed to discover tactile preferences of persons aged 15-23 having regard to gender. The research was conducted in Poland on a representative sample of 430 persons, who were secondary school students and university students. The research determines preferences of young persons that concern size of free space, wall coverings, type of floor, flooring and its softness, seat type and softness, softness of bed places, shape and surface of objects, surrounding oneself with soft objects.

The research broadens the knowledge on behaviours of young consumers on the market. It discovers a wide spectre of tactile preferences of persons aged 15-23, which go beyond a simple form of a physical contact “hands-material object”. The presented results of the research may prove beneficial for companies that provide services for young consumers inside their commercial and service facilities as well as interior furnishing manufacturers, including furniture destined for youngsters.

Literature Review

The scientific literature does not include results of research that concerns tactile preferences of young persons considered in this paper. The research that focuses on touch comprises various themes. One of the vital issues is investigating the role of the touch in product evaluation and also the relationship between visual stimuli and haptic perception. M.S. Balaji, Srividya Raghavan, Subhash Jha (2011) investigated what influence multisensory evaluation has on overall attitude and purchase intentions. Andreas Aldogan Eklund and Miralem Helmefalk (2018) developed a conceptual framework of visual-tactile interplay and consumer responses in brand, product and service scape contexts. Gwenaelle Briand Decre, Caroline Cloonan (2019) investigated the cross-modal correspondence between a visual stimulus (glossiness), haptic perception and reactions of consumers. The impact of spatial proximity on visuo-tactile integration was the subject of interest of C. Spaccasassi, D. Romano, A. Maravita (2019). Helena M. De Klerk, Stephna Lubbe (2008) concluded, based on conducted research, that especially colour and texture play a decisive role in bringing about the necessary aesthetic experiences. Miralem Helmefalk, Adele Berndt (2018) explained based on their research how retailers can utilise a multisensory cue to positively influence consumer behaviours. It is formed by combining three single cues – specifically time spent, touching and purchase. Maria Fransisca Njoman, Galih Nugroho, Sonia Dwi Puspita Chandra, Yoeska Permana, Suhadi Suhadi, Mujiono Mujiono, Agist Dwiki Hermawan, Sugiono Sugiono (2017) evaluated

sensitivity variance and fatigue effect, in human sensory. The research by Miralem Helmefalk (2019) revealed the linkages between multi-sensory cues, browsing behaviour and purchasing.

The researches also investigated issues with regard to various kinds of products. In particular, they evaluated bipolar pairs of fabric tactile attributes in order to describe their tactile sensory properties (Henry Wang, Trevor Mahar, Ron Postle, 2013), influence of the touch sense on evaluation of wood-based materials (Siv Lindberg, Anders Roos, Annika Kihlstedt, Mikael Lindström 2013), investigating the differences in the haptic perception among clients and designers involved with leather inside vehicles (Wonjoon Kim, Yushin Lee, Joong Hee Lee, Gee Won Shin, Myung Hwan Yun 2018), investigating in psychological aspects aesthetic preferences for different surface textures (Roberta Etzi, Charles Spence, Alberto Gallace 2014).

Some products were subject to research in a wider sensory perspective with regard not only to touch but also the appeal to other senses. The research by Johan Bruwer, Anthony Saliba, Bernadette Miller (2011) demonstrated that there are specific differences related to the wine consumption behaviour and sensory preferences of males and females and between age groups. In the research by Esther Gyedu-Akoto, Stephen Yaw Opoku, Emmanuel Ofosu-Agyei (2019) sensory evaluation of biscuits demonstrated that coffee had a significant impact on improving sensory attributes such as flavour and colour. Therefore, coffee power can be used to enhance both the nutritional as well as sensory qualities of products.

In the research that has been conducted worldwide the researchers have undertaken various themes related to sensory properties of places and the environment where sales of products and services take place. G. Berger, A. J. Petutschnigg (2006) investigated impressions of customers who being blindfolded were asked to examine the floor with their hands and feet. As Binh Nghiem-Phu proved (2017) in an outdoor out-store environment of shops the prevailing sensory cues are visual ones where marketers make use of sensory cues to provide their customers with the information about their shops and products/services. According to Siwon Cho, Jane Workman (2011), consumers who demonstrated a higher need for touch and used more than one channel for shopping for clothes preferred local and non-local stores. Fashion innovativeness as well as opinion leadership and multi-channel choice had an influence on non-touch channel preference. The research conducted by Kendra Fowler, Eileen Bridges (2012) led to the following conclusion: service provider evaluations of the physical environment improve if an appropriate ambient scent is present. Then, providers are perceived as more courteous and customers more friendly.

Some research that has been conducted worldwide concerned exclusively behaviours of young consumers on the market. However, it does not explain what the preferences of persons aged 15-23 are in the aspects analysed by the authors of the present paper. The research on young consumers has been conducted among others by the researchers specified below.

1. Toby C. Y. Yip, Kara Chan, Evon Poon (2012): in the research young consumers evaluated attractiveness of food outlets and apparel retailers. Attractiveness of these sales venues was primarily associated with the quality and price of product or service. Location and the behaviour of shop assistants was also important to them.
2. Paolo Ribeiro Cardoso, Sara Carvalho Pinto (2010): determined the main factors that explained the shopping motivations among young Portuguese consumers. They identified seven shopping dimensions. They proposed a new consumer profile of a Portuguese young adult based on hedonistic and utilitarian shopping motivations.
3. Dipanjan Kumar Dey, Ankur Srivastava (2017) proved that the impulsive buying intensions of youngsters are positively associated with dimensions of hedonic shopping value.
4. Monica Chaudhary, Suhail M. Ghouse, Omar Durrah (2018) presented the role of a young Arab consumer in family decision-making concerning purchases of various products and services and across different stages of buying process.

The research targeted at young consumers has also explained various issues regarding brands. According to the research by Gurvinder S. Shergill, Yuli Rosmala, Andrew G. Parsons (2010), young

consumers from New Zealand represent mid-level internationally in terms of ethnocentrism and ethnocentricity, which do not influence their perceptions of brands. What matters to them is price perceptions and self/brand user congruency perceptions. The researchers Ting Jin, Wei Shao, Deborah Griffin, Mitchell Ross, (2018) determined that Chinese brands are perceived positively by young Chinese consumers. Their choice of Chinese brands is motivated by symbolic values such as: pride, lifestyle, feeling of home, being happy. Roman Sidorchuk, Sergey Vladimirovich, Boris Vladimirovich Musatov, Aleksey Aleksandrovich Meshkov, Timur Alekseevich Tultaev (2018) analysed motivational influence of „high-level values" (HLV) on brands in certain product categories-markers in order to develop a methodology allowing for segmenting young consumers. The research by Dalia Abdelrahman Farrag (2017) explained the attitude of youths from Qatar towards luxury brands and intentions to purchase them. A significant influence on this attitude demonstrate: fashion involvement, brand consciousness, social comparison and experiential needs.

Also, the research that has been conducted in the area of tourism and hotel industry, where the results of the research conducted by the authors of the present paper may be applied, does not account for the type of preferences characteristic of persons aged 15-23 with respect to furnishing the interior of facilities. The behaviours and preferences of consumers in the area of hotel industry and tourism have been the subject of research of, among others: Agapito, Patrícia Valle, Júlio Mendes (2014), Dora Agapito, Patrícia Pinto, Júlio Mendes (2017); Ksenia Kirillova, Janelle Chan (2018); Yosr Ben Tahar, Coralie Haller, Charlotte Massa, Sebastien Bede (2018); Lianping Ren, Hanqin Qiu, Caiwei Ma, Pearl M.C. Lin (2018); Carmen Lam, Grace K.S. Ho, Rob Law (2015); Jonas Karisen Astrom (2017).

As the extensive literature search conducted by the authors of the present paper has demonstrated there exists a research gap regarding tactile preferences of consumers aged 15-23 analysed from the perspective of furnishing the interiors of various facilities. The results of our research fill this gap. We have focused in our research on the following sources of tactile sensations: free space inside facilities, walls and floors, types and softness of seats and bed places, shape and surface of the objects as well as surrounding oneself with soft objects.

In the further two parts of the present paper its authors present research methodology and results with relation to previously specified sources of tactile sensations that occur in commercial and service facilities.

Research Method

The underlying objective of the research conducted by the authors of the present paper was to discover preferences of young consumers aged 15-23 with regard to: size of free space, wall coverings, type of floor, flooring and its softness, seat type and softness, softness of bed places, shape and surface of objects, surrounding oneself with soft objects in the aspect of furnishing the interiors of various facilities. For the purpose of the research its authors developed a research tool in the form of a survey questionnaire, determined the minimum sample population and defined the manner of communication with the respondents. Having conducted the field research its results were summarised, analysed and the authors formulated the conclusions.

To achieve the adopted research objective the authors conducted the research that utilised the representative method. The survey questionnaire was addressed to 430 persons aged 15-23, secondary school students and university students. The research was conducted in 2019 based on personal contact with respondents. The questionnaire forms were distributed, then collected and analyzed after being filled in by the respondents. The indicated population of respondents meets the requirement of minimum sample size. The minimum sample size was determined so as to formulate the conclusions about the investigated population, which are characterised by a defined accuracy and certainty level, based on conducted measurements. Once the minimum sample size had been determined, the following steps were taken:

- estimation accuracy was established, assuming a defined maximum estimation error,

- high trust level was assumed,
- assumptions regarding the proportion of the investigated population were adopted.

Given that the order of magnitude of p success probability is unknown the minimum number of units amounted to 385 at the following assumptions: statistical significance $\alpha=0,05$, maximum estimate error $d=5\%$ ($u_\alpha=1,959964$).

Empirical Results

The size of free space in a facility affects the number and type of tactile contacts that are experienced by persons inside it. The smaller the free space is, the more contacts with objects that are present in it. The research has proved that youngsters prefer much free space (65.1% of the respondents). They have as much free space here as they need to move freely without experiencing tactile sensations. Proponents of very large free space (much more space to move than required) are not as numerous (25.2%). Only 3.2% of the surveyed prefer rooms with little free space. For 6.5% of the survey respondents the size of free space did not matter. Figure 1 presents the results of the research regarding preferences of youngsters related to free space in accommodation establishments as well as their preferences related to wall coverings. Most of the youngsters prefer staying inside rooms whose walls are covered with natural wood (22.6%) or paints put on plaster (22.1%). Least favoured are coverings made of fabrics (1.4%), plastic panels (2.7%) and wallpapers (3.3%). For 28.6% of the respondents the type of wall and ceiling covering was unimportant.

Fig. 1: Preferences of consumers aged 15-23 regarding size of free space and wall coverings.

An element of the building with which we remain in permanent tactile contact is the floor. Figure 2 demonstrates preferences of young consumers with regard to types, flooring and softness of floors. Similarly to walls, most youngsters prefer natural wood (34.7% of the respondents). In the second position come ceramic tiles (14.5%), while floors covered with carpets rank third (9.9%). Youngsters do not like walking on floors that are covered with PVC-based flooring (1.4%), other artificial materials (2.4%), natural stone (6.3%). Floor covering and its type did not matter in case of 18.8% of the survey respondents. Provided the floor is covered with a carpet, flooring or rug, then most youngsters prefer them to be soft (29.7%). Slightly fewer persons prefer coverings that are neither excessively firm nor excessively soft (27.5%). Very soft coverings are preferred by 24.9% of the respondents, while only 5.3% prefer them to be firm. Softness of the covering was unimportant for 12.6% of survey participants.

Fig. 2: Preferences of consumers aged 15-23 regarding floor covering, its type and softness.

The most important elements of facility furnishing constitute furniture in the form of beds, wardrobes, cabinets and seats. Most of young consumers prefer when beds, couches and sofas they sleep on are neither excessively firm nor excessively soft (41.5%). Proponents of soft surfaces constitute 31.8%, very soft ones – 14.0%, firm ones – 9.0%. This factor was considered unimportant by 3.7% of the respondents (Figure 3).

Fig. 3: Preferences of consumers aged 15-23 regarding softness of bed places.

The survey objective was also to determine the preferences of young customers with regard to seat type and softness (chairs, armchairs, coffee tables). These preferences have been presented in Figure 4. Youngsters like it most when seats are covered with fabric upholstery (34.3%), natural leather (22.8%) and made of natural wood (14.2%). The least preferred seats are made of aluminium (0%), metal (0.4%), natural stone (1.3%), plastic (2.3%) and other artificial substances. e.g. synthetic rattan (1.1%). For 13.3% of the survey respondents the type of seat was not important. Youngsters also demonstrate particular preferences regarding the seat softness. They prefer soft ones (36.7%) and neither firm nor soft ones (33.4%). Less popular are very soft seats (20.4%) and the least desired ones include firm (2.9%) and very firm (0.7%). Seat softness was unimportant for 5.9% of the survey respondents.

Fig. 4: Preferences of consumers aged 15-23 regarding seat type and softness.

Figure 5 illustrates preferences of youngsters regarding the shape and surface of objects and surrounding oneself with soft objects. Recognising the preferences in this scope is important as people being present in various types of interiors touch a lot of items, e.g. pieces of furniture, tableware in cafes and restaurants, fittings in toilets. They can also present various attitudes to soft objects that surround them (cushions on sofas and armchairs, decorations made of soft fabrics and others). As the research has proved, among youngsters there are over three times as many proponents of oval shapes (38.4%) as angular ones (12.1%). With regard to the surface youngsters mostly prefer smooth objects (48.3%) and very smooth ones (25.6%), while very rough objects are the least popular ones (1.6%). Soft objects in their surroundings are desired by 48.1% of the survey respondents and 23.6% do not like such objects around them.

Fig. 5: Preferences of consumers aged 15-23 regarding shape and surface of objects and surrounding oneself with soft objects.

Conclusion

As mentioned in the introduction, increasing customer satisfaction with the purchase supports the achievement of business goals. Tactile sensations can be a source of comfort or discomfort in all places where the young customer purchases material products or uses services (shops, offices, hotels, restaurants, cafes, gyms, waiting rooms and others). Here are some examples of situations in which the customer experiences discomfort in such places. Due to insufficient free space, the customer squeezes between shelves with goods in a self-service store, between furniture in a hotel room. Materials such as stone, ceramic tiles, metals and glass on floors or walls are perceived by the customer as hard and cold. Too hard and uncomfortable chairs in restaurants, cafes, hotel rooms, offices, waiting rooms discourage people from visiting these places again. The purpose of tactile marketing is to shape the customer's tactile sensations so that they are a source of comfort, not discomfort. This problem affects all companies that serve customers having direct physical contact with them.

The research has proved that young consumers aged 15-23 demonstrate particular tactile preferences, which is important from the perspective of designing and furnishing facilities in which they spend time. Majority of them prefer much free space where they can move around freely, without experiencing negative tactile sensations. They prefer it most to spend time in rooms whose walls are covered with natural wood or paints put on plaster. In case of floors, the ones covered with natural wood, ceramic tiles or covered with carpets are most favoured. If the floor is covered with carpets, carpeting or rugs, then most youngsters prefer them to be soft. Slightly fewer persons favour coverings that are neither hard nor soft. As far as bed places are concerned (beds, couches, sofas), most youngsters prefer them to be neither too firm nor too soft. Youngsters also demonstrate definite preferences regarding seats (chairs, armchairs, coffee tables). They like it most when seats are covered with fabric upholstery or natural leather, they are soft or neither firm nor soft. They also prefer if the objects they touch in a facility are oval and their surface is smooth. Majority of the survey respondents, women in particular, like to be surrounded with soft objects.

Discussion

Young consumers constitute an important and large market segment. By utilising tactile marketing it is possible to increase the satisfaction level related to their presence in facilities that render services or conduct a commercial activity. Thus, the research cannot be limited to discovering tactile preferences of youngsters related exclusively to purchases of material goods, which are expressed in a simple arrangement of physical contact “hands – material products (goods)”. We suggest that research should be conducted that will aim to recognise tactile preferences also in the arrangements: “touch receptors” – material surrounding of product purchaser”, “touch receptors – rendered services”, “touch receptors – material surrounding of rendered services”. While using the term touch receptors we mean the ones that are not only present on hands but also on other parts of human body. This means a necessity to consider in the research various sources of tactile stimuli and various parts of human body they appeal to. Therefore, there should be a shift in the research from the arrangement “one source of tactile stimuli appeals to one part of human body” to an arrangement “numerous sources of tactile stimuli appeal to various parts of human body”. One should remember that sensory comfort or discomfort that goes beyond the arrangement “hands – material products (goods)” is conditioned by a number of various tactile sensations, which are experienced by consumers in the venues rendering services or conducting sales of products.

In the conducted research its authors have focused on a particular age group of respondents, i.e. consumers aged 15-23, as they concluded that generalising tactile preferences on the whole population in many cases is inappropriate. The distribution of tactile preferences in particular age groups varies and has an impact on designing the furnishing of facilities.

Tactile marketing plays an important role not only in physical contacts of customers with products offered for sale but also in the service area, as well as in the surrounding where the sales occur. This

requires the research regarding tactile preferences of customers considered from the perspective of various age groups to be widened and deepened.

Abstract

The article considers the role of information technologies in the international economy and international relations' evolution. The article describes the place of the information space in the multinational companies and developed countries' global competitiveness formation. Information is presented as an important resource that affects the financial, industrial, innovation and investment spheres, and provides the companies and entire states' advantages in the global economy. The Internet's role in spreading planetary connections between people and infrastructure objects is analyzed. The world economy's transition to a new development stage is presented as a transition to the information and digital economy. The key Internet technologies' development stages are listed and the Internet state regulation problems are analyzed using examples of the Russian law "On information, information technologies and information protection", as well as the Chinese "Golden shield". The existing restrictions' key circumvention technologies with the use of Internet tunnels are characterized. This topic is particularly relevant in the context of numerous countries' accusations interfering in each other's internal affairs, including in the election process and influencing public opinion. Conclusions are made about the information and image confrontation's role in solving the developed countries' foreign policy problems.

Keywords: Global Challenges, International Economic Relations, Foreign Economic Policy.

Introduction

The dominant trends' change in the world economy continues. Tumin and Koryakov (2013) underlined that the industrial large-scale production that formed the world commodity markets in the last century was replaced by financial engineering, with its variety of financial instruments, speed and operations' globality. And if at the end of the 20th – first half of the 21st century the competitive advantage in the international labor division was obtained by multinational companies with a strong production base, design bureaus and research technology laboratories, able to open their branches in convenient areas of the earth, then at the beginning of the 21st century, the potential of companies was determined by the financial assets' market valuation, and international investment flows depended on changing stock prices. Bressanelli et al (2018) mentioned that little attention has been set on how new digital technologies can overcome in practice the main Circular Economy challenges. National financial spheres' globalization and unification with the total dollar domination generated a general belief in the inevitability of the entire world economy globalization. In the article by Sener and

Delican (2019) said that every new technological development brings societies closer to each other in a global world and helps to increase trade relations between countries. However, Montenegro and Araral (2020) in their article warn, that here is a growing divide in Internet quality of service (QoS) between developed and developing countries.

Review of relevant studies and problem statement

In the world largest companies ranking we could see a change of leaders: the largest equipment manufacturers (cars, first of all) were replaced by banks in Western Europe, the United States and Japan. According to Yang and Meyer (2020) study, when foreign and local firms compete, they face competitors acting quite differently from themselves.

Tumin et al (2015) underlined that some economists consider a special stage to be the computer technology introduction based on silicon chips, which really radically changed the production's organization. Computers changed the communication system, accelerated the transition to paperless documentation, electronic money, payment cards, smartphones, etc., which qualitatively changed not only the end user's world, but also design, control, and marketing technology. The "computer revolution" and its founders' names (S. Jobs, first of all) are deservedly recognized in the public consciousness. In a research study by Navrotskaia et al (2018) is mentioned that the IT technology leaders and computer technology developers certainly dominate the world markets today. Salih et al (2019) made a research, investigating the interrelationships between information systems (IS)-related capabilities and their effects on firm performance. According to the study by Meltze (2014) there are a range of restrictions that are hindering the Internet's ability from fully serving as a platform for international trade.

However, it is usually a product market updating question. And according to Myasnikova et al (2018), in the future world economy configuration exactly the competition mechanism is important. The next stage in the world economy development is connected with the transition to an information economy: a new competition space, the space of information flows is being formed. In the modern world the information value, as it affects society, is higher than the money value. In the article by Suppatvech et al (2019) is mentioned that the internet of things (IoT) is gaining attention from both scholars and practitioners regarding its potential as a key enabler of servitized business models; academic research on this emerging concept is increasing but overall underexplored. Liu et al (2020) underlined that in the current socio-economic environment, to face challenges such as the emergence of new technologies, globalisation and increasing demands from their clients it is inevitable that enterprises will collaborate with others and progressively shift their boundaries.

Research Methodology

The research methodology provided for the Internet technologies development's retrospective analysis and their impact on the world economy, both in the states and large companies and individuals' context. As a practical basis for the research, we used the world's largest companies experience using Internet technologies, the Big Data and blockchain technologies usage practice, as well as the regulatory and legal experience of the Russian Federation and the China in the field of Internet traffic regulation.

Today, information is available (which is both sold and bought), which gives almost exhaustive data about potential consumers. It allows you to generate demand, direct the buyer's interest, impose preferences and change the goods and services consumption structure.

In the financial economy, the market affected the goods, services, and possible investments supply conditions. And the economy of information determines the consumption conditions: who, where, when, in what volume, for how long. The competition's subject and tools are changing.

The international communication's material basis is the Internet, which became the most incredible invention of the last century. At present, the Internet is not just a network, but an entire information

universe, which is subject to various technical, social and state laws. The date of the Internet's origin is October 29, 1969. A full-fledged network with acceptable bandwidth, representing a set of many different networks and communication via modem lines falls on the last decade of the 20th century. This period was marked by the emergence of websites. To be more precise, the year 1995 is considered to be the time of the Internet service providers' emergence. At the beginning of the 21st century, the Internet's commercial block was formed: search engines arose; various operating systems appeared; server technologies began to actively develop; the number of sites in all countries of the world increased. As a result, the Internet is now a huge entertainment, educational, trade, financial and political sector. The rapid development of the Internet has become possible due to the progress in the various networks' bandwidth (including wireless Internet and mobile communications (3G and 4G generations)), and due to the computer and mobile components' capacity increase. 2017 clearly showed another new trend: mobile Internet has become many times more popular than computer Internet.

The Internet provides horizontal "planetary" connections between people. On its basis, social networks of group communication are formed, which function almost outside the state control (which does not exclude significant interference in the largest companies functioning: Google, Amazon, Facebook, VK, etc.). It creates the illusion of complete anonymity and participants' independence in communication. But any search engine (Yahoo, Yandex, Google) by their programs directs the search in the desired direction. Moreover, it even organizes the search space, cuts off unwanted results and so on. At the same time, the activity is mainly concentrated around the companies' commercial interests that control communication networks.

According to Chang et al (2020) research study FinTech (Financial Technology) and blockchain are prevalent topics among technology leaders in finance today. The information base for policy in the Internet space is the accumulated information's array about all participants in information contacts. "Big data" technology has become another element (along with computer programs for processing received information, global international communication and automatic search technologies). Sivarajah et al (2020) emphasized that the digital transformation is an accumulation of various digital advancements, such as the transformation of the web phenomenon. The participatory web that allows for active user engagement and gather intelligence has been widely recognised as a value add tool by organisations of all shapes and sizes to improve business productivity and efficiency.

However, information often affects the state interests' sphere (the secret data transfer, communication with terrorists, which is most often declared in justifications for restricting contacts on the Internet). The state is also interested in processing a population database for predicting demographics, social conflicts, political voting results, and so on. This data is not protected and is now available to all major provider companies in telecommunications networks. Such information becomes an external influence instrument, a threat to the socio-economic situation stability in the country.

Yang et al (2020) mentioned that blockchain as an emergent decentralized digital technology has been widely explored in many sectors to remedy the deficiencies of centralized solutions. In combination with blockchain technology and a new currency (cryptocurrency, in all its modifications), the information economy appears as a new space not only for commercial competition, but also for the inevitable (in the future) state control and regulation. China is a leader in the direction of the Internet state regulation. Russia has yet to solve this problem.

1.11.19 the Federal Law No. 90-FZ of May 1, 2019 "On Amending the Federal Law "On Communications" and the Federal Law "On Information, Information Technologies and Protection of Information" entered into force, with the exception of certain provisions for which other terms of their entry into force are set. According to Consultant Plus (2019) the provisions of the Federal Law "On communications" (article 56.2, paragraph 8, subparagraph 3), regarding the national domain name system use, shall apply from January 1, 2021. These laws have already been informally called the "sovereign Runet" law.

According to the national program "Digital economy", the law implementing costs should amount to more than 30 billion rubles, of which 20.8 billion rubles should go to the equipment's purchase. This law prescribes:
- All telecom operators in the country must install special equipment, provided by the Federal Service for Supervision of Communications, Information Technology and Mass Media (Roskomnadzor), on their networks.

- In case of the integrity, stability and security threats of the Internet, the Roskomnadzor will be able to manage the traffic's routing through this equipment.

- The specified equipment will also filter traffic, restricting users' access to the prohibited resources in Russia.

- A traffic exchange points register must be created, and restrictions are imposed on connecting communication networks to such points.

- The communication networks' owners, Internet companies and other market players must take part in the exercises, which will be held once a year.

- By January 1, 2021, a national domain name system should be created that will duplicate the domain names list and autonomous systems' numbers delegated to Russian users.

In the book by Ristolainen et al (2020) are made conclusions that it turns out that the state intends to control Russian Internet traffic.

In the study by the Russian International Affairs Council (RIAC) (2018) said that the intention to control the Internet traffic movement has already been implemented in practice in some countries, although the most advanced in the world is the Chinese system for limiting Internet content, which is called the "Golden shield", or "Great Chinese firewall". This system is based on the analysis of traffic that passes through three international gateways – Beijing, Shanghai and Guangzhou. It was developed in 1998 and became fully operational in 2003. The idea is that the system blocks certain sites from the blacklist by their IP- or URL-addresses, and also blocks sites using filtering data packets by keywords.

However, as the example of China shows, there are ways to circumvent these restrictions. The most commonly used method in China is to set up a tunnel to another country (a tunnel is when a special program on your computer establishes a point-to-point connection with another computer on the Internet). In this case, the global network acts as just a transport system, and your computer thinks that it is connected to another network directly.

Unfortunately, there are almost no open services for creating the Internet-tunnels, and you will have to search for the purpose for connecting the tunnel. Many Chinese work for foreign companies and can simply set up a tunnel to their company's office in another country, where there are no Internet restrictions anymore. But not many residents of the People's Republic of China have this opportunity. Although, undoubtedly, the main advantage of this method is the high connection speed, which is ten times faster than the proxy servers' speed.

In fact, there are many ways to carry out covert unauthorized access to enemy information. In addition, there are opportunities for suppression or forgery in the information exchange in telecommunications networks.

Currently, there are many accusations of foreign elections' interference by the United States and Great Britain. Secretary of state Mike Pompeo says the US is preparing to resist foreign interference in the 2020 presidential election. In his opinion, countries such as Russia, China, North Korea and Iran are allegedly interested in influencing the outcome of the vote. In the 21st century, information

warfare is a complex of measures aimed at preventing the enemy from obtaining the necessary, often secret, information.

Results

In this century, the most important factor in information is the image factor, or, in other words, the negative impact on the enemy's reputation, which should lead to a lack of attention, disinteresting and, as a result, discrediting the opposing side interests in the international community. In this regard, the last decade has shown a phenomenal growth of information technology methods and tools.

At present, the most promising technological platform for the further development of the global (world) and country-wide media and communication infrastructure is the Internet and new types of media services based on it. Today, the World Wide Web is an integral component of most human life's aspects, but thanks to the spread and improvement of information and communication technologies, its influence on global political, economic, and humanitarian development continues to grow rapidly.

Information wars and media terrorism are the information globalization result, which make us carefully analyze their possible consequences. We emphasize that the information and image confrontation can greatly distort the reality in the mass public consciousness, and the results of this confrontation are markedly different from the armed actions' results.

Let us note that the information warfare's results for all its participants in fact become many times more important than the armed conflicts' results. In this case, we consider it appropriate to recall the postulate of behavioral sociology, which underlines that if a situation is defined as real, then it is real in its consequences.

Conclusions

Modern information confrontation manifests itself in the widespread use of disinformation when covering any events, information blackmail using the electronic control results over people's lives, their political activities and personal plans, in using the full power of modern media in order to obtain unilateral advantages.

Most developed countries have a strong information potential. Publications monitoring in the media clearly shows that the main information struggle trend involves increasing its role in solving foreign policy problems as informatization becomes more established.

Note that at present, the information conflict no longer plays a secondary role and is not an addition to the "main" events. This confrontation has become the most important mechanism for conducting wars, as well as the armed forces and equipment use, becoming a legitimate method of political struggle.

Currently, the information and communication technologies' development level is becoming one of the determining factors for the country's involvement in world economic processes, the economy's technological development and the demand for national goods and services on the world market. With the Internet's rapid development, the most effective business organization models are being transformed, and various international strategic alliances are coming to the fore in the field of cooperation between countries and companies in order to achieve common information and other goals.

Information and communication technologies in the Internet space significantly affect the modern political regimes' content parameters functioning, as well as contribute to the traditional democracy models evolution.

Today, a society is being formed in which the main value is no longer information itself, but communication technologies and communication channels. Not information, but communication connections and communication opportunities are the main value in modern society.
Political and economic information loses its traditional value outside the context of its possible use in communication processes. On the contrary, the main value, including political, today is the possibility of communication interaction, and therefore modern communication technologies are aimed at creating effective global communication forms, new communication interaction mechanisms.

Abstract

This study provides the indispensable facts about the importance of the performance measurement for the organisation. Therefore, this paper will analyse one of the performance measurement tools – KPIs, by providing the theoretical details. After that, the strategy formed by the company to manage the KPIs will be identified. It helps to raise a milieu of awareness about the importance of implementation and maintenance of KPI among SMEs, particularly to the SMEs who are not aware about this. In addition, this study will serve as the basis for future plans of action by the SMEs. In this research, quantitative research methods were employed. This research is using a descriptive research design that seeks to describe the current status of SMEs implement the KPIs. A structured-questionnaire survey were used to collect the quantitative data by email and interview. The questionnaire of this research includes 5 sections. Multiple choices questions and Likert Scale questions were included in the questionnaire to collect the data. The questionnaire survey was developed in an easy-to-answer manner by providing options to survey participant. There are 155 SMEs that are registered with SME Corp. Malaysia in Batu Pahat, Johor. After all the completed questionnaires are collected from the respondent, 10 respondents' data is carried out to ensure the accuracy and the suitability of this research. After that, all the data were analysed by using the Statistical Package for the Social Science (SPSS) version 21.0 to interpret the data using descriptive and inferential statistics. This study helps to identify the significant relationship between the SME's strategic approach towards managing the business performance in their organisational strategy.

Introduction

In this paper, the concept of key performance indicators as well as small and medium sized enterprises will be defined. Besides that, the theoretical background of the KPIs will be stated. Issues that will be discussed through this chapter included of organizational strategic approach of managing KPIs with the business strategy, communication and monitoring system also discussed through this paper. Goodpasture (2003) defined the KPIs as tools for delivering measurement systematically and the management is needed to understand what is important to an organization, various techniques to assess

Cite this Article as: Abd Rahman Ahmad, Lim Chen Bin, Alaa S. Jameel And Hairul Rizad Md Sapry "Key Performance Indicators and Dimension of Organisational Strategic Approach" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the business present state and its key activities with the selection of performance indicators. KPIs are used to evaluate the factors or activity that are critical and crucial for the current and future success of an organization (Verzola, Bentivegna et al. 2009).

Key performance indicators (KPI) can be characterized as the navigational tools that empower the administration group of an association to have a straightforward picture of the association's execution and assist in real time decision making. This helps to enhance execution and decrease the up-coming negative outcomes to the association (Marr 2012).

Literature Review

KPI must be clearly and simple to understand, so that it can empower and enhance the management of company in resources allocation as indicated by the organization's business strategy (Parmenter 2015). KPI can be measured in various time periods. This can improve the effectiveness of real time decision making by the management. A KPI should be forwarded straight to the CEO of the organization to check the hierarchical execution, so that CEO can intercede on the matters to adjust the resources to the objectives (Parmenter 2015).

Figure 1: Characteristics of KPI

Source: Parmenter (2015)

A good KPI should be consistent with the particular organization's strategy, goals and vision. Besides that, KPI must concentrate on the organization wide vital values instead of non-critical business result. A wrong KPI selection can bring about counterproductive results (Parmenter 2015). A good KPI should fulfilled all the characteristics as shown in the Figure 1.

Balanced Scorecard (BSC)

Kaplan and Norton (1996) have introduced BSC in four perspectives. BSC includes of financial and non-financial measurement in one system and it recommends managers to view organization's performance based on the perspectives (as shown Figure 2). The KPIs are always linked to the BSC. Ayedh and Muslim (2007) found that BSC is the main tool to use to choose the KPIs and most of the Malaysian companies were widely adopted.

Figure 2: Four perspective of BSC

Source: Kaplan and Norton (1996)

There are four perspectives on the BSC approach which are customer perspective, financial perspective, internal process perspective and learning and growth perspective. The organization must develop performance measure strategy to improve these perspective in order to choose the right KPIs for the organization (Kaganski, Snatkin et al. 2013). With a combination of these perspectives, organization can translate their vision and strategy into actions across a balanced set of perspective (Kaplan and Norton 1996). Phusavat and Manaves (2008) have conducted a study which attempted to measure the SMEs performance through the KPIs for BSC design and development.

Small and Medium Enterprises (SMEs)

Small and medium enterprises (SMEs) are very important to the economic growth and the country's overall production network (Ueasangkomsate, & Jangkot, 2017). The Malaysian economy has been geared by the rapid development of SMEs since the 1970s. In the 1990s, Malaysia has started to alter its economics basis from local market to exports the products to the overseas (Zulkiffli 2009; Sapry et. al., 2020). There are many definitions for small and medium sized enterprises (SMEs) and different countries have different definition for SMEs. According to the National SME Development Council Official Website, a new definition was endorsed for SMEs in 2013. An enterprise is considered as an SME in each of the respective sectors based on the annual sales turnover or number of full-time employees. SMEs can be categorized into 3 types; there are micro enterprises, small enterprises and medium enterprises. Besides that, SMEs also divided into two sectors: (1) manufacturing, manufacturing-related service and Agro-based industries, and (2) services, primary agriculture and information and communication.

This research attempts to identify the significant level of SME's strategic approach towards managing the business performance as shown in Figure 3.

Figure 3: Conceptual Framework

The independent variables of the study were includes the business strategy, communication method and monitoring tool with the outcome of business performance.

Methodology

Before the real survey carried out, a pilot test was launched three weeks before actual test. 10 set of the survey questionnaires were distributed to the 10 SMEs by email and interview. This pilot test was a success and there were no special issues happened. In this survey, the section B, C, D and E of the questionnaire were tested in order to find out its validity and reliability before proceed to actual data collections. Section B contain items related to the business performance that measured by the SMEs in the performance measurement system. Section C was representing the link of business strategy with the KPIs. After that, section D representing the communication method among staffs and section E representing the monitoring method on business performance.

After all the questionnaires are collected from the respondents, the analysis process including identify the types of KPIs employed by SMEs; examine the methods for SMEs to link KPIs to their business; investigate the interaction of KPIs among staffs in SMEs; and determine the way of SMEs to monitor KPIs. After that, all the data will be analysed by using the Statistical Package for the Social Science (SPSS) version 21.0. Results and answer from the analysis is organized and presented in suitable forms such as charts, tables or graphs. Thus, the data could be interpreted and understood easily.

Results and Discussion

Demographic analysis was used to explain the pattern of the respondents' background who was involved in the survey. 62 respondents took part in this survey. The data collected included gender, age, designated position, number of employees at the company and category of the manufacturing firm because all these factors may influence the KPI that were adopted in a company towards the formation of business strategy, communication method and monitoring system. The data was analysed in the form of frequency and percentage. Following table shows the summary of average mean for all variables.

Table 1: Summary of Average Mean for All Variables

Variables	Average Mean	Mean Score Interpretation
Business Performance	5.05	High
Business Strategy	4.40	Moderate
Communication Method	4.63	Moderate
Monitoring Tool	4.56	Moderate

From Table 1, business performance obtained the highest average mean score, which is 5.05 at the high level according to the mean score interpretation. Communication method obtained the average mean score of 4.63; monitoring tool had the 4.56; the lowest average mean score was achieved by business strategy, 4.40. All of these three variables were at the moderate level according to the mean score interpretation. In other words, SMEs who took part in the survey was already employing distinct KPIs in the business. However, the strategic approaches which are business strategy, communication method and monitoring tool are requiring the more attention in managing the business performance.

Based on the finding of this research, the dimensions of the organizational strategic approach which are, business strategy, communication method and monitoring tools, will be used to analyse and observe their influence towards the SME's business performance measurement system. As state in the previous chapter, to create efficient KPIs, strategic planning processes are needed to be in conjunction with organization's goals and vision. Besides that, the cost and time frame problem might be influenced organizational strategic approach.

Conclusion

This study has proved the importance of organizational strategic approach towards managing the business performance. The finding of this research is to answer the research question and to achieve the objective establish in the early of the paper. By carrying out the appropriate analysis on research survey data, which has 62 respondents, it was found that there is a significant relationship between organizational strategic approach and business strategy. If there is a proper way of planning based on these three variables (business strategy, communication method and monitoring tool), it can improve the SME's business performance and sustain competitive advantages. Thus, the objectives of this research had been achieved.

Abstract

The practice of occupational safety and health (OSH) culture can prevent workers from getting injured in any activities carried out as well as improving factory productivity. In the processing of palm fruit oil, the factory use large machines with high risk, this can cause accident resulting in death, permanent disability and without disability. Such accidents can happen if there is negligence by the employer and the employee during the course of the operation of the machine. There are three objectives of this study. Firstly, to determine the factors contributed to the Occupational Safety and Health (OSH) awareness program in Palm Oil Mill in Malaysia secondly was to identify the dominant factors contributed to the awareness program and finally to investigate whether the awareness program could reduce the accident. The scope of the study include Malaysian workers in Palm Oil Mill. The study were conducted using quantitative method. There were 63 sets of questionnaire distributed but only 56 were returned. The data obtained was analysed using the software Statistical Package for Social Science (SPSS). The results showed that the behaviour factor contributed to the Occupational Safety and Health (OSH) awareness program is very high and the objectives of this research were achieved.

Introduction

According Richardson and Richardson (2014), safety and health of workers at the firm are important and need to be prioritized by employers because it can reduce the cost of panel clinics, treatment after the accident, reduce the risk of lawsuits and motivate employees to improve productivity of the firm. Moreover, the employee is an important variable inputs in the production process needs to be given attention on the state of safety and health so that they can work in a safe and secure situation to improve satisfaction and utility in carrying out the assignment.

Jameel And Hairul Rizad Md Sapry "Safety and Health Awareness Program among Employees in Palm Oil Mill Industry in Malaysia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Literature Review

According to Le bouar and Chauvin (2006) occupational safety and health (OSH) is a situation where an employee requires a work environment that is safe and healthy for themselves and others who may be affected by its activities. Risk management and safety and health can handle and improve morale and motivate employees while performing their duties and responsibilities in the workplace. Meanwhile, Reinhold et al, (2014), added that every action in implementing safety and health at work require strategic planning of the management. To complete the implementation of health and safety, management is divided into five parts, namely the establishment of safety and health, safety and health policies, health and safety hazard inspection, safety and health training and health and safety audit.

National Institute of Occupational Safety and Health (NIOSH) is a training, information and research centre for occupational safety and health (National Institute of Occupational Safety and Health, 2013). Since the training is one of the important components of accident prevention, NIOSH was set up with its main functions to serve as an institute which provide training and curriculum development, information dissemination, consultation and research and development (Zein, 2008). NIOSH not only provide the basic construction safety course, but also the special program which conducted for the operator of mobile and tower crane, and scaffold erectors. The activities are the expanded to include the regular Occupational Safety and Health training program at NIOSH's premises, conducting seminars at state levels for the small to medium scale industries, conducting in-house training programs for various industries and others (Centers for Disease Control and Prevention, 2011).

Safety and Health

Safety is a determination of the relative freedom of any risk and danger. Safety is also a degree of freedom of the risks and hazards in various industrial environments as well as freedom from danger, however, is difficult to avoid all danger. Some of the risks to be addressed and controlled easily compared with one another. Safety associated with a situation where it needs to be assessed and determined by the relevant cases such as the use of equipment that could be dangerous (Boholm, Möller, & Hansson, 2016).

Kankaanpaa (2010) have made clear that security considerations associated with the acceptance of the risk that it is a determinant of the risk of potential injury to employees. Safety is a condition that has a relationship with risk and danger. Therefore safety is an issue related to the protection from exposure to danger. Assessment of safety is determined by how the management control of any risks inherent in the industry and ensure that dangers can be avoided. Health refers to efforts to protect and liberate employees from any kind of illness that threatens their physical and emotional (Mondy and Noe, 2013). According to the World Health Organization (WHO), the World Health Organization in the context of the objectives is to improve and maintain the health of the mental, physical and social workers in all forms of employment. The disease caused by work can lead to all kinds of abnormal conditions caused by exposure to environmental factors work due to chronic illnesses such as heart disease, stress, disability or death by inhalation or direct exposure to toxic substances. Moreover, to prevent any workers from occupational diseases caused by work processes and work environment and control any risks caused by the work process and working environment (Bernardin and Russel, 2008; Myzabella et. al., 2019).

Employee perception of safety and health

The general perception is subjective and often zero is defined as a personal view of the subject. The perception of an individual's perception is different from one individual to another. It depends on how a person is faced with a problem in his belief. According to Toole (2001), the perception is defined as a mental process that is used to focus or pay attention to signs or stimuli selected. There are two types of social perception and perception of physical perception. Employee perception of safety and health (OSH) does exist among workers in the workplace. According to John et al., (2002), defines the perception of workers is the collection in terms of belief and human emotion which they now have to

work. Workers have high job satisfaction will give expression to his satisfaction towards the work they do. Positive thoughts and emotions affect the employment or work experience of an individual (Landy and Conte, 2008).

Research Framework

Research framework is a logically structured representation of the concepts, variables and relationship involved in scientific study with the purpose of clearly identifying what will be explored, examined measured or described. Hence, the current study examines the relationship between a set on independent and dependent variables.

Figure 1: Research Framework Review

This research framework is developed based on Nasyrah Ibrahim et al., (2015) who used behavior as one of their model to find The awareness level of behavior based safety (BBS) in construction Industry. Hence, According to Ozturan & Kutlu (2010), they used training as one of their research framework to find out employee satisfaction of corporate e-training programs. Beside, personal protective equipment (PPE) is used in (Oguntona & Adedeji, 2012) to identify the awareness and use of personal protective equipment (PPE) and practice of safety precautions among funeral home workers in Lagos state.

Methodology

The population of this study focused on the Malaysian employees in Palm Oil Mill which located at Johor. Based on information obtained there are 75 Malaysian workers including management level, engineering department, production and operation department, quality control department and others which become a sample of the study.

Research instrumentation is a tool or medium used in conducting a study. Instrumentation consists of a few tools that are used to collect primary data. Among some of the common instrumentations were questionnaire forms. Questionnaire is a set of pre-established questions further to be answered by a number of respondents according to options and alternatives available, ultimately channel a series of feedback to researchers. Survey's result that subjects to ease of process and analyse attributes widely adoption of questionnaire survey. Data gathered process is rapid, simple, practical and dynamically relevant to research's objective.

Results and Discussion

Demographic background of those respondents who participated in answering the questionnaire were being analysed to get a clear view about which group or category of people had taken part in this study. The questionnaire consists of total 7 questions, asking for the details of the respondents which included

gender, age, race, length of service, academic level, have you ever participated in Occupational Safety and Health (OSH) training before and how many times have you followed the OSH training during your service in this company. The analysis of this section, findings in terms of frequency and percentage of the data collected from this research will be discussed.

The objective of this study is to explore the factor contribute to the Occupational Safety and Health (OSH) awareness program and to identify the dominant factors contribute to the awareness program and to investigate the awareness program could reduce the accident. Table 1 below shows that the summary results made based on the findings obtained. It shows that the objectives of the study are achieved and the question of the study made

Table 1: Summary of findings

No	Research objective	Research questions	Finding
1	To determine the factor contribute to the Occupational Safety and Health (OSH) awareness in Palm Oil Mill.	What are the factor contribute to the Occupational Safety and Health (OSH) awareness in Palm Oil Mill	Behavior, training and personal protective equipment (PPE) are the factor contribute to the Occupational Safety and Health (OSH) awareness in Palm Oil Mill
2	To identify the dominant factors contribute to the awareness program at Palm Oil Mill	What are the dominant factors contribute to the awareness program in Palm Oil Mill.	Employee behaviour toward safety has highest mean score and this factor most dominant for Palm Oil Mill (BBPOM).
3	To investigate the awareness program could reduce the accident in Palm Oil Mill.	Does the awareness program could reduce the accidents in Palm Oil Mill?	Yes. It does reduce the number of accidents in Bukit Palm Oil Mill. It is because the causes for accidents to happen have been explained in order to create the awareness for being safer at working place.

Employee training toward safety has mean score 4.32. According to Wachter (2013), safety training is a fundamental safety practice emphasized by most federal and state safety and health legislative bodies. Safety training works by increasing knowledge and awareness of safety and health in the workplace. There is considerable variation in the ways that safety training is designed and delivered. Employees can also use the knowledge gained in OSH training when performing tasks. However, there are still errors and accidents in the workplace. In addition, the assessment of the level of treatment is to determine whether the trainer transfers what is obtained during training to the workplace. Assessment at this stage needs to be done after the trainer completes the training and returns to work. A strong

rationale for the assessment of treatment is that someone who has succeeded in an undisciplined learning will apply what he has learned in the work of which positive transfers do not necessarily happen. Most effective training programs are not only dependent on employee behavior during training that may respond positively and negatively to the training being developed, but the effectiveness of the training depends on developing changes in work behavior.

Conclusion

Overall, this study was successfully completed as the question of the study and the objective of the study was achieved. The findings for this study are based on analysis from the data obtained from the Palm Oil Mill. All the factors used in this study are important and have an impact on the effectiveness of occupational safety and health (OSH) awareness programs within the organization. It is hoped that this study will benefit and benefit to the organization's production and human resources division in further enhancing the level of awareness of their employees. Additionally, some of the opinions and suggestion given in this study can also help further research in the future for those who are interested in the topics studied.

Relation between the Introduction of Remote Teaching as a Result of the COVID-19 Pandemic and the Quality of the Academic Teaching of Accounting

Anna FUKS, MSc.
Wroclaw University of Economics and Business, Wroclaw, Poland,
anna.fuks@ue.wroc.pl

Abstract

The aim of this paper is to present the relation between the COVID-19 pandemic and the obligatory introduction of remote teaching and the quality of the academic teaching of Accounting. The aim was achieved through research. The selected research method was a survey questionnaire sent in an electronic form. The survey should be treated as a pilot study. It was carried out in 7 groups of first-year students pursuing a first cycle programme at a public institution of higher education in the field of Finance and Accounting (full-time and extramural modes) and Management (full-time mode), who attended classes in Financial Accounting run exclusively by the author of this survey during the summer term 2019/2020. The most important and crucial results of the survey permitted the formulation of new research hypotheses, which will be verified at successive stages of the research: (1) combination of elements of remote and traditional teaching (blended teaching) might lead to the best performance in teaching Accounting; (2) effective remote teaching cannot take place without building, sustaining, and improving proper interpersonal teacher–student relationships and, to an extent, relationships between students.

Keywords: teaching methods, remote teaching, blended learning, teaching Accounting

Introduction

In the initial months of 2020, Europe saw the arrival of the COVID-19 pandemic. As a result, many governments imposed various restrictions on social and economic activities. One of them was closure of higher education institutions by Polish authorities and introduction of obligatory remote teaching. Hence, the spread of COVID-19 considerably affected the way in which the academic community functioned. Remote education, which was merely an option in the early 2020, became the only possible solution during the pandemic.

This paper is an attempt at showing the influence of the introduced obligation to teach Accounting remotely on students' opinions and reactions as a measure of the quality of this type of teaching. The research is a pilot study carried out in July 2020, i.e. just after the summer term ended, when all remote classes finished and the students were properly examined.

The formulated hypothesis provided that the remote teaching of Accounting, despite the initial concerns about low quality of remote classes compared to the traditional ones voiced by students, could to a large extent replace the traditional teaching of Accounting and be of no lower quality. In order to verify the formulated hypothesis, research questions were asked in the survey questionnaire in the form of requests to indicate:

- the first reaction to the information about the necessity to have remote classes in Financial Accounting,
- the initial concerns and the actual drawbacks of such classes,
- the expected and real benefits from such classes,
- the opinion on the whole term with such classes,
- the preferred form of classes,
- the quality of the remote classes in Financial Accounting compared to other remote classes,

- the intention to recommend the classes to other students,
- the willingness to attend other remote classes in Accounting.

The research questions in the survey questionnaire have the following forms:

- single choice questions,
- multiple choice questions with a request to select up to 4 out of a dozen or so possible answers – the variants included also the option of adding a new answer by the respondent to the variants mentioned in the survey questionnaire.

The presented results are only a part of the research on the opinions and reactions of students pursuing various programmes of study, without limiting the research to students pursuing programmes typically related to Accounting, and teachers concerning the application and effectiveness of diverse methods of the academic teaching of Accounting.

Remote teaching of Accounting in the context of the current pandemic

There have been numerous studies in the field of teaching Accounting in different forms to date. Already almost 10 years ago, researchers stated that e-learning in the teaching of Accounting could contribute to the development of self-reliance in students and perfectly fit into university teaching [Kasperowicz, 2011]. Moreover, the scholars admitted that most of the academic community accepted remote forms of teaching and treated them as the natural consequence of the development of ICTs, and the education model desired in that case was a model combining traditional teaching and elements of remote teaching [Lubina, 2009].

A term which has recently become popular in both the relevant literature and the economic practice is VUCA [Waller, Lemoine, Mense, Garretson, Richardson, 2019]. It is an acronym formed from the following words: volatility, uncertainty, complexity, and ambiguity, which briefly characterise the conditions in which the contemporary human being functions in different areas of the continuously changing environment. The COVID-19 pandemic is such an unprecedented situation that it has intensified and enhanced the idea behind the concept of VUCA environment. This is because the reality of people functioning in every imaginable environment changed almost overnight. The changes could not be avoided by the academia either and it became necessary to shift from traditional to remote classes very quickly. Therefore, teachers had to reorganise the way in which they ran their classes and adapt their teaching materials to the new reality overnight.

Hence, making use of the equipment provided to them by their higher education institutions, academic teachers running classes in Accounting had to devise, for their own use, such ways and methods of running classes as would ensure at least:

- the achievement of the best possible teaching effects,
- the maintenance of proper positive teacher–student relationships,
- the avoidance of a considerable deterioration in the quality of remote classes compared to traditional ones.

Results of the Conducted Research

The pilot study was carried out in July 2020 in 7 groups of first-year students pursuing a first cycle programme at the Wroclaw University of Economics and Business in the field of Finance and Accounting (full-time and extramural modes) and Management (full-time mode), who attended classes in Financial Accounting during the summer term 2019/2020. The person running the classes was the person carrying out the research.

The survey questionnaire was sent to 139 students electronically in a message addressed to students from individual groups by means of the MS Teams application in the Office 365 Education package, i.e. the one used for all remote classes. Completed questionnaires were returned by 80 subjects. Nevertheless, due to fact that the term ended and students logged in the remote teaching application

much less frequently, the study sample was considered representative and the pilot study was conducted.

The outcome was as follows:

Table 1: Results of the research

• What was your first reaction to the information about the necessity to have remote classes in Financial Accounting?		
definitely positive – 9%	positive – 15%	neutral – 61%
negative – 14%	definitely negative – 1%	
• What were your first concerns regarding the information about the necessity to have remote classes in Financial Accounting? [4 answers with the highest number of indications by the respondents out of 13 are presented]		
lack of direct contact with the teacher – 32	lower quality of remote classes compared to traditional ones – 40	
attendance in classes dependent on issues related to technology (hardware in working order, Internet access, etc.) – 36	lack of internal motivation and self-discipline to learn during the term – 40	
• What are the real drawbacks of remote classes in Financial Accounting in your opinion? [4 answers with the highest number of indications by the respondents out of 13 are presented]		
lack of direct contact with the teacher – 16	limited contact with other participants in the classes –23	
attendance in classes dependent on issues related to technology (hardware in working order, Internet access, etc.) – 29	lack of internal motivation and self-discipline to learn during the term – 34	
• What were the possible (expected) benefits from having remote classes in Financial Accounting in your opinion just after you received the information of the necessity to have them in this form? [4 answers with the highest number of indications by the respondents out of 11 are presented]		
time savings – 43	possibility to learn in any place – 56	
reduced costs of learning (commuting, photocopying notes, etc.) – 51	continuous access to teaching materials – 44	
• What are the real benefits from remote classes in Financial Accounting in your opinion? [4 answers with the highest number of indications by the respondents out of 11 are presented]		
time savings – 38	possibility to learn in any place – 51	
reduced costs of learning (commuting, photocopying notes, etc.) – 46	continuous access to teaching materials – 54	
• What is your opinion on the remote classes in Financial Accounting after the whole term?		
definitely positive – 68%	positive – 30%	neutral – 1%
negative – 1%	definitely negative – 0%	
• In the winter term, you attended traditional classes in Accounting run by another teacher. In the current term, in turn, you attended remote classes (in a majority of cases) in Financial Accounting. If you were to compare the form of running both of the classes, which would you rate higher?		
Accounting (traditional classes) – 23%	Financial Accounting (remote classes) – 65%	
none of these – 12%		
• How do you rate the classes in Financial Accounting compared to other remote classes which you attended during the current term?		
definitely higher – 67%	higher – 29%	neutrally – 4%
lower – 0%	definitely lower – 0%	
• Would you recommend attendance in remote classes in Financial Accounting to other students?		

definitely yes – 45%	yes – 40%	neither yes nor no – 13%
no – 2%	definitely no – 0%	
• Would you like to attend other obligatory classes in Accounting remotely again (in the future)?		
definitely yes – 30%	yes – 34%	neither yes nor no – 20%
no – 16%	definitely no – 0%	

Assessment of the Value of the Findings

The formulated hypothesis was verified positively in the course of the conducted research. The remote teaching of Accounting, despite the initial concerns about low quality of remote classes compared to the traditional ones voiced by students, could to a large extent replace the traditional teaching of Accounting and be of no lower quality.

The highest percentage of the examined group described their first reaction to the information of replacing traditional classes with remote ones as neutral. Only 1 respondent indicated a definitely negative reaction. In most cases, the subjects' indications of their initial concerns coincided with their indications of the real drawbacks of remote classes. However, it needs to be noted that:

- despite the initial concerns about the low quality of classes voiced by 40 respondents (50%), only three subjects confirmed that this was the real drawback of such classes, and so the respondents' concerns did not materialise,
- in the question about the real drawbacks of such classes, the number of the respondents who indicated the lack of direct contact with the teacher decreased by a half (a drop from 32 to 16 indications) – the teacher was in touch with the students also outside the class time by exchanging chat messages and having voice calls during consultations,
- limited contact with other participants in the classes was indicated as a real drawback.

The subjects' indications that attendance was dependent on issues related to technology also seem to be significant. If a respondent's computer (or another hardware used by the student for e-learning purposes) was out of order, or he or she did not have a microphone or loudspeakers, or had problems with Internet access, his or her ability to actively participate in classes was largely hampered. Such cases occurred, however, very rarely in practice.

Nevertheless, one of the challenges related to the introduction of effective remote education should be counteracting digital exclusion, which – in extreme cases – could result in educational exclusion of impecunious students. On the other hand, remote teaching might contribute to reduced social exclusion. This is because it could lead to popularisation of education among the disabled since an educated person is more likely to find a place for themselves in the society [Hołowiecki, 2014].

It should be mentioned that 78 out of 80 respondents expressed their definitely positive and positive opinions on the remote classes in Financial Accounting after the whole term. Only 1 person described his or her opinion as negative.

Moreover, more than 95% of the subjects rated the remote classes in Financial Accounting definitely higher and higher than classes in other subjects run in the same form. None of the subjects rated the classes lower or definitely lower. Additionally, more than 85% of the respondents would recommend attending in the classes to other students. 3 respondents would not do so (2%).

The highest percentage of the subjects (64%) declared that they would be willing to attend other remote classes in Accounting in the future. Other subjects, despite their positive opinions on the analysed classes, indicated that they were undecided (20%) and that they would not want to participate in such classes (16%), which might result primarily from the drawbacks of remote classes they indicated.

Conclusion

As a result of the analysis of the first part of the obtained results of the survey and as an effect of the conclusions drawn from it, it is possible to formulate new hypotheses, which will be verified at the successive stages of the research: (1) combination of elements of remote and traditional teaching might lead to the best performance in teaching Accounting; (2) effective remote teaching cannot take place without building, sustaining, and improving proper interpersonal teacher–student relationships and, to an extent, relationships between students.

It must be emphasised here that the results are only a part of the research on the opinions and reactions of students and teachers regarding the application and effectiveness of diverse methods of the academic teaching of Accounting. At the stage of further research, individual research groups will be analysed separately with the specification of the mode, field, year, and cycle of study. Moreover, more attention will be given to the dependence of the opinions and reactions of the individual groups under study on the applied method of teaching Accounting in the context of the subjects' sex and age.

Towards The EU-Wide Non-Financial Reporting Standards: What Do Stakeholders Say?

Joanna KRASODOMSKA

Cracow University of Economics, Krakow, Poland

joanna.krasodomska@uek.krakow.pl

Abstract

The Directive 2014/95/EU is unquestionably an important step towards the development of non-financial reporting in the EU. However, the minimum harmonization approach and the considerable flexibility as regards the reporting frameworks that might be used by companies have resulted in a situation where stakeholders' information needs are not sufficiently met. Therefore, the European Commission (EC) announced the possibility of the introduction of a new set of European non-financial reporting standards (ENFRS). This paper aims to present the EU approach to the corporate non-financial disclosures in the Directive 2014/95/EU context, and the stakeholders' views on the new ENFRS. 588 responses obtained during the EC consultation process organized in February - June 2020 were analyzed. Research findings indicate that the ENFR should be based on the Task Force on Climate-related Financial Disclosures (TCFD) recommendations, developed by the body with the financial reporting expertise and with the active participation of preparers and investors. Also, the SMEs should be required to provide non-financial disclosures. The study contributes to the sustainability literature by providing new insights into the stakeholder views on the regulation of the non-financial disclosure and indicating possible avenues for future research.

Keywords: Directive 2014/95/EU, non-financial reporting, stakeholder engagement

Introduction

In October 2014, the European Union (EU) adopted the Directive 2014/95/EU. The Directive aimed to "increase the relevance, consistency, and comparability of information disclosed by certain large undertakings and groups across the Union" (EU, 2014, Introduction par. 21). Starting from 2018, around 6,000 large public interest entities (PIEs) in the EU, with an average of 500 employees or more, disclose non-financial information about their practices concerning environmental matters, social and employee-related issues, respect for human rights, and anti-corruption and bribery. Non-financial disclosures can be presented in the management commentary or in a separate report. They include a description of the company's business model, non-financial policies, as well as non-financial key performance indicators (KPIs).

According to the Directive 2014/95/EU, reporting companies can follow two sets of guidelines issued by the EC (2017, 2019) as well as various national, EU-based, and international recommendations. For example, EC guidelines (2017) reference 21 organizations involved in non-financial reporting and non-financial reporting frameworks (CDP (formerly the Carbon Disclosure Project); the Climate Disclosure Standards Board (CDSB); the OECD Due Diligence Guidance for Responsible Supply Chains from Conflict-Affected and High-Risk areas, and the supplements to it; the Eco-Management and Audit Scheme (EMAS) and the related Sectoral Reference Documents; the European Federation of Financial Analysts Societies' KPIs for Environmental, Social, Governance (ESG), a Guideline for the Integration of ESG into Financial Analysis and Corporate Valuation; the Global Reporting Initiative (GRI); Guidance for Responsible Agricultural Supply Chains of FAO-OECD; Guidance on the Strategic Report of the UK Financial Reporting Council (FRC); Guidelines for Multinational Enterprises of the

Cite this Article as: Joanna KRASODOMSKA " Towards The EU-Wide Non-Financial Reporting Standards: What Do Stakeholders Say?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Organization for Economic Cooperation and Development (OECD); Guiding Principles Reporting Framework on Business and Human Rights; ISO 26000 of the International Organization for Standardization; the International Integrated Reporting Council (IIRC) Framework; Model Guidance on reporting ESG information to investors of the UN Sustainable Stock Exchanges Initiative; the Natural Capital Protocol; Product and Organization Environmental Footprint Guides; the Sustainability Accounting Standards Board (SASB) standards; the Sustainability Code of the German Council for Sustainable Development; the Tripartite Declaration of principles concerning multinational enterprises and social policy of the International Labor Organization; the United Nations (UN) Global Compact; UN Sustainable Development Goals (SDGs), Resolution of September 25 2015 transforming our world: the 2030 Agenda for Sustainable Development; UN Guiding Principles on Business and Human Rights implementing the UN 'Protect, Respect and Remedy' Framework), which might be well used by companies, and this is not a definite list.

The Directive 2014/95/EU gives the Member States and companies a lot of flexibility. Still, at the same time, it is somewhat contradictory to the above-indicated aim of increasing the comparability of the information disclosed. As Venturelli *et al.* (2019) argue, the real role of the Directive was not to introduce a set of non-financial reporting rules but rather to provide a way to harmonize the content of non-financial disclosures to achieve a higher degree of information comparability (La Torre *et al*., 2018). However, the possibility of using different accounting standards presents several limits to achieving a sufficient degree of harmonization across the Member States. Although this minimal approach to harmonization has obvious advantages, the lack of a common standard may not help to improve the non-financial reporting transparency (Farneti *et al*., 2018, Muserra *et al*., 2019).

Out of the reporting frameworks referred to by the EC (2017), the GRI guidelines are used most widely. Recently, several initiatives have been put forward that aim at aligning GRI and other non-financial guidelines. One of them is *Better Alignment Project* (GRI, 2019). Within this project, CDP, CDSB, GRI, IIRC, and SASB are joining their efforts to drive better alignment of sustainability reporting frameworks, initially focusing on aligning standards with the recommendations published by the Task Force on Climate-related Financial Disclosures (TCFD). Another initiative is the publication of the *Sustainable Developments Goals Disclosure (SDGD) Recommendations* (Adams *et al.*, 2020), which align SDGs to the TCFD recommendations, the GRI Standards, and the IIRC International <IR> Framework. GRI and UN Global Compact also jointly issued a *Practical Guide to promote and facilitate corporate reporting on the SDGs* (GRI, UN Global Compact, 2020). Despite the apparent benefits of these initiatives, the idea of more standardized non-financial disclosure requirements appeared on the EU agenda.

On January 30, 2020, the EC published an initial, high-level roadmap for a consultation about possible changes to the Directive 2014/95/EU. In the related communication, EC stressed that the non-financial disclosures are not sufficiently comparable or reliable; they do not meet the stakeholders' information needs adequately, and companies providing them often incur unnecessary and avoidable costs. The causes for these problems are not sufficiently detailed Directive requirements, myriad of overlapping and sometimes inconsistent private non-financial reporting frameworks and standards, as well as the lack of enforcement (EC, 2020b). The process of consultation on potential revisions to the Directive that followed includes the possibility of establishing a new set of European non-financial reporting standards (ENFRS). The preparatory work is to be carried out by a multi-stakeholder Project Task Force (PTF) appointed by the European Financial Reporting Advisory Group (EFRAG). Therefore, the widely disputed issue of the legal status of non-financial reporting in the EU has become very up to date again (EFRAG, 2020).

This paper aims to present the EU approach to the corporate non-financial disclosures in the Directive 2014/95/EU context, and the stakeholders' views on the new ENFRS. This descriptive study uses 588 responses collected during the recent consultation process launched by the EC and provides new insights into the non-financial reporting landscape in the EU. It also indicates future research possibilities related to the unification of corporate non-financial disclosure practices.

The work is structured into three sections. The next section describes the mandatory, voluntary and *comply or explain* approaches to the non-financial disclosures and the role of stakeholder engagement in the reporting process. The section that follows provides information on the opinions about the introduction of the new common ENFRS expressed by the stakeholders participating in the consultations on possible changes to the Directive 2014/95/EU. The last section offers conclusions together with an indication of the potential avenues for future research.

Mandatory, voluntary or *comply or explain* approaches to the non-financial disclosures and the role of stakeholder engagement

There is an acknowledged need for access to reliable and comparable sustainability reporting. However, there is also a general lack of agreement on whether it should be mandatory or voluntary, and both approaches have certain advantages and disadvantages. When it comes to practice, despite the mixed opinions on that matter, it is observed that the voluntary approach is supported by the business. In contrast, stakeholders support a mandatory approach (Krasodomska *et al*., 2020).

The debate on voluntary versus mandatory non-financial reporting has been present in the literature (Stubbs and Higgis, 2018; Doni et al., 2019). The arguments in favor of the voluntary approach include its potential positive outcomes as regards corporate costs and social benefits (Gatti *et al.,* 2018). Regulation of non-financial reporting is seen as an unnecessary burden because companies' decisions to provide it are driven by the need to meet their stakeholders' expectations and legitimize their existence (Fallan and Fallan, 2009). So they would report even without legal obligation. However, the voluntary approach is also widely criticized due to the lack of transparency, credibility, comparability, accuracy, neutrality, objectivity, and the *ad hoc* nature (e.g., Stubbs and Higgis, 2018). Although non-financial reporting guidelines usually encourage reporters to use quantitative metrics (such as KPIs), voluntary reporting has tended to be heavily narrative and qualitative. What is more, voluntary disclosures are often released at different times than financial statements (e.g., on a less-than-annual basis), which makes an integrated analysis of financial and non-financial information difficult (Ho, 2017).

The positive consequences associated with the mandatory approach are better comparability and higher quality of the disclosures and an increase in organizations' accountability (Overland, 2007; Buhr *et al.,* 2014; Thirarungrueang, 2013, Gatti *et al*., 2018). However, legal regulations are also perceived as resulting in a reactive approach to non-financial issues and not a proactive approach. More specifically, mandatory disclosure might result in the reduction of corporate creativity and engagement in non-financial practices, and thus making them less effective (Gatti *et al*., 2018). Companies forced to provide mandatory disclosures are more likely to take the "tick-the-box" approach. The other possible drawbacks are high costs and a lack of independent assurance.

As regards the EU setting, the Directive 2014/95/UE is often referred to as a document, which has introduced mandatory non-financial reporting to the Member States (see, e.g., Matuszak and Rożańska, 2017; Caputo *et al*., 2019). However, the approach used in communication is *comply or explain.* As Ho (2017, p. 330) states, "*Comply or explain* (…) represents an intermediate approach to regulation, and there is some divergence of views on whether comply or explain is in fact a mandatory or voluntary approach." It might be seen as mandatory to the extent that all companies must either *comply or explain* why they did not comply based on the same code provisions. At the same time, because conformity to the code is not required, the codes themselves represent a form of soft law or self-regulation. It leads to the situation where *comply or explain* approach might be seen as neither fully mandatory nor entirely voluntary. Therefore, it is an attractive alternative in the EU context, where both flexibility and consistency are important, whether across jurisdictions or firms (Ho, 2017). The flexibility of a *comply or explain* approach to disclosure also makes it particularly well-suited to non-financial reporting, which is, to a large extent, driven by the industry in which a company operates and its specific characteristics (internal context). The principles-based disclosure approach also fits better with the nature of non-financial information, whether through regulatory guidance or a *comply or explain* disclosure regime, rather than prescriptive "one-size-fits-all" reporting rules.

In the situation where there is considerable flexibility as regards corporate reporting decisions, stakeholder engagement is seen as a crucial element of effective corporate communication. De Villers (2018) provides evidence that investors and other stakeholders not only use it in their investment decisions but also can demand such disclosures from companies. The GRI or IIRC reporting frameworks require that organizations establish who their stakeholders are and then engage with stakeholders to ascertain what material sustainability information should be disclosed. In line with this view, while issuing the Directive 2014/95/EU, the legislator assumed that the investors and other stakeholders would put pressure on corporate managers toward conducting business in a more sustainable way. This shift in companies' practice, in turn, was expected to result in the availability of reliable non-financial information provided by companies with the use of the available frameworks. It seems that by choosing the significantly cheaper minimum harmonization approach, not supported by detailed rules and standards on the collection and processing of the information, EC, in the end, did not obtain significant effects (Szabó and Sørensen, 2015). As noted in the EC communication (EC, 2020b), market pressures on their own have not proven to be sufficient to ensure that companies report the non-financial information that stakeholders say they need.

Stakeholders' opinions on the introduction of the new ENFRS

On February 20, 2020 the EC launched a public consultation to collect the views of stakeholders about possible revisions to the provisions of the Directive 2014/95/EU. In particular, the EC was seeking the opinions of preparers of reports containing non-financial information and of the end-users of such published information. The consultation period ended on June 11, 2020, and a total of 588 responses were received (EC, 2020a).

The selected results of the survey, according to the respondents groups' views are presented below. Because some responses were anonymized or incomplete, the final sample is smaller than the total number of consultation participants and varies across problems raised. The main stakeholders' groups were: academic/research institutions (e.g., universities, law schools), business associations (e.g., investment funds, banking associations, CIMA, BDO, accounting associations, insurers associations), company/business organizations (e.g., Microsoft Corporation, PepsiCo Europe, E&Y, PwC, KPMG, Daimler AG), NGO (e.g., WWF Deutschland, CSR Europe, World Business Council for Sustainable Development, Sustainability Accounting Standards Board, International Integrated Reporting Council, Transparency International UK, Climate Disclosure Standards Board), public authorities (e.g., European Securities and Markets Authority, national banks, member states' ministries, and supervisory authorities), trade unions (e.g., European Trade Union Confederation). The responses to the majority of questions were given on a scale from 1 to 4.

Table 1 presents the stakeholders' opinions on the extent of the incorporation of the existing reporting frameworks into the ENFRS. The mean of the scores assigned by the respondents is the highest with regard to the TCFD (3.40), which indicates that it is the most relevant framework on which the new standards could be based. The most popular GRI guidelines were assigned a lower score (3.23). Surprisingly, the <IR> Framework is seen as useful to some extent but not much in the development of the ENFRS. At the same time, the highest variability in the responses is observed in relation to this option (the coefficient of variation ratio equals 0.36).

Table 1: The respondents' opinions on the extent of the incorporation of the existing reporting frameworks into the ENFRS (N=268)

	Mean*	Standard Deviation	Variance	Coefficient of variation
GRI Standards	3.23	0.78	0.60	0.24
SASB Standards	2.90	0.82	0.68	0.28
IIRC <IR> Framework	2.56	0.92	0.85	0.36
TCFD Recommendations	3.40	0.74	0.55	0.22

**1= not at all, 2= to some extent but not much, 3= to a reasonable extent, 4= to a very great extent.*

Source: own calculations based on EC (2020a)

Table 2: The stakeholders' groups opinions on the extent of the incorporation of the existing reporting frameworks into the ENFRS

	N	GRI Standard Mean*	SASB Standards Mean*	IIRC <IR> Framework Mean*	TCFD Recommendations Mean*
Academic/Research institutions	17	3,06	2,59	2,76	3,00
Business associations	74	3,31	2,89	2,43	3,39
Company/Business organizations	89	3,13	2,93	2,58	3,47
NGOs	54	3,11	2,94	2,48	3,39
Public authorities	20	3,35	2,80	2,70	3,45
Trade unions	14	3,86	3,00	2,86	3,50

**1= not at all, 2= to some extent but not much, 3= to a reasonable extent, 4= to a very great extent*

Source: own calculations based on EC (2020a)

The analysis of the answers according to the respondents' groups allows stating that the stakeholders, who, to the largest extent, share the view that TCFD should be taken into consideration while developing the ENFRS, were business (business associations, companies and business organizations), NGOs, and public authorities' representatives. Academia and research institutions' members and trade unions representatives were more convinced that the future standard could be based on GRI guidelines (table 2).

Table 3: The stakeholders' groups opinions on the extent to which the body responsible for developing ENFRS should also have expertise in the field of financial reporting (N=327)

	N	Mean*	SD	Variance	Coefficient of variation
Academic/Research institutions	21	3.57	0.68	0.46	0.19
Business associations	92	3.41	0.68	0.46	0.20
Company/Business organizations	107	3.50	0.65	0.42	0.19
NGOs	63	3.40	0.55	0.31	0.16
Public authorities	27	3.44	0.64	0.41	0.19
Trade unions	17	3.06	0.24	0.06	0.08
Total sample	327	3.43	0.63	0.40	0.18

**1= not at all, 2= to some extent but not much, 3= to a reasonable extent, 4= to a very great extent*

Source: own calculations based on EC (2020a)

Table 3 presents the respondents' answers to the questions regarding the need to involve financial reporting specialists in the process of the development of a new ENFRS. The mean values of the scores assigned are higher than the mean value of 3.0, which suggests a positive attitude of the respondents towards the need to engage a body with the expertise in financial reporting in this process. Primarily, academics/researchers and companies/business organizations' representatives have supported this idea (mean scores are 3.57 and 3.50, respectively). The values of the coefficient of variation ratio are low, which indicates that the respondents were quite unanimous in their opinions.

Table 4: The respondents' opinions on the extent to which the various stakeholders' groups should be involved in developing ENFRS (N = 277)

	Mean*	SD	Variance	Coefficient of variation
Investors	3.57	0.72	0.52	0.20
Preparers	3.72	0.58	0.33	0.16
Auditors/ Accountants	3.08	0.80	0.64	0.26
Civil society representatives/ NGOs	3.03	0.84	0.71	0.28
Academics	2.79	0.86	0.73	0.31
National accounting standards-setters	2.74	0.91	0.83	0.33
Environmental authorities	2.62	0.97	0.93	0.37
Total sample	3.08	0.91	0.82	0.29

**1= not at all, 2= to some extent but not much, 3= to a reasonable extent, 4= to a very great extent*

Source: own calculations based on EC (2020a)

The survey showed that preparers and investors are the stakeholders' groups, which should be involved to a most significant extent in developing the new ENFRS (mean score 3.72 and 3.57, respectively) (Table 4). The inputs of such groups as environmental authorities, national accounting standards-setters, and academics are not seen as very relevant (mean score below 3.0). At the same time, the stakeholders' opinions on the involvement of the environmental authorities are the most diversified. The coefficient of variation ratio equals 0.37 and is higher than for the whole sample (0.29).

Table 5: The stakeholders' opinions on the extent to which the various stakeholders groups should be involved in developing ENFRS

	N	Investors – Mean *	Preparers - Mean *	Auditors/ Accountants - Mean *	Civil society representatives/ NGOs -	Academics - Mean *	National accounting standards-setters - Mean	Environmental authorities - Mean *
Academic/Research institutions	20	3,20	3,50	3,25	3,60	3,55	3,00	3,15
Business associations	78	3,60	3,90	3,09	2,56	2,44	2,65	2,19
Company/Business organizations	90	3,83	3,86	3,14	2,87	2,64	2,82	2,53
NGOs	50	3,66	3,62	2,90	3,58	3,06	2,74	2,90
Public authorities	24	3,63	3,71	3,38	3,17	3,29	2,92	3,04
Trade unions	15	1,93	2,60	2,53	3,67	2,73	2,07	3,00
Total sample	277	3,57	3,72	3,08	3,03	2,79	2,74	2,62

**1= not at all, 2= to some extent but not much, 3= to a reasonable extent, 4= to a very great extent*

Source: own calculations based on EC (2020a)

The analysis of the opinions by the respondents' groups allows concluding that businesses, NGOs, and public authorities see investors and preparers as the most important stakeholder groups as regards the ENFRS development process. Civil society representatives are perceived as important by academics, researchers and trade unions representatives. Businesses do not see the engagement of environmental authorities in the work on ENFRS as necessary. The mean scores assigned to environmental authorities by business associations and company/business organizations are 2.19 and 2.53, respectively. NGOs,

public authorities and academic/research institution members do not consider the involvement of national accounting standard setters as relevant.

Two questions in the survey were about the extension of the Directive's scope to encompass the SMEs. According to the respondents, the simplified standard and/or reporting format for SMEs should be introduced (table 6). Out of the 290 persons providing answers to this question, 89% expressed such an opinion.

Table 6: The stakeholders' opinions on the introduction of the simplified standard and/or reporting format for SMEs (N=290)

	N	Yes	No
Academic/Research institutions	19	15	4
Business associations	84	74	10
Company/Business organizations	94	66	6
NGOs	51	48	3
Public authorities	26	24	2
Trade unions	16	8	8
Total	290	257	33

Source: own calculations based on EC (2020a)

At the same time, the stakeholders' views on whether the simplified standard for SMEs should be mandatory or voluntary were quite diversified. Only 166 respondents out of 301 who expressed their opinions (55%) agreed that it should be mandatory (table 7).

Table 7: The stakeholders' opinions on whether the simplified standard for SMEs should be mandatory or voluntary

	N	No opinion	Mandatory	Voluntary
Academic/Research institutions	21	1	12	8
Business associations	99	8	30	61
Company/Business organizations	104	14	48	42
NGOs	71	14	44	11
Public authorities	27	1	15	11
Trade unions	17	0	17	0
Total	**339**	**38**	**166**	**135**

Source: own calculations based on EC (2020a)

Interestingly, more business associations' members share the view that it should be voluntary rather than mandatory (61 and 30, respectively). Company/business organizations' responses are almost equally divided: 48 respondents from this group opted for a mandatory, and 42 for a voluntary approach.

Conclusions and indication of future research possibilities

The EU initiative aimed at developing new ENFRS will introduce another reporting framework to a myriad of these that already exist. The question is, will it be truly mandatory, voluntary or introduced on the *comply or explain* basis. Given the nature of the EU, flexibility is an important advantage of the *comply or explain* approach. However, the experiences gained with regard to the EU Member States companies' non-financial disclosure practice and the need to make the disclosures more comparable may be an argument leading toward a more regulated approach.

The first stakeholders' reactions to the idea of developing ENFRS seem positive. According to the respondents' views, they might be based on the TCFD Recommendations to a larger extent than on the most popular GRI guidelines or <IR> Framework. TCFD recommendations, established in June 2017,

are "designed to solicit consistent, decision-useful, forward-looking information on the material financial impacts of climate-related risks and opportunities, including those related to the global transition to a lower-carbon economy" (TCFD, 2020). They are widely recognized as authoritative guidance on the reporting of financially material climate-related information and implemented into the national frameworks of several countries, including the EU Member States. TCFD Recommendations were also the basis of the EC guidelines on climate change issued in 2019 (EC, 2019). This opinion to use them when designing the new ENFRS is especially eagerly put forward by business representatives and might indicate their climate-change-related concerns. However, at the same time, the involvement of environmental authorities in the standard development process is not seen by them as necessary.

The low acceptance of the <IR> Framework as a concept that should be incorporated into the ENFRS might be explained by the fact that it is still a developing idea, which is currently under the revision process. What is more, despite several similarities between the Directive 2014/95/EU and the <IR> Framework (e.g., KPIs, business model), both initiatives are seen as having different addressees (providers of financial capital vs. stakeholders) and competing to some extent (Monciardini *et al*., 2017).

The need for the body responsible for developing ENFRS to have expertise in the field of financial reporting was unanimously supported by the respondents. In their opinion, preparers and investors should be the groups most extensively involved in their design. This finding indicates that the non-financial issues are relevant to the financial profession. Placing the responsibility for the development of the new non-financial reporting framework within the scope of their tasks and interests is supported by the stakeholders. They also acknowledge the need to extend the regulation scope beyond the large PIEs. According to the respondents' views, the simplified standard and/or reporting format for the SMEs should be introduced, but there is no evident agreement that it should be mandatory.

Given the fact that the current situation as regards the available non-financial reporting frameworks is very complex, the idea to develop a new ENFRS seems reasonable. Despite the various alignment initiatives, the companies might feel confused about which standards, guidelines or recommendations they should follow. Apart from the international and EU-based frameworks, they can also choose local guidance. Despite being understandable, this flexibility does not contribute to the comparison of non-financial reporting across the Member States. However, the development of the ENFRS should take into consideration the stakeholders' needs and opinions and should proceed with their engagement.

Despite the limitations, such as the descriptive character of the study, the paper's findings might be relevant to the researchers and practitioners interested in the future of the non-financial reporting. They might serve as a starting point for the subsequent research. Possible research questions might be as follows:

RQ1: Are there significant differences between the preparers' and users' opinions concerning the development of the new ENFRS or regulation of the non-financial reporting in general?

RQ2: What drives the reporters' decision to choose one non-financial reporting framework over another?

RQ 3: What is the role of academia and research institutions members in shaping the non-financial reporting landscape in the EU?

RQ 4: How do the Member States' characteristics (culture, economic and social development, religion, law system, capital market development, etc.) influence the opinions on the need for the new NFRS or regulation of the non-financial reporting in general?

Last but not least, the current COVID-19 pandemic might provide a new perspective to the research on corporate non-financial practices and disclosures. The way the companies will respond to the COVID-19 crisis, and the extent to which the non-financial issues will be considered in their strategies can shape the future of the non-financial reporting.

Abstract

Since the beginning of business management, optimization of enterprise's performance has been recognized as its main objective. However, a suitable motivation models had to be implemented to achieve that goal. This paper aims to present discussion on Object Management Group (OMG) Business Motivation Model (BMM) in theory and in practice. This model is confronted with ArchiMate model and Influence Diagram. The main finding is that discussed models expressed motivation comparably. Finally, SME Accountancy Bureau case study is presented to support conclusions.

Keywords: ArchiMate, Influence Diagram, Business Motivation Model, Accountancy Bureau.

Introduction

While business modelling does not provide business value per se, it serves as the backbone for many information system development projects and as such, can be considered a valuable discipline. In general, business models support communication among stakeholders, and aid their training and learning, persuasiveness and business situation analysis, compliance management, software requirements analysis, and knowledge management and reuse (Bridgeland and Zahavi, 2009). Business models are developed to present different organizational elements, e.g., business goals, organizational structure, business processes and rules. A model is always a certain abstract view of fragmented reality and as such is accepted as valid if it meets all the necessary constraints. The main focus of this paper is Business Motivation Model (BMM) (OMG, 2015), which describes what a business is going to accomplish. This model is considered in a business context, including business environment, strategy, stakeholders, resources, principles and assessments. The paper consists of four parts. The first part contains discussions on motivation of individuals and the whole business organizations. Next part focuses on motivation in business analysis and enterprise architecture (EA) frameworks, in ArchiMate model (The Open Group, 2019), and in Influence Diagram (ID) (Hall, 2010). The third part includes literature review on the Object Management Group (OMG) BMM. This article summarizes the twelve years of business motivation modelling experiences, taking into account the publications in prominent repositories of research papers. Finally, a case study of small and medium enterprise (SME) accountancy bureau is discussed and its business motivation models are presented.

Individual vs. Business Motivation

Generally, people perceive motivation in a positive aspect. Motivation is assumed as vital for social organization development and internal cooperation of its members. The factors, which encourage people to work intensively and creatively, are personal achievements, recognition, advancement, money and power. The need of power is the desire to have impact on other people, to be influential and recognizable, remembered, and to control others. Beyond that, motivation is defined as a mechanism, which influences people to reach organizational or community goals. The concept of motivation is particularly related to the business context and it includes the impact on work behaviour of the environmental factors, as well as business unit capacity, capability and competencies of individual employees (Gaque et al. 2014). The most popular motivation theories are as follows:

Cite this Article as: Malgorzata PANKOWSKA "Business Motivation Model for Information System Architecture Development Support" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- Maslow's Need Hierarchy, which orders the priorities, i.e., physiological needs, safety and security, associations with others, receiving acknowledgement from others, and self-actualisation needs;
- McClelland's Needs Theory, emphasizing the value of personal achievements pushing people to goals despite difficulties, and low rewards;
- Herzberg's Motivator-Hygiene Theory, according to which the achievements, recognition, the job itself, responsibility and advancement opportunities are encouraging people to huge efforts. Herzberg perceived institutional politics, the management methods, supervision, payments, relationships at work, and work conditions as demoralizing factors (Badubi, 2017);
- Vroom Expectancy Theory, which explains that motivation is a product of Valence (i.e., how much an individual wants a reward), Expectancy (i.e., probability that the effort will result in successful performance), and Instrumentality (i.e., estimation that performance will result in receiving the reward).

Business units' motivations concern business strategy, market, stakeholders, current and future economic situation in the enterprise location. At the top of hierarchy of business motives is to stay in market, survive or develop, maximize benefits for the owners and for other stakeholders. There are some other similar questions concerning motivations of business information systems development and the questions are just as important for system analysts, developers, and users. Business organizations choose one of the following strategies, i.e., aggressiveness, proactiveness, leadership, defensiveness, riskiness, market niche, low costs, or elimination of competitors (Bhattacharya, 2018). Business motivations results from these strategies and simultaneously they also play a role in creating business strategy, particularly business strategic goals and information processing strategic goals.

Motivation in Enterprise Architecture Frameworks

The Basic Motivation Model by Rheinberg (2008) explains human behaviour as a result of the current motivation. Motivation emerges from an interaction between personal values, goals, and needs, and the perceived potential incentives in a current situation. For example, analyses of e-business user's behaviour and motivations are useful for business forecasts formulation. Therefore, business analysts should ask:

- What personal motives drive users in online business to engage?
- How do the personal motives interact with incentives provided in online business?
- In what type of motivation do they result and what kind of engagement is achieved by what type of motivation?

In these questions, answers concern customers' behaviour, but beyond that, a similar set of questions can be formulated for business organizations. Business motivation is discussed and presented in enterprise architecture (EA) frameworks. The term "enterprise" is identified with a company, business organization or governmental institution. According to Robins, an enterprise is considered as a "consciously coordinated social entity, with a relatively identifiable boundary that functions on a relatively continuous basis to achieve a common goal" (Hoogervorst, 2009). The enterprise architecture is defined as a strategic information asset base, which defines the business mission, the information and technology necessary to perform the mission, the processes for implementing new technologies in response to the changing mission needs (Stenzel, 2007). For an enterprise, architectural framework as a conceptual structure related to a certain system type consists of areas of concern and a necessary and sufficient set of design domains. There are many frameworks that support the EA modelling and development, but only some of them (e.g., Zachman Framework, ZF, The Open Group Architecture Framework, TOGAF) consider the issue of motivation for architecture development. The ZF defines a basic structure for organizing business architecture through dimensions such as data, function, network, people, time, and motivation (Zachman, 2010). Zachman proposes the ontology for the creation of EA through negotiations among several actors. The ZF presents various views and dimensions of the enterprise architecture in a matrix form. It includes the following levels (i.e., rows) : Scope (contextual, planner view), Enterprise Model (conceptual, owner

view), System Model (logical, designer view), Technology Model (physical, builder model), Detailed Representation (out-of-context, subcontractor view), and Functioning Enterprise (user view). The lower the row, the greater the degree of detail of the level represented. The ZF model works with six aspects of the EA (i.e., columns): Data (what), Function (how), Network (where), People (who), Time (when), Motivation (why). All the views create a complete picture of the enterprise. The question "why" is asked at each level to explain the motivations of enterprise to develop the EA. This reveals the enterprise goals, business plan, and business rules.

Beyond enterprise architecture framework, business motivation issue is also included in business guidelines, i.e., BABOK, Business Analysis Body of Knowledge (BABOK, Guide 3, 2015), EABOK, and Enterprise Architecture Body of Knowledge (EABOK, 2004). Although BABOK primary goal is to define the profession of business analyst and provide a set of commonly accepted practices, this guide emphasizes the meaning of company's reputation value and employee morale. Therefore, these can be considered as motives of business and information system development. The EABOK presents the idea of drivers, which are stimulants for business and architecture development. The same concept is also included in the Federal Enterprise Architecture Framework (FEAF) (FEAF, 2012) and in ArchiMate language (The Open Group, 2020). In EABOK, the drivers are factors, conditions, resources, and other forces significantly impacting the organization and stimulating change. Although drivers are de facto outside the control of EA practices, the influence is important. The TOGAF model comprises three core layers, i.e., Business, Application, and Technology layers. They are supplemented by the Motivation layer extension. Elements of this layer enable modelling the strategy and motivation underlying an enterprise architecture. The Motivation extension in ArchiMate, the TOGAF language, is applied to support the Business Requirements Management, Preliminary and Architecture Vision phases' realization in the TOGAF architecture modelling process.

A key element of ArchiMate Motivation layer is the "stakeholder" that represents an individual or an organization interested in the EA modelling. By definition, customers, business partners, business and application architects, or legislative authorities are stakeholders. Each stakeholder is motivated, as they enjoyed and are challenged by cooperation on the EA development. Their intrinsic motivations can be as follows: culture, personal values, organizational goals, belief system, fairness issues, but extrinsic motivations include group's norms, values, principles, reward and penalty system, recognition, market position, organizational leadership, or group belief. Another key element in ArchiMate Motivation layer is the "goal", which represents some end that a stakeholder wants to achieve. The end is to represent anything a stakeholder may desire, such as a state of affairs, business value or real effect. Typical examples cover revenue increase, service time reduction, or online service duration. However, discussion about these issues needs to be extended. In the context of the EA modelling, a business organization should ask itself the questions: What information do we owe to people with whom we work, and on whom we depend? In what form? In what time frame? What information do we need ourselves? From whom? For EA development, the strategic information modelling needs to consider the purposes of information processing for business decisions. Therefore, the question of "Why" and the justification of information processing are important. Information system analysist should seek answers to the following:

- Why is information necessary to competing in the business today and in the future?
- What priorities for information use and management are appropriate?
- How should managers implement their strategic priorities and achieve improved business performance through people, information, and ICT?
- When and why will the users be satisfied?

The user-customer loyalty is visible in buying behaviour and in communication channel preference for each customer. The satisfaction is visible in repurchasing, revisiting or aftersales questioning.

Literature Review on BMM

The OMG Business Motivation Model (BMM) (OMG, 2015) contains a set of built-in concepts that define elements of business plan, and answer the question "Why" enterprise architecture is to be developed. They are associated in a structure which is technology-neutral. The BMM combines the enterprise goals, strategies and motivations. As usual in the model development process, the BMM identifies fundamental concepts essential for business functioning and the relationships among them. The proposed BMM is to be interpretable by software developers, to communicate with managers, to illustrate the most important issues. A business motivation model describes what a business is going to accomplish, i.e., goals, named here the Ends. The model should explain how the business organization intends to accomplish the goals, what opportunities and threats there are to the business and what the business organization's strengths and weaknesses are. These concepts are included in the Assessments. The Means address how to achieve the Ends and comprise concepts like Organization Units, Business Processes, and Business Rules. There is still the open question of what the fourth element of BMM is, i.e., the Influencers. In this paper, influencers are identified with motivators, incentives, stimulus, or drivers, as it is in the ArchiMate language. In this paper, tendencies of selected economic phenomena are treated as Influencers. Assuming that motivation refers to reasons upon which one acts, the literature distinguishes between intrinsic and extrinsic motives. For example, intrinsic business motives includes the pursue of profit, but it may also involve social responsibility and moral obligations. As regards extrinsic motivations, business managers are stimulated by competitors, customers, or governmental regulations.

This study outline is presented in Figure 1. The numbers of searching results are summarized in Figure 2. The rudimentary reviews were done using the following databases: Association for Information Systems Electronic Library, IEEE Xplore Digital Library, SAGE journals, Science Direct, Emerald Insight, Scopus, and Web of Science.

According to the suggestions on the systematic literature review (SLR) process, firstly, taking into account the mentioned above repositories, the phrase "Business Motivation Model" was searched. However, the number of received results was very high, due to the word "Motivation" appearing in various contexts different from the OMG BMM. Moreover, use of the "BMM" acronym for search did not yield desired results, because it also has other extensions, different from business motivation model. Therefore, further searching was conducted via the search string "Business" AND "Motivation" AND "Model" included in the paper title.

Fig. 1: This Study Structure

Fig. 2: Repository Searching Results

Table 1 summarized different research approaches and findings concerning the BMM characteristics and domains of usage. Regrettably, there are no papers, which strictly answer questions on the BMM for e-business system architecture development. Although the BMM is considered as the most appropriate for motivation analysis, there are also other techniques and notations, which should be taken into account. The Table 2 is about a comparison among ArchiMate, BMM and ID notation aspect. Generally, the influence diagrams are considered as probabilistic graphical models that are particularly suitable to deal with uncertainty as well as with incomplete and imprecise information. The influence diagram (ID) is a visual representation of a decision problem dependent on business functions, determinants, uncertain chances, and business values (Hall, 2010). In this paper, the ID decision reasons are considered as business motives. Business organization has got material and financial resources which are by rules well defined, described and maintained. Business functions have also deterministic character. Business objectives and values are criteria that are expected to be maximized. Constraints on business design and modelling are assumed to be decisions. Business rules, regulations, principles are treated as deterministic reasons.

Table 1: Findings on BMM application in Representative Research (RR)

No	RR	Findings
1	Cui and Paige, 2012	Proposal of a framework that integrates the development of motivation and requirements model at the business, product, system, and software levels. Authors focus on links between the OMG standardized BMM and Systems Modelling Language (Sims).
2	Hinkelmann and Pasquini, 2014	Authors conclude that current motivation model languages are mainly designed to model business strategy, and they do not give the opportunity to distinguish business view elements and IT view elements. Authors propose a modelling technique to improve transparency of the dependencies between business and IT elements.
3	Suri et al., 2017	Authors provide a model-based approach for creating and communicating business strategies and bridging the gap between the

		business strategies and operational processes using BMM model and BPMN notation. They simulate processes to check KPIs to different strategies.
4	Roubtsova, 2012	Author presents how Protocol Modelling semantics can be used both for business process modelling and motivation modelling. Author argues that OMG predicts that BPMN will be merged with the BMM.
5	Vicente et al., 2014	Authors define a specific EA to design organizations according to ITIL's best practices to perform ITSM. They aim to establish architecture's motivation model and the ITIL BMM
6	Lu et al., 2011	Authors extend WS-Policy4MASC language that specifies the BMM concepts for modelling business event.
7	Berkem, 2008	Author links business vision, goals, strategies, tactics and business rules according to BMM for Service Oriented Architecture (SOA) specification.
8	Tonisson and Matulevicius, 2016	Authors apply the semiotic quality framework to compare quality of the BMM and i* modelling language.
9	Feglar et al., 2006	Authors modify the BMM, so instead of SWOT analysis, they propose an ANP (Analytic Network Process) based BOCR (Benefit-Opportunity-Cost-Risk) analysis

Table 2: Similar constructs in ArchiMate, BMM and Influence Diagram

ArchiMate	Business Motivation Model	Influence Diagram
Stakeholder : role of individual, team or organization	Organizational Unit	
Motive: Driver, condition that motives an organization to define its goals	Motive: Influencer, cause of change	Motive: Uncertain reason, event, condition, a chance variable which cannot be controlled directly

SME Accountancy Bureau Case Study

The enterprise architecture model is assumed to help business organizations to specify business requirements and transform them into system requirements to ensure the ICT is functioning in a cost-effective, flexible and reliable way. Modelling system architecture can be interpreted as modelling the structures of processes, information, application components and ICT parts. Taking into account Chandler's idea that "structure follows strategy", business analysis for information system development should begin with the strategy, mission, and vision formulation. However, Chandler (1962) argues that organizational structure is necessary for strategy realization, particularly for production volume expansion, geographic dispersion and vertical integration. The business structure modelling is derived from principles that are based on empirical deduction of observed behaviours or practices. Similarly to system requirements, principles define intended properties of the enterprise architecture (Stair and Reynolds, 2010). Business principles and the EA development principles are formulated not only in scientific research, but also in practice. They are the laws and observations of nature underlying the artefacts. Business analysis is defined as a set of activities that support discovery and creation of business and system architecture principles. The business analysis is an empirical process that is realized by defining the needs and recommending solutions that provide value to stakeholders.

In presented case study, the business analysis was realized at SME accountancy bureau. The selected business organization exists since 2000 and its offer is directed to micro, small and medium enterprises, which want to reliably realize their business. The SME enterprises employ fewer than 250 people. Generally, they focus on their core functions and use outsourcing for non-critical activities. Accountancy services, offered by the bureau, are highly customised in accordance with the client business organization profile. The accountancy bureau supports their customers in bookkeeping, taxpaying and insurance. It is responsible for bills and accounting documentation, and reconciliation. The accountancy services offered by the bureau include trading account books, books of income statements and expenditures, tax cards, payments and social insurance. The bureau provides advisory services on how to begin and decommission a business, as well as account books controls and auditing, tax payment review, financial analysis and reports elaboration. Mostly, the services are realized offline, however, the accountancy bureau needs e-business information system to present actual offers, forms of documents, information on prices and promotions, and current legal acts. This business organization's structure is stable view of the entire enterprise. Taking into account the SWOT (strengths, weaknesses, opportunities and threats) analysis for the accountancy bureau (Figure 3), this business unit's strategy is defined as market penetration and proactiveness. This organization aims to increase its revenue using its existing offers, i.e., accountancy services in existing market of SME clients. However, beyond that, the accountancy bureau is looking for opportunities for revenue increase by creating new services (or increasing the volume of services) targeted at its existing markets. The accountancy bureau has implemented service customisation. This organization does not consider the revenue increase through expanding into new markets, i.e., customer segments, geographic regions, countries. They are not interested in acquiring or merging with any other organization.

Fig. 3: Accountancy Bureau Architecture Motivation and Business Layer View in ArchiMate 3.1

Figure 3 includes Motivation and Business Layer View in ArchiMate language. This language is subordinate to the architectural semantics. In the EA modelling process, stakeholders focus on the following three issues:

- Business – ICT alignment context, i.e., the evolution of ICT systems to align them with business goals and business requirements (Figure 3);
- Context of strategic management of ICT, i.e., the implementation of a road map to transform business requirements into system requirements;
- Context of operating level management of the ICT systems.

The goal of business-driven ICT management is to determine mappings between business and technical requirements, and leverage these mappings to make ICT systems' management decisions that maximize business value metrics. These metrics are presented as key performance indicators (KPIs).

The OMG BMM is expected to specify the high level business motivations as input into design, development and implementation of ICT systems. Even though the BMM integrates four primary motivational elements, i.e., ends, means, influencers and assessment, one may additionally consider checking if the tool supports pursuing answers to questions asked by Zachman, i.e., Why, Who, What, How, Where and When. Similarly as it is in ArchiMate language, the Assessment is a judgement of the impact of an Influencer on the Organization Unit. Assessment includes SWOT analysis and evaluates potential impacts in terms of Risks and Rewards (Figure 3 and 4). On the one hand, the Organizational Unit is able to recognize External and Internal Influencers, define Goals, identify the Strategy and conduct the SWOT analysis. On the other hand, the business Strategy determines the Organizational Unit, what is strictly according to Chandler's thesis. The Strategy is formulated based on domain rules, i.e., SME Accounting Rules, and it is a component of the plan for the organization's Mission realization. The Organization Unit pursues the achievement of its Vision. Goals defined by the Organizational Units operationalize the business Vision. Realization of the

business Strategy requires Business Policy as well as Means, which are understood as human, material and financial resources (Figure 4).

Fig. 4: SME Accountancy Bureau Business Motivation Model in Visual Paradigm 16.2

Regrettably, in comparison with the Zachman Framework, BMM does not contain a simple question of "Why". Nevertheless, the model concepts allow to define business rules, policy, strategy, mission, vision, assets, liabilities, offering, and even influencing organizations, so the model permits to better express an enterprise's governance and management than the models in ArchiMate. In the aspect of motivation, the concept of Value is needed, as it is defined in ArchiMate, because even the Goals and Objectives are not able to express the fundamental values. In fact, the Assessment and SWOT analysis are the basis for an enterprise evaluation in this model. A fundamental assumption of the BMM is that all enterprise activities are driven by how the enterprise decides to react to change. Therefore in the BMM, the changes of economic phenomena are hidden in influencers, as they are included in the ArchiMate drivers. The long term reactions to changes are visible in trends of Key Performance Indicators (KPIs). The recognition of changes caused by influencers and the assessment of their impact on the enterprise website design and e-business development are crucial. The problem is that BMM does not include a specific process on reaction to changes. The BMM is only to support the traceability of business processes, strategy, rules, means, goals, influencers and assessments. There is still the open question on the construction of KPIs. Usually, they concern fundamental economic metrics in a business organization, e.g., cost per sale, revenue, profit, customer satisfaction, margins, customer inquiries, invoice volume (Turban et al., 2011). However, beyond that, there are indicators which concern specific aspects of enterprise functioning, e.g., safety and security, e-commerce, or business sustainability (Parisi and Maraghini, 2010). Generally, they are associated with a process and monitored in real time. Managers are interested in the implementation of KPIs, because organization performance always refers to how well business unit is working to reach its goals. Although there are several typical Google Analytics metrics, the business analyst's task is to specify an idiosyncratic set of metrics for enterprise performance evaluation. Proposed KPI list for the accountancy bureau is included in Table 3. The indicators concern only the analysed accountancy bureau and the transfer of these indicators to another enterprise should not be proposed. Monitoring the KPIs motivates the company managers to constantly reformulate business strategy and operations. Figure 5 presents the business strategy as decision dependent of uncertain and deterministic variables in ID diagram.

Fig. 5: Influence Diagram on SME Accountancy Bureau Motivation in SmartDraw Online

Table 3: Key Performance Indicators for Accountancy Bureau e-Business System

Assessment			
External Positive Impact	**Internal Positive Impact**	**External Negative Impact**	**Internal Negative Impact**
Users and New Users	Website Goal Completion	Bounce Rate	High Cost per Sale
Sessions	Number of Sessions/User	User Language different than Website Language	Long Time of Order Execution
Average Session Duration	Page View Browser	User Geographic Location	Amount of delay
Percentage of New Sessions	Sales per Download	Business Rules Changes in Year	Lack of Competent Employees
Returning Users	Profit per Sale	Legislation Changes	Lack of Knowledge Management to deal with Customer Requests
Frequency of Sales	Revenue per Sale	Insurance	Number of Questions per Employee
Website Content Downloads	Customer Satisfaction	Tax Payment	Number of Emails or Phone Calls per Employee
Valid Contacts	Profitability	Interest Rates	High Complexity of Business Procedures
Brand Image	Margins	Foreign Exchanges	Long Process Realization Duration
Reputation	Investments	Debt and Lease Compliance	Process Changes
Customer	Invoice Volume	Social Changes	Inefficient Cash Flow

Inquiries			
		Staff Turnover	Credit-bad Debts
		Salary Inflation	ICT Resources Obsolescence
		Theft	Fraud and Resource Misuse

Conclusions

Noting that a large volume of publications on work motivations exists, authors focus and justify mostly individual motivations, although there are journal papers and books on business organization motivations as a separate issue. However, there are still too few publications on the EA development motivations as well as on motivations for any computer application implementation and deployment. In motivation models the focus should be on drivers, influencers, motivators stimulating or discouraging to act. In this paper, case study has been presented and three different notations applied to emphasize the motivation of information system development. Proposed KPIs allow for an assessment of the Influencers' impact and they are connected with the business strategy.

m.okreglicka@wp.pl

Abstract

The entrepreneurial orientation is a very important construct to assure the proper functioning of an organization. For the purpose of this article, a five-dimensional concept of the entrepreneurial orientation has been adopted. This article aims to identify the challenges and threats that must be faced by individuals within an organization, depending on their position in the hierarchy. In order to collect some necessary data we conducted interviews with employees representing various levels in the chosen organization. The data reveal that the perception of the entrepreneurial orientation differs depending on the held position. Based on the collected figures, we formulated an additional conclusion of how important it may be for all employees to stay informed and acknowledge the adopted strategy, regardless their position within the company. When being properly informed and thus entirely aware of the implemented strategy, employees are prone to entrepreneurial activities.

Keywords: Entrepreneurial Orientation, Organizational Culture, Organizational Level

Introduction

Recent decades have brought relentless interest in research into the role of the entrepreneurship in business development. Therefore, the entrepreneurial orientation (EO) is perceived as one of the most important elements having a significant impact on the position of enterprises in their business environment. Entrepreneurial activities undertaken by organizations require substantial commitment and courage to go beyond common operating schemes, focus on research and development, take risky activities, promote innovation, and autonomy in action. The entrepreneurship cannot be planned, and what is more, it cannot be caught up in the pre-defined variants, nor can it be subordinated to the vision imposed by power or belief (Bratnicki, 2007).

The EO is a strategic orientation of an organization that defines its strategic activities, its management philosophy and entrepreneurial behaviour (Anderson et al, 2009). It is based on a coherent set of interrelated activities and processes that support autonomous activities such as seeking for new solutions, readiness for risk-taking and being aggressive towards competition. Entrepreneurially oriented organizations have the ability to discover and seize market opportunities (Ferreira, 2015).

A substantial number of publications concerning the role of the entrepreneurship in various organizations encouraged me to carry out an analysis of the EO perception by employees on various levels of the hierarchy. However, we decided to focus on a company from the SME sector with an undeveloped organizational structure, since only very few research in this area have been published. This article aims to identify the challenges and threats to the entrepreneurial orientation and analyse them from different points of view, depending on the position in the company.

Cite this Article as: Agnieszka FILIPOWICZ And Małgorzata OKRĘGLICKA " Need for Entrepreneurial Orientation from The Perspective of Different Organizational Levels" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

For this purpose, we chose the case study method. Individual, partially structured in-depth interviews were conducted with people employed at various hierarchical levels of the selected enterprise. This approach can be considered as innovative in the field of research on entrepreneurial orientation in Poland.

The article consists of four parts. To begin, the first part introduces the theoretical background, followed by the second part describing the research methods, the third part presents the obtained results, and the conclusions and discussion end the article.

Literature Review

Entrepreneurial orientation and the impact of organizational culture on entrepreneurship development

Entrepreneurial orientation was originally defined as a three-dimensional construct, where innovation, risk-taking and proactivity were key aspects/dimensions describing entrepreneurial-oriented organizations (Covin, Slevin, 1991; Miller 1983). By the same token, these three dimensions are, so far, the most known and they have been the most studied (Rauch et al., 2009).

Ongoing research of entrepreneurial orientation let scientists supplement this construct with two new dimensions: autonomy and competitive aggressiveness. According to the definition proposed by Lumpkin and Dess, "construct EO"' is an aggressive, innovative, proactive, risky and autonomous process/behavior (Lumpkin, Dess, 1996), and a set of actions based on human, technical or managerial resources, requiring diverse skills and knowledge for its implementation (Illés, Dunay, Jelonek, 2015). These dimensions may occur with different intensities, depending, among others, on the environment of the firm (Dyduch, 2008).

According to the empirical research conducted so far, companies with a higher degree of the EO achieve better results (Wang, 2008; Wiklund, 1999; Zahra, 1991; Zahra, Covin, 1995). It is also important to outline that the entrepreneurial behaviour within the company can be, both, encouraged or impeded by the organization itself (Covin, Slevin, 1991). Therefore, the thorough understanding of the EO process by the firm and its added value for the development of the company is crucial. The key factors supporting the process of implementing the EO in an organization have been identified as follows: organizational structure, leadership and organizational culture. Covin and Slevin mention these three factors in their scientific work and emphasize that the organizational culture have a very strong impact on entrepreneurial attitudes (Covin, Slevin, 1991), since it is an integral part of the enterprise and should be treated as an important organizational tool (Zouhayer, 2013). The work environment of a given entity is essential for the development of entrepreneurship within this organization. Therefore, building a strategy based on autonomy, cooperation and commitment helps create a conducive environment for entrepreneurship (Kyrgidou, Hughes, 2010).

In consequence, it is pure evidence that a company focused on achieving better financial results, should constantly acquire entrepreneurial units, develop an organizational culture conducive to entrepreneurship and entrepreneurial leadership. D.F. researchers Kuratko, R.V. Montagno and J.S. Hornsby set five conditions that must be met to stimulate internal entrepreneurship:

a) adequate remuneration, which aims to stimulate entrepreneurial behaviour of the employee,
b) support from the management in undertaking entrepreneurial activities,
c) access to resources (including time) enabling undertaking entrepreneurial activities,
d) support of the organizational culture,
e) latitude at work (Kuratko, Montagno, Hornsby 1990).

The role of various hierarchical levels of an organization in shaping entrepreneurial attitudes of their subordinates, is the key factor to effectively develop entrepreneurship within a company. The input of an individual to their company and the time they work for it, is strongly connected with the quality of the relationship with their managers (Wudarzewski, 2012). The main challenge of modern management is to use properly the skills and commitment of individuals in the organization and to allow them participate actively in shaping the strategy of the organization (Bratnicki, 2004).

Challenges related to entrepreneurial orientation at various levels of the organizational structure

As revealed by the previously quoted scientific studies, entrepreneurship should be an inseparable element of every organization, and its employees should demonstrate a high degree of entrepreneurship, regardless of their level in the hierarchy. Nevertheless, the position in the hierarchy of the company may considerably influence the challenges to face by an employee. By consequence, the entrepreneurial orientation may be perceived in slightly different ways.

The highest level of an organization is responsible for developing and then communicating to subordinates the vision and mission of the firm coherent with the established strategy. It is the role of the top management to allow carrying out experiments or questioning the beaten tracks leading to success (Bratnicki, 2002). The top level of the organization is responsible for obtaining resources, assessing development possibilities, implementing new ideas or estimating risks associated with projects implementation (Belousova et al. 2010; Havierniková et al., 2019). Its role is to promote and encourage entrepreneurial behaviour among lower level managers or employees.

Lower level managers represent a real connection between low level employees and the top management of an organization, therefore their role in the good functioning of a firm is invaluable. They are supposed to apply a top-down approach not only to communicate the company's vision and strategy to lower level employees, but also to clearly express the company's expectations towards its employees. Lower level managers take actions to influence their subordinates to show entrepreneurial attitudes in their daily duties (Grzegorzewska-Mischka, 2010).

The role of an ordinary employee is, in essence, quite simple and they expect the company to clearly precise and communicate its requirements towards them. By consequence, it is crucial to eliminate all potential administrative and formal barriers between ordinary employees and their subordinates that could eventually impede a proper communication. The emotional support of an employee such as encouraging and comprehensive attitude towards their initiatives and sometimes unsuccessful attempts to introduce changes, is more efficient to develop entrepreneurship than general declarations or meaningless assurances (Francik, 2009).

In addition, the character of an individual, is also a strong factor which determines a capacity to adopt or not the entrepreneurial attitude. Personality may often become a source of difficult to overcome self-limitations and barriers. However, an access to some necessary knowledge at university, can help develop and stimulate entrepreneurial attitudes that will be transformed into an entrepreneurial behaviour at work (Okręglicka et al., 2017).

Methodology of empirical research

The aim of this article is to identify challenges and threats to the entrepreneurial orientation, perceived by members of the organization at various levels of the organizational structure. To this end, we carried out a qualitative study based on partially structured individual in-depth interviews with employees of a Silesian company, operating in the children's industry since the nineties.

The research was carried out at three levels of the organization - employees, managers and top managers/CEO. Two representatives were selected from each group. The selection of representatives from the group of ordinary employees and managers was based on the scope of duties and seniority.

Each interview consisted of two parts: the first part explains the purpose of the interview, while the second part is the substantive part of the interview. Each interview lasted about 60 minutes.

The research questions were related to the selected issue, and the interviewees were asked the following questions:

Table 1: Questions in the interview questionnaire

EO dimension	Question
Autonomy	1. Do you know what is a role of the autonomy as a component of the entrepreneurship orientation? 2. How do you assess the approach of the company to suggestions and ideas of change submitted by employees? Should employees at all levels submit their ideas? 3. How the company supports independent actions of employees, leading to the development of new products or services? 4. Can you evaluate, how many ideas of changes submitted by employees have a chance to be implemented?
Innovation	1. Does the company take into account the innovative ideas of its employees which have an impact on research, development and innovation? If yes / no, why? 2. What new products have been introduced to the market during the last 3 years. Have they let the company remain innovative in comparison with the competitors? How many of them were proposed by the employees? 3. What changes proposed by the employees have been implemented to the products, in order to make them innovative on the market? 4. Do you think that the implementation of innovative ideas, research and development is important for the company?
Proactivity	1. Do you think that it is important for the employees at all levels to be proactive? If yes / no, why? 2. What are the recent activities, undertaken by the employees, that you consider as proactive? 3. Do you think that the company tends to copy the solutions already available on the market or is the company more breakthrough-oriented to become a precursor of the industry? Please explain your answer. 4. What is the company's attitude towards competitors?
Risks-taking	1. How do you assess the risk-taking capacity of the employees at your organizational level? 2. Can any activity recently undertaken by the employees of a given organizational level be considered risky? If so, why?
Competitive aggressiveness	1. What actions should be taken at a given hierarchical level to strengthen the competitive position of the company on the market? 2. Please specify whether the actions taken towards other competitors can be considered as aggressive. If so, please list these actions and provide arguments.

Source: Own study

Results of empirical research

The employees on all levels of the organization mentioned the entrepreneurship as important for the company, no matter the held position. However, each of the five dimensions was assessed as more or less important for different hierarchical levels in the company. The study put on evidence how essential is for the company to clearly communicate the organizational culture and the adopted strategy to its employees on lower levels of the hierarchy. By the same token, getting a clear message from the top management helps the employees understand the company's expectations but also its long-term goals and priorities.

Perception of the entrepreneurial orientation from the level of senior managers

Top level management, represented by the CEO and the Head of Sales department, considers autonomy and proactivity as the most important dimensions of the entrepreneurial orientation on its level of responsibility, whereas the competitive aggressiveness and the risk-prone attitude do not seem essential

for the senior management. On the contrary, the last dimension of the EO concept, the innovation, is a subject of some substantial points of divergence within this group.

According to one of the managers: *innovation is "an important dimension because it has a direct impact on the development of products and offered services",* however, this opinion does not meet the CEO's approach to innovative ideas, who declares that:

"Some theories recommend not to involve the entire organization in this process, therefore, we decided to deal with innovative ideas on the ownership level. The rest of the organization comes into the process only when the idea has been approved. The initial process of changing the brand strategy or repositioning of products and services is entirely managed by the owners of the company. Our employees are invited to collaborate only when the idea has been set in motion. Recommendations of the marketing, sales and quality control departments are of course taken into account, but they represent only a small part of the innovation process. In other words, a new, innovative idea is always a result of long-term goals set by the owners. Therefore, we pay attention to a feedback provided by the aforesaid departments, but in fact the concept is initiated and elaborated by the owners or by cooperating companies, e.g. brand strategy specialists. "

Perception of entrepreneurial orientation by lower level managers

The group represented by lower-level managers put an accent on the three of the five EO dimensions: innovation, propensity to risk and competitive aggressiveness, whereas autonomy and proactivity were considered of moderate importance. Given that it is in the interest of all organizations to stimulate autonomy and proactivity among lower level managers, the results may seem surprising and rise questions. A strong focus on autonomy and proactivity within a company encourages its employees to take up independent actions and initiate improvements that contribute to a development of their position or of the whole organization. Moreover, a lack of support from the organization was pointed out, by one of the managers, as the real issue for a development of autonomous activities at the company: "*The person who submits an idea is immediately charged with the responsibility of its execution and supervision during the entire process, from the beginning up to its implementation, even if certain activities go far beyond their skills."*

Perception of entrepreneurial orientation from the level of an ordinary employee

In this group, we can notice the greatest discrepancies in the perception of individual dimensions of the entrepreneurial orientation. Almost all dimensions are poorly represented in this group. Ordinary employees see no need to take up autonomous or risky activities, and consider proactive behaviour at work as moderately useful. On the contrary, the innovation is seen as the only dimension having a strong impact. By consequence, the low-level employees declare a strong need for submission of innovative ideas, but can this attitude persist in the future if not supported and encouraged by the CEO? The risk to discourage the employees from submitting innovative ideas is real, and this not only regarding their own position but also when it comes to products or services of the company. Against the background of the entire organization, this group assesses the risk propensity dimension as the least important. This may result not only from the fear of taking risky actions but mainly from the fear of baring possible financial consequences resulting from these actions. By the same token, it is the responsibility of the organization to encourage ordinary employees to take up risky activities in a predetermined framework, if they can have a positive impact on the productivity of the entire organization. Senior or lower level managers should be responsible for setting the latitude framework of an employee in order to let him take up risky actions without being afraid of consequences.

Table 2: Perception of the entrepreneurial orientation at various levels of the studied organization

EO dimension	Ordinary employees	Lower level managers	CEO (owners)/ Senior managers
Autonomy	+/++	++	+++
Innovation	+++	+++	+/+++
Proactivity	+/++	++	+++
Risk-taking	+	+++	++
Competitive aggressiveness	+	+++	+

„+" – weak; „++" – moderate; „+++" – strong
Source: Own study

According to the collected data, there is a substantial difference in the assessment of the importance of the EO dimensions from the perspective of the particular hierarchical levels of the organization. However, the most striking aspect of this analysis is a completely different perception of the innovation by the ordinary employees and the lower-or higher-level managers in comparison with the perception of this dimension by the owners of the organization (CEO). By consequence, one can draw a conclusion that the company suffers from some significant lacks in the inter-hierarchical, top-down communication in terms of goals and priorities. The top-level management delivers an inconsistent message regarding the company's priorities to the employees of the lower hierarchical levels, which discourages them from submitting innovative ideas. An insufficient internal communication may also push the employees of the organization to focus on activities considered as irrelevant by the CEO. Therefore, the key factor to achieve better financial results is to properly formulate and deliver a clear message to the lower levels of the hierarchy, in order to synchronize the priorities of the top-management with the actions taken by the members of the entire organization. In addition, some special attention should be paid to the weak assessment of the proactivity and autonomy by one of the ordinary employees. During the research, the aforesaid employee clearly expressed that proactive or autonomous activities are not in his nature. In relation to the above, the HR department should consider to put a stress, during a recruitment process, on personal characteristics of an employee's character. This may help avoid later frustration on both sides caused by the discrepancy between an employee's attitude and expectations of the enterprise that cannot be met, because they are not in the nature of the employee. On the other hand, if the organization decides to hire without checking personal predispositions, it must, as an organization, put more effort to develop expected behaviours for each particular level of responsibility within the company.

Conclusion

As already presented at the beginning of my article, the EO is one of the most important parameters influencing the success of an organization. Without a highly developed EO, it is impossible to build an entrepreneurial organization, successful within its industry. The purpose of this article was to examine the perception of the EO dimensions from different organizational levels, in order to observe to what extent, the individual perception of each dimension may vary depending on the level of the organization. Nowadays, most companies must operate in the fast-paced business environment, therefore the entrepreneurship of owners becomes a key factor to guarantee the effectiveness of an organization they manage (Listwan, 2004; Havierniková et al., 2017). Furthermore, the entrepreneurial attitude should also become a priority for every member of the organization regardless of their role. Communicate long-and short-term goals to each member of an organization seems essential to let them have a full knowledge of the company's strategic choice, adjust their actions and thus build a coherent entrepreneurial orientation.

We would like to emphasize that this article has some limitations. The research was conducted within one enterprise only, each level of the organization was represented by only two members, and the respondents' answers may be affected by an error. The provided answers may not be fully consistent with the actual perception of the examined issue due to the willingness of the respondents to embellish the reality. The study contributes to increasing the knowledge resources in the field of the

entrepreneurship and encourages the authors of the article to further study the perception of entrepreneurial orientation by members of both Polish organizations and organizations located in other European countries or organizations based in e.g. Asian countries.

The Measurement of Organizational Efficiency In Chosen Food Processing Enterprises in Poland

Anna ZIELINSKA-CHMIELEWSKA

Poznań University of Economics and Business, Institute of Economy, Poznań, Poland,
E-mail address: anna.zielinska@ue.poznan.pl

Abstract

The issue of efficiency of food processing enterprises is ever-present because of the continuous process of improving the quality standards of raw materials, complying with the procedures in food production, introduction of modern production technology and, above all, due to the large number of actors who are competing for customers in the domestic and foreign food market. In the coming years Polish food processing sector will be facing significant challenges with the inevitable slow and gradual decrease in the cost advantages of raw materials' prices, as well as ready to eat products. Enterprises, as they constitute the majority in manufacturing business, in the long run will need to determine the efficiency, and hence competitiveness of Polish food processing sector. The aim of the paper is to review the domestic and foreign literature in terms of classification and systematization of the concept of organizational efficiency in chosen food processing enterprises in Poland. In the theoretical part of the study methods of descriptive, comparative, deductive and synthetic analysis are used. In the practical part of the study appropriately selected qualitative methods such as questionnaire is presented. The results of the analysis is based on the results of authors' own calculations, as well specific findings from business practice both from inland and abroad.

Keywords: Effectivity, Efficiency, Organizational Efficiency, Food Processing Sector.

Introduction

Food economy is one of the most important sectors of economy in every country because of its significance for production and employment, but above all, in connection with the supply of food to the society. Food economy is a collection of many different economic systems that influence organizational structure, methods of operation and financial performance of the production chain actors. Entities in the food processing sector operate in an environment with high exposure to the risk of business activity (Zielińska-Chmielewska, 2014).

Food processing enterprises strive for continuous and steady supply of raw materials to carry out production which would correspond to the changing needs and preferences of the consumer. The food market is an arena where various operators, which are different in character, intensity, strength and direction of impact, come into play. One of the main obstacles for food processing enterprises is the difficulty of obtaining stable and predictable income which would guarantee the continuation of production and remaining a going concern. What is characteristic and typical for agriculture and agro-food industry, is the fact that prices of raw materials fluctuate all-year round but retail prices of finished products remain relatively rigid. All of the above strongly affect the efficiency of the agribusiness operators in the market. In Polish food processing enterprises occurs concentration and integration between entities in the production chains, which has accelerated after Poland's accession to the European Union. Existing foreign publications in this field based on decades-old experiments confirm the need for conducting multi-step quantitative and qualitative research, in the field of systematic identification and evaluation of economic efficiency of food processing enterprises. On the basis of theoretical analysis and empirical results of previous studies, a hypothesis has been formulated: The organizational efficiency of food processing enterprises results from optimizing the use of modified

activity areas and trade policy which are affecting the level of effectivity achieved by the examined enterprises.

The paper consists of 5 sections: *Introduction*, which defines the problem, subject matter and puts forward the hypothesis of the research, *Discussion on the classification of efficiency measurement in the economic studies* defines efficiency and effectivity including modern context with crucial points referring to current knowledge based on the relevant results of recent research, presentation of *Methodology, empirical data and analysis* subjected to re-testing existing documentation background, *Results and discussion on the assessment of organizational efficiency* focused on explaining its economic significance and insights, and *Conclusions* supplemented by verification of the hypothesis, assessment of research results, attention to problems and limitations of the research, guidelines for future research and assessment of institutional and systemic implications and solutions for current state of research. In the last section of the article *References* are listed.

Developing research on efficiency of food processing enterprises is extremely needed and constitutes a useful tool for policy makers on food market in terms of obtaining information about the validity of its operations, the need to make the necessary modifications, eliminating the potential risk of operation, and thus minimizing risk of bankruptcy and liquidation (Zielińska-Chmielewska, A., Alihodzić, A., Smutka, L., 2019, p. 1087).

Discussion on The Classification of Efficiency Measurement in The Economic Studies

The article reviews domestic and foreign literature in order to present and make the necessary comparison of economic efficiency, methods of measuring it, taking into account various advantages and disadvantages of its use. The study applies method of analysis and reasoning, and in particular the methods of descriptive, comparative, deductive and synthetic analysis. The results of the analyses are based on the results of author's research and studies.

Based on literature, it can be concluded that the concept of efficiency consists of efficiency and flexibility. Efficiency (also known as economic effectiveness) includes economic, technical and non-economic efficiency. The economic effectiveness can be viewed from two independent perspectives: financial and productivity-related. Non-economic efficiency includes organizational, operational and dynamic efficiency. Economic efficiency is the ratio of the obtained result to inputs. According to the principle of rational economy, it means that certain results should be achieved at the lowest expenditures (costs) possible, or the best possible result should be obtained with a given quantity of inputs (costs). The higher the efficiency is, the greater result per unit of effort is. Efficiency is applied both in assessing the effects which are of a quantitative nature (as a ratio of the effects to expenditures) and qualitative (as the ability to achieve the desired effect). Methods commonly used for assessing overall efficiency are based on three approaches: relying on ratio, parameters and non-parameters.

Economic effectivity is the primary standard valuation in economics (Wilkin, 1997, p. 25). It should be distinguished from the English-language word effectiveness, often translated into Polish as *skuteczność*, meaning that a desired effect was eventually achieved by more or less effective method. Effective operation does not mean that it was at the same time efficient. For the process to be efficient and effective, goals must be properly planned, and the results have higher value than costs.

Table 1: Comparison of economic processes according to the criterion of efficiency and effectiveness

The economic process	Efficient	Inefficient
Effective	planned economic objectives of the process are achieved, and the final results are of higher value than expenditures set for the planned economic objectives	Planned economic objectives of the process are achieved, but the final results are of lower value than incurred expenditures
Ineffective	Planned goals of the economic process are achieved, but the value of final results is higher than incurred expenditures	planned economic objectives of the process are not attained, and the value of final results is lower than incurred expenditures

Source: (Nowosielski, 2008, pp. 39-46).

In the systemic approach efficiency is the ability of a company to shape its environment, so that it becomes favorable and has the ability to overcome any obstacles. From this perspective, businesses are open systems that try to optimize the processes of acquisition and use of scarce resources from the environment. In this way, they are able to gain or maintain a competitive position. Therefore, effectivity is the ability to overcome the uncertainty surrounding the company. The essence of effectivity are incurred expenditures, transformation processes and final results. Evaluation of effectiveness involves identifying the ability to obtain resources, and then determining the extent of their use.

Economic Efficiency – Concept, The Advantages and Disadvantages of Parametric and Non-Parametric Approach

The analysis of domestic and foreign literature in the field of measuring organizational efficiency, as a part of economic efficiency lead to the conclusion that the concept of efficiency is diverse, multi-dimensional and can be classified in various ways. Science and economic practice increasingly often use measures constructed on the basis of microeconomic definition of effectiveness (Domagała, 2007; Mielnik, Szambelańczyk, 2006). Economic efficiency can be measured in a parametric and a non-parametric manner. Table 2 presents advantages and disadvantages of parametric methods.

Table 2: Comparison of advantages and disadvantages of parametric methods

Advantages	Disadvantages
Not necessarily large in size, the population of research objects makes it possible to conduct an analysis on the basis of which it is possible to formulate substantive conclusions	The need to make assumptions about the form of the production function and define the relationship between inputs and outputs
	Difficulty of observing "all" possible combinations of inputs and outputs for the analyzed entity
	Difficulty in specifying the mathematical form of the production function and consequently its mathematically identified interpretation
	The necessity of averaging data when estimating its parameters, as a result of which the empirical values deviate from the values of estimated model
	The regression curve determined on the basis of model values is not a limit of effectiveness since it does not cover all observations

Source: own preparation.

In the parametric approach, efficiency is calculated on the basis of the production function, which determines the relation between inputs and outputs with regard to technologically efficient production

processes. The parameters of this function are determined using classic econometric estimation tools. The parameters of the production function are estimated or calibrated based on statistical observations. The values of the production function are determined on the basis of a normative efficiency model, and deviations from them result from random errors or inefficiency of the examined entity (Panek, 2002). In parametric methods, the measure of effectiveness can be the rest of the model or the quotient of the empirical value of the result and its value obtained from the model. Table 3 presents advantages and disadvantages of non-parametric methods.

Table 3: Comparison of advantages and disadvantages of non-parametric methods

Advantages	Disadvantages
The design of the model is not fixed *a priori*, but adapted to the data, making it more flexible compared to parametric models	The need for knowledge of linear programming procedures
Lack of knowledge and skills required by previous methods to divide input (inputs) and output (outputs) variables properly[1]	Achieving a similar level of materiality as in the parametric models requires more objects in the sample
No need to formulate the functional relationship between inputs and outputs beforehand	The results are less, or not at all, independent of population distribution and outlier observations
Multi-criteria evaluation, i.e. the impact of multiple input variables on multiple output variables	
Non-parametric methods are insensitive to outliers, which is why they are so-called robust methods.	
The interpretation of the results does not require the adjustment of parameters to any distribution, thus eliminating methodological and interpretation difficulties	
No need to take into account a random factor in determining the effectiveness of the entity and the impact of potential measurement errors	

[1] *In non-parametric models, it is possible to check which of the variables are input and which are output, such that if the input variable does not lead to an increase in efficiency, it is the output variable.*
Source: own preparation.

In a non-parametric approach, efficiency is calculated as the ratio of actual productivity to the highest possible productivity (Helta, 2009). Functional parameters are determined on the basis of models that do not require a functional relationship between inputs and outputs. Using mathematical programming methods and empirical observations the shape of the efficiency limit is determined. The value of the efficiency measure is determined on the basis of the position of the examined entity relative to the efficiency limit. The basic methods of non-parametric approach include DEA (Data Envelopment Analysis) and FDH (Charnes, Cooper, Rhodes, 1978). Table 3 presents advantages and disadvantages of non-parametric methods.

Organizational efficiency – concept, the advantages and disadvantages of questionnaire-based methods

The first documented measurements of the organization's performance id dated for the 13th century A.D. and concern the double accounting records (Bitititci, Garengo, Dörfler and Nudurupati, 2012). However, it was only in the 1990s that strong development of methods for measuring the efficiency of enterprises. Researchers agreed that the concept and measurement of effectiveness are of a complex nature and require the use of both internal and external information, both of a qualitative and a quantitative nature. Pun, White (2005, p. 50) are of the opinion that, by appropriately compiling all the

necessary information a company can compare its efficiency with its competitors and at the same time can identify areas for modification and improvement, as well as establish long-term monitoring plans for progress and achievements. In response new concepts that take into account multidimensional aspects of efficiency companies have been developed.

Katz and Kahn (1966, p. 164) proposed to understand the concept of organizational efficiency as 'maximizing the return to the organization by technical, economic and political means". On this basis Zbierowski (2008, p. 10) developed a model of a highly effective organization in which he took into account the most important features, such as: strategy, culture, people, structures, tasks, systems. Whereas Rummler and Brache (2000, p. 46) presented organizational effectiveness in three dimensions: organization, process and workplace. In each of these dimensions they indicated different factors that affect the organization's effectiveness. They found that effectively managed efficiency requires the formulation of objectives while managing each of the three dimensions. Bielski (1997, p. 114) identified the following dimensions of organizational effectiveness: factual, economic, systemic, political, cultural and behavioral patterns to which he assigned certain indicators and measuring instruments. According to Weiss (Szymańska, 2011, p. 42) effectiveness may be considered according to criteria: productivity, production, morale, adaptation, development organizational, survival, which should permeate each other, and the direction of their mutual. The impact depends on the system model functioning in the economy economic, financial or legal. Price and Lawless, on the other hand, believe that the evaluation efficiency requires taking into account productivity, morale, conformism, flexibility, institutionalism, stability (Skurzyńska-Sokora, 2011, p. 11).

In the paradigm of a new institutional theory organizational efficiency has its social and organizational context with the relationship between enterprises and people. The operational context of an enterprises is expanded. Table 4 presents advantages and disadvantages of questionnaire-based methods.

Table 4: Comparison of advantages and disadvantages of questionnaire-based methods

Advantages	Disadvantages
The study is of a systematic nature	Conducting the study is expensive
It is possible to determine the scale and size of data variables	The tests are time-consuming
Groups can be compared with each other	Difficulty in obtaining representativeness of studies
Determination of factors influencing the examined phenomenon	
The mechanisms of activities of the analyzed issues can be better understood	

Source: Creswell, 2013; Grabowski, 2013; Paluchowski, 2010.

The latest concepts for assessing organizational efficiency include models business excellence model taking into account the trend of a comprehensive quality management. These models define the management areas requiring the development and application of the best leading solutions to the lasting, long-term success of members of the organization, customer satisfaction and society. Ziębicki (2010, p. 12) presented the concept of organizational efficiency together with changes in the course of development and evolution of the theory of organization and management. The results of the assessment of efficiency are presented in the form of a comparison of contemporary concepts of effectivity assessments.

According to Bratnicki and Austen (2010, p. 41-48), the efficient organizational measurement system should consist of the following attributes:

- to analyze and discuss phenomena of interest in a clear and concise manner for stakeholders,
- to go beyond control and give credible insight to improve efficiency,
- to develop and continuously stimulate a company's improvement,
- to focus on processes and these issues of business, which are affected by them, such as:

quality, time, finances, customers' satisfaction, human resources,
- to help to predict a company's direction,
- to allow the use of measurement measures resulting from current combination of activities strategies with strategic objectives of a company,
- to provide quickly detailed information in order to support appropriate decisions and action which could have been taken,
- to be simple, understandable, economical,
- to take into account different analysis' perspectives as well as cause-and-effect relationships.

Methodology, Empirical Data and Analysis

In theory of organization and management the organizational efficiency is defined as the ability of an enterprise to adapt to current and strategic changes in the environment and the productive and economical use of the resources available to implement the adopted structure of objectives (Penc, 1997, p. 100). In the article a structured questionnaire with a clearly defined research objective to measure the organizational effectivity was used. All questions were presented to the respondents in exactly the same way as regarding content and form. The questionnaire contained closed questions, so called simple questions (answer: yes/no), questions with options for answers (a/b/c/d), questions requiring a scale of assessment of responses (1 - least, 5 - the most), deeply closed questions (deliberately reopening the question in another parts of the survey to check the accuracy of the respondent's answers) (Finstad, 2010, pp. 104-110; Sobczyk 2003), closed questions giving respondents the possibility of ticking and completing the answer "other - what?" and the questions to track changes over time were used. In the questionnaire, the options for answering were not exhaustive for a respondent. The order scale has been used for reasons of clarity and for the sake of mapping the diversity and ordering the measured characteristics.

Table 5: Presentation of the research characteristics

Research subject	Objects, territorial and temporal scope	Measurement methods and tools	Current application of methods
Evaluation of organizational efficiency	Database on enterprises operating in food processing sector in Poland	Questionnaire: CAWI technique	A few analyses in Poland and in the world

Source: own preparation.

According to Kaczmarczyk (2011), surveys belongs to qualitative measures, collected in a database that have to be cleaned, verified, and analyzed by means of statistical methods. The questionnaire consisted of the main part dealing with the organizational efficiency to indicate the scope of enterprises' operations, modified areas of their operations and trade. The supplementary part consisted of information on the spatial and geographical location, legal personality and the number of permanent employees in a company. The overall size of the research sample was determined on the basis of standard sizes for specific types of research presented in the literature on marketing research (Kramer, 1994). Entities were selected based on the EMIS Intelligence/Professional database from the period 2010-2017. The criterion for dividing meat processing enterprises into small, medium and large was determined by the volume of processing of the slaughter, the number of employees employed on a permanent basis and the volume of net sales revenue obtained. Small enterprises employ from 10 to 49 people, process more than 7.5 tons to 20 tons of slaughter per week, and generate sales revenue of up to 100 million PLN per year. Medium-sized meat enterprises employ 50 to 249 people, process 20 to 100 tons of slaughter per week, and earn sales revenue of 101-499 million PLN per year. Large meat companies employ more than 250 people, process more than 100 tons of slaughter raw material per week, and generate sales revenue of more than 500 million PLN per year. The main study was preceded by a pilot study conducted in chosen ten food processing enterprises in Poland. Analysis of completed questionnaires in the pilot study showed that the respondents had no difficulties filling them in. The same questionnaire was used in the main study. The data had been collected, processed and analyzed with regard to the following operations:

- editing and checking the questionnaires,
- entering and encoding the data in the STATISTICA worksheet (version 13.1),
- taking into account the level of measurement of the variables in the qualitative, orderly scales) and the value categories of the variables under investigation according to the format survey questions (answer categories, text/label values, numerical values, scales 0/1, 1-3, 1-5), thus enabling their categorization,
- random control of the results in terms of the completeness of the questionnaire answers,
- the final sample N = 100 companies functioning in domestic meat sector,
- all surveys with a single one lacked answer were rejected,
- to carry out tabulation, i.e. counting the cases belonging to different categories,
- statistical grouping by type and nature variables,
- determination of descriptive statistics depending on the type and nature of variables,
- conducting additional analyses for selected variables, cluster and factorial analyses,
- generating partial reports in STATISTICA (tables/charts),
- developing a collective result report with a graphical presentation data in the version for editing (WORD MS Office).

The aggregate raw data in the Excel file to the statistical package STATISTICA for further statistical treatment has been transferred. The CAWI method was carried out in the period from 1.01.2017 to 31.12.2017. The questions required answers about the state of the examined phenomenon in 2017 and 2010 to compare the changes taking place over time. The return of the online questionnaires was about 20%.

Research Results and Discussion

Table 6 shows the scope of activities of the analyzed meat processing enterprises. From the opinions of respondents, a picture emerges, in which small meat processing enterprises concentrated theirs activities in the production and sale of meat and meat products to the local market. Small meat processing enterprises are family businesses, most often established in the 1990s. Their owners gained experience and boast a tradition in production. They are not geared towards consolidation. Ownership changes follows the transfer of companies to younger members family, restructuring or disposing of unnecessary assets. Small businesses have maintained their presence on the market because customers have purchased meat and meat products from domestic producers at their home villages. Unfortunately, after 2013 the increase in consumption of poultry meat did not compensate for the fall in beef consumption and some small businesses went bankrupt (Chechelski and Krawczuk, 2015, p. 26). Difficulties of small and medium-sized enterprises meat results from a low level of specialization, producing several dozen types of products which does not allow for effective use of the equipment or to conduct effective marketing and advertising. On the meat market, the chances are good the largest and most specialized companies have to survive (Chechelski and Krawczuk, 2015, p. 27).

Table 6: Scope of activities of analyzed groups of meat processing sector in Poland

The most important trade markets	Meat processing enterprises					
	Small		Medium-sized		Large	
	2010	2017	2010	2017	2010	2017
Local	yes	yes	yes	-	No	-
Domestic	no	no	yes	yes	yes	yes
International	no	no	no	yes	yes	yes

Source: own study.

Medium-sized meat processing enterprises produced and offered products for the local and domestic market, and some of them tried to expand their activity outside the country. Large meat processing enterprises did not intensify their efforts to maximize sales of meat and products to the regional market, but maintained domestic sales and expansion outside Poland. The biggest threat to medium-sized and

low-turnover companies may be the so-called average revenue trap - about PLN 50-150 million (Soliwoda, 2012). The research shows that the following directions of business activity will develop (Drożdż, 2013, p. 20-24; Chechelski, Krawczuk, 2015, p. 28; Chyłek, Niepytalski and Śliwa, 2016, p. 2-6):

- concentration of small and medium-sized enterprises on production on the local market involves a search for market niches and/or holding an established position of a local brand, f. ex. production of traditional products on local markets, development of own store chains, cooperation with small retail chains on the domestic market;
- cooperation of medium-sized and large enterprises with retail chains involves the production of several product ranges in long batches, under the following conditions and under the brand name of retail chains, which means dependence on retail corporations and cost reduction;
- branded manufacturers' association under “brand name” (f. ex. *Polish sausage*, *Cracow ham*) involves a search for the expansion on the foreign markets by major meat companies with foreign capital. It means strong competition from transnational corporations and the need to increase sales revenue;
- building its own company brand involves a search for investment in research and development of innovative production and large financial outlays. It is a strategy suitable for large, economically strong companies as it requires competition with transnational corporations;
- building its own corporate brand and working with commercial corporations. It is a combination of cooperation of medium and large companies with retail chains and building its own corporate brand. This strategy is being pursued by large companies and global corporations with an established position in the market.

Fig. 1: The validity structure of modified areas of activities in meat processing enterprises in Poland

Source: own study.

Figure 1 presents the validity structure of modified areas of activities in meat processing enterprises in 2010 and 2017. In 2010 and 2017 the most frequently introduced changes in the functioning of all analyzed size groups of meat processing enterprises involved a search for increasing the number of improvements and innovations. In 2010, for 72% of medium-sized and 66.7% of large meat companies the key to improving their operations was the introduction of improvements, mainly organizational and innovations in the production process. The second, equally strongly modified area of functioning indicated by 64-66% of medium-sized and large meat companies and 38% of small businesses resulted from the increased use of technologies which improved the production processes. The implementation of so-called "modern" investment technologies, which are rationalizing the consumption of raw materials, materials and energy played the decisive role. The third area indicated in 2010 by 60% of large and 60% of medium-sized meat companies, and in 2017 by 72% of large and 72% of medium sized meat companies was an increase of the machinery and technology park use. This was due to the basic action to reduce material intensity and optimize the design of machines and equipment,

technologies and products. In 2010 54%, and in 2017 83.5% of small meat companies did not introduce changes in the use of the machinery and technology park. As the only ones they have intensively increased their means of transport from 7.7% (2010) to 23% (2017) and thus extended the territorial impact area.

Fig. 2: Structure of the answers on existing marketing relationships in and between analyzed groups of meat processing enterprises in Poland

Source: own study.

Figure 2 presents the structure of answers to the question about the nature of relations in the analyzed groups of meat processing enterprises in Poland. In 2010 and 2017 60% of respondents in slaughterhouses indicated that they competed with each other and fought for the customer. Many of the small, local meat processing enterprises have cooperated with others slaughterhouses, which was due to the fact that all of them operated the same purchasing facilities. In 2010 20%, and in 2017 10% of the analyzed slaughterhouses were cooperating with each other and did not fight for the customer. In 2010, 10%, and in 2017, 17.5% of slaughterhouses tried to find niches for themselves, so as not to fight for the customer. This was the case with slaughterhouses producing cold cuts. Large and medium-sized meat processing enterprises competed with each other and fought for the customer. Outside the protocol, in backstage conversations, the owners of local slaughterhouses admitted to working with their rivals, which was due to the rigidity of demand and little chance of increasing the number of customers. Small meat processing companies took steps to find market niches. In the years 2010-2017 poultry enterprises did not cooperate with each other, but competed and fought for the customer.

Poultry enterprises operating on a local scale also searched for market niches in order to ensure a relatively safe area of operation. High competition and pressure to act very quickly was noted in poultry enterprises, finding market niches in poultry production and processing was difficult.

Table 7: Countries with which there was trade in analyzed groups of meat processing enterprises in Poland

Specification	Export		Import	
	EU countries	Non-EU countries	EU countries	Non-EU countries
2010				
Slaughter-houses	Germany, the Netherlands, Belgium, France	Bulgaria, Romania	-	-
Large meat enterprises	Austria, Germany, France, the Netherlands, Belgium	Sweden	Germany, Denmark, Spain	-
Medium-sized meat enterprises	Germany, Lithuania, Latvia, Estonia, Repubic of Ireland	Belarus, Bulgaria, Romania	-	-
Small meat enterprises	Germany, Czech Republic, Slovakia	-	-	-
Poultry companies	Germany, France, Belgium, the Netherlands, Austria	-	-	-
Commercial enterprises for meat and meat products	Germany, France, Belgium, the Netherlands, Austria	Switzerland	-	China, USA,
2017				
Slaughter-houses	Germany, the Netherlands, Belgium, France	South Korea	-	-
Large meat enterprises	United Kingdom, Italy, Germany, Slovakia	China, South Korea, USA, Japan	Germany, Danemark, Spain, the Netherlands,	Argentina
Medium-sized meat enterprises	Slovakia, Czech Republic	-	Germany	-
Small meat enterprises	Czech Republic, Slovakia, Germany	-	Germany	-
Poultry companies	Germany, France, Belgium, the Netherlands, Austria	Ukraine, Hong Kong, South Korea	Germany, Slovakia	-
Commercial enterprises for meat and meat products	Germany, France, Belgium, the Netherlands, Austria	South Korea	-	China, USA, Argentina

Source: own study.

Table 7 shows a list of countries with which the analyzed groups of meat processing enterprises have traded. In 2010 slaughterhouses exported carcasses to Germany, the Netherlands, Belgium, France, as well as Bulgaria and Romania, which at that time were not EU countries. In 2017, slaughterhouses continued to export to most EU countries as well as to non-EU countries such as South Korea. Large meat processing enterprises exported carcasses and meat products abroad. Between 2010 and 2017, the number of countries and directions of trade increased, mainly exports. In 2010, carcasses and meat products were exported to Western European countries, f. ex. Germany, France, the Netherlands, Belgium, Austria, Sweden, and to the south - Bulgaria and Romania. In 2017, Polish meat was exported to the UK, Italy, Germany and Slovakia, and outside the EU to China, South Korea, the USA and Japan. Large meat processing enterprises imported carcasses and meat products from Germany, Denmark, Spain and the Netherlands. Poultry companies in 2017 in comparison to 2010 expand their trade to include exports of meat products with non-EU countries, such as: Ukraine, Hong Kong, South Korea, and imported to a small extent alive from Germany and Slovakia. Trade and service undertakings for meat and meat products have been widely traded with countries both within and outside the EU. In 2017 they traded with China, the USA and Argentina.

To sum up, polarization on the Polish meat market is expected in the coming years. Small and medium-sized companies will cover local and regional demand. Large enterprises should be prepared for production on a large scale and in narrow specialization, f. ex. production of products for mass consumer (retail chains) and for export. Such a model is already implemented in developed European countries. A small number of large meat companies with national capital will compete with global companies. Most Polish meat companies will have to subject to conditions imposed by transnational corporations, which "push local companies into the role of subcontractors and sub-suppliers, leaving them as the main coordinators, organizers and market creators (Chechelski and Krawczuk, 2015, p. 27).

Conclusions

To highlight future reflections it has to be said that the basic process of human activity is management, which is a process of conscious, rational, unforced decision making, which, on the one hand, must balance unlimited human needs, and on the other hand, limitation of resources. It is extremely important to stress that in the environmental context, a company uses human resources, land, tangible and financial capital, so as natural resources, raw materials, energy carriers, geographical space and capacity assimilation of the natural environment. It means that the company has right to emit pollution due to the fact that results of the production process are pollution and waste (Hałasa and Rumianowska, 2000).

According to the conducted research, the hypothesis has been positively verified. Organizational efficiency depends on the level of optimizing of modified activity areas along with trade policy based on crucial foreign partners.

The analysis of domestic and foreign literature in the field of measuring organizational efficiency of food processing enterprises lead to the conclusion that the concept of efficiency is diverse and multi-dimensional and can be classified in various ways. The difficulties concerning the efficiency measurements have arisen from the characteristics and properties of different approaches and methods of its assessment.

Therefore, the obtained results will be used in further analyzes of factors affecting the level of maximization use of inputs using existing and modified methods of the efficiency measurement. An attempt to develop a new concept for measuring and assessing the efficiency of food processing entities may have an influence on actions, entities affected by those actions, and may lead to the redefinition of the state's role in the stabilization of domestic food processing sector.

The results can be helpful in creating a strategy for companies, development institutions and creating economic policy programs in agriculture, helping adjust the activities of related entities in the agro-food market, as well as determine the role of the state in terms of stabilization of the domestic meat market and to gain the significant competitive advantages.

Abstract

The volume and the structure of bank's loans depend on a number of factors. They include the level of financial system development and market competition, the structure of the economy, market demand and risks, the relevant regulation, bank size, the management and the shareholders preferences, etc. The structure of loan portfolio directly affects the profit and loss account, as well as the level of bank's exposure to risks, which is in the core of bank management. The paper analyses the sectoral structure of banks' loans in the USA, the Eurozone and especially in the Republic of Croatia. The credit policy of banks in Croatia is in the focus of this research, with the aim to determine the causes and consequences of the loan portfolio structure among banks distributed by size. The results of the research confirm the dominant importance of granted loans in the balance sheets of all observed banks and regions, as well as the similarities in the sectoral structure of loans among banks. Finally, on a sample of Croatian banks, the paper presents some findings that sectoral restructuring of banks' loan portfolios in recent decades, at least from a profitability perspective, is not always justified.

Keywords: bank loan structure, bank credit policy, bank profitability, market trends, Croatia

Introduction

Banks are traditionally the most significant financial institutions. As financial intermediaries, they buy direct financial receivables characterised by a set of specific features, and transform them into indirect receivables with a different set of features. Essentially, Madura (1997) states that banks grant non-liquid and risky loans on the basis of liquid and non-risky deposits, given that they are familiar with the needs of their clients, and with required risk management of such transformations.

However, due to recent changes and developments in the global financial system, banks are slowly losing their specific and privileged position. Today's highly competitive local and international financial markets are marked by new and improved methods and models of financial services creation, distribution, by simplified and accelerated communication among financial market participants, and by lower costs of labour and of data storage and processing. In addition, there are new market participants, namely different financial specialists who base their business operations on applying modern technologies (FinTech).

The result of these trends and changes is increased competition among banks, as well as between banks and other financial institutions in nearly all segments of their business operations. Under these conditions, most banks in the developed countries are redefining themselves in order to adapt to the

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

new environment. To accomplish business de-specialisation, banks are changing their strategies and business models. The idea that the de-specialisation of the banking business has become a pre-condition for their sustainability and market competitiveness has become widely accepted. Therefore, banks are engaging in a growing number of new, non-traditional and off-balance sheet activities. One of the consequences of these changes is the growing complexity of the structure of banks' profit and loss account.

However, the possibilities, needs and dynamics of banking business transformations are not the same everywhere, nor are they the same among banks of different sizes. As a result of either external or internal limitations, the share of modern, non-traditional credit and non-credit services and the related income differs among banks. For instance, small banks, due to the lack of economy of scale, do not have the same opportunities for modernising their business operations as do large banks, which frequently operate on the international market as well. This is due to limited financial and human resources, as well as the limited demand on the local market small banks usually serve.

Finally, in the bank-based financial system such as Croatian, banks, as the most dominant financial institutions on the market, do not have the same need to change their business philosophy and strategy, as do banks in market-based financial systems. In those markets the competition between banks and other financial institutions is much fiercer, hence their need for more frequent changes.

The aim of this research is to determine the impact of the structure of banks' loan portfolio on their profitability, particularly on the average return on assets (ROA). The paper is structured in following way. In the introductory part of the paper, the changes in the contemporary banking environment are presented, as well as their impact on banks' business policies. The second part of the paper looks at trends, significance and sectoral structure of loans in banking systems of selected developed countries (the US, Eurozone). The third part provides a descriptive analysis of the banking system of the Republic of Croatia, and the fourth part gives an overview of data sources, methodology and panel analysis variables. Research results are presented in part five, followed by discussion and conclusion.

The significance and structure of loan portfolio of contemporary banks

The volume and the structure of loans in bank's assets depend on a number of factors. They include the level of financial system development and market competition, the structure of the whole economy, the relevant regulation, market risks, bank size, affinities of the management and the shareholders, etc. In the traditional sense, loans generate the greatest income, but also pose the greatest risks. In other words, the structure of loan portfolio directly affects the profit and loss account, as well as the level of bank's exposure to risks, which is in the core of bank management. For those reasons, bank's specific credit policy is the concern not only of the management and the shareholders, but also of supervising authorities and, given its impact on the overall economic developments, of the general public.

The portfolio analysis approach usually implies that loans account for more than 50% of banks' assets, and the rest are other investments. These include investments in government and agency bonds, reserves with the central bank, or foreign currency receivables, etc. Likewise, banks invest little in stocks or shares, especially if investment in the subordinate financial institutions are exempt. On the other hand, Koch and MacDonald (2014) state that the most important source of loan financing and other forms of banks' investments are households' deposits, while deposits received from other sectors and other forms of debts hold much less significance.

The arguments suggesting the key importance of loans for banks' business conduct in developed countries are supported by the data published by Federal Deposit Insurance Corporation (2019) and European Central Bank (2019). At the end of 2018, granted loans made up an average of 56% of total assets of US banks, in the EU this percentage is nearly 63%. However, some countries in the EU deviate from the average (Fig. 1), so the share is around 89% in the Czech Republic, 76% in Austria, 75% in the Netherlands, around 72% in Poland and Italy, or quite low 55% in Great Britain.

Fig. 1: The structure of banks' assets in selected EU countries, 2018

Source: Prepared based on ECB, Statistical Data Warehouse, 2019

The sectoral structure of loans provides a very important view of bank's business conduct. The analysis of the data on total loans granted to households and non-financial corporations (Table 1), as the two most significant sectors in the overall structure of loans, shows that the lending activity of banks, or of monetary institutions in the Eurozone (money issuing sector in the Eurozone; includes credit institutions and money market funds, excludes Eurosystem), was in almost any given year to a greater extent directed at households.

There are many reasons for this practice. In any case, the sectoral distribution of loans is a consequence of concrete decisions and perceptions of banks' management regarding the ratio of potential profit and risk in the conditions of a specific competitive market environment.

Therefore, the fact that banks target the household sector more is in some countries, such as the US, largely a result of increased competition in financing non-financial corporate sector on the financial market. Specifically, in the past several decades investment and pension funds, hedge funds, and other institutional investors have been taking a more prominent role in developed countries, thus becoming a more important source of financing of the non-financial corporate sector. Under these conditions, it becomes quite understandable that banks increasingly prefer granting loans to households as a pragmatic alternative. Household demand for loans is mostly predictable and stable, the loans granted to households are in most cases less risky and/or easier to foreclosure, and interest rates are usually higher than on loans granted to non-financial corporations. In addition, banks' lending and other activities related to households provide them with a growing number of services and non-interest income. It is therefore no surprise that banks focus their activities over last couple of decades at households, supported by modern technology.

However, greater focus of banks on the household sector can be found in the markets in which the described competition still does not exist, or has only a symbolic meaning. In these countries, banks are evidently motivated solely by commercial criteria and profitability, and they assume that the focus on loans to household will make it easier for them to meet their targeted profitability. In this process, the non-financial corporate sector's needs for external financing are to a large extent deliberately neglected, at their expense, of course. In the conditions of underdeveloped or unavailable alternative sources of financing, inadequate financing of the corporate sector results in multiple negative consequences. Policy paper by Deutsche Borse Group (2015) mentions following negative consequences which were all visible during the latest economic crisis in the EU: frequent cases of illiquidity and inability of fast recovery of a large number of non-financial corporations, increased job instability in the corporate sector, delaying key investments, which are in fact the precondition for their recovery and the overall economic growth, increased uncertainty and generally negative expectations.

Descriptive analysis of the Croatian banking sector

The situation in Croatia is similar to that in other countries analysed so far, as granted loans are by far the most important asset of the entire banking system. What is more, since the adoption of the first market-based Act on Banks and Savings Banks in 1993, banks have increased their lending activities significantly, and their share in the total assets has continually grown. In particular, from a very low 42.8% in 1993 to 67.6% in 2011, the year when granted loans reached their percentage peak, followed by a slight decline due to the 2008 recession and subsequent slow recovery of the Croatian economy. Finally, in late 2018 granted loans reached a respectable 58.1%, which matches its share in developed countries.

Table 2: The share of loans and their structure in Croatia's banks (%)

Year	Total loans / total assets	% loans to households	% loans to corporations
2018	58.1	60.1	39.9
2017	57.9	58.8	41.2
2016	60.7	58.0	42.0
2015	62.7	58.8	41.2
2014	63.9	57.8	42.2
2013	66.3	57.1	42.9
2012	67.0	57.3	42.7
2011	67.6	54.1	45.9
2010	67.0	55.8	44.2
2009	66.7	56.0	44.0
2008	66.7	57.2	42.8
2007	62.7	57.2	42.8
2006	61.6	55.3	44.7
2005	58.4	56.0	44.0
2004	54.6	55.2	44.8
2003	53.8	52.8	47.2

1993	42.8	11.4	88.6

Source: Based on the Croatian National Bank's official data, 2019

The structure of granted loans by Croatian banks also points out to the general trend of a relative decrease of non-financial corporate loans compared to household loans, a trend which is much stronger in Croatia than in other analysed countries. The fact that in 1993 far more loans were granted to non-financial companies than to households (88.6% vs. 11.4%), whereas in 2018 the situation reversed and the ratio changed to 60.1% for households and 39.9% for corporations, represent one of the most significant changes that occurred in the Croatian banking system so far. Reaserch by Leko and Stojanović (2006) concluded that this trend of increasing loans to households is a result of a turn in credit policy made by large banks in Croatia.

Data and methodology

The data was obtained from the Croatian National Bank, which is, among others, responsible for the supervision of credit institutions. The research covers the period from Q1 2004 to Q2 2017 (54-time observations, quarterly and anonymized data). Although the retrieved data contains the information from the financial statements of all active banks in each quarter, the research focused on 26 banks which were active in the entire period, equalling to 1,404 observations for each variable. For the purpose of the statistical analysis, banks were divided into subgroups according to their size and loan portfolio structure, as shown in Table 3.

Table 3: Bank groups – size and loan portfolio structure

Groups by size		
Group name	Description	Number of banks
Small banks	Average individual assets less than 0.5% of total banking sector assets	11
Medium banks	Average individual assets between 0.5% and 5% of total banking sector assets	9
Large banks	Average individual assets greater than 5% of total banking sector assets	6
Groups by loan portfolio structure		
Group name	Description	Number of banks
Household	Percentage of loans to households greater than 50% of total approved loans	8
Neutral	Percentage of loans to households or non-financial corporate sector less than 50% of total approved loans	8
Non-financial corporative	Percentage of loans to non-financial corporate sector greater than 50% of total approved loans	10

Source: Prepared based on the data retrieved from the Croatian National Bank, 2018

At this point it must be highlighted that categorising banks into the first group (>50% of loans granted to households) or the third group (>50% granted to the non-financial corporate sector) by no means indicates that they do not grant loans to clients belonging to other sectors. It merely points to the majority share of the sector selected based on the credit policy. Therefore, despite the fact that none of the large banks granted more than 50% of their total loans to the non-financial corporate sector, in absolute terms these banks remain the most important creditor of all business sectors, including corporations. For instance, out of the total of 68.8 billion HRK of granted bank loans to corporations in 2016, large banks approved as much as 53.3 billion HRK, amounting to 77.5%.

Fig. 2: Banks performance indicators, according to size and sectoral structure of loans, quarterly (%)

Source: Prepared based on the data retrieved from the Croatian National Bank, 2018

The data from Graph 2 indicate that in relative terms small banks approve far more loans to non-financial corporations than to households. On the other hand, the distribution of loans granted by large and medium-sized banks across sectors is quite similar, although the size of their average assets differs significantly. If the use of loan potential is analysed through the ratio of total approved loans and total received deposits, it seems that in the longest observed period the loan activity of medium-sized banks is the lowest, although that of small banks is not much better. Ultimately, in the past several quarters, small banks have achieved the lowest loans to deposits ratio. When also relatively high general administrative expenses and depreciation costs of small and medium-sized banks, their higher value of provisions and impairments (except for one quarter), and, finally, increasingly equalized net interest margin among all banks are taken into account, the dinamics of banks' ROA indicators distributed according to their size becomes quite understandable.

In other words, banks' lending policy across sectors is not decisive for their success or failure. The key variables of banks' acceptable profitability are size and economies of scale, cost efficiency, and finally the quality of loan portfolio. Under these conditions, it is no surprise that in the longest part of the observed period large banks achieved the highest and the most stabile ROA, whereas medium-sized banks, despite their quite similar sectoral loan distribution, achieved significantly worse results (even the worst in some quarters). Unfortunately, average ROA indicators of small banks were, for similar reasons, the lowest in most cases.

This hypothesis was tested using the econometrical analysis. In order to analyse the determinants of banking profitability and cover individual bank data (cross-sectional aspect) and time observations (longitudinal aspect), the panel analysis is used. ROA is used as a dependent variable and a proxy of banks' profitability. At the same time, the ROE indicator was not used due to its high dependence on financial leverage.

Since based on the Levin-Lin-Chu test certain variables had a unit root, all variables were transformed using first differences to ensure stationarity. Both fixed and random effects models were conducted, where the effects of omitted individual-specific variables are, by Hsiao (2014), treated as either fixed constant over time or random variables, depending on the model. Additionally, the Hausman test was conducted to estimate which of the two models should be preferred.

Upon choosing the dependent variable, a set of key independent variables was chosen to determine the factors influencing the level of banks' profitability. Most of the variables refer to bank-specific variables, while GDP was chosen as a key macroeconomic variable. The detailed description of all variables is presented in Table 4. Three sub-models were considered based on the inclusion of a different number of variables in each model. Firstly, only variables related to the loan portfolio structure, size and risk level were taken into account, followed by the addition of the loan-to-deposit ratio in the second model, as a proxy of loan scale potential. Finally, gross domestic product was added in the model as a macroeconomic variable. Panel analysis was conducted using EViews 10.

Table 4: Variables description

Notation	Variable	Measure
DEPENDENT VARIABLE		
ROA	Return on assets	Net profits after taxes/total average assets
INDEPENDENT VARIABLES		
Bank specific determinants		
L_COR	Loans to non-financial corporate sector	Loans to non-financial corporate sector/total loans
L_HOU	Loans to households	Loans to households/total loans
SIZE	Bank size	Logarithm of total assets (log)
RISK	Expenses on value adjustments and provisions	Logarithm of expenses on value adjustments and provisions (log)
LTD	Loan-to-deposit ratio	Total loans/total deposits
Macroeconomic variable		
GDP	Gross domestic product	Year-on-year rate of growth (in %, constant prices, quarterly)

Results

The descriptive statistics of all included variables is shown in Table 5. The average ROA in the Croatian banking sector in the observed period is 1.01%, ranging from -22.08% to 9.70% in different periods and different banks. A somewhat higher percentage of loans is on average given to households and the minimum and maximum values indicate that individual banks favour certain economic subsectors. The average GDP growth rate is 1.17%, demonstrating internal weaknesses of the Croatian economy and longer recession effects.

Table 5: Descriptive statistics of included variables

Variable	Mean	Median	Standard deviation	Minimum	Maximum
ROA**	1.01	1.12	0.58	-22.08	9.70

** Billions of HRK (Croatian kuna). ** %.*
Source: Authors' calculation based on the data retrieved from the Croatian National Bank, 2018

The results of the panel analysis indicate key determinants of the banking sector profitability in the Republic of Croatia. Firstly, the size of the bank and the risk level are the key factors determining bank's performance and success, both in fixed and random effects model at the 1% level. According to the results of the Hausman test and relevant p values (which are greater than 0.005), random effects model should be preferred. The highest coefficient is assigned to bank size and positive value indicates that larger bank size increases the ROA indicator. The expenses of value adjustments and provisions have the highest negative effect on bank's profitability.

Regarding the loan portfolio structure, only the percentage of loans to non-financial corporate sector is significant at the 5% level, but with a very weak positive coefficient. The percentage of loans to households is additionally significant at the 10% level when loan-to-deposit ratio and GDP are added to the model, although with low coefficient level, similar to the one for non-financial corporations.

Therefore, other bank-specific variables besides loan portfolio structure seem more important for a bank's performance and profitability level. Surprisingly, GDP growth rate is not a significant factor for the banks' profitability. This can be explained by the fact that the Croatian banking sector maintained relatively stable profitability levels despite the recession between Q4 2008 and Q3 2014. Finally, at the onset of the economic recovery in 2015, the banking sector recorded losses of HRK 4.6 billion, associated with extraordinary one-time expenses arising from the implementation of regulatory changes related to the negative impact of the Swiss franc – HRK exchange rate growth, which was not related to the issue of sectoral credit policy of banks.

Discussion and Conclusion

The analysis of the structure of loan portfolio of the banks in the US, in the Eurozone and in Croatia indicate a general trend of a relative decline in granting loans to non-financial companies and growth of granting loans to households. There are multiple reasons for this development, and the two most significant ones are competition and focus on profitability in a risky environment. Strong competition between banks and other financial institutions, or banks and the capital market in some cases (e.g. in the US, where according to the The Federal Reserve System (2019) the share of banks' assets in total

assets of all financial institutions was only 20.4% in 2018;), resulting in the loss of a part of corporate clients, can be considered a justified reason for a change in banks' sectoral lending policy. The question is how the same trend observed in countries in which such competition is not present is to be explained.

In those countries, including Croatia, banks still do not have serious competitors in non-banking financial institutions, let alone in the capital market (the share of banks' assets in financial institutions' total assets in 2018 amounted to 64.9% according to the Croatian National Bank and Croatian Financial Services Supervisory Agency (2019)). In addition, the analysis of the sectoral distribution of bank loan portfolio in Croatia shows that the biggest relative turn from non-financial corporations to households was made by large banks, which in fact do not have strong competitors in either smaller banks or the rest of the financial system. Unfortunately, the available data do not enable the analysis or the quantification of specific reasons or expectations from banks' strategic decisions, but their business results and general market trends do point to some conclusions. It seems that banks motivated solely by commercial criteria and the imperative of profitability expect that their focus on extending loans to households will facilitate their profitability preferences.

And yet, the change of interest rate spread on selected sectoral deposits and loans justifies such expectations only partially. As Graph 3 shows, only the household interest rate spread on kuna deposits and loans deviates significantly from the interest rate spreads in other cases. On the other hand, given that Croatian households prefer saving in foreign currency, with kuna loans remaining the most expensive ones (due to limited household sector kuna deposits), the level of interest spread for kuna deposits and loans is not surprising, but it should not be the key reason for a strategic turn of banks' lending policy across sectors in Croatia. For instance, after the crisis arose in Croatia in the second half of 2008, the significance of household foreign currency deposits increased further. So, in late 2011 they reached nearly 80% of total deposits of that sector. On the other hand, that same year kuna loans dropped to only 23% of total granted loans to households. Data by the Croatian National Bank (2019) indicate that ffter the crisis, the trust in domestic currency increases again, so by the end of 2018 household foreign currency deposits dropped to a still high 65%, whereas the share of kuna - domestic currency loans grew to only 53% of total granted household loans, the level still unimaginable in developed countries.

Fig. 3: Credit institutions' interest rates spread on deposits and loans to households and non-financial corporations (percentage points, on annual basis)

Source: CNB, Statistical data, Interest rates, 2019

On the other hand, the level of individual interest rates should not be analysed alone. That is, when interest rates and interest spread are combined with widely present, technology-enabled standardisation

and automatization of financial services provided to the household sector, it is not surprising that some banks have expectations that household loans will result in regular operational costs decrease, and eventually in greater profit. However, if this concept is right, why don't small banks follow the logic of the large ones? It seems that only reasonable answer to this question is – because they cannot, or, in other words, they have no choice. It can only be assumed that small banks would like to see the change in their existing credit policy, given that in the longest observed period they achieved the lowest average profitability on assets. However, they have no possibility of doing so in the very limited potential of local market they serve.

Finally, and most importantly, middle-sized banks' business results suggest that the sectoral structure of granted loans does not necessarily contribute to the rise in profitability alone; the panel analysis has shown that the volume and quality of loans contribute to the profitability to much greater extent.

The conducted analysis does not lead to definite and final conclusions on the appropriateness and justification of sectoral loan policies of the banks in either the Croatian or the global market. However, it does indicate that the expectations of some professionals and the market participants from the "easier path to profit" through the household sector alone are not justified. What is more, they can have direct negative consequences on economic development. Purposefully avoiding granting loans to non-financial companies, in the conditions of undeveloped or unavailable alternative sources of financing, has multiple negative consequences, which is an issue that requires further research. It must be emphasised that the described changes in sectoral lending policies are not the result solely of the of bank management decision. They are also the result of bank shareholders' expectations, created in coordination with the expectations from other, comparable investments. In addition, they are the result of the risks in the environment, and of regulatory institutions and the government, whose laws affect not only banks' lending policies, but also their entire business strategies, frequently without a clear vision of the potential consequences.

Abstract

This study aims to examine the dynamic causality relationship between energy consumption and nonoil-gas economic growth in Indonesia. ARDL and Granger-Causality model are used in this study for the annual data for the period from 1988 to 2018, or total samples are 31 years. The results show that energy consumption has a positive and long-run effect on nonoil-gas economic growth in Indonesia, vice versa. The effect of energy consumption on nonoil-gas economic growth than the effect of nonoil-gas economic growth on energy consumption. Besides, energy consumption has a short-run effect on nonoil-gas economic growth, and causality is a one-way direction. This means that energy consumption is crucial for nonoil-gas economic growth both in the short-run and in the long-run. Because energy consumption is essential to the Indonesian economy, it is recommended to provide green energy to support further economic growth as well as environmental protection.

Keywords: Energy Consumption, Nonoil-Gas Economic Growth, ARDL, Granger Causality

Introduction

Energy is a significant need for economic activities. With energy, the demand for goods and services will be created to impact the economic growth of the real sector (nonoil-gas) of a region. Besides being used to meet various needs, the energy itself can be used to achieve prosperity for the community for its management. The existence of energy influences the production of all goods and services, which is, therefore, very important in industrial development (Nnaji, 2013). Not only industrial and household activities that require energy, but technology, the creation of sophisticated manufacturing and transportation tools also require energy in its application.

Indonesia currently has a net oil importer status, where oil consumption is more derived from imports compared to production. This is done considering the energy needs in the country experienced a significant increase. Figure 1 shows Indonesia's energy consumption; there is an increase in comparative growth every year. The growth trend of energy consumption in Indonesia that moves significantly to achieve the economy in Indonesia not have too much impact on the slowdown in global trade, as is the case between the United States and China in 2019.

Figure 1: Energy Consumption and nonoil-gas GDP of Indonesia, 1988 – 2018
Source: BPS, 2018.

From 2003 to 2013, Indonesia's energy consumption continued to increase from year to year in line with the increasing rate of development and the improvement of people's lifestyles. The increase in almost all sectors of industry, transportation, commercial, household, power generation, and other sectors, in fact, the higher the level of national energy consumption is directly proportional to the economic improvement (Shen, 2018). Increasingly, the growing number of industries supporting the economy. With the increase in industry players in Indonesia, the economy has also shown an increase. The more widespread the industry that stands in Indonesia, they also helped improve the trade balance so that it directly affects the country's foreign exchange.

Indonesian economy continues to grow by 5.02 percent (YoY), while household consumption is still growing 5 percent which is one of the pillars of national economic growth, which is 2,298 9 trillion or 56.52 percent of the national gross domestic production (GDP) which reached 4,067.8 trillion in the third quarter of 2019. The increasing tendency of energy use also affects the increase in economic activity, which will automatically lead to the rise in society's economic growth. Also, there are obvious obstacles that can be seen with the increasing demand for energy. Meanwhile, the energy source itself has decreased, so it needs to be empirically assessed so that the role of energy consumption on economic growth can be analyzed empirically quantitatively. The study on the effect of causality between energy consumption and nonoil-gas economic growth is significant, considering that as one of the developing countries, development and supply of energy are substantial. This analysis can be one of the studies that can meet the shortcomings of this study in Indonesia. Based on these considerations, this study was conducted so that it could fill the gap in the absence of empirical evidence about this in Indonesia.

Literature Review

There are several studies between energy consumption and economic growth. Like Jaganath (2015), examining the difference between energy consumption and economic growth in India from 1970 to 2011 with the Granger causality and variance decomposition approach states that the level of GDP growth leads more to natural gas demand and no energy growth variable has an influence on GDP growth. In contrast to the decomposition variance test shows that there are two directions of causality between electricity consumption and future economic growth and shows the direct effect of economic growth on natural gas consumption. Dogan and Deger (2016) say that globalization and the economic growth of Brazil, Russia, India, and China affect energy consumption in the long run. They also find based on the Granger Causality Test, which states there is a direct causal correlation between total energy consumption and economic growth, and similar also occurs in the globalization variable on economic growth.

Faisal et al. (2017) examine energy consumption and economic growth in Belgium starting from 1960 to 2012, showing a long-term relationship between energy consumption and economic growth using the Granger Causality test. Besides that, economic growth is seen from GDP has a positive effect on energy consumption both in the long term or short term. Whereas Hasanova et al. (2017) assess energy growth in ten oil-exporting countries find some variables are co-integrated, but between GDP and energy consumption do not have a short-term causal relationship. They concluded that energy

consumption is cointegrated with GDP and has a positive effect in the long run. Based on tests, Granger shows the unidirectional causality between energy consumption and GDP. Yasar (2017) documents a causal relationship between energy users and economic growth, and in the long run, there is a positive causal relationship of economic growth to consumption energy.

The relationship between electricity consumption and economic growth in Southeast Sulawesi using the Granger Causality test and the Autoregressive Distribution Lag (ARDL) states there is a robust causal relationship and has a positive effect. From the results of this study, the researchers also concluded that every 1 percent increase in electricity consumption would increase by 0.3 percent. In the short term, there is a weak relationship between electricity consumption and economic growth but provides a substantial contribution to Southeast Sulawesi in the long run (Rahim et al. 2018). Aliasuddin and Ramadhana (2019) examined the economic growth of energy consumption in APEC countries and India with the Panel ARDL approach. This study uses alternative energy that is renewable energy, such as water energy. Alternative energy use, such as renewable energy, is an essential key in meeting future energy consumption. The study results explain that economic growth has a positive and significant effect on water energy in the short and long term. Increased water energy can reduce the number of carbon dioxide, especially for those producing carbon dioxide.

According to Ozturk (2010), there are four possible causal relationships between economic growth and energy consumption. Growth hypothesis (growth hypothesis) in which the condition of one-way (unidirectional) influence of energy on growth. Growth requires energy, and energy reduction will hinder growth. Furthermore, shows they also conclude that a country is not wholly dependent on energy for growth, and the policy of energy conservation can be done with little or no adverse effect on growth. When the economy grows, energy demand increases, and vice versa. The neutrality hypothesis, which confirms energy and economic growth, is neutral with each other, and the implications of energy conservation policies do not affect economic growth.

Research Method

This study uses annual data for non-oil and gas economic growth and energy consumption from 1982 to 2018, with a total sample of 31 years. Economic growth data uses nonoil-gas GDP data sourced from the Central Statistics Agency, while energy consumption is from the Ministry of Energy and Mineral Resources. The data used in thus study is very limited because the data are not available. This study uses the Autoregressive Distributed Lag (ARDL) model. The ARDL model is a method introduced by Pesaran and Shin (1999) and developed further by Pesaran et al. (2001). The ARDL model has the singularity of first, integration of various variables I(0) and I(1). Second, cointegration can be done with a small sample. Third, produce valid estimates (Harrism and Sollis, 2003). Fourth, the ARDL model allows different amounts of lag between variables. Following Odhiambo (2009), Ozturk and Acaravci (2010) and Aliasuddin and Reka (2019) who use log-linear models, the model representation is explained in equations (1) and (2):

$$\ln Y_t = \alpha_0 + \alpha_1 \ln ENERGY + \varepsilon_t \tag{1}$$

$$\ln ENERGY_t = \beta_0 + \beta_1 \ln Y + \varepsilon_t \tag{2}$$

Where Y is non-oil and gas economic growth (constant 2010 billion rupiah), ENERGY is energy consumption (total primary and secondary energy consumption of million tons), ε is errorterm. Because the equation is in the form of logs, the estimation is in the form of electricity. The ARDL cointegration model is expressed as follows (Rahim et al, 2018):

$$\Delta lnY_t = \gamma_0 + \sum_{i=1}^{n} \gamma_{1i} \Delta lnY_{t-i} + \sum_{i=1}^{n} \gamma_{2i} \Delta lnENG_{t-i} + \gamma_3 \ln Y_{t-1} + \gamma_4 lnENG_{t-1} + \varepsilon_t \tag{3}$$

$$\Delta lnENERGY_t = \delta_0 + \sum_{i=1}^{n} \delta_{1i} \Delta lnENERGY_{t-i} + \sum_{i=1}^{n} \delta_{2i} \Delta lnY_{t-i} + \delta_3 \ln ENERGY_{t-1} + \delta_4 lnY_{t-1} + \varepsilon_t \tag{4}$$

Where Δ is the first-difference, γ1, γ2, δ1, and δ2 are the short-term coefficients, γ3, γ4, δ3, and δ4 are the long-term coefficients, t is the year, and i is the lag sequence determined by AIC, and ε is the error term. To determine the existence of short-term relationships in equations (3) and (4) are utilized, and the following hypothesis can be formulated (Bekhet and Matar, 2013):

H_0: No short-run relationship	H_1: There is a short-run relationship
$\gamma_1 = \gamma_2 = 0$	$\gamma_1 \neq \gamma_2 \neq 0$
$\delta_1 = \delta_2 = 0$	$\delta_1 \neq \delta_2 \neq 0$

And for the long-run hypothesis:

H_0: No long-run relationship	H_1: There is long-run relationship
$\gamma_3 = \gamma_4 = 0$	$\gamma_3 \neq \gamma_4 \neq 0$
$\delta_3 = \delta_4 = 0$	$\delta_3 \neq \delta_4 \neq 0$

Bound F-test cointegration procedure used Wald F-statistic restriction and compared it to the upper band and lower band critical value. Pesaran et al. (2001) explained that there are three possible results from the Bound F-test, namely (1) If the F-stat obtained is a greater upper band and lower band critical value, then cointegration occurs or rejects H0 (uncointegrated). (2) If the F-stat obtained below the upper band and lower band critical value, then receives H0. (3) If the F-stat obtained between the upper band and lower band critical value is no decision. The critical value used is the critical value Narayan (2004). Narayan (2004) used for small samples, while Pesaran et al. (2001) used when the sample is large enough.

If cointegration occurs, a short run error correction model / short-run dynamics is performed (Hasanova et al, 2017). This correction condition (ECT) is expected to have a negative and significant sign on the dependent variable (Ozturk and Acaravci, 2010). The specifications of the short-term correction model in this study are as follows:

$$\Delta lnY_t = \lambda_0 + \sum_{i=1}^{n} \lambda_i \Delta lnY_{t-i} + \sum_{i=1}^{n} \lambda_j \Delta lnENERGY_{t-i} + ECT_{t-1} + \varepsilon_t \quad (5)$$

$$\Delta lnENERGY_t = \theta_0 + \sum_{i=1}^{n} \theta_i \Delta lnENERGY_{t-i} + \sum_{i=1}^{n} \theta_j \Delta lnY_{t-i} + ECT_{t-1} + \varepsilon_t \quad (6)$$

Through equations (5) and (6), it can be seen the relationship between non-causality Granger in the short and long term between energy consumption and economic growth (Faisal et al., 2017). The equation is a dynamic VEC model. In contrast to the traditional Granger causality, the future does not impact the past, but the past impacts the future (Takendesa and Odhiambo, 2007). The short-term energy consumption of economic growth is tested by using Wald test restriction, namely H0: λj = 0. While the short-term economic growth on energy consumption is H0: θi = 0, ECT both of these equations explain the long-term relationship.

Result and Discussion

Statistics of Variables

Statistics of variables are vital to explain the correlation among the variables. Both variables are transformed into natural logarithms. Table 1 describes the average economic growth of 11.12 with a standard deviation of 0.80, whereas the average energy consumption of fault is 18.47, with a standard deviation of 0.40. Based on this standard deviation, that fluctuation in economic growth is higher than energy consumption. Normally distributed data or symmetry can be determined by looking at the Skewness value is 0. The table results obtained equality or good enough because of the two Skewness values , namely -0.22 and -0.57, close to the amount of 0.

Table 1 : Statistics of Variables

	lnY	lnEnergy
Mean	11.12	18.47
Maximum	12.23	19.09
Minimum	9.56	17.57
Std. Dev.	0.80	0.42
Skewness	-0.22	-0.57

Correlation between Energy Consumption and Nonoil-Gas Economic Growth

Furthermore, the data are tested in advance on the closeness between energy consumption and economic growth. This test is done with the Pearson correlation approach. Also, the analysis serves as an initial estimate of the coefficient sign of the variable under study. Table 2 explains between energy consumption and economic growth, having a correlation of 98.3 percent with a positive and significant sign at a 99 percent confidence level.

Table 2: Pearson's Correlation between Energy Consumption and Economic Growth

Variable	Y	Energy
Y	1	
Energy	0.983 (0.000)***	1

*Source: Estimates Results, 2020. *** represents prob. < 0.01*

Stationarity Test

Stationarity testing is essential in the time series model. Table 3 explains economic growth at the level obtained t-stat value of -2.092 with prob 0.248. This result is concluded that it is not stationary, so transformation needs to be done in the form of first-difference. At this level economic growth has rejected H0 or stationary with a confidence level of 1 percent (t-stat = -4,452, prob = 0,000). Meanwhile energy consumption is stationary at the level of (t-stat = -7,293, prob = 0,000) and first-difference (t-stat = -3,888, prob = 0,000) with a confidence level of 1 percent. On the right side of the table is the conclusion of the integration of each variable. Economic growth in integration I (1) and energy consumption in integration I (0). Based on this conclusion, the use of the ARDL model in this study is appropriate because we obtain different integrations in the form of I (0) and I (1).

Table 3: Phillips-Perron Test for Stationarity

Variables	***At-level***	**Prob.**	***First-difference***	**Prob.**	**Integration**
Y	-2.092	0.248	-4.452	0.001***	I(1)
Energy	-7.293	0.000***	-3.888	0.000***	I(0)

*Sumber: Estimated Results, 2020. *** represents prob. < 0.01*

Optimum Lagged Length

Determination of the lag used in this study through the Akaike Information Criteria (AIC) approach. Unlike the VAR / VECM model, the use of lag in the ARDL model is not always the same or can use a different lag (Ozturk and Acaravci, 2010). For the economic growth model, the number of dependent lags is 9, and the independent lag is 5, while the energy consumption model shows the dependent and independent lags as much as 2.

Table 4: Lagged Length Selection

Dependent /Independent	AIC	Lag dependent	Lag independent
lnY/lnEnergy	-1.910	9	5
lnEnergy/lnY	-3.716	2	2

Source: Estimated Results, (2020).

Bound Cointegration Test

Cointegration testing in research is needed to see whether there is a long-term balance between the independent variable and the dependent variable. For this cointegration test, the bound test is used, which has several advantages, which can be integrated with different orders I (0) or I (1), or the number of samples used is small.

Table 5: Bound Cointegration Test

Dependent/Independent	F-statistic	Sample	Narayan (2004) Critical Bound Lower/Upper 5%	Conclusion
lnY/lnEnergy	4.705**	22	4.09/4.66	Cointegrated
lnEnergy/lnY	4.499**	29	4.09/4.66	Cointegrated

*Source: Estimated Results, 2020. ** represents prob. < 0.05*

In this study, there are two models examined: the economic growth model and the energy consumption model. Based on Table 5, it appears that the two models obtained f-stat values of 4,705 and 4,499. The F-stat obtained is greater than the critical value of Narayan (2004) at the 5 percent threshold, so that it concludes that there is a short-term cointegration to the long term.

Estimated Long-Run Model

The discussion of the first estimation of the ARDL model is to look at the long term of the economic growth model and the energy consumption model. The estimation results can be seen in Table 6. The long-term test results above show that in the economic growth model, energy consumption has a positive and significant effect (prob 0.000). The energy consumption coefficient of 2.006 explains that energy consumption will drive economic growth by 2 percent in the long run in Indonesia if there is an increase in energy consumption by 1 percent, assuming ceteris paribus. These results are consistent with research by Faisal et al. (2017), which explains the more energy consumption, the availability of this energy will have an impact on economic growth.

Table 6: Estimated Long-Run Model

Model	Economic Growth (Y)	Energy Consumption (Energy)
C	-26.27 (0.000)***	14.36 (0.000)***
lnEnergy	2.006 (0.000)***	
lnY		0.39 (0.000***

*Source: Estimated Results, 2020. *** represents prob. < 0.01*

The long-term estimation results for the energy consumption model explain that economic growth will increase energy consumption by 0.39 percent if it grows by 1 percent, assuming ceteris paribus. These results are consistent with research by Aliasuddin and Ramadhana (2019). In comparison, the impact of the coefficient on economic growth is not as significant as the impact of the coefficient on energy consumption. Indonesia is an importer of energy raw materials such as oil when importing; countries must consider the main component of energy, namely the price of energy itself (Berk and Yetkiner, 2014). With unstable prices, energy consumption becomes unstable too. Hasanavona et al. (2017) also

find another impact of this considerable difference: the reduction in energy consumption will jeopardize economic growth in Indonesia and explain that economic growth is highly dependent on energy consumption in the long run.

Estimated Short-Run Model

ECM short-term estimation results are carried out to determine the effect of lag variables and determine the balance. ECT serves to determine the level of speed of adjustment on short to long-term stability. One of the ECT requirements is a negative sign that explains convergence. If it is positive, it is divergent or away from the balance point.

Table 7: Estimated Short-Run Model

Variable	Economic Growth (Y)	Energy Consumption (Energy)
ΔlnY		0.136 (0.038)**
ΔlnY_{t-1}	1.212 (0.006)***	0.007 (0.911)
ΔlnY_{t-2}	1.126 (0.011)**	
ΔlnY_{t-3}	1.695 (0.004)***	
ΔlnY_{t-4}	1.56 (0.008)***	
ΔlnY_{t-5}	1.392 (0.012)**	
ΔlnY_{t-6}	1.626 (0.007)***	
ΔlnY_{t-7}	1.937 (0.004)***	
ΔlnY_{t-8}	1.169 (0.031)**	
$\Delta lnEnergy$	0.852 (0.111)	
$\Delta lnEnergy_{t-1}$	-2.811 (0.031)**	-0.057 (0.765)
$\Delta lnEnergy_{t-2}$	-3.695 (0.002)***	
$\Delta lnEnergy_{t-3}$	-2.851 (0.026)**	
$\Delta lnEnergy_{t-4}$	-1.923 (0.035)**	
ECT_{t-1}	-1.04 (0.004)***	-0.16 (0.000)***
R-Squared	0.854	0.405
Adj. R-Squared	0.617	0.334
Durbin-Watson	2.05	1.97

*Source: Estimated Results, 2020. **, *** represent prob. < 0.05 and prob. < 0.01, respectively.*

Table 7 shows the comparison of the two models in the short run. For the economic growth model, the lag of economic growth of 9 indicates a positive and significant effect. The range of effects of previous economic growth was 1.12 percent to 1.93 percent. The effect of lag 8 is close to the coefficient in the long run. However, different signs of the coefficient of energy consumption are not as expected. The effect of energy consumption from lag 2 to lag 5 shows a negative and significant effect. Only lag 1 has a positive but not significant effect.

Meanwhile, the energy consumption model shows the lag in energy consumption, which has a significant negative effect on decreasing energy consumption. While lag 1, economic growth as expected, is a positive effect. However, statistically, the variable is not significant. The speed of adjustment to economic growth is -1.04 and is significant at the 1 percent level. The ECM results explain 104 percent of the imbalances that occur in the short term can be adjusted in the 1.48 year.

According to the ECM concept, this adjustment is too far from the required 0-1. But this problem can be explained by Narayan and Smyth (2006). If the ECM coefficient is found to be -1 to -2 there will be a slowdown in reaching the equilibrium point so that it needs to be adjusted before convergence occurs quickly towards the equilibrium point. The meaning is in the short-term economic growth and energy consumption requires a long process, new to the long term. ECM energy consumption obtained by -0.16. Adjusting the short balance towards the long-term is very fast. The time needed is only 1.92 months.

Granger Non-Causality and Dynamic VEC

Answering the second problem about the relationship (direction), researchers used the dynamic VEC method by equations (3.5) and (3.6) in looking at the directional relationship of energy consumption and economic growth in Indonesia. This category of non-causality is divided into short-term and long-term represented by the ECM. Like Granger causality testing in general, if the variable X to Y is significant, then there is a relationship of X to Y and vice versa. Possibilities obtained in one direction, two directions, and no direction. The results of the Granger non-causality are shown in Table 8 as follows

Table 8: Granger Non-Causality between Economic Growth and Energy Consumption

Model	Short-run		Long-run (ECM)
	ΔlnY	ΔlnEnergy	
ΔlnY		12.94 (0.023)**	-1.04 (0.004)***
ΔlnEnergy	4.03 (0.132)		-0.16 (0.000)***

Source: Estimated Results, 2020.
*Note: **, *** represent prob. < 0.05 and 0.01, respectively.*

Short-term statistical results explain the energy consumption of 12.94 with a prob of 0.023. This figure shows energy consumption has a relationship to economic growth in the short term (unidirectional). While the economic growth statistics of 4.03 indicate that economic growth has no relation to energy consumption. It is supported by the evidence that the prob value obtained 0.131, greater than the 5 percent significance. Therefore, energy consumption and economic growth in the short term support the growth hypothesis.

This study's results are consistent with the study of Rahim et al. (2018), where the impact of energy consumption is weak but still contributes to economic growth. Meanwhile, both models have a significant sign at the level of 1 percent in the long run. This means that both are mutually influential (bidirectional) between energy consumption and economic growth. In the long term, the hypothesis that occurs is the feedback hypothesis (feedback hypothesis). The results of this study are consistent with studies conducted by Jaganath (2015), Dogan and Deger (2016), and Yasar (2017). The illustration of this non-causality relationship is shown in Figure 2.

Figure 2: Granger Non-Causality between Energy Consumption and Economic Growth

Finally, testing the stability of the model (CUSUM and CUMSQ) is necessary to see the consistency of estimates throughout the year studied, especially in using the ARDL model. The test results of these two models were found not to cross the 5 percent significance line or to accept H0, so the estimated model obtained was quite excellent and feasible to use. An overview of CUSUM and CUSUMQ can be seen in Figure 3 and Figure 4.

Figure 3: CUSUM and CUSUMQ for Economic Growth Model

Figure 4: CUSUM and CUSUMQ for Energy Consumption Model

Conclusion

This study aims to examine the effect of energy consumption on economic growth and causality in Indonesia from 1988-2018. Based on the regression results between energy consumption and economic growth, a cointegration was found between the two. The effect of long-term economic growth is positive and significant. Meanwhile, energy consumption has a positive and significant effect on economic growth. The impact of energy consumption on economic growth is 2 percent, and the impact of economic growth on energy consumption is 0.39 percent. The Granger non-causality test explains that there is a one-way effect of energy consumption on economic growth in the short run. These results support the growth hypothesis. In the long run, there is a two-way relationship between economic growth and energy consumption to endorse the feedback hypothesis.

The advice taken in this study is that economic growth is highly dependent on energy consumption, so there must be an ongoing increase so that the economy continues to grow positively. Then Indonesia needs to increase energy consumption again so that economic growth increases on target. However, as a net oil-importing country, relying on energy consumption such as fossil oil, coal, and gas by way of imports is an obstacle for Indonesia, especially when the oil prices are unstable. The price instability will disrupt energy consumption and impact economic growth exploration, and the use of energy sources are needed. Another so that energy consumption is maintained. With this research study, it is hoped that the government will focus more on energy issues and their impact on economic growth. As the sole energy provider, the Government of Indonesia must continue to provide additional energy by building new power plants. Considering the consumption of energy derived from fossil oil, coal, and gas, which are non-renewable resources, the government also needs to use new and renewable energy alternatives that are environmentally friendly.

Abstract

Dropping out of school is a real problem, especially among first-year students, both at European and national level. In this context, the purpose of the research was to identify the main factors that determine Romanian students to drop out of college. Based on this results, it was identified solutions, means and tools useful in reducing the high dropout rate and increasing the academic performance of students. An online questionnaire was applied within the project ``*E-tutoring: web tools and resources for study and career management*`` in order to identify the main needs of students. The analysis of the data collected was performed using the Qualitative Content Analysis. The result of the analysis highlighted the fact that the main factors that contribute to school dropout are generated by financial problems, teaching methods, inappropriate choice of specialization and lack of support for counseling. The results demonstrate the need for an innovative system, based on peer learning and a lifelong career approach.

Keywords: career guidance, Cronbach's alpha, students` drop out

Introduction

Romania is the third country in the European Union in terms of early school leaving in education and training systems, for people aged 18-24 (EUROSTAT, 2019). According to data published in the ``Training and Education Monitor, 2019: The report for Romania`` early school leaving (18-24 years) indicates a percentage of 16.4% for young Romanians, compared to an EU average of 10.6%. Also, the share of graduates (30-34 years) is 24.6% for Romania, and the European average is 40.7%.

As noted EUROSTAT (2019), „the largest gender differences among the proportion of young people who were early leavers and not wanting to work were recorded in Romania (6.9 percentage points higher for young women than young men)". In 2018, Romania registered a high level of early school leaving, of 16.4%, as well as a low rate of the population aged between 30 and 34 who graduated from higher education (24.6%). In light of these data, study success is high on the policy agenda in Europe and one of the goals of the Europe 2020 strategy is that at least 40% of 30-34–year-olds complete higher education.

Cite this Article as: Paulina SPANU, Mihaela ULMEANU, Cristian DOICIN And Roxana MECHNO "Expectations of Students to Improve their Academic Performance: Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

In recent years, at the national level, the trend of school dropout is increasing and has a significant impact on the unemployment rate and social inclusion. The employment rate among students in Romania, on the age segment of 20-25 years, in the chosen field of study, is well below the European average of 80%. Moreover, the *National Council for Statistics and Forecasting of Higher Education* states that more than 53% of students come from rural and disadvantaged backgrounds. The reasons why they leave the education system are mainly financial. To these is added the diminished motivation of students to complete their undergraduate university studies.

Although the Europe 2020 program in the field of education and training aims to reduce the number of people leaving the education and training system early below 10%, in recent years, there has been an increasing trend in the drop-out rate at national level. According to U-Multirank, coordinated by the European Commission, the highest dropout rate of students was registered in Romania (U-Multirank 2014), most of them being students enrolled in the first year.

As G. Raftu (2019) said, students choose a faculty at the recommendation of their parents or out of the desire to leave home, being attracted by the "student life". Most of the time their expectations are not met. The academic and social difficulties they face, the inability to manage time, workload, budget and interpersonal relationships are factors that generate academic dropout.

Studies conducted at national level have shown that Romanian universities are facing a significant decrease in the number of students, especially students enrolled in the first year of college (SAVA S, 2015). The number of students is drastically reduced during the undergraduate studies, only about half of the enrolled students succeed in completing the undergraduate studies. The identification of solutions and measures of educational policy that would lead to the improvement of the phenomenon of decreasing the students' motivation represent objectives that the Romanian universities have assumed.

Numerous projects have been approved at European level, in order to reduce the number of students who do not complete their undergraduate studies. The pourpose of the projects are to identify the main factors favoring school dropout and to develop new resources to improve students' academic performance. One such project is E-tutoring. This is a project funded by the Erasmus + program (2018-1-IT02-KA203-048005) that works to reduce academic drop-out rates with the development of a set of tools and a new tutoring system that combine career guidance, peer learning, social networks and new digital technologies (https://www.etutoring.eu/). The project consortium involves eight partners from six countries: Romania, Italy, Turkey, Spain, Greece and Lithuania. The partnership wants to create the following resources that will improve the student's academic performance:A research report on Career Management Skills in academic students:

- E-tutoring in Europe, a collection of good practices.
- A methodological framework to guide the design of e-tutoring services.
- E-tutoring App.
- E-learning platform for training tutors.

Research Methodology

There are many reasons why students drop out of college, especially in the first year of study. Most of the time, these reasons are complex and interconnected. The main objective of this study was to determine the level of students` satisfaction and identify the difficulties encountered by them, respectively what are the determining causes of dropout, especially for students in year I. Studies on the tendency to drop out and the correlations between factors that determine such decisions have been made in recent years by many researchers. Van Sangodiah (2015) states that the age of students, gender, financial situation, specialization and form of education time management, etc. are factors that contribute to student dropout.

The research results presented in this article were obtained by applying an online questionnaire to students following the bachelor's program in the Faculty of Industrial and Robotic Engineering,

within the University Politehnica of Bucharest. The decision to implement the questionnaire at this faculty was based on a study conducted at the Faculty of Industrial Engineering and Robotics, on the situation of people who dropped out of undergraduate studies since the first year. According to this study, in the period 2013 - 2014, 112 students dropped out the faculty, representing 17.83% of the total number of students enrolled in the first year (628 students). In the next two years, there was a slightly decreasing trend as follows: in 2014 - 2015, 95 students dropped out of university, out of 600 enrolled in the first year (15.8%), and 2015-2016 the number decreased more significantly to 8 ,4. %, compared to the last years, the number of withdrawn students being 53 out of 627 enrolled students. In the following period, 2916 -2017 there was an increase in the dropout rate of 16.6% (81 students out of 500 students enrolled in the first year). In 2017 - 2018, 66 students out of 524 (12.59%) dropped out of school. Therefore, the university aims to identify the main reasons for school dropout and find solutions to achieve the proposed target by Europe 20 project to reduce the dropout rate below 10% by the end of 2020.

The survey was developed based on a procedure that was set up by a group of experts from the E-tutoring project consortium. The data were collected through an online questionnaire, which was elaborated using a validated framework and analyzed accordingly.

Data Analysis

The questionnaire was available for students on the E-tutoring project website, and the data was centralized by the project coordinator and made available to all partners. The study carried out at partnership level is much more laborious and includes the results obtained at European level, these being available free of charge and accessible on the project platform. This article presents the results obtained at the Faculty of Industrial Engineering and Robotics level, in order to identify the major requirements of students based on which recommendations will be made to improve the adaptation of students to academic life.

12 items were considered for this reasearch:

Q1. Gender
Q2. Have you ever thought about dropping out the faculty
Q3. Methods of teaching and evaluation
Q4. Personal learning difficulties
Q5. Personal difficulties in managing time and plans
Q6. Financial reasons
Q7. Relevance of courses for the chosen specialization
Q8. Perception that the degree won't be useful for accessing the world of work
Q9. No interest in the topics (perception of a wrong career choice)
Q10. Limited knowledge of the professional profiles associated with that university course
Q11. Lack of counselling services (tutoring services)
Q12. Not feeling socially included

The sample on which the research was carried out in the university consisted of 113 students, most of them being enrolled in the first year. Of these, 68 were boys and 45 were girls (Figure 1). This result is not a limitation for research.

Fig. 1: Distribution of Gender participants

The participants` gendere (Q1) is not a limitation for research.

For items Q2 - Q12 a Likert scale was used which allowed respondents to choose from a linear set of answers on a scale from 1 to 5, where 1 threat "not at all" and 5 means very much. For each item analyzed calculated average, variance and standard deviation. The results obtained are presented in table 1.

Table 1: Q2 – Q12 results

ITEM	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12
Average	2.212	2.823	2.92	2.858	3.301	3.204	2.841	3.159	3.071	2.903	2.717
Variance	2.043	2.004	1.578	1.502	1.803	1.383	1.656	1.532	1.322	1.628	1.513
Standard deviation	1.429	1.416	1.256	1.226	1.343	1.176	1.287	1.238	1.15	1.276	1.23

Regarding the way in which the students evaluated the analyzed aspects, it was found that there were no significant differences according to gender.

The study of the internal consistency of the items was performed using the Analysis of Variance (ANOVA). The MS and Error values were used to calculate the Cronbach's Alpha coefficient (table 2) according to formula 1. Cronbach's Alpha is a measure used to assess the reliability of the internal consistency of a set of scale.

$$\alpha = 1 - \left(\frac{MS}{Error}\right) \tag{1}$$

Table 2: ANOVA result

Source of Variation	*SS*	*df*		*MS*	*F*	*P-value*	*F crit*
Rows	758.9992	112		6.776779	5.971499	8.09E-59	1.244463748
Columns	97.87289	10		9.787289	8.624273	1.09E-13	1.839140301
Error	1271.036	1120		1.134854			
Total	2127.908	1242					
Cronbach's Alpha				**0.832538**			

Based on the data in the table above, using formula 1, a value of the Alpha Cronbach`s coefficient equal to 0.83 was obtained. The obtained coefficient shows that the internal consistency level in the case of the applied questionnaire is very good for using the data obtained in the data analysis. As Keith S. Taber (2018) said, the values of the Cronbach's Alpha between 0.70 and 0.90 suggest a good internal consistency in science education studies.

In order to avoid the dependence between two quantitative variables of the sample of data collected by applying the questionnaire, Pearson's correlation coefficient (r) was determined. The obtained coefficients had values between –1 (perfectly negative correlation) and 1 (perfectly positive correlation). The sign of the coefficient represents the meaning of the correlation, namely: the positive value corresponds to the variations of the same meaning and the negative one to those of the opposite direction. The absolute values of the correlation coefficients, presented in table 3, express the intensity of the association between the items.

Thus, for α <0.05, values of the correlation coefficient from - 0.25 to 0.25 were obtained, representing a weak or zero correlation, from 0.25 to 0.50 (or from - 0.25 to -0.50) acceptable degree of association, from 0.50 to 0.75 (or from -0.50 to -0.75) very good correlation.

Table 3: Coefficients Correlation

	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12
Q2	1.00										
Q3	0.23	1.00									
Q4	0.02	0.35	1.00								
Q5	-0.06	0.35	0.54	1.00							
Q6	-0.19	0.14	0.34	0.43	1.00						
Q7	0.14	0.52	0.35	0.45	0.31	1.00					
Q8	-0.04	0.43	0.38	0.46	0.32	0.58	1.00				
Q9	0.02	0.46	0.33	0.41	0.34	0.40	0.43	1.00			
Q10	-0.01	0.34	0.46	0.48	0.27	0.46	0.40	0.53	1.00		
Q11	0.09	0.30	0.36	0.29	0.34	0.43	0.35	0.28	0.63	1.00	
Q12	0.08	0.32	0.29	0.26	0.31	0.39	0.31	0.27	0.48	0.59	1.00

As it results from the table of correlation coefficients, it is found that most correlation coefficients are positive, resulting in a direct correlation (the two correlated variables vary in the same direction) and only between perers Q2 - Q5, Q2 - Q6, Q2 - Q8, and Q2 - Q10, we have an inverse correlation, the pairs of correlated variables vary in the opposite direction (when one increases, the other decreases). A correlation coefficient of 0.63 was obtained between items *Q11. Lack of counseling services* if *Q10. Limited knowledge of the professional profiles associated with that university course*. Thus, in the students' opinion, the counseling services would help them to overcome the obstacles related to the association of the courses with their professional profile. A significant number of students consider that certain courses that they study in the first year of study, will not be useful in the profession of engineer.

As it can be seen in Table 3, there are items for which the absolute value of the correlation coefficient is weak, very close to zero. Between these variables there is a statistical link that can be taken in the analysis and interpretation of results, although the dependence is not linear.

A significant part of the students ernrolled in the first year (47%) stated that they had never thought about dropping faculty (Figure 2). But, at the same time, the extreme values are not to be ignored at all, namely 12% (5 - on the Likert scale) of the analyzed sample expressed their firm intention to

abandon the studies, respectively 12% (4 - on the Likert scale). The elements that leading the student to develop such thoughts are the `` *Methods of teaching and evaluation*``.

Fig. 2: Studetns` opinion related to leaving faculty

As it can be seen in Figure 3, 32% of students consider that ``Methods of teaching and evaluation`` *influences students' decision to drop out of school.``*

Fig. 3: Students' decision to drop out of school.

Higher averages for the analyzed factors were obtained, in decreasing urine for Items ``*Q6. Financial reasons*`` (3.301), *Q7. Relevance of courses for the chosen specialization* (3,204), *Q9. No interest in the topics (perception of a wrong career choice)* (3,159), *Q10. Limited knowledge of the professional profiles associated with that university course* (3,071).

A high percentage of students prefer to work while they study. Although some of them work part time, they have difficulty finding a balance between the work schedule and the teaching activities. Most jobs are not specific to college specialization, which is why students consider certain courses irrelevant, sometimes even unnecessary. This is also reflected in the significant number of students who appreciate that certain courses are not suitable for the specialization they have chosen.

Conclusion

From the analysis of the data obtained by applying the questionnaire, the following conclusions were drawn:

- The results of this study highlighted the main needs of students. These will be the basis for formulating recommendations to reduce the phenomenon of school dropout.

- Analyzing the distribution of options expressed by students, the lack of financial resources is the main factor that contributes to increasing the dropout rate. The implementation of programs designed to support students from vulnerable groups, the provision of scholarships and part-time jobs for students supports students in maintaining their academic careers. Employment agencies set up in universities can provide the necessary support to students in choosing a job that ensures a flexible schedule, appropriate to the students' schedule.

- Difficulties that students face are related to adapting to the specifics of higher education in terms of the pace of teaching - learning and managing the volume of information. To mitigate this effect of this factor, the Ministry of National Education and Scientific Research (MENCS), through the Externally Funded Project Management Unit (UMPFE), implemented the ROSE program. Within this program, through the project "Involved students, engineers for the future! (SIMPLE) - ROSE AG 150 SGU NC II there are remedial modules complementary to the courses taught by faculty members. These modules are needed to improve students 'knowledge of subjects where students' difficulties have been identified.

- The decision to drop out of college in the first year of study is also generated by the personal motivation of students. In the opinion of the students who participated in this study, the different personalities of the students and the environment from which they come influence the development of friendships and social integration in the university environment. Tutoring and counseling activities involving teachers, year tutors, counselors and student associations can be beneficial for increasing personal satisfaction. Personal counseling sessions help students identify sensitive points, self-knowledge, and increase a sense of belonging to a group. Facilitating the transition from high school to university life and adapting students to academic life can also be supported by intensifying mentoring activities by teachers and counseling and career guidance sessions.

- In the opinion of the interviewed students, not all subjects in the school curriculum are absolutely necessary in their profession. This aspect can be improved by involving students in joint activities with employers to confirm that what they will study in courses and laboratories is useful and has applicability in the labor market. In addition, by promoting job offers by employers, students will have the opportunity to know the employment options in the field studied, thus increasing students' interest in graduating. Visits to companies can also arouse students' interest in the fields they have chosen and increase their academic performance. Internships can help students identify a job according to the field studied and in accordance with their professional aspirations and interests, thus intensifying their desire to complete their studies.

- The recommendations made in this study should be among the major concerns of higher education institutions and career counseling and guidance centers to increase the pass rate at the end of the first academic year.

- The results demonstrate the need to design and develop an innovative system, based on peer learning and the lifelong career guidance approach. Improvements in the education system can be achieved through political cooperation, benchmarking and funding programs, such as the Erasmus + program. The E-tutoring project, supported by the Erasmus + program, aims to develop an innovative system and useful tools for tutors, teachers, counselors and students to help reduce the dropout rate.

Acknowledgements

The research leading to these results has received co-funding from the European Community's ERASMUS+ PROGRAMME under grant agreement no. 2018-1-IT02-KA203-048005 "E-tutoring: web tools and resources for study and career management".

The article is financed by the University POLITEHNICA of Bucharest through the project `` Inginer in Europa`` in online system, registered at MEC with number 457 / GP / 06.08.2020 by using the fund for financing special situations that cannot be integrated in the form of financing state higher education institutions.

Leading Factors of the Effectiveness of the Legislative Regulation of Criminal Proceedings at the Stage of Criminal Case Initiation

Yaroslava RYAPOLOVA

Department of Criminal Procedure and Criminalistics,
Southwest State University
50 Let Oktyabrya str. 94, 305040 Kursk, Russian Federation
yarosslava@mail.ru

Abstract

The article deals with socio-economic, theoretical and legal issues related to the definition of key factors that should be taken into account when assessing the effectiveness of the legislative regulation of criminal procedural activities implemented at the stage of criminal case initiation. The assessment of the outcome of the initial stage of criminal proceedings in terms of reporting indicators of judicial and law enforcement activities cannot be considered sufficient, since criminal proceedings do not belong to the production sphere of activity. It is substantiated that the current and predictive assessment of the effectiveness of the legislative regulation of the criminal case initiation stage requires a pluralistic approach: it should address techniques developed by social sciences and criminal procedure science to identify criteria for this effectiveness and ways to improve it. It is necessary to take into account not only the law perfection in technical and legal and substantive terms, but also the social mechanism and regulatory potential of relevant criminal procedural rules.

Keywords: stage of criminal case initiation, factors of law effectiveness, criminal and procedural activities, criminal procedure legislation

Introduction

Currently, the issue of ensuring the effectiveness of legal regulation of criminal procedure at the pre-trial stage of criminal proceedings determines the existence of opposite approaches to determining the legal future of the stage of criminal case initiation in the Russian criminal justice system: the elimination of the stage itself or its components (pre-investigation check, the institution of dismiss of the initiation of a criminal case, etc.) (Gavrilov 2019, Aleksandrov et al. 2015, Smirnova and Shadrin 2019) or improvement of the criminal procedure regulation of the disputed stage within the framework of the existing procedural institutions (Spirin 2019, Rostova 2019, Bravilova 2019). At the same time, the studied doctrinal models of reforming pre-trial proceedings by means of initial stage elimination have been insufficiently investigated and the results of the assessment of the existing risks and potential adverse effects of the proposed reform are inadequate. In this regard, there is an urgent need to develop theoretical and legal issues related to the study of the current and predictive assessment of the effectiveness of the legislative regulation of criminal procedural activities implemented at the stage of criminal case initiation, and key factors definition that can influence certain indicators of such effectiveness (Dandurand 2014, Cameron, 1990). This issue becomes particularly topical in the time of discussion and anticipation of changes related to the modernization and rationalization of the pre-trial procedure (Kuntii et al 2019), ensuring its technological effectiveness (Maslennikova 2019), which is righty recognized as a priority direction of the criminal procedure strategy at the state level.

Literature Review

Social sciences and criminal procedure science have developed a methodological basis for measuring the effectiveness and characteristics of its components in relation to various legal complexes, identifying conditions, criteria and means of its improvement (Holzer 1984). Even in the Soviet period, scientists - processualists determined the effectiveness of various criminal procedural categories by the ratio of the actual result of legal rules functioning and the social goals for which these rules were adopted (Petruhin 1975), while the modern approach to understanding effectiveness implies not only the goal and the result of a criminal procedural activity, but also other criteria for its assessment (Stefanou and Xanthaki 2016). In addition, approaches of various theoretical law schools to defining conditions and factors of the effectiveness of legal regulation in general have been updated (Mousmouti 2018, Zamboni 2018). Provisions of modern interdisciplinary research defined within the framework of "legal riskology", in terms of developing measures to reduce legal risks (planning of law-making activities; interpretative correction of laws and regulations by judicial decisions; legal experiment (Sivitsky and Sorokin 2016, Khayitov 2019), involvement of sociological techniques and methods in the processes of law forecasting (Xanthaki 2018), legal monitoring, 'effectiveness test' (Mousmouti 2012) etc.) have important applied significance since based on the findings in this relatively new research area it is possible to provide future efficient modernization of the initial stage considering and minimizing possible risks.

Research Methods

In the process of working on the research problem, the dialectical method was used. It allowed us to identify features, mechanism and existing contradictions of the legislative regulation of criminal procedural activities conducted at the stage of criminal case initiation. The methodological basis of the research also included a method of legal modeling, logical, formal legal, comparative legal, historical and other methods.

Results and Discussion

A formal goal-oriented approach describing a formula for measuring the effectiveness of regulations as the relationship between the actual result in the form of a positive change in the subjected to legal regulation public relations and social goals for which these rules were created, is widely recognized (Stefanou and Xanthaki 2016). The theory also distinguishes between the legal efficacy of the law (compliance of the behavior of the subjects of legal relationships with the requirements established by law provisions) and the social effectiveness of law (ensuring an appropriate balance of fundamental social values, reducing the level of legal coercion in the society) (Allott 1980, Rodgers and Hanson 1974).

In the doctrine of criminal procedure law, this approach was also developed while formulating the concepts of the effectiveness of various criminal procedure categories. According to one of the founders of the theory of criminal proceedings effectiveness, this phenomenon was defined as the achievement of the goals of a criminal procedure in every specific criminal case with a minimum of infringement of the legitimate interests of persons involved in a criminal procedure (Tomin and Popov 2015). A goal-oriented approach is used by researchers when assessing the efficiency of justice which depends on how accurately and realistically the goals of the law are defined and whether there are procedural and other means (guarantees) to achieve them; quantitatively it is determined by the degree of approximation of the achieved level of justice to its ideal goals (Petruhin 1975). When determining the effectiveness of a pre-trial investigation, the most acceptable concept is considered to be the goal-oriented concept of effectiveness which expresses a certain conformity (correlation) of the practical results to the targets of criminal proceedings at its pre-trial stages.

The dynamic component of the effectiveness is the mechanism of the process of goal achieving including features of means used to achieve it (Mousmouti 2018, Zamboni 2018) which are understood as the consumed time, financial resources, material and spiritual labour, adverse and perverse effects of the legislative act issue. In the field of legislative regulation of pre-trial proceedings, definition of the parameters of the goal achievement process inevitably involves a decision on the feasibility of measures of criminal procedural compulsion which at the stage of a criminal case initiation should be minimal.

Thus, the concept of legal regulation effectiveness of the stage of criminal case initiation implies a qualitative characteristic of the process of designing rules of a criminal procedure, and legal remedies contained in them which can, under current social circumstances, optimally and purposefully influence legal relationships arising at the stage of reception, registration and review of initial information about a crime with minimum statutory restrictions of the rights and interests of participants of such relations.

For the purpose of a comprehensive and systematic examination of the concept under study, considering theoretical aspects of assessing the legislative regulation of the stage of criminal case initiation, we will analyze the key factors that influence the indicators of such effectiveness.

- **Perfection of law in technical-legal and contensive terms** means clarity, specificity, comprehensibility of the language, completeness, absence of corruptogenic factors (Bulanova and Abramenko 2018), scientific validity, carefully adjusted balance between flexibility and stability of laws (Karpen 2012), compliance with the goals of legislation development, full incorporation of a law into the legal system, ensuring consistency and complementarity of regulations, etc. Examples of ineffectiveness of the legislative regulation regarding this criterion include examples of unstable legal regulation of the stage of criminal case initiation. It is estimated that during the 18 years of the new RF Code of Criminal Procedure in the 10 key articles of Section 7 of the Code dedicated to the regulation of the institution of criminal cases initiation, about 70 changes were made, at the same time there are examples when novels after a short period of their operation were excluded due to their inefficiency and negative assessment by the scientific community and practitioners. There are also cases when the provisions of some departmental legal acts come into direct conflict with the provisions of the Criminal Procedure Code of the Russian Federation; examples of asystem and unbalanced regulation of various institutions related to the initial stage of criminal proceedings (initiation and termination of criminal cases at the pre-trial stage, paralyzing the rules connected with the possibility of participation of a lawyer (defender) in legal proceedings involving a person in respect of whom reports of a crime are being reviewed, the issue of detention of a person before criminal case initiation, unresolved within the framework of the criminal procedure law and from the viewpoint of ensuring individual rights, etc.).

- **Expediency** as a factor of ensuring effectiveness of legislative regulation lies in the opportunity provided by law to choose a method of resolution of a criminal conflict, this is the freedom provided by law for the discretion of the prosecuting authority to make a procedural decision based on considerations of efficiency, benefits for achieving the public procedural interest protected by it (Hendry and King 2017). In general, effectiveness in the considered aspect of expediency, on the one hand implies application of mandatory rules that give the enforcer a certain discretion, but on the other hand, it calls for avoiding the actual substitution of legal instructions with the discretion of professional participants in the process.

- **Procedural economy factor** involves fixing a sufficient set of necessary procedural remedies for the highest productivity of procedural labor, correct and rapid review of reports (allegations) of a crime with the least expenditure of forces, resources and time of persons involved at the stage of pre-investigation check, and with a minimum legal criminal procedural compulsion. Considerations of procedural economy determine the legislative trend to differentiate the format of reviewing reports of a crime depending on the crime category, the type of the grounds for criminal case initiation, and so

on. Substantively, the condition under consideration provides for saving resources and costs, including budget funds when structuring the regulation. Despite the fact that, for obvious reasons, the amount of state funding is not a determining factor of the quality of criminal proceedings, today we cannot deny its influence on the stance of the legislator regarding the existing regulation of the procedural form of pre-investigation check. This condition also means that it is permissible to include “free” elements that are not related to strict formal requirements of the Criminal Procedure Code of the Russian Federation, for example, the existence of "free" grounds or the uncertain procedural status of the key participants of the check. The uncertainty of the contours of the evidentiary activities at the stage of criminal case initiation and associated with the systemic functioning of a number of provisions of the Russian Criminal Procedure Code and Criminal Code need for unnatural extensions of the circumstance and limit in proof of a crime report check should be noted as a disadvantage of the legislative regulation of the institution under study within the distinguished factor of effectiveness.

- **Rationality of techniques and methods for legal leverage contained in the rules of criminal law and procedure.** These are such characteristics as optimality of terms, procedural arrangements, etc., procedural possibility to use a variety of information sources, technologies, compliance with management rules, as well as reliability (legal opportunity to react to most of the grounds for criminal case initiating) (Stockiy 2020). In turn, a promising direction for improving the initial stage of pre-trial proceedings is replacing outdated written record keeping with the extensive use of modern information technologies. Criminal procedure rules that regulate the use of technical means and technologies in evidentiary activities at the initial stage of pre-trial proceedings require close attention of the law-making body in terms of appropriate development and modernization. According to many researchers it seems that the use of artificial intelligence systems to process the statistical data, assist in the preparation of legal documents, browsing the websites for information and making decisions on the criminal act qualification will be the most successful (Sushina and Sobenin 2019). At the same time, it is noted that the digitalization of pre-trial criminal proceedings is fragmentary, inconsistent and slow, the law-making body delays the integration of the proposed "electronic innovations" into the criminal proceeding, and even does not pay attention to the fact that the Criminal Procedure Code of the Russian Federation in this matter is noticeably behind other Russian procedural laws Kostenko at al.2019).

- **Realism –** is an adaptability (acceptability) of legal remedies to the current historical, socio-economic, psychological, political and ideological prerequisites for the development of the society and the state, the demand of the society (Karnaushenko 2020, Belyaev at al. 2020); the efficacy of the legal mechanics of the realization and protection of rights and freedoms of non-professional participants of criminal procedure relations at this stage. In respect to this stage, this condition mainstreams the issues of ensuring timely access to justice for the aggrieved, improvement of legislative measures to objectify criminal statistics and prevent abuse in record and registration work.

Conclusions

The study of the effectiveness factors of the legislative regulation of criminal procedure activities implemented at the stage of criminal case initiation in scientific terms contributes to the identification of promising directions for the development of the Russian criminal procedure legislation within the framework of the discussed modernization of pre-trial proceedings. The consideration of the formulated in the work key factors of the effectiveness of the legislative regulation of criminal and procedural activities implemented at the stage of criminal case initiation facilitates optimal selection of legal instruments when designing future rules of criminal procedure with regard to their regulatory potential, acceptability, potential risks and costs, environment parameters.

50 Let Oktyabrya str. 94, 305040 Kursk, Russian Federation
yarosslava@mail.ru

Abstract

Prospects for the implementation of electronic document management in criminal procedure implementation at the stage of criminal case initiation are described in the article. Proposals to consolidate procedural capabilities of submitting and registering crime reports online are formulated. Creating, issuing and using electronic documents as court review materials are also described. The main attention is paid to theoretical aspects and practical applicability of modern computerization mechanisms for relations arising at the stage of criminal proceedings initiation. The study of foreign experience in legal regulation of electronic document management in criminal proceedings allows to enrich domestic regulatory system with current and effective developments, contributes to strengthening of legal means of individual rights ensuring. The author describes possible procedure of received crime reports in electronic form, analyzes advantages and positive changes that can happen due to digitalizing at the initial stage of criminal proceedings: the use of electronic documents and electronic signatures on documents will significantly speed up documents flow, simplify evidence collecting procedure and reduce time costs in legal proceedings. The limitations to be overcome in informational improvement at the stage of criminal proceedings initiation are described. It is advisable to make a list of procedural documents that can be compiled and signed in electronic form at the stage of criminal proceedings initiation, as well as to regulate the procedure for their document circulation. It should be done as a part of initial changes towards the reform of pre-trial proceedings and the creation of a regulatory platform for conducting so-called electronic criminal case in the future.

Keywords: Initiation of A Criminal Case, Stage, Verification, Crime Report, Electronic Document

Introduction

Modern criminal procedure form of crime reports checking does not meet the level of development of electronic document management technologies, which is successfully applied in other procedural branches of Russian law over the past years. There is no secret that current norms of the Code of Criminal Procedure of the Russian Federation in this part reflect mainly the level of technology that was in the 70s of the last century and which does not correspond to the modern state of human-technical relations. Only some recent legislative changes (federal laws of 04.03.2013 No. 23-FZ, of 03.07.2016 No. 323-FZ, of 27.12.2018 No. 533-FZ) are aimed at filling a certain gap, however, they unfairly ignored legal regulation of relations in this area at the stage of pre-investigation verification. Russian criminal procedure legislation provides for the possibility of using electronic documents in criminal proceedings (article 474.1 of the Code of Criminal Procedure of the Russian Federation). However, at present, this opportunity is realized exclusively during the judicial stage of a criminal process. And therefore there is scientific and practical interest in electronic reception and registration of a crime report and further proceedings on it. On the other hand, there is no absolute prohibition on the compilation of documents in electronic form in the Code of Criminal Procedure of the Russian Federation.

Literature Review

The need to improve pre-trial criminal proceedings by introducing an electronic criminal case is discussed in scientific community and among practitioners. So it is necessary to regulate the possibility of using digital technologies. Desirability of limiting the operation of electronic document management only by judicial stages of a criminal process is questioned. Procedural scientists think that electronic document management can eliminate excessive formalism of criminal proceedings, increase openness, accessibility, economy and speed of justice, can systematize and structure criminal case materials automatically (Kachalova, Tsvetkov 2015; Abdulvaliev, 2013, Lazareva V. A., etc., 2019); can ensure remote interaction between the bodies of inquiry, other investigative units, prosecutors, courts; can strengthen guarantees of persons involved in criminal proceedings (Grishin, 2019). At the same time, many researchers rightly note that digitalization of pre-trial criminal proceedings at the legislative level is fragmented, inconsistent and non-operative. The legislator is slow to integrate proposed "electronic innovations" into the criminal process, not even paying attention to the fact that the Criminal Procedure Code of the Russian Federation is noticeably behind other Russian procedural laws in this area (Volunteer O.V., 2019).

Some researchers rightly note modern trends in the penetration of information technologies, the existence of "futuristic" forms of electronic document management that are not directly provided by the Code of Criminal Procedure of the Russian Federation, based on their application locally: sending a refuse decision to initiate criminal proceedings to the applicant, calls for giving explanations by e-mail and etc. (Haliullina, 2016).

It is also noted that relevance of this issue is due to the development of the society digitalization, objective factors of digital technologies development and the state as a whole. In addition, with considerable advance, creation of so-called electronic criminal cases in foreign countries is accumulated, for example, the USA, Kazakhstan, Turkey, Estonia, Canada, Germany, Belgium, South Korea, etc. (Nissan E. 2008; Zuev, 2017; Kuzhabayeva, etc., 2019).

Problem Statement

There is an urgent need to study, find and substantiate optimal directions for reforming Russian criminal procedure legislation, taking into account the experience of other countries and their own national interests in the rational use of electronic document management at the initial stage of a criminal process in order to increase effectiveness of preliminary investigation bodies.

Research Questions

The subject of the article is the norms of Russian and foreign legislation which can regulate the possibility of using electronic document management in the implementation of criminal procedure at the stage of crime report accepting and resolving, as well as theoretical provisions developed in criminal procedure science that reveal prospects for improving the stage of criminal proceedings initiating in this direction.

The aim of the study is to develop a set of proposals for improving criminal procedure legislation, fixing the possibility of introducing electronic document management technology in receiving and reviewing of crime reports.

Methodology

Methodological basis of the research: general scientific method of materialistic dialectics, comparative, formal-legal, logical methods, as well as method of legal modeling.

Results and the Discussion

Electronic document management can be defined as a systematic set of hierarchically organized automated processes for servicing criminal proceedings, as a structured system of interconnected document management tools when they are used and stored electronically.

The idea of electronic document management at the stage of a crime report reviewing is the creation of software (platform), which allows subjects of verification to receive, register and have further work on crime report in electronic form with the possibility to create electronic documents, sign them by electronic digital signature, store them, as well as to have access to it by employees carrying out departmental control. All incoming verification materials that are not electronic must be digitized and attached to so-called "electronic file" in the form of files. Documents are digitized by scanning, photographing or video recording.

The introduction of electronic document management would facilitate timely and proper registration of crime reports; ensure prompt monitoring of compliance with the fixed deadlines for verification and registration of its results. Therefore, latent violation of procedural deadlines by law enforcement officials can decrease, cases of crime hiding can also decrease, which also contributes to the implementation of legal certainty principle (Usachev, 2019, Chebotareva, 2019).

The system can notify the applicant and the person under review electronically by sending an electronic copy of procedural decision. This can be done after the completion of crime report verification. In case of disagreement with the decision taken as a result of the review, the person can also appeal against it by submitting a complaint to the prosecutor, to the head of the investigative body or to the court in electronic form.

At the same time, it is advisable to make a certain list of procedural documents that can be compiled electronically at the stage of criminal proceedings initiation. It is noteworthy that prerequisites for using electronic form of the report and reporting of committed crime or about a crime to be committed are in existing regulations. Unlike the Code of Criminal Procedure of the Russian Federation, the provisions of the Instruction approved by the Decree of the Ministry of Internal Affairs of the Russian Federation in August 29, 2014 No. 736, "On the procedure for receiving, registering and resolving reports and crime reports, administrative offenses, incidents in the territorial bodies of the Ministry of Internal Affairs of the Russian Federation" make it possible to receive crime reports in electronic form. Software that requires the applicant to complete details necessary to work with crime reports is used, while electronic reports are printed and further work is carried out with them in written form.

The possibility of operating on information about a crime received in electronic form and used as an alternative (along with written or oral) form of reasons for a case initiating should be in article 141 of the Code of Criminal Procedure of the Russian Federation, while the details of a completed form of a crime report should contain a note about warning of criminal liability for patently false denunciation.

It is difficult to determine the possibility of issuing an electronic digital signature for documents, when the party is obliged to confirm personally correctness of the information contained in documents and his personal attitude to them. Mechanism for performing a hand-written signature is connected to psychophysical characteristics of human body. So this signature is inextricably connected with biological personality of the signer (Fatkullin, 2018). In this regard, it is almost impossible to certify the text of explanations received, protocols of investigative actions (for non-professional participants - applicant, eyewitness, lawyer, interviewed person, etc.) by electronic digital signature and other analogues of a hand-written signature. Electronic format of such documents can be provided by creating scanned copies of corresponding paper copies or adapt videoconferencing for this purpose.

Due to the fact that transactions with personal data of participating persons will be carried out during the formation of electronic verification materials, it can be possible to store personal data of participants secretly, in separate encrypted computer files, modify and use them if pre-investigation situation requires this in order to protect potential witnesses, suspects, etc. The institute of information rehabilitation, introduced in the German Code of Criminal Procedure in 2017 (Zazulin, 2018), is also interesting. The essence of this Code is in relation to the area of legal relations and would be that personal information contained in electronic file can be removed from the archive if a decision was made to refuse to initiate criminal proceedings.

It is also necessary to mention the barriers that would require the introduction of an electronic format for crime report reviewing. There is a problem in ensuring information security in the field of identity identification, the possibility of unauthorized access and falsification of stored electronic documents from outside. High-quality technical solution is necessary to solve this problem (Zuev, 2017), because the effectiveness of any legal norms is directly dependent on the level of technical support of law enforcement agencies and the population. It is worth to mention the proven standards for ensuring information security and information protection in any electronic document management system: authentication of the system user, distribution of access rights for system users, support of electronic signature, data encryption, recording and auditing of users in the system in real time (Bychkov, Popov, 2013). The question of so-called "digital inequality" is still open, where individuals are still not able to understand or use the advent of electronic technology and this should not, in fact, become an obstacle to access the justice. Therefore, at first it is advisable to develop acceptance and recording of crime reports in electronic form as an alternative model for creating a reason to initiate criminal proceedings. So the development of an adequate program of electronic document management and measures for its application at the first pre-trial stage of a criminal process should eliminate negative consequences of digitalization.

Conclusion and Limitations

Thus, after a short period of "testing" the preparation and use of procedural documents in electronic form in criminal proceedings, it is necessary to make a clearly defined list of procedural documents, which can be drawn up electronically at the stage of criminal proceedings initiation. It is also necessary to regulate application procedure, which could be a starting point as a kind of pilot project towards reforming pre-trial proceedings and creating a future regulatory platform for conducting so-called electronic criminal case.

Abstract

Due to their complexity and longtermness, construction activities require a scientific approach to strategic management. To form and implement an effective strategy of a construction organization, a special place is given to the analysis of the macro environment and internal environment of a construction organization, identifying the risks faced by construction sector companies. The paper deals with strategies based on the analysis of management decisions with allowance for risk. The results of the study can be used by managers of construction organizations to plan their activities.

Keywords: construction sector, construction company, management, strategy, risk.

Introduction

The construction sector is a system that has a layered structure, bonds of different nature, a specific technology of production processes, based on the functional organization of activities of the construction sector's entities and various problems which are in the form of implementation of investment construction projects (Garretsen H., McCann P., Martin R., Tyler P., 2013). Modern construction is a variable dynamic system both in terms of management entities' selection and in the functional aspect of activity (Zabrodin Yu. N., Kolikov V. L., Shapiro V. D, 2014; Bredikhin V.V., Shleenko A.V., Bredikhina N.V., 2016; Bredikhina N.V., 2017).

The analysis of dynamic processes occurring in such systems under the influence of perturbations of different nature makes it possible to assess them, identify risks encountered by construction companies. In the end, it allows us to develop relevant approaches in making strategic decisions for development (Akifiev I. V., Khrustalev B. B., 2011; Kovan S. E., 2013; Bredikhin V.V., Bredikhina N.V., Aksenteva I.Y., 2019).

Risk factors in making strategic decisions

As part of our research task, the following three main groups of factors can be identified:

1. The first group includes factors, exposure to which is inherent in the structure of construction sector companies. Their action is continuously destructive (unprofitable). They can be divided into subgroups:

Cite this Article as: Vladimir Viktorovich BREDIKHIN, Natalia Vladimirovna BREDIKHINA And Anna Ilinichna CHERNYAEVA "Analysis of A Construction Company's Strategy With Allowance for Risk" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- physical factors: noise, chemical pollution, temperature;
- economic factors: inflation, deflation, financial and credit instability of companies and suppliers, changes in demand for products, etc.;
- environmental factors: greenhouse effect, humidity, seismic activity;
- demographic factors: population migration, morbidity, birth rate, and mortality;
- social factors: living standards and others;
- geopolitical factors: the geographical location of the operating area, the effectiveness of tax and social policy, and so on.

2. The second group consists of discrete emergency factors that depend on the state of the environment in which a construction sector company operates, and it is impossible to influence the probability of their occurrence. However, it is still possible to reduce the degree of their impact on a construction company (their weight). Similarly as in the second group, these factors can be divided into subgroups:

- physical factors: fire accident, explosion, power delivery failures, transport disruptions;
- economic factors: fails to deliver materials, fluctuations in the financial market;
- legal factors: changes in tax legislation, administrative prohibition of activities;
- environmental factors: earthquake, flood, hurricane, etc.

3. The third group includes activities to reduce the impact of factors of the first and second groups, which can be implemented through preventive measures, the introduction of new technologies, insurance, the use of consulting and engineering services, and other measures.

The risk structure is different, and not all of these groups of factors will significantly affect the degree of a particular risk overall. However, it is important to pay attention to the factors presented in the classification under consideration. Those factors can have both negative (increase of risk factors of the 1st and 2nd groups) effect on the amount of risk and positive effect on it (stabilizing factors of the 3rd group).

The stabilizing factors can be directed both to weaken the destructive risk factors, and to reduce the probability of their manifestation.
The division of factors into groups is due to both the main provisions of the reliability theory and the approach to risk analysis and assessment applied in the research.

The Concept of Acceptable Risk in A Company's Strategy

During the development of a construction company's strategy, the concept of acceptable risk is implemented in the form of a two-stage set of procedures: risk assessment and risk management (see Figure below)

Fig.1: Risk management scheme for making strategic decisions in the company: S_i – tentative decision (strategy); S_{i+1} – risk-based solution: (strategy).

⇨ - material flows;

→ - functional and information flows

Risk assessment is a set of regular risk analysis procedures, i.e. identification of the sources of occurrence, revealing possible consequences of risk factors, and determination of the role of each source in the overall risk profile of a given company. Risk assessment of a company's strategy is based on a comprehensive (scientific, technical, technological, marketing, sociological, etc.) study of construction industry companies and their business environment as sources of risk, analysis of external and internal risk factors, building a risk profile under the influence of certain risk factors, determining indicators for assessing the level of risk, as well as establishing mechanisms and models for the relationship of indicators and risk factors (Grabovoi P. G., 2017).

In order to judge the significance of a particular risk factor and the adequacy of preventive measures taken, a risk must be shown in comparable terms. The risk level of strategies (strategic plan) is taken as a total characteristic of risk. That level of risk, as a result of a corresponding special study, is expressed by some integral indicator of risk level.

All types of risk factors must be taken into account to ensure reliable operation of construction sector companies under the conditions of transformational economy: both genetic, i.e. inherent in economic activity as a whole in any conditions, and specific ones, being inherent in the transition period (Pike A., Rodriguez-Pose A., Tomaney J., 2006). All risk factors must be identified, analyzed, and ranked by importance or contribution to the overall risk profile of a particular company.

A good result in the analysis of risk situations is shown by a systematic approach. This result is obtained by considering a complete set of all possible external structures and their connections with the object under study (Khrustalev B. B., Demyankova V. S., Ganiev M. G., 2012)

If one makes such an analysis:

1. Risk factors in internal and external environments are singled out;
2. An economic and mathematical model for the analysis and risk management in the system is developed;
3. The strategic function of a company is selected depending on the existing risk factors.

Thus, as a theoretical basis for creating an organizational risk management system for production and economic activities of construction sector companies, one can distinguish:

- risk in the company's activity is the result of objectively existing and fundamentally ineradicable uncertainty in the external and internal environment of its operation (it always exists);
- risk is a manageable parameter – its level can be affected;
- an integral indicator of the strategy's risk level is used to assess the risk level of strategic decisions made in construction sector companies;
- a systematic approach is applied to analyze risk situations in construction companies.

Company's strategy with allowance for risk

As is commonly known, there are three types of solutions in the activity of a construction company: strategic, tactical and operational ones. Following this division, risk is analyzed separately when making strategic, tactical and operational decisions.

The most important are strategic decisions for construction sector companies. They can dramatically affect the activities of such companies and determine their goals for the long term period. This means that the implementation of strategic decisions changes the potential of a company, and it is almost impossible to return to the previous state of management object. It is common with strategic decisions that their adoption is carried out by selecting the optimal one according to a given criterion.

The authors identify the following main strategies of production and economic activity of a construction sector company:

- product-market;
- resource-market;
- technological;
- investment;
- business management (development).

Strategic decisions are made and implemented under the conditions of ambiguity (uncertainty) caused by scientific and technological progress and in the presence of real socio-economic processes, a variety of ways and options for turning opportunities into reality, a range of possible states and situations of decision implementation. In practice, at the moment of decision-making, it is impossible to have accurate and complete knowledge about the environment for implementing a company's strategy being remote in time, about all existing or potentially emerging internal and external factors.

Strategic decisions of a company are assessment and management objects, strategic plan that contains proposals for future development of the external environment in relation to a company, recommendations on a course of actions of the management and staff of a company, forward-looking statements about the reactions to planned strategic activities of product consumers, raw-material suppliers, competitors, etc. (Fabrizio Barca, 2009).

Risk management includes the development and implementation of recommendations and measures that are economically justified for a given company, aimed at reducing the initial level of risk to an acceptable level.

The relationship of company's major strategies to various risk factors is shown in Table below.

Table 1: Major strategies of construction sector companies

Strategy	Range of accepted strategic decisions	Risks caused by uncertainty
Product-market	Product strategy (nomenclature and its updating; assortment; production volume; product quality); Market strategy (sales market structure; market expansion; market competition; pricing)	1. Risk of unrealization of manufactured products; 2. Risk of the buyer's rejection of the received and purchased products; 3. Risk of non-receipt or overdue receipt of payment for products sold without prepayment; 4. Risk of incorrect forecasting of a situation
Resource-market	Resource strategy (volume of resource reserves; quality of resources); Strategy in the resource market (structure and suppliers)	1. Risk of raw materials undersupply due to failure of concluded supply agreements; 2. Risk of non-return of prepayment by the supplier; 3. Risk of incorrect forecasting of a situation
Technological	Choosing the type of a company (technological, market, marketing); Technological dynamics of a company	1. Risk of unrealization of the core technology; 2. Risk of equipment failures; 3. Risk of incorrect forecasting of a situation
Investment	Strategy for attracting external financial resources (choosing the structure of funds' sources; determining the period of obtaining loans); Refund of funds raised; Investing existing funds	1. Risk of non-receipt of external funds and loans; 2. Risk of inefficiency of the current organizational structure; 3. Risk of incorrect forecasting of a situation
Business management	Choosing the type of management (strategic, tactical, operational); Organizational structure; Management structure	1. Risk of disruption of own production plans or innovative projects; 2. Risk of inefficiency of the current organizational structure; 3. Risk of incorrect forecasting of a situation

Conclusion

A fundamentally irremediable uncertainty that takes place when making strategic decisions always exists in reality and leads to the fact that the risk of strategic decisions never amounts to nothing. The current state of construction sector companies is characterized by a fairly high level of uncertainty of the external infrastructure. One should also note that due to the uncertainty of the external environment, there may be uncertainty of goals. By subjecting a new idea or solution to a rational critical analysis, it is possible to provide measures to neutralize or mitigate the undesirable manifestations of certain risk factors by identifying the potential danger and its sources and analyzing the consequences. In addition to that, in many real world situations, in order to support the reliability of a new solution or idea, it is sufficient to form some reserves (financial or material), insure the transaction, or provide other actions in case of an undesirable course of events.

Abstract

It follows from the current trends in the development of society that the current educational practice of professional training, aimed at transferring the maximum amount of knowledge, has lost its relevance. Accordingly, the formation of a new paradigm of training a competitive specialist, aimed at creating conditions for the formation and education of graduates of professional educational institutions, able to optimally dispose of the knowledge obtained, effectively self-realized, be in demand by society-the result of a conscious need. This determines the relevance of the presented work. The purpose of the article is to theoretically justify the need to overcome the value neutrality in the field of methods and technology of training a competitive specialist through the humanitarian culture of the teacher and the formation of the educational environment of the OU.
The main research methods in the work are such General logical methods as: analysis, analogy, generalization.

Keywords: teacher's humanitarian culture, educational environment, professional training, overcoming value neutrality, cognitive value of fiction.

Introduction

The process of learning accompanies modern man from the moment of his birth to his death. Speaking about professional training, we must understand that its purpose in the modern world is not so much to teach terms and professional knowledge, but to develop personal abilities and skills of students that allow them to become a competitive specialist. And, according to L. A. Semyonova (2014), the teacher plays an important role in this.

A teacher in a professional educational organization (professional colleges, technical schools, etc.) often does not have a special pedagogical education, but in his professional activity faces real pedagogical problems, the solution of which can not be found in textbooks or manuals. According to the authors, the basis of pedagogical activity of a teacher should be a humanitarian understanding of the pedagogical problems of forming a specialist. This includes humanitarian knowledge, conducting

Cite this Article as: Lyudmila Anatol'yevna SEMENOVA, Lyudmila Ivanovna KONOVALOVA And Natalia Vladimirovna BREDIKHINA " Humanitarian Culture of a Teacher in The System of Professional Education" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

a dialogue with the subject of educational activities (students), and overcoming value neutrality in the field of methods and technologies of professional training. In this regard, the humanitarian culture of the teacher is considered by us as a condition that can ensure the professional development of the student's personality. However, the humanitarian culture of a teacher cannot exist in isolation from the educational environment, they are indivisible and are integral parts of the pedagogical culture as a whole.

The development of a student's personality largely depends on what educational environment they are in, what innovative methods and tools are used in it.

Methodological base of the research

The methodological basis of the research is the concept of professional formation of the individual, as well as the concept of B. G. Ananyev (1953) about functional and operational mechanisms of mental processes that act as driving forces for the development of the subject.

In the problem of forming the humanitarian culture of the teacher, the authors distinguish hermeneutical and axiological approaches based on the cognitive-heuristic and creative capabilities of students.

The subject-activity and contextual approaches described by Klim-Klimashevska, A. (2015) became the basis for the formation of the educational environment, since "all academic subjects in an educational organization should be studied in the context of the future activity of a specialist "and" the entire training system should be aimed at the formation of certain professional qualities " .

Research Results

It should be noted that along with the traditional approach to professional training of specialists, it is increasingly possible to see an innovative equal attitude to the student, which contributes to the faster formation of professional consciousness.

Pedagogical research of the last decades, devoted to the personal-oriented approach in pedagogical activity and technologies of its implementation, is aimed at understanding the deep meaning of this activity. In our opinion, the deep meaning of pedagogical activity is very accurately expressed in the Humanities. Speaking about the nature of humanitarian knowledge, about the birth of humanitarian thought, about the development of humanitarian thinking, we refer to the opinion of M. M. Bakhtin (1979), who noted its "special two-dimensionality and two-personality".

Pedagogical reality in practice is much more diverse than theoretical thought can suggest, richer than all models, technologies and pedagogical didacticism. That is why in their teaching activities, the teacher should be able to understand the Humanities and comprehend pedagogical problems and tasks. Consideration of the problems of pedagogy and pedagogical knowledge in the system of culture is reflected in the research of A. S. Robotova (2006) et al., where science and art are represented as correlating components that reflect the inner side of a person who knows this reality.

Innovative, according to the authors, is the definition of the subject position of the teacher in their activities as the most significant. In relation to the student, this allows us to actualize the positive motives of educational and cognitive activity and make the learning process personally significant for him.

And Russian classical literature, which is not used in professional education, has such opportunities. However, the huge cultural and artistic heritage of Russian classical literature would have enriched the content side of knowledge, forced the teacher to put value orientations in the center of training. However, the implementation of this provision requires a developed humanitarian culture of a professional education teacher. It is necessary to form the concept of artistic and imaginative

knowledge of pedagogical reality. The authors are convinced that the formation and implementation of such a concept is possible through the means of fiction, but this requires the development of methods, techniques and tools aimed at generating interest in professional disciplines based on a value attitude. Krylova (1990) also mentions this in her research.

At the same time, the humanitarian culture of the teacher , in the opinion Gessen, S.I. (1995) and Dyomina, O.A. (2001), is a reflection of the value-spiritual essence of the teacher's personality.

Teaching professional disciplines requires the teacher to be creative in teaching activities. Creativity combines both the logic of understanding pedagogical categories and the emotional and artistic component of pedagogical reality and the teacher's own emotional and imaginative sphere of personality, his emotions, feelings, experiences and empathy. However, modern education, "getting into the most distant abstractions", does not address emotions and imaginative thinking, its cognitive capabilities, and thus creates great difficulties for students. In the works of L. I. Konovalova (1996), it is said: "Thinking, devoid of elements of imagery, is formulaic, fruitless, formal".

Confirming this idea, let us recall the attitude of scientists from various fields of knowledge to artistic images and works of literature that are revealed when presenting their scientific ideas (P. F. Kapterev, S. I. Gessen, M. K. Mamardashvili, I. S. Cohn and others). In the works of B. M. Teplov (1985), based on literary works, the problems of abilities and giftedness (Salieri and Hermann), as well as temperament and character formation (Tatyana Larina) are considered.

Innovative is the understanding that the appeal to the world of artistic images, the study of various aspects of upbringing, education, human development, can and should become the basis of professional development of both the teacher of professional education and the student. Real opportunities to refer to works of literature in the course of professional training are impossible without analytical consideration of the text.

Thus, professional pedagogy, studying various aspects of upbringing, education, and human development, can and should turn to literature, which is a "form of personal existence of a person" (O. Mandelstam), and pedagogical culture will become a factor in the effectiveness of professional training.

Conclusion

In this article, the authors search for innovative ways and means to overcome value neutrality in the field of methods and technologies of professional training, in determining the significance of the humanitarian culture of the teacher in professional education. This will help to activate the student's subjective position in education, foster positive motivation for educational and cognitive activities, and make the learning process personally significant. Today, professional training does not use a huge cultural and artistic layer of Russian classical literature, which would enrich the content side of pedagogical knowledge, strengthen the value side of the educational process.

Evaluating Founders of Start-Up Companies When Business Angels Decide on Investment

Levs FAINGLOZS

RISEBA University of Applied Sciences, Riga, Latvia, e-mail: lev.faingloz@gmail.com

Abstract

Business angels' investments are an important funding source of start-up companies at the earlier stages of development. Analysing the existing scientific literature in terms of the investment criteria applied by business angels made it possible to identify more than 200 various criteria. Within the framework of this study, in view of so large number of investment criteria, the author has decided to consider only the criteria applied by business angels to start-up company founders. This was decided because most of the previous studies authors singled out exactly the entrepreneur and the team as the most important criterion. At the same time, note that these authors used to make only qualitative assessment by comparing between the investing criteria. That is why the goal of this research is: making quantitative assessment and defining the level of assessment of start-up company founders at which business angels are ready to invest in the start-up company. To achieve the goal of the study, a survey took place among 118 business angels with different investment experience. The analysis of the survey has revealed that the most significant criterion for business angels making decision on investing is trust the founders - regardless of the business angels' experience, while the least significant criterion is the managerial skills of start-up founders. Moreover, it was stated that, with the growth of investment experience, the requirements of business angels to start-up founders are becoming more stringent.

Keywords: Business Angels, Founder's Assessment, Investment Criteria

Introduction

Business angels' (BA) investments are an important funding source of start-up companies at the earlier stages of development. Mason and Harrison (2015) note that, during the financial crisis of 2008, business angels played an important role in the UK economy, while banks and venture capital funds lowered their investment levels.

The question of how business angels decide on investments is very important for start-up companies looking for external financing sources. Analysis of the existing scientific literature in terms of the investment criteria applied by business angels showed a wide variety of these criteria. The previous studies have identified more than 200 various investment criteria. Most frequently, researchers mention the following groups of investment criteria: product characteristics and scalability, market size and growth rate, financial potential (business plan, profitability of the project, exit opportunities), entrepreneurs and management team (Bachler and Guild, 1996; Mason and Harrison, 1996; Rostamzadeha et al., 2014; Carpentier and Suret, 2015; Paul et al., 2007). However, despite the variety of investment criteria, many researchers agree that one of the most important investment criteria for business angels is the management team and the founders of start-ups (Bachler and Guild, 1996; Mason and Harrison, 1996; Landström, 1998; Brettel, 2003; Sudek, 2006; Harrison and Mason, 2007; Paul et al., 2007).

Unfortunately, researchers often do not separate between the investment criteria applied by business angels to the team and to the founders of a start-up company. Possibly such an approach is associated with the fact that the founders themselves are the project management team at the earlier stage of the project development. However, as the start-up company grows and new participants start joining it, there occur fundamental differences between the team and the start-up founders.

Cite this Article as: Levs FAINGLOZS "Evaluating Founders of Start-Up Companies When Business Angels Decide on Investment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Based on a large number of investment criteria, it was decided as a limitation of this study to consider only the criteria applied by business angels to founders of start-ups. This decision was because most of the previous studies authors single out the entrepreneurs (founders) and the team as the most important criterion. For example, Mason and Harrison (1996) indicate that, in terms of importance, the criteria related to the entrepreneurs are the first priority to business angels and only after them come the criteria related to the product and the market growth potential. Bernstein et al. (2017) are of a similar opinion concluding that experienced business angels deciding on the investment consider the management team related information as the most significant to respond.

Moreover, we can state the following research gaps based on studying the previous investigations. A small number of studies were identified wherein the investment criteria applied by business angels to start-up founders were assessed. Basically, investigations that took place before 2010 were revealed only. Only one study has been identified where BA were divided into groups: Virgin BA, BA with a brief experience and BA with a vast experience (Smith et al., 2010). Authors of previous investigations make only qualitative assessment by comparing between investment criteria; at the same time, they do not make any quantitative assessment.

To bridge the gaps described above, this study aims at the determination of the assessment level of start-up founders at which business angels are ready to invest into the start-up. We will consider the following as the investment criteria applied by business angels to start-up founders: entrepreneurial, managerial, and professional skills of the founders as well as the business angels' trust the founders and the founders' reputation.

The scientific novelty of this study is that quantitative assessment of criteria identified in the course of investment studies and applied by BA to start-up founders is made. Moreover, the level of importance of each of the investment criteria was assessed with respect to business angels with different investment experience.

Review of literature

Young innovative companies play an important role in the knowledge-based modern economy (Block et al. 2016). However, those companies frequently suffer from financial limitations (Brown and Earle 2015; Carpenter and Petersen 2002; Cosh et al. 2009). This is because start-up companies find it hard to attract bank financing at the early stages of their development, since they still lack a stable cash flow of funds and cannot pay deposits claimed by Bank (Hall and Lerner 2010).

In contrast to venture capital funds, business angels predominantly make investments at earlier stages of companies' development (Laukkanen, 2007; Wong et al., 2009; Van Osnabrugge and Robinson 2000; Sohl 2006; Dutta and Folta, 2016). According to the data from World Bank (2018) and Hellman and Thiele (2015), in terms of the amount of financing, transactions by business angels are minor as against those of the formal venture capital. However, the transactions are concluded at earlier stages of the companies' development. Aridi (2018) holds the same view, asserting that the vast majority of early stage investments are made not by venture funds, but business angels. According to the data from EBAN (2018), the total European early stage investment market is estimated to be worth of 12.3 billion EUR in 2018. In 2018, business angels represent the biggest share of the investment market with 7.45 billion Euros, equal to approximately 60% of the total market. The total number of business angels was 345,000 (EBAN, 2018).

Wessendorf et al. (2019) note that the assessment of start-ups at an early stage of development is a complicated and subjective process associated with risk and uncertainty. This especially refers to technological start-ups. On the other hand, it is very important for young start-up companies to understand based on which criteria business angels decide on investment.

The investigation of the previous studies has identified a wide variety of criteria. However, this study will consider only the criteria associated with founders and managerial team of start-up companies.

Haar et al. (1988) note that the project selection criteria applied by business angels significantly differ from those applied by venture capitalists. For instance, business angels are not interested in a well-elaborated business plan, which is a necessary condition for venture capitalists. According to Haar et al. (1988), business angels agree with venture capitalists on the importance of managerial team, consumer value of product or service, and high market potential for the product or service provided by the company. Haar et al. (1988) found out that the importance of the management team came first compared to other investment criteria.

The study performed by Bachler and Guild (1996) examines the investment criteria of Canadian investors, used when taking decisions on funding the early stages of technological companies. The authors have considered three types of investors: business angels, private funds of venture capital, and public funds of venture capital. Bachler and Guild (1996) have examined 95 investment criteria divided into 5 groups: characteristics of the entrepreneur, characteristics of the market, characteristics of the venture offer, investor requirements and characteristics of the investment proposal. Bachler and Guild (1996) have found out that, with regard to all the three examined types of Canadian investors, the characteristic of the entrepreneur is the most important criterion when deciding on investment.

Becker-Blease and Sohl (2015) examine other groups of investment criteria. The researchers assess projects possibly to be invested by business angels according to five criteria as follows: characteristics of managerial team, contents of business plan, product development stage, availability of advisors and employees. Becker-Blease and Sohl (2015) found out that positive assessment of the project by business angels is influenced by the management team, the presence of certain types of advisors and products/services already generating income at the time of the assessment.

Bretell (2003) describes the process of investment decision-making by German business angels. Bretell (2003) notes that, after a quick review of possible investment options, business angels, as a rule, take a quick decision on whether or not the project is worth of a more detailed consideration. At that stage, business angels are ruled by two considerations only: first, their initial impressions and, secondly – their investment preferences. Bretell (2003) notes that the majority of all projects are rejected already at the first stage. The next stage includes a detailed analysis of the projects, including personal contacts with the company seeking for financing. Bretell (2003) emphasizes that a detailed analysis of projects is carried out based on a number of criteria, the most significant of which are: managerial team, the market growth potential, and the uniqueness of the product or service.

Stedler and Peters (2003) have investigated the opinion of 232 business angels from Germany. They found out that business angels scrupulously study the business and the respective managerial team before they decide on investment. Moreover, investors assess such criteria as management, product, market, and financial and investment peculiarities. Stedler and Peters (2003) have discovered that the most important criterion is the entrepreneur and the managerial team.

The study by Sudek (2006) based on the investigation of 72 business angels from Southern California considers the kinds of investment criteria being of higher priority when assessing projects. According to Sudek (2006), business angels spend most of their time and energy on four main topics: the passion of a leading entrepreneur; the reliability of a leading entrepreneur; the quality of the management team and the availability of exit strategy.

Note that some specific studies were identified in the process of analysing the previous studies. Within their framework, the criteria associated with founders and managerial team were not of higher importance for business angels taking decision on investment. That situation could arise for a few reasons. The first one could be the country differences of the studies examined. For example, Bruton & Ahlstrom (2003), Bruton et al. (2004), Naqi & Hettihewa (2007), Burke et al. (2008) believe that the investment criteria applied by business angels may differ depending on their cultural (country) differences. The second reason could be a small number of business angels taking part in the above-stated studies. So, only four business angels took part in the study by Mason and Stark (2004), while in the study by Smith et al., (2010) the business angels were divided into three groups of four angels each.

Summing up the literature review, we can state that most of the researchers consider start-up founders as the most important investment criterion for business angels. When analysing the founders, researchers single out such aspects as leadership skills of entrepreneur, entrepreneur's previous experience, entrepreneurial motivation, relationship between the entrepreneur and the investor, entrepreneur's ability to develop his company, managerial skills of entrepreneurs, personal traits of entrepreneur (honesty, reliability, determination, enthusiasm, etc.), trust in the entrepreneur, and the passion of the leading entrepreneur.

Methodology and Data

To determine the level of assessment of start-up founders, at which business angels are ready to invest, a questionnaire was developed and a survey of business angels was conducted. The development of the questionnaire consisted of two stages. At the first stage, the questionnaire was developed based on a study of the existing scientific literature related to the investment criteria applied by business angels. At the second stage, there was a joint discussion of the content of the questionnaire. Five experts were attracted to take part in the discussion. The experts were five high-level business angels from the UK, Belarus and Latvia. Communication with experts has improved the structure and content of the questionnaire.

The final version of the questionnaire included issues associated with the assessment of entrepreneurial, managerial, and professional skills of start-up founders by business angels, as well as the level of trust of business angels in the founders and the reputation of the founders of start-ups. Thus, the questionnaire presented questions related to five groups of investment criteria.

In the course of the survey, Likert scale was used. When assessing the start-up founders, the respondents (business angels) had to choose one of the following answer options:

1. low evaluation;
2. below-average evaluation;
3. average evaluation;
4. above-average evaluation;
5. high evaluation;
6. very high evaluation.

The next stage of the study was associated with the search for respondents (business angels) ready to take part in the survey. The search for business angels was carried out through:

- the contacts of business angels' networks stated on the Home Page of European Business Angels Network;
- websites of business angels associations and networks;
- searching business angels at LinkedIn;
- personal contacts.

Looking for respondents resulted in finding 118 business angels from 32 countries who had undergone the survey. The largest number of respondents was business angels from Latvia – 40 people, next – BA from Lithuania (8 people) and from Belarus – 5 people. From other countries, 1 to 3 business angels took part in the survey. Unfortunately, this situation does not allow one to identify the peculiarities of the investment decisions taken by business angels from various countries. However, it allows us to assess the overall opinion of the respondents on the importance of evaluating the founders of start-up companies.

Note that, within the framework of the survey, the respondents were asked some questions about their investment experience. It turned out that 14 out of 118 business angels who have undergone the survey were Virgin BA – that is to say, they had not invested in start-ups yet. Therefore, the opinion of that group of business angels was not taken into account within the framework of the study in question. Therefore, the total number of respondents (business angels) based on which the founders of start-ups were evaluated was 104 BA. As a result, two groups of business angels evaluated founders of start-

ups: first, business angels whose investment practice was less than 3 years and, secondly - business angels who had been investing for three or more years.

At the next stage of the study, in order to pass over from qualitative to quantitative assessments, the respondent's answers were assigned scores from 1 to 6 (see Table 1).

Table 1: Translation of qualitative assessments from respondents (business angels) into quantitative assessments

Qualitative assessment	Quantitative assessment
Low evaluation	1 point
Below average evaluation	2 points
Average evaluation	3 points
Above average evaluation	4 points
High evaluation	5 points
Very high evaluation	6 points

This approach enabled one to calculate the average number of points with respect to each of five groups of the investment criteria used by business angels, and to compare between them.

At the final stage of the study, a comparison between the investment criteria used by business angels with different investment experience was made.

Research results and discussion

To start with, let us consider the overall scores of the survey among business angels, not splitting them up into groups according to investment experience. Table 2 shows the collective results of start-up founder evaluation by business angels.

Table 2: Average estimates of start-up founders at which business angels are ready to invest in a start-up

Start-up founders evaluation criteria	Average score
Business angels' trust in founders	5.08
Professional skills of founders	4.53
Entrepreneurial skills of founders	4.53
Founders' reputation	4.48
Managerial skills of founders	4.17
Total score	**4.53**

As we see from Table 2, business angels believe that their trust in start-up company founders gained the highest average score – 5.08 out of 6. The second main criterion turned out to be the entrepreneurial and professional skills of the founders, which gained 4.53 out of 6 scores. The next criterion of importance is the reputation of founders – 4.48 out of 6 scores, and the managerial skills of founders have gained the lowest average score, i.e., 4.17 out of 6.

At the next stage of the study, the answers of business angels were split up by the level of the angels' investment experience. Business angels were divided into two groups as follows: those who had been investing from 1 to 3 years and those who invested more than 3 years. As already described above, business angels who have not yet invested in start-ups were not included in this part of the study.

The results of start-up founders evaluation by business angels with different investment experience are presented in table 3.

Table 3: Average scores of start-up founders at which business angels are ready to invest in a start-up (taking into account the BA investment experience)

Start-up founders evaluation criteria	Business angels who have been investing from 1 to 3 years	Business angels who have been investing for 3 or more years
Business angels' trust in founders	4.75	5.21
Professional skills of founders	4.38	4.60
Entrepreneurial skills of founders	4.41	4.58
Founders' reputation	4.41	4.50
Managerial skills of founders	4.03	4.24
Total score	**4.39**	**4.63**

As we can see from Table 3, the most significant factor inherent in the two groups of business angels with different investment experience is trust in the founders of start-ups. The most experienced business angels rated the trust at 5.21 points, while the less experienced - at 4.75 out of 6 points. Next, we will consider the differences in the assessment of start-up founders made by different groups of business angels.

The results of the study show (see Table 3) that for the most experienced business angels, the next most important factor coming after trust is the professional and entrepreneurial skills of the founders who scored 4.60 and 4.58 points, respectively. Then follows the reputation of the founders (4.50 points). The least significant are managerial skills of the founders of start-ups (4.24 points).

Business angels with investing experience up to three years think that the entrepreneurial skills and founders reputation ranked second (4.41 points), followed by the professional skills (4.38 points) and managerial skills (4.03 points) of the start-ups founders.

The obtained results reflecting the importance of business angels' trust in start-up founders confirm the point of view of many researchers. For instance, Mason and Harrison (2002) having questioned 74 business angels of UK stated that one of the main drawbacks (which is a reason for projects' being rejected) is untrustworthy entrepreneur and team. Moreover, Mason and Harrison (2002) emphasize that, if the entrepreneur and his team had a high reputation, business angels are ready to reduce their investment criteria – for instance, financial ones.

Many researchers note that trust is a key component of economic relations (Gambetta, 1990; Fukuyama 1995; Kramer & Tyler, 1996) and entrepreneurial activities (Low & Srivatsan, 1993; Dibben, Marsh, & Scott, 1996). Besides, Low & Srivatsan (1993) note that, at the level of entrepreneurial activities, trust is an important factor in building relationships. Within the framework of this study, we can speak of the interrelations between business angels and start-up founders.

Gulati & Sytch (2008) and Dirks & Ferrin (2001) emphasize that trust is especially important in situations characterized by risk and uncertainty, directly related to venture capital investment. Indeed, business angels' investments are always associated with a high level of uncertainty and information asymmetry. Bottazzi, Da Rin, and Hellmann (2010) hold a similar position, proving that in venture capital investment, trust has a positive effect on readiness to invest.

Mason and Harrison (1996) note the importance of expertise possessed by entrepreneurs. At the same time, Hindle and Lee (2002) emphasize the significance of previous work experience of start-up founders. Wessendorf et al. (2019) hold a similar view. They believe that the key factors having impact on business angels' decision on investment are individuality and experience of founders as well as the

market potential. Let us consider the differences in assessing the entrepreneurial and professional skills of founders by business angels with different investment experience. As we can see from table 3, business angels with less investment experience gave higher marks to the entrepreneurial rather than professional qualities of start-up founders. We believe that the position of the most experienced business angels who gave higher marks to professional skills of founders looks more reasonable and substantiated. Indeed, exactly professional skills of founders allow one to turn dream into a feasible project and achieve high multipliers, which angels and other venture investors are counting on.

Now let us consider the influence of reputation upon business angels' decision on making investment in a start-up company. In previous studies like Shapiro (1983), Weigelt & Camerer (1988) the authors note that reputation is highly valuable in the conditions of high uncertainty – especially, at the initial stages of start-ups activities. Favourable reputation can help interested parties make decisions on investing in young companies. Stuart, Hoang and Hybels (1999) underline that start-up companies enjoying high reputation have easier access to capital even when their uncertainty level is high enough. Nicolò (2015) notes that, if the company's reputation is positive, with all other things being equal, the level of business risk is perceived as a lower one.

The results of this study show that the most experienced business angels ranked reputation only in the fourth place among other investment criteria. This situation could arise because, as some researchers point out, there is a connection between reputation and trust. For example, Nicolò (2015) and Zhukova (2017) note that a positive reputation allows the company to gain the trust of parties. Thus, we can assume that when choosing between trust and reputation, business angels lay greater emphasis on trust in the founders of start-ups.

Within the framework of this study, it was found out that, when taking decision on investing, managerial skills of start-up founders are the least important to all the groups of business angels.

Whereas Mason and Harrison (2003) point out in their paper that impression management skills of entrepreneurs are critical in raising finance from external investors, still we would like to comment on the result obtained.

First, a study by Mason and Harrison (2003) did not compare the importance of managerial skills of entrepreneurs with other investment criteria applied by business angels to start-up founders. Secondly, one can assume that the angels valued managerial skills at a low rate, ranking them as the least in importance, since, after investing in a business, angels can take an active part in the activities of the enterprise and help founders to adjust the managerial aspects of their activities.

In the final part of the study, we compare the general average scores for all the five groups of investment criteria applied by business angels to the founders of start-ups. As can be seen from Table 3, the most experienced business angels scored a higher overall average score of 4.63, while business angels who invested up to 3 years had a total average score of 4.39 out of 6 points.

The analysis of the data presented in Table 1 shows that for all five groups of investment criteria, the most experienced business angels place higher demands on start-up founders.

Conclusions

The results of the analysis of the opinions of 104 business angels show that when making a decision on investing regardless of experience, the most significant criterion for business angels is trust in the founders, and the least significant are managerial skills of start-up founders. The most experienced business angels are ready to invest at the following level of assessments of start-up founders: trust in the founders - 5.21 points, professional skills - 4.60 points, entrepreneurial skills - 4.58 points, reputation of the founders - 4.50 points and managerial skills – 4.24 points out of 6.

The results of this study show that, with respect to all five groups of investment criteria, the most experienced business angels place higher demands on start-up founders. Thus, we can conclude that with the growth of investment experience, the business angels' requirements to the founders become more stringent.

Business angels with different investment experiences can use the results obtained in order to make more reasonable and substantiated investment decisions. On the other hand, the results of this study will allow start-up founders to better understand expectations of business angels, increase their competencies, form the professional team and build their relationships with potential investors more efficiently.

Abstract

Technology plays an important role in our life and it has become a need for our day to day life. In tandem with the development of technology, social media entrepreneurship has become widely popular among university students in Malaysia. Here, they are the most extensively used social media as the medium of communication, searching for information, creating networking, and doing online business. With this regard, social media has a significant impact on online business activities in Malaysia. Therefore, this study aims to explore the relationship between factors that influence university students to use social media as part of the medium to do online business. This quantitative research with a survey questionnaire that contains questions related to information on the respondent profiles, factors that influence the university students of using social media in doing business, and the cause or desire for them to engage in the social media were being developed. 140 respondents got involved in this study which includes respondents from different backgrounds and universities. In this study, data were analyzed by using the Statistical Package for Social Sciences (SPSS) software and a descriptive type analysis method. The findings of the study showed that each defining factor had a significant relationship with the desire of factors that influence the university students venturing into the online business.

Keywords: Technology Acceptance Model**,** Online Business, Social Media, Youth, Human Capital Development

INTRODUCTION

According to Kaplan and Haenlein (2010) social media can be defined as an internet-based application that being develops using Web Technology of 2.0, and which enables the creation and exchange of information and networking. Media serves to convey a type of information that in the form of entertainment, such as Instagram, Twitter, Facebook, Youtube, and more than that has enhanced the way of sharing information and communication. According to Destiana, Salman, and Rahim (2013), social media has had an impact on the involvement of the community as a whole.

In this study, the focus on the relationship between social media involves university students in Malaysia who are venturing into entrepreneurship activities where it has transformed the collaborating and interaction (Aral, Dellarocas, & Godes, 2013). It is pointed out that the young generation is now more likely to use social media as a medium of communication and doing business. Thus five top social media platforms today are Facebook, followed by Instagram, LINKEDIN, Google + and Pinterest.

Facebook, originally founded by Mark Zuckerberg as a medium to communicate and share information for Harvard students alone is now the world's most phenomenon social media.

According to Fadzil and Yaacob (2014), most of the customer have access to internet facilities such as social media platform and this has changed their lifestyle where they prefer to do online purchases. This is because the convergence of traders has changed towards the online platform. Furthermore, according to Rahim (2015) the global marketing, today focused on the digital market which is more effective the traders and buyers actively use social media as a medium of business. In regards to the research problem stated, this study seeks to answer the following questions on: (1) what are the factors that influence university students to use social media in doing business; and (2) is there a relationship between social media and online business intention among university students.

This study is significantly important to university students, entrepreneurs, and the public that has the intention to get involved in online business via social media. In addition, this study also provides an important knowledge gaps to the other researchers to be able to use the findings from this study to make future research related to the desire factors that influence the university students venturing into the online business/

LITERATURE REVIEW

This social media combines the internet, computer and information technology, networks, and digital media content. The information that is generated might differ from the traditional technology in the previous era because the new media has the characteristics of digital networks, global access, interactive, and communications that combine all elements of oral communication, writing, visual, data, and sound by using computers and telecommunication that available in a single platform.

The surge in Internet users has led to dramatic changes in the way of doing business. From our daily life to online businesses, the Internet has impacted and changed the way people managing their life. Business on social media offers a great opportunity for both users and businesses around the world (Lee, Park & Ahn, 2001; Pourkhani, Abdipour, Baher, B., Moslehpour, 2019). While in accordance with Erdoğmuş (2012) social media has tremendous advantages in assisting the businesses, particularly in developing product branding through networking and online communication.

According to Rawi and Omar (2012), several factors influence university students of using social media to exploit an online business such as the usefulness and convenience to use, social influences, beliefs as well as cost factors. The usefulness and ease of use were adapted from the acceptance model (TAM) which was developed by Davis (1989). Meanwhile, social influence and cost are based on a survey framework built by Rawi and Omar (2012). Based on the previous research, researchers can conclude that the usefulness and easy-to-use factors, social influences, beliefs, and costs are seen to have a relationship with the involvement of university students in entrepreneurship activities by using social media.

Perceived Usefulness and Easy to Use

According to Ramdhani (2007) the perceived usefulness refers to a technology that is easy to use, simple, and quick. While McCloskey (2004) states that easy to use is an important factor that affects or has a direct relationship in affecting consumers to do buying online or not. Based on the previous research discussed, the following is the hypothesis formed by researchers:

Hypothesis 1: There is a significant positive relationship between the perceived usefulness and easy to use among university students to engage in online business.

Social Influences

Rashotte (2007) defines social influence as a person that can influence others in terms of feelings, attitudes, and behaviors whether intentionally or unintentionally. Fan, Saliba, Kendall, and Newmarch

(2005) found that users like to provide suggestions and recommendations regarding a service that they used to others if they are satisfied with the services. They usually will then will try to influence others to try the services and sharing the same experiences (Fan and Friends, 2005; Olanrewaju, Hossain, Whiteside, & Mercieca, 2020). Therefore, social influences affect the user's desire to use the E-commerce platform (Wei, Marthandan, Chong, Ooi & Arumugam 2009). Here, it indicated that social influences have a profound impact on the use of an application such as online businesses. Based on the past study, the following is the hypothesis formed:

Hypothesis 2: There is a significant positive relationship between social influences and the intention to engage in online business.

Beliefs

According to Isaac (2015) beliefs refer to a level where a particular system will improve individual performance. Studies by Jarvenpaa, Tractinsky, and Vintale (2000) found out that confidence factors are important factors in sharing the risk and making electronic payments. In addition, Lim, Lim and Heinrichs (2008) stated that the confidence factor is a fundamental factor in doing business online. Based on that, the following is the hypothesis formed:

Hypothesis 3: There is a significant positive relationship between trust and intention to engage in online business.

Costs

According to Rahman (1998), the cost is a source that is taken into consideration in fulfilling the production requirement of a product, which is recognized in the form of currency value to producing new products or the establishment of a new company. Park (2010) and Aydiner, Tatoglu, Bayraktar, Zaim, & Delen, (2019), pointed out that the cost has a significant relationship to the involvement in online business intention. Therefore, consumers are very concerned with the cost of conducting business activities using social media. Based on the findings, the following were the hypothesis formed:

Hypothesis 4: There is a significant positive relationship between cost and intention to engage in online business

Methodology

Kerlinger (1973) pointed out that the survey questionnaire is more suitable in data collection due to its vast scope and has a wide range of information that could be obtained within a short time of period. In addition, information obtained is also more accurate.

The research design of this study is based on a model developed by Rawi and Omar (2012). In this study, researchers have identified a lean variable which is the deciding factor that influences the university students using social media in doing online business. Four deciding factors were used in this study which are the usefulness and convenience, social influences, beliefs, and costs. While the dependent variables used by researchers in this study was the intention to engage online business. In order to obtain the data, researchers have used online survey methods to distribute the questionnaire to the potential respondents who conduct business online. In this regard, a questionnaire is divided into three parts, namely section A, B and C. Section A of this questionnaire includes information on respondents, Section B deciding factors, while Section C is in respect of intention to engage online business. To analyze the data obtained, researchers use the software Special Package for the Social diminished (SPSS) for Windows" version 22.0

Table 1: Pilot Study

Dimension	*Cronbach Alpha (α)*	Items
Factors affecting	0.939	18
Invovlement	0.921	18

Prior to this study, the pilot study was carried out. A total of 20 survey questionnaires were distributed to the respondents. Questionnaires are used as a research tool as it is the main method for measuring the defining factors and involvement of university students in online business. Here, based on Table 1, the pilot study was carried out to the 20 respondents involved in business using social media. The Cronbach Alpha on the factors affecting the university students using social media is 0.94, meanwhile for the involvement of university students in the online business is 0.921. Thus, none of the items used in these studies were modified and being used in the next process of data collection.

Results and Discussion

Most of the respondents agreed that the perceived usefulness and ease of use, social influences, beliefs, and costs were highly influenced them to use social media in doing online business using social media. The deciding factor that influences the university students using social media in doing business is at a high level indicates that every factor surveyed has a similar level of influence to the previous study. They believe that the deciding factor is important in influencing them to use social media.

The perceived usefulness and ease of use factors have influence factors to the university students. Based on the analysis gather from the study, it is found that hypothesis 1 that mentioned previously in the study is accepted. Therefore, data shows that there is a significant relationship between the perceived usefulness and ease of use among university students involved in the online business activities. The findings supported by Hassan and Hassan (2008), where the perceived usefulness and easy-to-use factors have moderate significant relationships with the desire to use websites among non-user sites.

Meanwhile, the social influences factors have a significant relationship with university students involved in online business activities. This indicated that hypothesis 2 was accepted. Thus, there is a significant relationship between social influences and the university students involved in online business activities. Tsu Wei, Marthandan, Yee-Loong Chong, Ooi, and Arumugam (2009) argued that social influences might be contributed to the decision by the users to get involved in online business.

Furthermore, the confidence factor also has a relationship with the students involved in online business activities. Based on the findings, therefore, trust factors also have a significant relationship. The findings support the previous research statement by Yee-Loong Chong (2009) that the confidence factor had a positive significant relationship with the online purchase.

Finally, the cost factor has strong relationships with the involvement of university students in online business activities. Therefore, based on the findings of the study, the hypothesis of 4 built was accepted. This is because the cost factor has a modest significant relationship. However, the studies from Chu and Lu (2007), stated that the cost factor had a negative relationship with the desire to make purchases of online music which is $P = 0.001$ and $r = -0.63$.

Conclusion

Malaysia is also one of the country that emphasizes digital business that encourages entrepreneurs to use social media platform as a catalyst for business. The university students also take advantages of this technology in doing business online. Indeed, with the current features available in social media has create intention to the entrepreneurs in manage, equip, organize and advertise the information related to

their products and the services to be more attractive to attract customer interest. Here, the articles, writings, photos, videos, or any other forms of information can be included in social media that are visible to all users on the Internet.

Abstract

The main task of smart cities is to strive for sustainable development in such a way as to meet the needs of the present generation without compromising the living conditions of future generations. The limited resources and the need to maintain or increase the quality of the services offered at the same time as various problems arise, require the use of solutions, including innovative technologies and concepts, which by definition fall within the scope of smart city. The aim of the article is to discuss theoretical aspects related to the construction of smart city concepts, including an in-depth bibliometric analysis related to the topic, as well as to indicate the scope and areas of the innovations in the implemented concepts. The authors will define the concept of smart city, elements, dimensions and areas included in the main assumptions of the concept. Special attention will be paid to the aspect of sustainability and "green" practices taken in cities. In this paper will be show what areas are of interest to researchers, how popular this area of research is, what are the links between authors and to what extent articles on this topic are cited. Authors present the own taxonomy relating to the classification and assignment of the smart city concept to particular fields of science and to refer innovative solutions implemented in the smart city concepts.

Keywords: bibliometric analysis, smart city, innovation.

Introduction

The concept of the smart city is becoming increasingly popular not only among practitioners (city managers) but also among scientists. It is confirmed by the growing number of scientific publications, from various fields of science. Concepts are an innovative field of scientific considerations, and the constantly growing urban population requires the application of space management tools in a modern and sustainable way with using innovative and sustainable methods.

The aim of these considerations is to: (1) present the taxonomy of the smart city concept in terms of scientific domains (according to OECD), based on the adopted author's definition of smart city, (2) quantitative analysis of scientific publications in the field of smart city, (3) relate the smart city concept to the aspect of sustainable innovations and solution in the cities.

The considerations are accompanied with research thesis, indicating that the created classification of fields, whose research interest relates to the smart city, speaks about the high interdisciplinary of the concept and the need to link solutions with different areas of business, economy, social, legal or environmental aspects. The solutions have an impact on every field and every area of life of the

inhabitants of urban areas. In addition, the focus on sustainable innovations within the smart city concept indicates a link between the concept and traditionally understood urban logistics supported by information tools and technologies and different research and economy fields.

A systematic and critical review of the literature made it possible to identify the directions of research undertaken. The architecture of the concept, links and main areas of research were also indicated. A novelty of the considerations is the selection of texts dealing with the above issues in economic and social sciences. The interdisciplinary of the concepts and assumptions of the smart city and the inseparable link with information technologies also indicate a business context that can be used for better organization of the pillars of the smart city concept. The concepts are linked to practical solutions and the implementation of sustainable innovations.

Problem Description

In 2018, 4.2 billion people (55% of the total population) lived in urban areas, and it number is projected to grow by 2.3 billion by 2050. This means that the proportion of the urban population will rise to 68% of the total population. (Revision of World Urbanization Prospects, 2018). Both the growth of the urban population and its pace pose a challenge to spatial managers and users, particularly with regard to environmental and social aspects. Cities consume about 70% of the world's resources, are major consumers of energy resources and account for a significant share of greenhouse gas emissions (Bibri, S. E., & Krogstie, J. 2017). This is related to both population density and development, as well as to the intensity of economic activity in urban areas. This situation points to a number of challenges facing cities, which are related to increasing pressures on their resources and infrastructure (Breetzke, T., & Flowerday, S. V. 2016). The limited resources and the need to maintain or increase the quality of the services offered at the same time as various problems arise, require the use of solutions, including innovative technologies and concepts, which by definition fall within the scope of smart city. Smart city is a complex and interesting research area, the results of which arouse interest of scientists, researchers and business practitioners. Cities use the smart city concepts to improve various aspects of their functioning and management. They use ICT technologies, which constitute one of the foundations of smart city in the scope: local economy, transport, traffic management, environment, quality of life for citizens, and electronic delivery of public services (Li et. al., 2017). It should be noted, however, that the subject matter itself is still in the research phase. A rich review of the considerations can be found in the literature, but there is no clear taxonomy to standardise the definition and terminological inaccuracies.

The multitude of emerging ideas and practical solutions related to smart cities often contributes to the lack of clarity of understanding of the concept. The presented deliberations have an aim, on the basis of an in-depth analysis of literature, using the method of content analysis, dedicated tools for bibliometric measurements and strategic documents, to define the concept of smart city, as well as the elements, dimensions and areas included in the main assumptions of the concept. Exemplification of literature helps to achieve the main objective. Collection of different shots and terminology related to smart city will contribute to the development of a broad definition and validation of the meaning of the term depending on the term used (for example: smart, intelligent, knowledge). Digital Smart city research is interdisciplinary, established theory and based on qualitative research. (Bibri, S. E., & Krogstie, J. 2017). The second part of the consideration will refer to the definition of concepts for practical implementations specifically related to sustainable innovation in cities.

A novelty in the considerations is the analysis of the content and its interpretation in the conceptual scope of the smart city as well as the presentation of this taxonomy. The reflections indicate how precisely this area is identified and understood in the smart city. The cognitive dimension, on the other hand, has a part of paper related to the sustainable innovations in the smart city concept.

Methodology

To achieve the research goals and presented objectives have been used different research methods. It was reviewed the literature, which refereed to: a systematic, explicit, and critical analysis for identifying, evaluating, and interpreting the existing scientific texts (Fink, 2013). The aim of such an activity was to collect as much information as possible concerning the definition of smart city, as well as the areas related to it. This method, including the selection of available which contain information, ideas, and data have written from a particular standpoint documents helps to fulfil certain aims and the effective evaluation of these documents in relation to area being proposed of the research (Hart, C. 2001).

Due to the rich and numerous sources of literature, in the research process the authors adopted the proposed 4 steps research model (Seuring, S., & Müller, M., 2008; Mayring, P. 2003). Research studies was applied with content analysis. This method is a type of qualitative study (Moldavska, Welo, 2017) and is used for this type of research. Content analysis enables a better understanding of the studied phenomenon and determination of correct and repeatable conclusions from the research (Griffin, 2013; Krippendorff, 2004).

This detailed analysis of Smart City publications were use a descriptive, qualitative content analysis design with conventional content analysis. The publications were searched in the Web of Science and Scopus databases, which contained the expression "smart city" or "intelligent city" in their title, abstract or key words. The literature review covered the years 2002-2020. A case study methodology was used to develop aspects related to sustainable innovations in the smart city concept to illustrate the contents and practical elements of the concept.

State of the art

Smart City as A Research Area

A detailed review of the scientific literature allows to observe the multifaceted development of urbanized urban areas. The concept has been communicated as: smart cities, knowledge-based cities, Smart City and City Logistics or digital city, intelligent city, cognitive city, and knowledge city (Peprah, C., et. al. 2019). The interest of scientists representing various fields of knowledge and areas of science indicates that it is difficult to identify and adopt a clear and universal definition of smart city. Practitioners and researches of smart cities have a different approach to the concept according to their main orientation and directions of the research, for example, technology, economy, society, environment, and governance (Yigitcanlar, T. 2017).

Smart City concept goes beyond the narrow understanding of "smart" development, based largely only on ICT. Technologies support smart city conceptions, as well as improve sustainability, economic development and quality of life. (Dawe, S. N., & Paradice, D., 2016). In the literature, in the absence of a uniform, generally accepted definition of the phenomenon of the Smart City concept, two main trends can be observed in defining this concept. A part of the work is defined by Smart City as a city where ICT technology co-creates the infrastructure of cities used to a large extent in economic and social initiatives aimed at improving cities' economic growth, creating social capital and improving the efficiency of using urbanized urban areas. The authors of this approach are N. Komninos, S. Mohanty et. al 2016; Zanella et. al 2014; who define Smart City as a city that uses network infrastructure to improve economic and political efficiency and enable the social, cultural and urban development of city users. Initiatives and concepts related to the implementation of smart city are aimed at improving a city's quality of life (Neirotti et. al, 2014). Other areas that can be upgraded and enhanced with smart city are: performance, efficiency and sustainability through the use of technology (Albino, et.al. 2015; Komninos, et. al, 2013). Smart City uses Information and Communication Technologies (ICTs) and other means, concepts and ideas to improve quality of life; efficiency of urban operation and services; competitiveness; while ensuring that it meets the needs of

present and future generations with respect to economic, social and environmental as well as cultural aspects (Ibrahim et. al, 2018; Khan, 2018).

According to S. Mohanty (Mohanty, 2016) Smart City is a place where traditional networks and services are made more flexible, efficient, and sustainable with the use of information, digital and telecommunication technologies, to improve its operations for the benefit of its inhabitants. In a smart city, the digital technologies translate into better public services for inhabitants, and for better use of resources while impacting the environment less. A smart city connecting the physical infrastructure, the information-technology infrastructure, the social infrastructure, and the business infrastructure to leverage the collective intelligence of the city (Berardi, et. al. 2015). From the other side smart city is an innovative city that uses information and communication technologies (ICTs) and other means to improve quality of life, efficiency of urban operations and services, and competitiveness, while ensuring that it meets the needs of present and future generations with respect to economic, social and environmental aspects (Sundaravadivel, et. al., 2017, https://www.itu.int/en/ITU-T/focusgroups/ssc/Pages/default.aspx). Describing a smart city it should be pointed out that it is an area of influence increasing urban efficiency with regard to energy, transportation, land use, communication, economic development, service delivery, and so forth (Bibri, S. E., & Krogstie, J. 2017).

On the other hand Batty et.al (Batty et. al, 2012) and Bibri, S. E., & Krogstie, J. (Bibri, S. E., & Krogstie, J., 2017) indicate exemplary smart city goals now and in the future. The most important of these include: mobility and travel behavior; modeling urban land use; integrated databases across urban domains; sensing, net-working, and the impact of social media; participatory governance and planning structures; modeling network performance; trans-port and economic interactions; and decision support as urban intelligence. All these elements must be based on ICT and advanced technologies, with the support and participation of citizens and other users of urban space. The concept of smart city has gained an increasing attention during the past decades with main focus on the hardware (e.g. technology, infrastructure) as well as the software (e.g. human, society). (Yadav et. al. 2019; Li et. al. 2019; Palomo-Navarro & Navío-Marco, 2018; Yigitcanlar et. al, 2018). The Smart City areas and paradigms were showed in Figure 1.

Figure 1: Areas of application of the smart city concept

Source: own elaborations.

Frequently indicated areas of smart city are: governance, citizen, energy, building, mobility, infrastructure, technology, healthcare (Frost and Sullivan, 2012; Peprah, C., Amponsah, O., & Oduro, C. 2019). The presented models and areas are not perfect, but they refer to the most important

elements of urban space in a comprehensive way. From a consideration point of view, attention will be focused on the area of mobility, which refers to the organisation of transport in cities, in accordance with logistical rules, taking into account the greatest possible use of ICT, in the implementation of projects. The most important goals of the smart city should be considered: pollution, reducing traffic congestion, increasing people safety, reducing noise pollution, improving transfer speed, and reducing transfer costs. It can therefore be concluded that Smart Mobility, included transport and information and communication infrastructure (ICT). This area includes: well organised public transport, transport accessibility of the city at national and international level, provision of ICT infrastructure, sustainable, modern and safe transport systems, implemented logistics solutions for freight transport (in terms of city logistics).

Sustainable Innovation in The Smart City Concept

Innovation plays a two-fold role for sustainable development: in the following, it is pointed out that innovation about sustainability, can both be a supporting means for attaining sustainability but innovation can itself be considered sustainable (Steiner, G. 2008). Both approaches can be applied to the smart city concept. Sustainable innovations include an economic, ecological and a social aspect, and their implementation takes place within the scope of the specific pillars of the smart city concept. Smart cities are mostly technology oriented advanced cities. The people must be motivated to use technology to get benefitted from the smart system (Kumar, H., Singh, M. K., Gupta, M. P., & Madaan, J. 2020). The area of innovative phenomena is extremely vast, they differ in the nature of events, the functions of the target and the ties between them. One of the most important and crucial aspects is the process of learning, knowledge management and supporting creativity. This approach fits perfectly into the smart city concept.

The concept of eco-innovation is not clear. It is interpreted differently and covers different thematic areas. In general, it can be pointed out that: sustainable innovation is defined as “the development of new products, processes, services and technologies that contribute to the development and well-being of human needs and institutions while respecting natural resources and regeneration capacities” (Tello, S. F., & Yoon, E. 2008). They are innovations in which the renewal or improvement of products, services, technological or organizational processes not only delivers an improved economic performance, but also an enhanced environmental and social performance, both in the short and long term have the capacity to generate positive social and environmental impacts (Cillo, V., et. al, 2019). The link to the smart city is clear. The pillars of the smart city include economics, life, social inclusion, environment, government and mobility. Smart cities are mainly about collecting and disseminating data (Lom, M., & Pribyl, O. 2020). Each of these areas uses modern technologies, which for most cities are associated with implementation of innovation, and the directions of development of cities and economies (sustainable development) in connection with the objectives of their inhabitants (including quality of life) clearly indicate that innovations should be sustainable.

Data collection and limitations

Data Collection

Taxonomic approach to smart city concepts is related to the identification (at this stage of research) of areas and fields of scientific research in which smart cities are described and considered from a scientific point of view. By performing bibliometric analyses of two databases Scopus and Web of Science, the following conclusions can be drawn. Scientific publication can be generally grouped according to the categories based of the OECD classification. The most popular areas show Table No. 1 Smart city is used by scientists from various fields and could be correlate with the areas and paradigms of the smart city to indicate and create the taxonomic approach to the issue under consideration.

Table 1 : Most popular areas of science related to smart city publications

Web of science	No. of publications	Scopus	No. of publications
Engineering Electrical Electronic	3650	Computer science	3787
Computer Science Information Systems	2308	Engineering	2316
Telecommunications	2143	Social science	1519
Computer Science Theory Methods	2119	Mathematics	765
Computer Science Artificial Intelligence	1117	Energy	576
Urban Studies	1,054	Business, management and accounting	561
Computer Science Interdisciplinary Applications	1,018	Environmental science	477
Green Sustainable Science Technology	853	Decision sciences	434
Computer Science Hardware Architecture	791	Physics and astronomy	298

Environmental Sciences	484	Biochemistry, genetics and molecular biology	106
Regional Urban Planning	459	Arts and humanities	97

Source: own elaboration.

Analysing publications related to smart city, it should be pointed out that the interest in the subject is constantly growing, and the breakthrough year was 2012, when both the Scopus and the Web of Science databases exceeded 100 publications in this area (WoS -228, S - 118). The first scientific article containing smart city issues was published in 1985 in the Web of Science, in the Scopus database the first appeared in 1994. In 2017, both databases were published in more than 1000 publications, which even to some extent referred to the smart city. In 2019 there were over 2800 such publications in the Web of Science and over 1700 in the Scopus database. This clearly indicates the interest of researchers and an interesting area of scientific exploration.

Considering such a large number of publications, it is possible to create a taxonomic basis connecting the areas of implementation of smart city and fields of science, with the greatest publishing activity. Its construction results from bibliometric analysis. (Figure no. 2)

Fig. 2: Taxonomy of smart city

Source: own elaboration.

Moving on to further systematic, based on the OECD classification into scientific disciplines, we can indicate the dominating ones in the field of smart city. Thus, on the basis of Web of science (100 most popular areas), most publications assigned to engineering, technical and social sciences have been identified, natural and agricultural sciences also play an important role, medical sciences are less important and link them to defined smart city areas (figure no. 3).

Fig. 3: The systematic of smart city areas with link to scientific fields.
Source: own elaboration.

By analysis of publications, it is possible to indicate in an in-depth analysis in which area of knowledge systematics (according to OECD) is reflected in the area of research interests of scientists (Table no. 2).

Table 2 : Most popular areas of science related to smart city publications

science systematic (OECD)	**area of knowledge**

Limitation

The structured literature review was conducted among documents written in English, in reviewed and indexed journals, covered the years 2008-2020. Documents that appeared in several databases have been eliminated. The total number of papers for further analysis is N=356. The final number of publications was achieved after in-depth analysis (Table 3).

Table 3: Stages of the research process

STEPS OF THE RESEARCH PROCESS			
Limitation	**Step**	**Scopus**	**Web of science**
"smart city"; "2008-2020'; "topic"	first	5431	5467
"smart city"; "2008-2020'; "title";"abstract"; "keywords", "article", "language -english"	second	1740	2240

Source: own elaboration.

Interpreting the results of the research from Table 2, can indicate that the interest in the concept of "smart city" is very high. Also interesting from the scientific point of view is the interdisciplinary of the research undertaken. However, the applied filters, and in particular the limitations related to the areas of business, economy and management, made it possible to select the appropriate number of articles for research. In the next table there is a descriptive statistical analysis concerning the increase of interest in publications related to "smart city" divided into individual years. In this case, only issues related to social sciences have been taken into account. The progress is clearly visible (Table 3).

Smart city solutions are interesting and popular, and we can draw such a conclusion taking into account the number of journals in which the above issues are published. In the Scopus database it was 84 and in the Web of Science it was 100 titles. The largest number of publications in one journals in a given field is more than 30 texts.

While analyzing the most popular journals, it can be pointed out that the authors most often publish in Cities, Technological Forecasting and Social Change (which can be found in both databases), Advances in 21st Century Human Settlements, Journal of Cleaner Production, Smart Economy in Smart Cities (Table 4).

Table 4 : Journal title (most popular) - in the field of economy, business, management

Source: own elaboration.

In scientific articles, innovation and sustainability appear just behind the smart city keyword. This approach shows that this area is extremely interesting and is one of the basic elements of the above concepts not only in terms of scientific development, but also practically.

Sustainable innovation solution in the cities – case studies

Innovative solutions in support of sustainable development in cities can be based on a variety of considerations. They can help cities to be more sustainable, they can be part of a smart city concept or a stand-alone innovative solution. Their implementation gives the city a distinctive, competitive advantage and meets the requirements of its stakeholders in terms of quality of life, friendliness, usability and environmental performance.

On the basis of case studies it is possible to indicate solutions that not only fit into the trend of innovative, sustainable solutions or smart city, but also show how cities can eliminate their development barriers, bottlenecks or problems occurring in them. The selected solutions are presented in table no. 6.

Table 6: The selected case studies for the sustainable innovation in the concepts of the smart cities

City	Name of concept/description	Characteristics
Laos (Nigeria)	Providing Incentives for Recycling in Low-Income Communities	Wecyclers is fueling social change for the environment by allowing people in low-income communities to capture value from waste using low-cost collection infrastructure. Wecyclers harnesses the power of urban communities to reclaim neighborhoods from unmanaged waste using a crowdsourced, rewards-for-recycling platform. Wecyclers uses a fleet of low-cost cargo bicycles to offer a convenient household recycling service in densely populated low-income neighborhoods.
San Francisco, USA	Mobilizing Behaviour Change for a Zero Waste City	Through extensive outreach and citizen engagement, San Francisco is pursuing a goal of zero waste by 2020 and has achieved an 80% land- fill diversion rate with environmental and social benefits. San Francisco's Zero Waste Program pursues the best use of materials, in collaboration with producer and consumer responsibility. The pro- gram conducts extensive outreach and assistance to encourage participation and mandatory compliance. It is entirely funded by "pay- as-you-throw" rates, providing financial incentives for both citizens and businesses to divert waste.
Washington D.C., USA	Energy Savings Finance the Switch to LED Lighting	By means of a 10-year performance lighting contract, Philips will install LED lights in the city at no upfront cost. Having secured a 10-year performance lighting contract with the Washington Metropolitan Area Transit Authority (WMATA), Philips will upgrade more than 13,000 garage lighting fixtures in the city. While Philips will be responsible for installation and continual maintenance, the city will benefit from the opportunity to circumvent the upfront costs of LED installation.
Lima, Peru	Waterless Toilets for Slums	-runner brings an appealing waterless sanitation solution to low-income households without access to conventional toilets in the capital of Peru, Lima. With subscription to a pick-up plan, households receive a waterless, resource-separating toilet combined with a weekly service that collects waste directly from the home. At the treatment hub, human feces are safely processed through composting, thereby generating a supply of natural fertilizers for farmlands.
Forres, Scotland	Floating Ecosystems for River Restoration and Water Quality	Biomatrix Water Active Ecosystems have been developed to provide a concentrated natural solution to improve water quality. The designs harness the power of nature to provide a long-term sustain- able water quality management solution, which uses no chemicals and gets better with time as the system grows.
Mannheim, Germany	Communication Platform for Integrating Renewable Energy	By means of a real-time communication platform, "energy butler" devices help homes to optimize consumption according to the availability of renewable energy. This solution, based in the German city of Mannheim, involves an intelligent power grid that balances energy demand and supply.
London, UK	Citywide Parking Sensors for Lowering Congestion	By installing parking bay sensors across the city, this solution allows motorists to directly access available parking spaces – reducing congestion, air pollution, and fuel consumption in the process. This solution delivers real-time information regarding parking space availability to smartphone users in order to improve urban air quality and reduce congestion.
Portland, USA	Porous Asphalt for Stormwater Management	By allowing rainwater to seep through it, porous asphalt is an effective stormwater management tool that can increase road safety, improve water quality, and replenish water tables. Made without the need for additional materials or equipment, this material achieves its porous qualities through the removal of fine particles. Coarse particles allow water to seep through to the underlying recharge bed, and ultimately to the soil, during rainfall.
Melbourne, Australia	Public-Private Partnership for Citywide Retrofitting	Melbourne's Environmental Upgrade Agreement (EUA) system is part of the city's efforts to meet its goal of reaching carbon neutrality by 2020. It consists of an agreement between a property owner, a bank, and local government that facilitates a building upgrade to improve energy efficiency.
Göteborg, Sweden	Innovation in port	To compete for the business of a company that wanted to green all aspects of its shipping, Göteborg, Sweden developed a wind-powered onshore electricity port to power ships. Typically ships are powered by diesel auxiliary engines. The system cuts port-side emissions by 94-97 percent.
Reykjavik, Iceland	Renewables energy	Using geothermal energy for heat isn't new to Iceland, Reykjavik has been doing it since 1930. So it's no surprise that they have the world's largest geothermal heating system and the city is powered completely by geothermal. Because of this, CO2 emissions have been reduced by up to 110,000,000 tons from 1944 to 2006. The system keeps 4 million tons of CO2 out of the atmosphere each year.

Bogotá, Colombia	Transport	One of the most advanced bus rapid transit (BRT) systems in the world can be found in Bogotá. The Bogotá Transmilenio system averages 1,600 passengers a day on each bus (nearly 1.5 million passengers daily). It has cut travel time by 32 percent, eliminated the need for many public service vehicles, reduced gas emissions by 40 percent, and decreased accident rates by 90 percent.
Copenhagen, Denmark	Waste	Copenhagen's waste management system sends only 3 percent of waste to the landfill. The city promotes waste prevention by encouraging recycling and composting. Consumers can recycle some of their waste at the stores where products were purchased. And about 40 percent of the city's waste is incinerated, which has generated about 1 million megawatt hours of energy.
Tokyo, Japan	Water management	Tokyo's water management system is one of the world's most advanced. Through an efficient leak detection system, the city has cut the amount of water it wastes in half. In the last 10 years the amount of wasted water dropped from 150 million cubic meters to 68 million. It's leakage rate has dropped from 20 percent to 3.6 percent.
Chicago, USA	Lighting system	By switching many of its traffic lights to LED lighting, Chicago has reduced its energy output from traffic lights by 85 percent. The change saves the city $2.55 million and reduces 23,000 tons of CO2 annually. So far 1,000 traffic lights have moved to LED and the rest will be completed in the next three years.
Berlin, Germany	Buildings	The "Berlin Energy Saving Partnership" is an innovative program that helps building owners invest in energy-saving retrofits. It's popular in the city because building owner don't have to make upfront payments on the retrofits. So far 1,400 buildings in the city have benefited from the program and are saving about 26 percent on their energy bill, while cutting their energy use by about the same amount.
Toronto, Canada	Energy	A lake water air-conditioning system is reducing energy use by 90 percent compared to traditional cooling systems. Enwave Energy Corporation uses cold water from Lake Ontario to air-condition 29 million square feet of buildings in downtown Toronto.

Source: own elaboration on the basis: https://www.zdnet.com/article/8-innovative-cities-leading-the-way-to-a-sustainable-future/ (15.08.2020).

When interpreting and analysing the indicated cases, it should be pointed out that innovative solutions are applied not only in rich countries, but also in developing countries or countries facing completely different problems in cities than highly developed countries. The solutions can serve as examples for implementation in other cities, and can be inspiration for the another.

Conclusions

Topics related to the implementation of the smart city concept are extremely interesting and popular among researchers. It is confirmed by the bibliometric analysis. Researchers from various fields undertake studies related to smart city, covering various fields of knowledge. A multitude of publications appearing in recent years, as well as the observed continuous progress indicate that research on smart city is one of the most interesting and popular areas of research. Knowledge of the concept, possibilities and above all the definition of smart city can contribute to better management of the city, increase the quality of life of its inhabitants, but also make cities more friendly to all stakeholders. Research on the smart city, and above all the new taxonomy, limited to the area of management and economy, indicates the directions of research, as well as the main centres dealing with this issue. Most of the inhabitants of the globe live in cities, which means that the subject matter is interesting and important for the majority.

In the presented deliberations, the taxonomy of the smart city was proposed in connection with scientific fields and areas selected on the basis of bibliometric analysis. Quantitative analysis was carried out in selected areas of the smart city. The considerations proved the high interdisciplinarity of the concepts and the need for further research in this area, including the linking of social sciences and technical research in particular. The study indicated that concepts should be understood as a holistic approach, including ICT solutions supported by traditionally understood implemented tools and

concepts of urban logistics. The introduction of the smart city is related to three categories of challenges that modern smart cities have to face: social, technological and governance. Helpful in implementing area will be both scientific studies and practical solutions.

As practical solutions show, sustainable innovations are present in smart city concepts, supporting them and at the same time distinguishing cities from others. Also the analysis of the literature shows that sustainability and innovation play an important role and are reflected in science and research.

Implementation of The Cyber Terrorism Prevention, And Rehabilitation Policy in Polda Metro Jaya Police in Central Jakarta

Dian Damayanti

Institut Ilmu Sosial Dan Manajemen STIAMI DKI Jakarta Indonesia

DianDamayanti17@gmail.com

Abstract

Crime of terrorism is not only done through the internet, but can also be done through networks that can send signals such as telephone communications. Implementation this system, terrorism cases will decrease every year. Implementation of cyber terrorism policy at the Police. Implementation of policy to overcome the problem of terrorism in Indonesia. This study uses a qualitative method. Based on the results of research and discussion of the implementation of cyber terrorism prevention, and rehabilitation policy at the Polda Metropolitan Police, the following conclusions can be drawn: Researchers in analyzing the of cyber terrorism at the Polda Metro Jaya Police in Central Jakarta used the concept of Van Horn and Van Meter (1975). Whereas the line of communication is already underway, with the existence of cyber patrols to reduce the number of criminal acts involving terrorism in cyberspace, the police are cooperating with parties related to all providers, the police and anti-terrorism agencies and the Ministry of Communication and Informatics. The aim of the implementation of cyber terrorism policies at the central Jakarta police station is to realize domestic security that includes maintaining public security and order, orderly and upholding the law, carrying out protection, protection, and services to the community, and maintaining public peace by upholding human rights.

keywords: Policy Implementation, Cyber Terrorism, Prevention, Rehabilitation and Cybercrime.

Introduction

The risk of terrorist attacks in Indonesia in recent years can be classified as low. Compared to other countries, there are only a few incentives so far. During the last 5 years there were 121 terrorist cases, where 89 people were killed and 111 injured. Among them there are 7 suicides. In 9 incedents, a total of 1,310 people have been kidnapped or held hostage, although ransoms are rarely made for the 2013-2017 period. Terrorist organizations in Indonesia, namely Jamaah Ansharut Daulah, have attacked 2 times, killed 27 cases and injured 48 people. both Lekagak Tegangati organizations had 2 attacks, 9 killings and 2 injuries. and Jihadi-inspired extremists, the number of attacks was 1 time, 0 cases were killed and 2 were injured (https://badanpendapatan.riau.go.id/home/hukum/8495315769-doc-20170202-wa0015.pdf accessed on 13 August 2020 at 14.00 WIB).

The legal basis for implementing the cyber terrorism prevention, rehabilitation and reintegration policy is Number 19 in 2016 article 1, regarding electronic transactions of Electronic Information and / or Electronic Documents and / or printed results that are legal legal evidence, and law Number 5 of 2018 concerning changes to laws number 15 of 2003 concerning the stipulation of government regulations in lieu of law number 1 of 2002 concerning the eradication of criminal acts of terrorism into law.

Literature Review and Previous research

Implementation Policy

The policy implementation approach model formulated by Van Meter and Van Horn is called the A Model of the Policy Implementation (1975). This implementation process is an abstraction or the performance of a policy embodiment which is basically deliberately done to achieve a high policy implementation performance that takes place in the relationship of various variables. This model presupposes that policy implementation runs linearly from political decisions, implementation and performance of public policies. This model explains that policy performance is influenced by several interrelated variables, these variables are:

1. Policy standards and objectives / measures and policy objectives
2. Resource
3. Characteristics of the implementing organization
4. The attitude of the implementers
5. Communication between related organizations and implementation activities
6. Social, economic and political environment

Van Horn and Van Meter (1975) effect on the rate of successful implementation of the policy. Disposition for Edward III (1980:53) is defined as the tendency, desire or agreement of the executive to implement the policy. If you want to be successful policy implementation effectively and efficiently, the executor is not just knowing what to do and have the willingness to carry out that policy, but they also have to have the will to implement the policy Meter & Horn (1975:472) states that there are three kinds of response elements that can affect the desire and willingness to implement a policy, among others, consist of knowledge (cognitive), and deepening understanding (comprehension and understanding) of the policy; toward their responses whether accept, or reject neutral (acceptance, neutrality, and rejection); intensity of the policy. An understanding of the general intent of the standards and policy objectives are important because after all, a successful policy implementation can fail (frustrated) when the executor (Officials) are not fully aware of the standards and policy goals. Directions disposition of the implementers of the standards and policy goals is also a crucial thing.

The executor might be failing in implementing policies because they reject what the objectives of the policy. Instead according to Kaufman in Meters & Horn (1975:473) and deep spread acceptance of the standards and policy objectives among those responsible for implementing the policy is a great potential to the successful implementation of the policy. The implementation of public policy in the context of local government bureaucracy is a matter that should be implemented, because they are there to serve the public. In the end, the intensity of the disposition of the implementers can influence the executive (performance) policy.

Cyber Terrorism

The world community hopes to predict acts of terrorism that will occur next because everyone believes that acts of terrorism will occur. One of the factors that can predict their actions is what methods they use to send their terror to the target population (Brenner, 2002: 149). This is where the media relate to terrorism as their means of communication. Terrorism is no longer a local problem for certain countries but an issue that covers a number of international aspects. Terrorism is an international phenomenon, so the response must also be international (Ganor,2002: 130). The terrorists are scattered everywhere by using the media as their means of communication as well as their communication medium in communicating their existence to the whole world. Their communication media starts from using books,

magazines, newspapers, music, films, software, games ranging from physical form (hardcopy) to softfiles which are distributed throughout the world (Brenner, 2002: 150).

Media and terrorism are two central themes that attract attention because they have a common thread. The common thread between the media and terrorism cannot be separated from the aspect of news commercialization. Terrorism is a social fact that can be used for the benefit of increasing news consumption. Meanwhile, modern terrorism makes use of communication media to create an effect on audiences through the form of propaganda terror. There is a symbiotic relationship between the two who meet at the point of interest in the need for information and the desire to be covered by the media. (Sukarno, 2011: 360-361). The relationship between terrorists and the media was also revealed by Hendropriyono (2009: 218) that there is a mutually beneficial situation (symbiotic mutualism) between terrorists and the media. The media have reinforced terrorist acts as politically out of proportion to what they should be. Terrorism is the deliberate use or threat of using violence against civil society or against civil society targets, to defend political objectives. The definition of terrorism is based on three important elements according to Ganor (2002: 126) including:

1. The essence of terrorism is in the use of threats or violence. Under this definition an activity that does not constitute violence or the threat of violence will not be defined as terrorism (including non-violent protests, peace demonstrations, tax rebellions, and the like).
2. The objectives of acts of terrorism are always political. Its goals are maintaining political goals, changing regimes, changing people with power, changing social or economic policies. In the absence of a political goal, a political act cannot be defined as terrorism. An act of violence against civilians that has no purpose, crime or criminal acts not related to terrorism. Some scholars include ideological or religious goals in the list of goals that are political.
3. The target of terrorism is civil society. Terrorism exploits the fragility of civil society to create great anxiety and and provokes an intense media reaction by striking against civilian targets.

Al-Qaeda's use of the Internet is based on the reason that mass media such as television and magazines have recently threatened the security of organizations and their members. Television has limited time to broadcast along, dense news as an application of their ideology. Even, mass media are considered unsafe by those who allows their message to be picked up by parties who have an interest and pervert the facts which influences public opinion on actions they. (Soriano, 2008: 16) Terrorists build a stronger network with the Internet. Even though there are many members who was jailed and died, an act of propaganda they are constantly being carried out and are expanding, even without a trace in the presence of this Internet.

Such that carried out by the Al-Qaeda in Pakistan after the American Air Force attacked Damadola Pakistan, they're trying to infiltrate United States web with its propaganda that they remind the Americans that they are will continue to terrorize. (Soriano, 2008: 15). Internet provides message boards and chat rooms for recruitment of terrorists, buy bombs, buy airplane tickets, coordinate attacks and gathered in one place without being physically present (Lumbaca & Gray, 2011: 47). The existence of the Internet they are trying to hack some sites belong to the United States government and some of its Western allies. Therefore, they try to erase their weakness by putting the organization into use new technology.

Osama Bin Laden's organization on it chooses to spread the word development they are mostly currently on the Internet. This internet then gave rise to the term cyber-terrorism where a group of terrorists using cyberspace (various Internet applications) in carrying out their acts of terrorism. Internet enables rapid dissemination of information, less risk, and cheap to a variety of constituents, ranging from potential to potential recruitment get prospective partners in the organization terrorists (Seib & Janbek, 2011: 21).

Many of them using cyberspace, for example a group found Abu Musab Al-Zarqawi from the Al Qaeda in Saudi has almost never been in direct contact with the mass media, they focus their activities their communication in cyberspace. This method keep them from receiving attention media at large. Paradoxically, the mass media himself using the web to find traces and messages about the latest terrorism they commit which will encourage the emergence of public opinion international. (Soriano, 2008: 15) For Al-Qaeda, the Internet is not the only method to reach for safer and more media fast, but also a turning point of its rise effective communication strategy compared to traditional media. First time to cyberspace able to allow direct communication between terrorists and the public.

The internet is not just fill the limitations of the mass media, but the Internet also allows them to avoid a number of moral rules contained in the media the masses and limit their actions, and this thing profitable for the strategy of acts of terrorism they. As did a group of jihadists along with the 2003 invasion of Iraq, the Internet not only lets them avoid operational risk, but allow them gain access by infiltrating the media system traditional such as Al-Jazeera (Soriano, 2008: 16-17).

Crime Prevention, Rehabilitation

Crime prevention has come to mean many different things to many different people. Programs and policies designed to prevent crime can include the police making an arrest as part of an operation to deal with gang problems, a court sanction to a secure correctional facility, or, in the extreme, a death penalty sentence. These measures are more correctly referred to as crime control or repression. More often, though, crime prevention refers to efforts to prevent crime or criminal offending in the first instance—before the act has been committed. Both forms of crime prevention share a common goal of trying to prevent the occurrence of a future criminal act, but what further distinguishes crime prevention from crime control is that prevention takes place outside of the confines of the formal justice system. In this respect, prevention is considered the fourth pillar of crime reduction, alongside the institutions of police, courts, and corrections (Waller 2006). This distinction draws attention to crime prevention as an alternative approach to these more traditional responses to crime.

In one of the first scholarly attempts to differentiate crime prevention from crime control, Peter Lejins (1967, p. 2) espoused the following"If societal action is motivated by an offense that has already taken place, we are dealing with control; if the offense is only anticipated, we are dealing with prevention." What Lejins was trying to indicate was the notion of "pure" prevention, a view that had long existed in the scholarship and practice of American criminology (Welsh and Pfeffer 2011). It is this notion of crime prevention that is the chief concern of this volume.

(p. 4)There are many possible ways of classifying crime prevention programs.2 An influential scheme distinguishes four major strategies (Tonry and Farrington 1995b). Developmental prevention refers to interventions designed to prevent the development of criminal potential in individuals, especially those targeting risk and protective factors discovered in studies of human development (Tremblay and Craig 1995; Farrington and Welsh 2007). Community prevention refers to interventions designed to change the social conditions and institutions (e.g., families, peers, social norms, clubs, organizations) that influence offending in residential communities (Hope 1995). Situational prevention refers to interventions designed to prevent the occurrence of crimes by reducing opportunities and increasing the risk and difficulty of offending (Clarke 1995b; Cornish and Clarke 2003). Criminal justice prevention refers to traditional deterrent, incapacitative, and rehabilitative strategies operated by law enforcement and agencies of the criminal justice system (Blumstein, Cohen, and Nagin 1978; MacKenzie 2006) In Building a Safer Society: Strategic Approaches to Crime Prevention, Michael Tonry and David Farrington (1995a) purposely did not address criminal justice prevention in any substantial fashion This was because this strategy had been adequately addressed in many other scholarly books and, more importantly, there was a growing consensus for the need for governments to strike a greater balance between these emerging and promising alternative forms of crime prevention and some of the more traditional responses to crime. Also important in their decision to focus exclusively on developmental, community, and situational

prevention is the shared focus of the three strategies on addressing the underlying causes or motivations that lead to a criminal event or a life of crime. Crucially, each strategy operates outside of the criminal justice system, representing an alternative, perhaps even a socially progressive, way to reduce crime. For these same reasons, we have adopted a similar approach in this volume.

A chief aim of this essay is to provide some background on this view of crime prevention. It also serves as an overview of the key theories that support these three main crime-prevention strategies, important research on effectiveness, and key issues that challenge the prevention of crime. Several observations and conclusions emerge:

• Crime prevention is best viewed as an alternative approach to reducing crime, operating outside of the formal justice system. Developmental, community, and situational strategies define its scope.
• Developmental prevention has emerged as an important strategy to improve children's life chances and prevent them from embarking on a life of crime. The theoretical support for this approach is considerable and there is growing evidence based on the effectiveness of a range of intervention modalities.
• Community crime prevention benefits from a sound theoretical base. It seemingly holds much promise for preventing crime, but less is known about its effectiveness. Advancing knowledge on this front is a top priority. Nevertheless, there are a wide range of effective models in community-based substance-use prevention and school-based crime prevention.
(p. 5)
• The theoretical origins of situational crime prevention are wide ranging and robust. The strategy boasts a growing evidence base of effective programs and many more that are promising. There is also evidence that crime displacement is a rare occurrence.
• Crime prevention is an important component of an overall strategy to reduce crime and is widely supported by the public over place and time. A special focus on implementation science and higher quality evaluation designs will further advance crime- prevention knowledge and practice. Striking a greater balance between crime prevention and crime control will go a long way toward building a safer, more sustainable society.

Reviewing the findings related to the motives and causes of terrorism, it can be concluded that rehabilitating terrorists is a complex job and requires a concept. This should include an individual assessment, a systematic plan and parameters of effectiveness. With the aim of rebuilding human capacities and functions in society, rehabilitation is always associated with efforts to return to a previous good condition. Rehabilitation must include the following steps: (1) The preparation stage, including the determination of rehabilitation objectives, survey and data collection, analysis and verification of information, initial assessment and needs analysis, detailed rehabilitation arrangements, analysis and risk management, coordination with related parties, preparation prisoners or rehabilitation participants, and prepare trainers or resource persons; (2) The stages of implementation, including general development activities, for example character development, basic economic skills, self-empowerment and specific development activities such as religious teachings, woodworking skills, anger management skills; (3) The follow-up stage, which includes ongoing counseling, friendship (discussion or dialogue), evaluation of the success of rehabilitation, receiving feedback for improvement, and community or service involvement. The target of the follow-up stage is prisoners who support ethical and social norms, display a positive attitude, and demonstrate readiness to rejoin the wider community. This aims to maintain the improvements that have been achieved by prisoners or former terrorism activists (Sukabdi, 2015)

Research Model

Law Number 19 in 2016 article 1, regarding electronic transactions of Electronic Information and / or Electronic Documents and / or printed results that are legal legal evidence, and law Number 5 of 2018 concerningthe eradication of criminal acts of terrorism into law.

Policy implementation variables, these variables are: Policy standards and objectives / measures and policy objectives, Resource**,** Characteristics of the implementing organization**,** The attitude of the implementers**,** Communication between related organizations and implementation activities**,** Social, economic and political environment**,**

Obstacles and efforts made in implementing cyber terrorism prevention and rehabilitation policies at the polda Metro Jaya Police Station in Central Jakarta

The aim of the implementation of cyber terrorism prevention and rehabilitation policies at the central Jakarta police station is to realize domestic security that includes maintaining public security and order, orderly and upholding the law, carrying out protection, protection, and services to the community, and maintaining public peace by upholding human rights.

Methodology

Qualitative research is a means for exploring and understanding the meaning individuals or groups ascribe to a social or human problem. The process of research involves emerging questions and procedures. Data typically collected in the participant's setting. data analysis inductively building from particulars to general themes. and the researcher making interpretations of the meaning of the data. The final written report has a flexible structure. Those who engage in this form of inquiry support a way of looking at research that honors an inductive style, a focus on individual meaning. and the importance of rendering the complexity of a situation (Creswell. 2013).

Informant

- Head of Section of the Special Criminal Regiment cybercrime Unit of the Polda Metro Jaya Central Jakarta Regional Office.
- Head of the special criminal terrorism unit of the Polda Metro Jaya Regional Police of DKI Jakarta Office.
- Head Densus 88.

Research Results, And Research Discussion

The implementation of the cyber terrorism prevention and rehabilitation policy at the Metro Jaya Police Station in Central Jakarta

Based on the results of research regarding the implementation of cyber terrorism prevention and rehabilitation policies at the Regional Office of the Jakarta Metro Jaya Regional Police in accordance with Law Number 19 of 2016 concerning Electronic Transactions 1, concerning Electronic Information and / or Electronic Documents which are valid legal evidence and Law number 5 concerning the eradication of criminal acts of terrorism. and using the concept of Van Horn and Van Metter (1975) that policy implementation is influenced by six variables, namely: standards and policy objectives / measures and policy objectives, resources, characteristics of implementing organizations, attitudes of implementers, communication between related organizations and implementation activities.

The social, economic and political environment in the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies for the community and the implementer knew what to do, where policy objectives and targets had to be transmitted to the target group, reducing distortions in implementation. , reduce the number of crimes to achieve domestic security which includes maintaining security. and public order, orderly and upholding the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding high human rights.

How is the implementation of the cyber terrorism prevention and rehabilitation policy at the polda Metro Jaya Police Station in Central Jakarta?

The existence of cyber patrols to reduce the number of crimes involving children in cyberspace, we will collaborate with related parties such as the telkom and the Minister of Communication and Information. cyber patrols are carried out to prevention and rehabilitation cyber terrorism involving minors and the operation of the cybercrime investigation headquarters, the polda Metro Crime Police Office Cyber Crime Investigations Satellite Office implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies for the community and the implementer knew what to do, where policy objectives and targets had to be transmitted to the target group, reducing distortions in implementation. , reduce the number of crimes to achieve domestic security which includes maintaining security. and public order, orderly and upholding the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding high human rights.

Policy standards and objectives / measures and policy objectives

Does in the polda Metro Jaya Central Jakarta Regional Office, Central Jakarta have an SOP for cyber terrorism services, conduct reviews and have units that manage cyber terrorism services, and evaluate the implementation of cyber terrorism?

In the polda Metro Jaya Central Jakarta police station, there is an SOP for Cyber terrorism services and also conducts reviews and has a unit that handles cybercrime and cyber terrorism cases. the evaluation of the Cyber terrorism prevention and rehabilitation policy The high occurrence of cyber terrorism cases in central Jakarta due to the lack of socialization on cyber terrorism prevention and rehabilitation policies by officers handling cybercrime and cyber terrorism cases, and many central Jakarta people who do not

know about cybercrime and cyber terrorism, there are still many people who easily access information without being processed properly so that it often occurs hoax news.

Standard and target policies / measures and policy objectives in implementing cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta were successful because the implementation of cyber terrorism prevention and rehabilitation policies has clear SOPs (Standard Operating Procedures) in preventing and rehabilitation cyber terrorism, reducing distortions in implementation, reducing crime rates to realize domestic security which includes maintaining security and public order, orderly and enforcing the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding human rights. Based on the results of research regarding the implementation of cyber terrorism prevention and rehabilitation policies at the Regional Office of the Jakarta Metro Jaya Regional Police in accordance with Law Number 19 of 2016 concerning Electronic Transactions 1, concerning Electronic Information and / or Electronic Documents which are valid legal evidence and Law number 5 concerning the eradication of criminal acts of terrorism. and using the concept of Van Horn and Van Metter (1975). implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention policies for the community and the implementer knew what to do, where policy objectives and targets had to be transmitted to the target group, reducing distortions in implementation. , reduce the number of crimes to achieve domestic security which includes maintaining security. and public order, orderly and upholding the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding high human rights.

Resource

Is there an increase in quality and quantity and continuous improvement of employee performance and socialization of excellent service culture? explain what obstacles are in resources?

In the polda metro Jaya central Jakarta police station there has been an increase in the quality and quantity and continuous improvement of employee performance such as training and scholarships for employees. The socialization of the excellent service culture at the central Jakarta police station was aimed at providing an understanding of excellent service to the community and could be implemented in daily activities. Broadly speaking, the outreach material presented is as follows: Information & complaint desk clerk must have product knowledge so that they can provide excellent service. Reliable communication skills are also crucial in understanding what the public wants, Focus on the community, provide efficient service, personal approach, fostering good relations with the community. Show sympathy, talk with feeling, and provide solutions to show that you understand the wishes of the community. Ask for feedback from the community in the form of a service satisfaction survey to be able to improve if there are deficiencies in services. Limited constraints of personnel such as IT and cyber forensic experts, another crucial obstacle is the limited operational budget funds, a crucial problem besides legal instruments, namely insufficient human resources, budget and facilities and infrastructure to support disclosure of cybercrime cases. At present there is only enough budget for one case per month. Even though in fact one month can be up to 15 cases, the weak supervision of internet usage has the potential to create opportunities for cybercrime and cyber terrorism. The procedural constraints of UU IT Law and from the Ministry of Communication and Information (KOMINFO) which are directly related to the policy of using information technology and internet facilities in Indonesia. From the information obtained by the authors of the police department, they are still not too literate about technology, even many members of the cyber police Indonesia are still using computers. It could be said that Indonesian polyclinic ability in cyberspace is still in the standard stage or beginner.

Resource in the implementation of cyber terrorism prevention and rehabilitation policies at the polda Metro Jaya Police Station in Central Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies for the public and implementers knew what had to be done, where the goals and objectives of the policy had to be transmitted to the target groups, reducing reducing the distortion of implementation, decreased crime rate to realize domestic security which includes maintaining the security and public order, orderly and upholding the law, carrying out protection, protection, and services to the community, as well as maintaining public peace by upholding the public high human rights.

Characteristics

how Characteristics of the implementing organization in the implementation of cyber terrorism prevention and rehabilitation policies at the polda Metro Jaya Police Station in Central Jakarta?

Characteristics of the Directorate of Special Crimes of Polda Metro Jaya (Ditreskrimsus PMJ) is one of the police functions in the field of law enforcement at PMJ which performs investigative and investigative functions in the field of Industry and Trade; Fiscal, Monetary and Foreign Exchange; Environmental Resources sector; Cyber Crime and Corruption.

Ditreskrimsus PMJ is a division of the Criminal Research Directorate (Ditreskrim) and is under the Head of the Metro Jaya Police (Kapolri Decree No. Pol.: Kep1541X12002 dated 17 October 2002). Ditreskrimsus Polda Metro Jaya is regulated in Article 27 which regulates the definition, duties, functions, responsibilities and organizational structure of PMJ Ditreskrimsus. The Chief of Police's decision above was followed up by the Kapolda Metro Jaya by making an order letter for the Kapolda Metro Jaya No. Pol. : Sprin / 36 / I / 2003 dated January 15, 2003 concerning Orders for the Implementation of Duties of Dirreskrimum, Dirreskrimsus and Dimarkoba as well as a Letter of Order of Kapolda Metro Jaya No. Pol .: Sprin / 03 / I / 2003, dated January 28, 2003 concerning the Personal Pamen Ditreskrimsus Polda Metro Jaya. Based on the Kapolda's order, the Dirreskrimsus prepares a Job Description which regulates the organizational structure as well as the division of tasks and responsibilities, including the division of tasks for Operational Unit (Satopsnal) I to Satopsnal V. Departing from the organizational structure above, the tasks carried out Cybercrime Sub-Directorate, namely: Investigation of cases related to electronic transactions, money lounding, capital markets, taxes, banking, etc.)

Investigation of cases related to communication and information technology (telephone tapping, VoIP abuse, fraud via mobile phones). Crime investigation using Internet facilities (cyber gambling, cyber terrorism, cyber fraud, cybersex, cyber narcotism, cyber smuggling, cyberattacks on critical infrastructure, cyber black mail, cyber theatening, data theft, defamation, etc.) Crime investigation computer (entering the system illegally, ddos atack, hacking, tracking, phreacing, creating and spreading destructive things such as malicous code al viruses, worms, rabbitstrojan, etc.).

Crime investigations related to Intellectual Rights (Pirated Software, sound recordings, changing website appearance) Cybercrime organization unit is reflected in the organizational structure, the organization's position is the Sub-Directorate for Cyber Crime (Sub-Directorate IV of the Special Crime Directorate), has 5 (five) Heads of Unit and 'backed up' by the IT team which consists of an analysis team, a direction finder team, a digital forensic team, and an IT security team.

Characteristics of the implementing organization in the implementation of cyber terrorism prevention and rehabilitation policies at the polda Metro Jaya Police Station in Central Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies for the public and implementers knew what had to be done, where the goals and objectives of the policy had to be

transmitted to the target groups, reducing reducing the distortion of implementation, decreased crime rate to realize domestic security which includes maintaining the security and public order, orderly and upholding the law, carrying out protection, protection, and services to the community, as well as maintaining public peace by upholding the public high human rights.

Attitude

Does in the polda Metro Jaya Central Jakarta Regional Office have implemented reward and punishment for employees and carried out continuous improvements to employee performance in your opinion?

In my opinion the polda metro jaya central Jakarta police station has implemented reward and punishment for employees. Employees who get awards for their service and also promotions and salary increases. while employees who get punishment usually get a reprimand from the discipline, sekor sing or the worst is dismissal. The attitude of the implementers in the implementation of cyber terrorism prevention and rehabilitation policies at the polda Metro Jaya Police Station in Central Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies for the public and implementers knew what had to be done, where the goals and objectives of the policy had to be transmitted to the target groups, reducing reducing the distortion of implementation, decreased crime rate to realize domestic security which includes maintaining the security and public order, orderly and upholding the law, carrying out protection, protection, and services to the community, as well as maintaining public peace by upholding the public high human rights.

Communication

Has the polda Metro Jaya Police Chief in Central Jakarta informed the employee and has been socialized about the Cyber terrorism prevention and rehabilitation policy? explain the obstacles and innovations used in countering cybercrime!

The polda metro jaya Central Jakarta Police Precinct has conducted socialization of cyber terrorism prevention and rehabilitation policies using brochures posted on the bulletin board. the obstacle in providing information on the Cyber terrorism prevention and rehabilitation policy is the police officer Limited constraints of personnel such as IT and cyber forensic experts, another crucial obstacle is the limited operational budget funds, a crucial problem besides legal instruments, namely insufficient human resources, budget and facilities and infrastructure to support disclosure of cybercrime cases. At present there is only enough budget for one case per month. Even though in fact one month can be up to 15 cases, the weak supervision of internet usage has the potential to create opportunities for cybercrime and cyber terrorism.

The procedural constraints of UU IT Law and from the Ministry of Communication and Information (KOMINFO) which are directly related to the policy of using information technology and internet facilities in Indonesia. From the information obtained by the authors of the police department, they are still not too literate about technology, even many members of the cyber police Indonesia are still using computers. It could be said that Indonesian polyclinic ability in cyberspace is still in the standard stage or beginner. Innovation used in fighting cyber terrorism The existence of cyber patrols to reduce the number of crimes involving children in cyberspace, we will collaborate with related parties such as the telkom and the Minister of Communication and Information. cyber patrols are carried out to prevent cybercrime involving minors and the operation of the cybercrime investigation headquarters, the Metro Crime Police Office Cyber Crime Investigations Satellite Office

Communication between related organizations and implementation activities Communication in the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central

Jakarta was successful because the implementation of cyber terrorism prevention and rehabilitation policies to the public and executors know what to do to prevention and rehabilitation cyber terrorism, where the objectives and policy objectives must be transmitted to the target group, reducing distortions of implementation, reducing the number of crimes to achieve domestic security which includes maintaining security and public order, order and law enforcement, implementing protection, protection and services to the community, and maintaining public order by upholding human rights .

Mention the results of the evaluation of the Cyber terrorism prevention and rehabilitation policy in the polda Metro Jaya Police Chief, Central Jakarta!

The high occurrence of cybercrime and cyber terrorism cases in central Jakarta due to the lack of socialization on cyber terrorism prevention and rehabilitation policies by officers handling cybercrime cases, and many central Jakarta people who do not know about cyber terrorism, there are still many people who easily access information without being processed properly so that it often occurs hoax news.

Communication between related organizations and implementation activities Communication in the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention policies to the public and executors know what to do to prevention and rehabilitation cyber terrorism, where the objectives and policy objectives must be transmitted to the target group, reducing distortions of implementation, reducing the number of crimes to achieve domestic security which includes maintaining security and public order, order and law enforcement, implementing protection, protection and services to the community, and maintaining public order by upholding human rights .

Socio- Economic and Political

How the socio-economic and political environment influence cyber terrorism prevention and rehabilitation?

The number of acts of terrorism taking place in Central jakarta is of course based on several reasons. These reasons are partly motivated by the conditions and environment in the community. Several causes for the emergence of acts of terrorism. poverty problems that exist in society that can lead people to commit violence which then leads to acts of terrorism. This economic factor can influence people to join terrorist networks or groups because of the guarantee of a decent life and freedom from poverty.

Political issues. The existence of influence and belief in political ideology sometimes causes a group of people to take actions that can violate a country's rules or regulations. In carrying out their actions, they usually carry out violence, as well as acts of terror against the civilian population and government, with the aim of changing the ideology of the State concerned. Acts of violence and terror then create public anxiety and fear and raise public opinion regarding State security as well as create doubts and a loss of public confidence in government because people think the government cannot protect their people from acts of terrorism. Social problem. The existence of a sense of injustice in society has resulted in the emergence of the thoughts of several groups who consider the government to be unable to prosper the community and lead to acts of violence as part of conveying the aspirations of the community. One of the acts of violence committed by these community groups is in the form of acts of terror which slowly lead to acts of terrorism in society.

Social, economic and political environment between related organizations and implementation activities. In the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because Social, economic and political running stable and conducive.

To prevention and rehabilitation tackle terrorism, extraordinary measures are needed because terrorism is an extraordinary crime and is transnational in nature because it is cross-border in the prevention and rehabilitation of cyber terrorism, the social environment is very influential in changing people's behavior here. knowledge, mental attitude, and ability to control the social environment in activities in the community and there will be socialization from the family environment, RT, Rw and also at the village level and also at the sub-district and school places, worship and also workplaces regarding the prevention and rehabilitation of cyber terrorism, security / safety: people can carry out their activities without fear of disturbance, both man-made and natural. Comfortability: providing opportunities for every element of society to articulate deep socio-cultural values. peaceful state. Productivity: providing an effective and efficient infrastructure for the production and distribution process in order to increase added value. Sustainability: providing better environmental quality not only for current generations but also for future generations.

Economy is very influential in implementing the prevention and rehabilitation of cyber terrorism, among others, is the effort to meet the needs of human life, through the provision of market jobs, shops, recreational facilities, and sports paying attention to community welfare, increasing employment opportunities, and healthy economic growth, which are expected to improve quality. community life.

Politics is very influential in the implementation of the prevention and rehabilitation of cyber terrorism between the reactivation of the TNI Anti-terror Desk. Formed a Special Detachment called Densus 88 on August 26, 2004 which aims to maximize the countermeasures of terrorism. Densus 88 is part of the National Police which is prepared to be able to tackle the types and forms of terrorism. Prioritizing the issue of terrorism and increasing cooperation with Australia related to counter-terrorism to maintain Indonesia's national security. Enhancing international cooperation to prevent and eradicate terrorism, by means of multilateral or through the United Nations, bilateral, regional, which aims to increase capacity, enforce the law, improve legislation / legal framework, exchange information and share experiences, send experts and provide expert advice, and other technical cooperation. In addition, the government also prevents and eradicates terrorism by means of "soft power" or diplomacy, which includes efforts to cooperate in eradicating underlying causes of terrorism. This is assisted by the Ministry of Foreign Affairs by making efforts to increase encouragement for interfaith dialogue to build mutual care and trust and improve good relations between religious communities from countries in the world.

Obstacles have been faced in implementing the policy of implementing cyber terrorism prevention and rehabilitation at the Polda Metro Jaya Police Station in Central Jakarta

Resource constraints, namely limited expertise such as IT and cyber forensics experts, cyber terrorism. financial constraint is the limited operational budget funds. Crucial problems other than legal instruments are the lack of human resources, budget and facilities and infrastructure to support the disclosure of cyber terrorism cases. Currently the budget is only sufficient for one case per month. Whereas in one month there can be up to 15 cases, weak supervision of the use of the internet has the potential to open up opportunities for cyber terrorism. Procedural constraints on the IT Law and those from the Ministry of Communication and Information Technology (KOMINFO) are directly related to policies on the use of information technology and internet facilities in Indonesia and the law of terrorism. From the information obtained by the author from the police, they still do not really understand technology, even many members of the Indonesian cyber police still use computers. It can be said that the ability of Indonesian clinical polyclinics in cyberspace is still at the standard or beginner level.

The efforts made in implementing the cyber terrorism prevention and rehabilitation policy at the Metro Jaya Police Station in Central Jakarta.

There is training by either the police or public or private universities and colleges in information technology faculties. This step needs to be taken to recruit information technology experts, especially students and students who have expertise in the field of IT (Information technology). The roles of lecturers and students are very strategic because they are the ones who can keep up with IT developments. Practitioners can also play an important role in providing input to the government in securing computer networks and the internet. The urgency of the need for experts must also be balanced with the presence of sophisticated and sophisticated facilities and equipment to support network security and also to facilitate tracking criminals so that cases of cyber terrorism can be resolved quickly. in Jakarta it is implemented by empowering and employing cyber experts and experts in Indonesia for network security, although it requires a short time at least these steps can be implemented by the government to reduce the limitations of experts. and the formation of agencies and cooperation between the government and the private sector in countering cyber terrorism. With cyber patrols to reduce the number of crimes involving children in cyberspace, we will cooperate with related parties such as providers and the Minister of Communication and Information. Cyber patrols are conducted to prevent cyber terrorism involving minors and the operation of the cyber terrorism investigation headquarters, the Metro Crime Police Office.

Based on the results of research regarding the implementation of cyber terrorism prevention and rehabilitation policies at the Regional Office of the Jakarta Metro Jaya Regional Police in accordance with Law Number 19 of 2016 concerning Electronic Transactions 1, concerning Electronic Information and / or Electronic Documents which are valid legal evidence and Law number 5 concerning the eradication of criminal acts of terrorism. and using the concept of Van Horn and Van Metter (1975) that policy implementation is influenced by six variables, namely: standards and policy objectives / measures and policy objectives, resources, characteristics of implementing organizations, attitudes of implementers, communication between related organizations and implementation activities.

The social, economic and political environment in the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention policies for the community and the implementer knew what to do, where policy objectives and targets had to be transmitted to the target group, reducing distortions in implementation. , reduce the number of crimes to achieve domestic security which includes maintaining security. and public order, orderly and upholding the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding high human rights.

Conclusion

That policy implementation is influenced by six variables, namely: standards and policy objectives / measures and policy objectives, resources, characteristics of implementing organizations, attitudes of implementers, communication between related organizations and implementation activities.

The social, economic and political environment in the implementation of cyber terrorism prevention and rehabilitation policies at Polda Metro Jaya, Central Jakarta was successful because the implementation of cyber terrorism prevention policies for the community and the implementer knew what to do, where policy objectives and targets had to be transmitted to the target group, reducing distortions in implementation, reduce the number of crimes to achieve domestic security which includes maintaining security. and public order, orderly and upholding the law, implementing protection, protection and services to the community, as well as maintaining public order by upholding high human rights.

Whereas the line of communication is already underway, with the existence of cyber patrols to reduce the number of criminal acts involving terrorism in cyberspace, the police are cooperating with parties related to all providers, the police and anti-terrorism agencies and the Ministry of Communication and Informatics.

Sociocultural approach and community outreach through seminars, training and competitions. Meanwhile, the efforts made in implementing the cyber terrorism eradication policy at the Polda Metro Jaya Police in Central Jakarta are improvements in all aspects, namely when coordinating the division of duties in implementing cyber terrorism policies, there must be an increase in human resources, facilities and infrastructure. Create a special standard operating procedure (SOP) for cyber terrorism because the police do not yet have a standard operating procedure (SOP) for cyber terrorism and still follow the standard operating procedure (SOP) for cybercrime. The aim of the implementation of cyber terrorism prevention and rehabilitation policies at the central Jakarta police station is to realize domestic security that includes maintaining public security and order, orderly and upholding the law, carrying out protection, protection, and services to the community, and maintaining public peace by upholding human rights.

Suggestion

1. The improvement of the cyber terrorism service delivery system must have experts who must be provided in the DKI Jakarta Polda Metro Jaya Regional Office and good coordination with the Ministry of Communication and Information.
2. Improvements from the private sector are in the form of providing service providers such as Telkomsel, and others. To improve the service system again and impact Implementation of the cyber terrorism policy at the polda Metro Jaya Police Station in Central Jakarta: Increase parental awareness and attention to child, women supervision. The National Police of the Republic of Indonesia has also launched a child protection program on the internet (save children on the internet). State Code and Cyber Codes (BSSN). Sociocultural approaches and community socialization through seminars, training and competitions.
3. Whereas the efforts made in the implementation of the policies to combat cyber terrorism in the DKI Jakarta Regional Office of Jakarta, namely improvements in all aspects, namely when coordinating the division of tasks in implementing cyber terrorism policies, there must be improvements in human resources, facilities and infrastructure Making operational standard procedures (SOP) specifically for cyber terrorism because the police do not yet have standard operational procedures (SOP) for cyber terrorism and are still joining cybercrime standard operating procedures (SOPs).

Abstract

The purpose of the paper is to measure the scope and degree of differences in the level of seniors' involvement in the labour market in the conditions of ageing population, covering the regions of Poland, Czechia, Slovakia and Hungary in 2015-2019. The involvement of senior citizens in the labour market is described using 4 variables: economic activity rate of the population aged 65 or over, employment at the age of 65-74 per 1000 total employment, employment rate of the population aged 65 or over, average number of weekly working hours in the main job of the population aged 65-74. The study was based on the data from Eurostat REGIO database. A dynamic relative taxonomy was adopted for the purpose of the study. The level of professional activity of seniors on the labour markets in the examined countries and regions shows an upward tendency. The seniors in Czechia presented a relatively high economic activity and clearly a lower one was recorded in the surveyed regions of Hungary and Slovakia. In Polish regions, however, significant interregional disparities were revealed in this respect. The results of the study also confirmed a significant correlation between the professional activity of seniors and the level of unemployment in a given region. A lower overall unemployment rate level in a region resulted in higher economic activity of seniors.

Keywords: silver economy, labour market, relative taxonomy, composite indicators

Introduction Rationale for The Study and The Related Works

Population aging is a global process. A significant increase in the share of senior citizens has been recorded both in Europe and in other parts of the world. At the same time, the European society remains much older than the societies living on other continents and, moreover, major differences have been observed in this respect among the European countries. The statistical presentation of this process is shown in Table 1.

While, on a global scale, the share of the population aged 65 and over increased in 1950-2019 from the level of 5.1% to 9.1%, in Europe it went up from 8.0% to 18.8% in the aforementioned period. It means that approximately every fifth European is a senior citizen. Among the Visegrad Group coun-

tries, the society of Slovakia remains relatively the youngest (people aged 65 and over constitute 16.2% of the total population), whereas the oldest ones are the populations of Czechia and Hungary.

Table 1: The share of population aged 65 and over worldwide, in Europe and in the Visegrad Group countries in 1950-2050

Year	World	Europe	Poland	Czechia	Slovakia	Hungary
1950	5.1	8.0	5.2	8.4	6.6	7.8
1970	5.3	10.5	8.2	12.1	9.2	11.6
1990	6.2	12.7	10.0	12.7	10.2	13.5
2000	6.9	14.8	12.0	13.8	11.3	15.1
2010	7.6	16.3	13.5	15.4	12.5	16.1
2019	9.1	18.8	18.1	19.8	16.2	19.7
2030	11.7	23.0	23.2	22.2	21.0	22.0
2050	15.9	28.1	31.1	28.9	28.9	28.0

Source: authors' compilation based on the UN data (World Population Prospects 2019, Volume II: Demographic Profiles).

In addition, the increasing old-age dependency ratio has been recorded, which reflects the growing number of people aged 65 and over per 100 population aged 15-64. This indicator values in both dynamic and spatial perspective are presented in Table 2.

Table 2: Old-age dependency ratio worldwide, in Europe and in the Visegrad Group countries in 1950-2050

Year	World	Europe	Poland	Czechia	Slovakia	Hungary
1950	12.0	16.5	11.3	15.9	14.1	15.4
1960	12.1	17.8	12.2	18.1	14.4	17.5
1970	13.6	21.7	18.1	24.7	20.3	22.7
1980	14.8	25.2	21.2	27.4	22.6	26.7
1990	14.6	24.3	19.6	24.8	20.8	25.9
2000	15.2	27.4	23.4	25.4	21.8	28.4
2010	15.8	29.5	23.5	26.6	21.5	28.4
2019	18.4	34.3	32.0	35.7	27.9	35.6
2030	23.5	45.0	44.3	42.6	39.0	41.0
2040	28.7	52.4	50.2	50.3	46.5	48.7
2050	32.3	59.4	66.2	61.8	60.3	58.2

Source: authors' compilation based on the UN data (World Population Prospects 2019, Volume I: Comprehensive Tables).

The processes of population aging result in numerous and diverse consequences, both economic and social (Samorodov 1999; Krajňáková and Vojtovič 2017, p. 321). The scale of these consequences is reflected, e.g., in the level and systematic increase in old-age dependency ratio. Its level also varies in the Visegrad Group countries.

The economic implications of the population aging process are not only correlated with the growing costs of public services and benefits (primarily covering health and care) for seniors as well as high financial burden incurred by the budgets of states and local government units. They are also visible in the sphere of labour market functioning, changes in economic activity or transformations in the structure of workforce. The social consequences of population aging are noticeable in the sphere of living conditions, attitudes and behaviours towards social and economic rearrangements, or intergenerational relationships.

The range of needs reported by senior citizens remains abundant. Among them, the need for further professional activity despite reaching retirement age is becoming increasingly apparent. The seniors present on the labour market are subject to the same rules as other employees competing for work in the conditions of market economy (Schimanek 2012, pp. 83-84). Hence, the analysis of their professional activity on these markets should take into account both the supply and demand for their work, including the general trends on the labour markets, the level of socio-economic development in territorial terms, or the applicable labour law provisions.

The research focused on the situation of older adults on labour markets covered diverse populations and territorial cross-sections. The conducted analyses studying the problems of seniors functioning in the working environment included many European countries (Van Dalen et al. 2009; Heywood and Siebert 2009; Thalassinos et al. 2019; Aging Europe 2019, Working ... 2019; Wyszkowska 2020). For this purpose various methods of multivariate comparative analysis were applied as well as numerous indicators and sources of information were used. The review of the existing indicators and possible sources of information about the situation on the labour market was performed by, e.g., the International Labour Organization (Decent ... 2018). An interesting research covered, e.g., the problem of measuring the unemployment risk and the degree of stability level of employees by age on the labour market (Hijzen and Menyhert 2016), the probability of employment and professional deactivation of older people (Magda and Ruzik-Sierdzińska 2012) and the participation of seniors in trainings dedicated to work environment (Canduela et al. 2012). Many studies were also carried out addressing the multifaceted situation of seniors on the labour market in regional cross-sections (e.g. Steiner 2017; Obadić 2004). The scope of these studies, however, is limited, mainly due to the unavailability of some data characterizing individual regions.

A dynamic relative taxonomy in positional version was used in the article to analyse senior citizens' professional activity in the Visegrad Group regions in the period 2015-2019. Two research hypotheses were formulated in the study:

H_1 – professional activity of seniors in the regions is increasing and the disproportions between regions in this respect are declining.

H_2 – lower overall unemployment rate in the region enhances higher professional activity of seniors.

The second hypothesis was formulated based, e.g., on the results of the research carried out in Canada for 1991-2007 at the regional level (Galarneau et al. 2015; Bélanger et al. 2016). Galarneau et al. (2015) examined the relationship between the expected retirement age and the unemployment rate of the economic region. The authors concluded that over the considered period, the workers in economic regions characterised by higher unemployment rates were expected to retire two years earlier, on average, than the workers in economic regions presenting lower unemployment rates.

Research Methodology – Relative Taxonomy Method in Dynamic Version

The method of relative taxonomy in classical terms was proposed by Wydymus (2013) and its positional version was developed by Lira (2015). Both versions of the relative taxonomy method apply a static approach despite using it for panel data. The relative taxonomy method, although being comparatively new, has already had many empirical applications (see Walesiak and Dehnel 2020). The applications of relative taxonomy method are presented in the following studies: Szopik-Depczyńska et al. (2017), Müller-Frączek and Muszyńska (2016), Głowicka-Wołoszyn et al. (2018), Cheba and Bąk (2019), Ziolo et al. (2019), Cheba (2020), Lira (2015), Lira et al. (2014).

The article applies a modification of relative taxonomy for the purposes of a dynamic approach presented in the study by Walesiak and Dehnel (2020).

In the static version (see Wydymus 2013, Lira 2015), the relativization in formula (4) is performed separately for each period of the study $t = 1, \dots, T$. In the dynamic version, the value of *j*-th variable is relativized jointly based on the data matrix from *T* periods. The relative taxonomy procedure in its

dynamic version covers the following steps:

1. In the first step, the observations on m variables for n analysed objects and T periods are compiled into one data matrix:

$$[x_{ijt}]_{n\cdot T\times m} = \begin{bmatrix} x_{111} & x_{121} & \cdots & x_{1m1} \\ \vdots & \vdots & \cdots & \vdots \\ x_{n11} & x_{n21} & \cdots & x_{nm1} \\ \cdots & \cdots & \cdots & \cdots \\ x_{11T} & x_{12T} & \cdots & x_{1mT} \\ \vdots & \vdots & \cdots & \vdots \\ x_{n1T} & x_{n2T} & \cdots & x_{nmT} \end{bmatrix}, \tag{1}$$

where: $i = 1, \dots, n$ – object number (e.g. country), $j = 1, \dots, m$ – variable number, $t = 1, \dots, T$ – period number (e.g. year).

2. In the second step, stimulants S (where higher values are more preferred), destimulants D (where lower values are more preferred) and nominants N (where the nominal value is most preferred) are distinguished in the set of variables. Destimulants are transformed into stimulants using the quotient transformation (see e.g. Walesiak 2002, p. 18):

$$x_{ijt} = \left(x_{ijt}^{D}\right)^{-1} \tag{2}$$

Nominants are transformed into stimulants using the quotient transformation (see e.g. Walesiak 2002, p. 18):

$$x_{ijt} = \frac{\min\{nom_j; x_{ijt}^{N}\}}{\max\{nom_j; x_{ijt}^{N}\}}, \tag{3}$$

where: nom_j – nominal level of j-th variable.

3. In the third step, the values of j-th variable are relativized in accordance with the below formula:

$$\left[\frac{x_{1j1}}{x_{ijt}}, \dots, \frac{x_{njT}}{x_{ijt}}\right], \text{ for } i = 1, \dots, n \text{ and } t = 1, \dots, T \tag{4}$$

resulting in the matrix of relativized values for j-th variable presenting $n \cdot T \times n \cdot T$ dimensions. As a result of relativization the values of variables are dimensionless.

4. In the fourth step, the average similarity (using the arithmetic mean or the median) of a given relativized observation is calculated in relation to the other relativized observations of j-th variable:

   a. In the classical approach (arithmetic mean):

$$[z_{ijt}] = \begin{bmatrix} \frac{1}{n\cdot T}\sum_{t=1}^{T}\sum_{i=1}^{n}\frac{x_{111}}{x_{i1t}} & \cdots & \frac{1}{n\cdot T}\sum_{t=1}^{T}\sum_{i=1}^{n}\frac{x_{1m1}}{x_{imt}} \\ \vdots & \vdots & \vdots \\ \frac{1}{n\cdot T}\sum_{t=1}^{T}\sum_{i=1}^{n}\frac{x_{n1T}}{x_{i1t}} & \cdots & \frac{1}{n\cdot T}\sum_{t=1}^{T}\sum_{i=1}^{n}\frac{x_{nmT}}{x_{imt}} \end{bmatrix} \tag{5}$$

   b. In the positional approach (median):

$$[z_{ijt}] = \begin{bmatrix} \text{med}\left(\frac{x_{111}}{x_{111}}, \dots, \frac{x_{111}}{x_{n1T}}\right) & \cdots & \text{med}\left(\frac{x_{1m1}}{x_{1m1}}, \dots, \frac{x_{1m1}}{x_{nmT}}\right) \\ \vdots & \vdots & \vdots \\ \text{med}\left(\frac{x_{n1T}}{x_{111}}, \dots, \frac{x_{n1T}}{x_{n1T}}\right) & \cdots & \text{med}\left(\frac{x_{nmT}}{x_{1m1}}, \dots, \frac{x_{nmT}}{x_{nmT}}\right) \end{bmatrix} \tag{6}$$

5. In the fifth step, the values of SM_{it} aggregate measure are calculated using one of the below formulas:

   a. Classical approach:

$$SM_{it} = \sum_{j=1}^{m}\frac{1}{z_{ijt}}/m \tag{7}$$

   b. Positional approach:

$$SM_{it} = \text{med}\left(\frac{1}{z_{i1t}}, \cdots, \frac{1}{z_{imt}}\right) \tag{8}$$

The values of SM_{it} measures presenting (7) and (8) form can be higher or lower than 1. The lower the value of SM_{it} measure the better the position of i object in relation to the remaining objects in the time interval from $t = 1$ to $t = T$. Contrary to the static approach, the dynamic approach not only shows the relationships between the objects in particular periods, but also the occurred changes in the level of the analysed phenomenon between the objects in the entire period covered by the study. The dynamic version allows for the presence of NA values in matrices. Such data are not included in the calculation of the aggregate measure SM_{it} presenting (7) and (8) form.

Empirical Results

A dynamic relative taxonomy in the positional version was used in the article to analyse professional activity of seniors in the Visegrad Group regions in the period 2015-2019. The following variables were applied in the study:

x1 – economic activity rate of the population aged 65 or over (%)

x2 – employment at the age of 65-74 per 1000 total employment

x3 – employment rate of the population aged 65 or over (%)

x4 – average number of weekly working hours in the main job of the population aged 65-74

Variables x1-x4 represent stimulants where higher values are more preferred. The study was based on the data from Eurostat REGIO database.

Table 3 presents SM_{it} aggregate measure values showing changes in the level of professional activity of seniors in the Visegrad Group regions in 2015-2019. The positional approach of SM_{it} measure was applied in the study, using the median presenting (8) form. The lower the SM_{it} measure value, the better the position of *i*-th object in relation to other objects in the individual analysed years and the entire 2015-2019 period. The dynamic approach shows not only the relationships between the objects in particular periods, but also the occurred changes in the level of the analysed phenomenon between the objects in the entire period under study.

Table 3: SM aggregate measure values of (8) form showing changes in the level of professional activity of seniors in the Visegrad Group regions in the years 2015-2019

The graphic presentation of changes in the level of seniors' professional activity covering the Visegrad Group regions in 2015-2019 is provided in the form of line charts for the regions of V4 group countries (Fig. 1 – Fig. 4) and also a line chart comparing V4 countries against the EU average (Fig. 5).

The verification of H_1 research hypothesis was carried out using the dynamic approach of relative taxonomy method (Table 3 and Fig. 1 – Fig. 5) and dispersion measures (standard deviation and median absolute deviation).

Throughout the entire analysed period, a systematic decrease in both the mean value of aggregate measure and its differentiation can be observed (see Table 3, Fig. 1 – Fig. 5). This proves that, firstly, a systematic improvement in the level of seniors' professional activity in the Visegrad Group regions is recorded. Secondly, the differentiation between the regions of V4 group (standard deviation and median absolute deviation values in Table 3) and between the regions within each of the analysed countries (Fig. 1 – Fig. 4) is declining. H_1 research hypothesis has been verified positively. In addition, it is worth adding that the recorded higher professional activity of seniors occurred at a faster pace in Hungary (Fig. 2) and Slovakia (Fig. 4), i.e. in the countries where active presence of older people on the labour market was the lowest at the beginning of the analysed period.

The verification of H_2 research hypothesis was performed using the Pearson correlation coefficient. The significance and strength of the correlation between SM aggregate measure (Table 3) measuring

the economic activity of seniors (relative taxonomy method – dynamic version) and the overall unemployment rate in the regions (Table 3) were examined separately for each year. The results are presented in Table 4.

Table 4: Pearson correlation coefficients between SM aggregate measure (measuring economic activity of seniors) and the overall unemployment rate in the regions of V4

Specification	2015	2016	2017	2018	2019
Pearson correlation coefficient	0.3160	0.2913	0.4437	0.5580	0.5486
$p - value$	0.0207	0.0306	0.0016	6.156e-05	8.433e-05

H_2 research hypothesis has been verified positively. All Pearson correlation coefficients are statistically significant with the declared significance level of $\alpha = 0.05$. A lower overall level of unemployment rate in a region is conducive to greater economic activity of senior citizens. Moreover, a clearly stronger correlation takes place if the situation on the labour market is better – the unemployment rate is lower. It has been observed at the end of the analysed period, when the Pearson correlation coefficient level went up from 0.3160 in 2015 to 0.5486 in 2019.

Additional conclusions can be formulated on the basis of the conducted research after analysing the graphic presentation results of the changes in the level of professional activity of seniors in the Visegrad Group regions in 2015-2019 (Fig. 1 – Fig. 5):

1. In the analysed period, the above average level of professional activity presented by seniors in the European Union can be observed for Czechia only (Fig. 5). The situation is much worse in this respect with reference to Hungary and Slovakia.

2. The level of professional activity of senior citizens is the highest in the capital regions of the Visegrad Group countries (Praha region for Czechia, Budapest region for Hungary, Warszawski stołeczny region for Poland and Bratislavský kraj for Slovakia).

3. The strongest differentiation between V4 group regions in 2015 was observed in Slovakia and Hungary. In 2019 only Slovakia recorded a strong differentiation.

4. In the analysed period, the level of professional activity presented by seniors was significantly higher for the regions of Czechia and Poland comparing to the regions of Hungary and Slovakia.

Concluding Remarks

The demographic processes taking place in recent years, referred to as *Population ageing*, have resulted in major changes on the labour market. A growing potential ingrained in senior citizens has been noticed. The development of economic conditions delaying the moment of retirement, and thus extending the working life of seniors, has become one of the essential goals to be followed by the regional social policy. It is, therefore, crucial to perform a multidimensional assessment of the trends and the situation in terms of seniors' economic activity, taking into account such factors as, e.g., demographic variables or employment conditions in a given region.

The article presents an attempt of carrying out such an analysis. Its novelty consists in the application of a dynamic relative taxonomy following a positional approach to assess changes in the economic activity of older people at the regional level of V4 countries. As a result of the dynamic approach application it was possible not only to assess the correlations occurring in the phenomenon level between the regions in individual years of the analysed period, but also to assess mutual relationship between them in the entire period covered by the analysis. Thus, the application of a dynamic relative taxonomy allowed tracing the changes which took place both in the cross-sectional and longitudinal perspective.

The results of the study clearly indicate that between 2015 and 2019 the level of professional activity presented by seniors on the regional labour markets of V4 countries was systematically improving, although the rate of these changes was diversified. On average, it was faster in those countries where the activity of seniors was lower at the beginning of the reference period. The changes which occurred over the course of 5 years brought about a decrease in the number of variations between the regions in terms of professional activity presented by seniors. Regardless of the above, the highest level of seniors' professional activity was recorded, in all analysed years, in the capital regions of the Visegrad Group countries. In addition, the results of the study confirmed a significant correlation between the professional activity of seniors and the unemployment rate in a given region. A lower overall level of unemployment rate in the region was conducive to greater economic activity of senior citizens. Along with an improving situation on the labour market the discussed relationship was becoming increasingly recognized.

The calculations were performed using R scripts developed by one of the authors (R Core Team 2020).

Abstract

The new super-sophisticated technological pattern forming at the beginning of the 21st century demands its interpretation from the human and societypoint of view. The purpose of this interpretation is the search of adequate ways of human and new technical environment synergy. It is necessary to create new instruments of representation, monitoring and managing the complex phenomena of social techno sphere in order to explicate these processes. We are continuing to study this topic through constructionist development of sociotechnical landscape (STL) concept, the formation of anthropological keys of its understanding and interpretation. The methods of synergy, quantum theory and quantum synergy anthropology are used to search of the instruments and work with STL, create local landscapes based on different taxons in the conditions of complex topology and create anthropological keys in order to find out the basic characteristics of evaluating STL.

Keywords: Sociotechnical Landscape, Digitalization, Anthropological Key, Generalized Embodiment, Anthropological Profile.

Introduction

The problems of the digitalization of modern technological pattern reflected in generally accepted concept economics of Industry 4.0, Big data, Internet of Things, Blockchain and the theory of complexity with imminence assumes the understanding the processes of the engagement of the new technological way into the human and social lifeand its synergy with them. In order to explicit these processes it is absolutely necessary to create the new instruments of representation, monitoring and management of the complex phenomena of social and technological sphere, and we develop this topic in our research through deepening the concept of sociotechnical landscape (STL), creating the anthropological keys of its understanding and interpretation.

Methodology

In the recent decade's attempts have been taken to explain many phenomena of anthroposphere and sociality through holistic phenomena of coherence, dynamic chaos and quantum RCS effect being viewed as the new basis of holism (A. Mindell, R. Penrose, I.V. Danilevsky, B.M. Mensky). The same ideas form the foundation for the quantum-synergetic anthropology developed by V.G. Budanov [1]. This theory unites the methodologies of synergetic [2] and quantum approach, which enables us to explain the complex developing hierarchic systems of our generalized embodiment [3], and is used to create the anthropological key of reading the Sociotechnicallandscapes.

Cite this Article as: Vladimir BUDANOV, Vladimir ARSHINOV And Irina ASEEVA" The Idea of Anthropological Key in the Sociotechnical Landscape Concept " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The second ground of our methodology is the concept of sociotechnicallandscape. Let us remind you the conceptual understanding of STL, the coordinate network of which is set by the direct product of an array of meaningful social practices (SP) and an array of digital technologies (DT) or SPxDT [4]. The elements of these arrays are the taxons of generally accepted digital technologies and social practices accordingly. Due to the fact that these arrays are finite, the coordinate network will be set not by the coordinates of points on the continuous surface, but by discrete elements organized in the form of a table or matrix. Let us make the convention that the elements of SP array mark the rows of the table and the elements of SP array mark its columns. Further on we will call this coordinate matrix the matrix base of Sociotechnicallandscape. We point out that the choice of the taxons and practices as well as the formation of their tuple is a result of the expert' agreement and the convention of the researchers. In other words, unlike the geography we are used to with its metrical characteristics(closer-further), digital geography has more variety in building the coordinate base and thus introducing landscapes, which is definitely in the character of naturally not orderable or incommensurate objects.

As the third dimention («height») the degrees of social demand on technologies, riskogenics and other actual characteristics, indicators and markers, construction and analysesare used forecasting the behavior of which is the final objective of finishing the construction of the landscape. Thus over the matrix base various profiles arise(surfaces in three dimensions) which we will call suspensions or responses over the base which define particular sociotechnical landscapes. Their combination is an integral sociotechnical landscape or, to be more precise, multilandscape.

Every sublandscape creates an effective, sensitive, specific and resultative three dimension profile, which is an observable and controlled object in the terms of cybernetics possessing definite interface in order to be bound with the other sublandscapes. This allows us to organize the process of monitoring, diagnosis and analyses of the condition and the development of techno and anthroposphere on one of its characteristic (chosen indicative) parameters with the help of well-known techniques of registration, measuring and qualimetry. Such concept of STL was offered by us earlier in basic articles [5], [6] and was developed in a monography [7]. Further development of the STL concept demands a constructive definition of the understanding of suspensions over the base and the criteria of its estimation via anthropological key which is offered below.

The structural design of the STL concepts described

In the definition of landscape which we gave above we factually deal with the symbolic presentation of the direct product of practice and technology sets into the sets(clusters, assembles of objective functionals) of results: risks, perspectives and competences which are symbolically specified as SPxDT→ RI - (Results, Response of Interaction). It is principal that for every taxon and its subtaxons or response a special identification is set, which is its symbolic narrative part or its name, which allows us to create both its disposal in the symbolic databases and digital or quality description of its characteristics and concepts if such are possible in the alphabet and terms of the language being used in the topical area under analyses.

The symbolic and the digital parts together are defined as a "container" (Kont) for this taxon. We suppose the term "container" to include linguistic and digital data to represent the taxons and the responces. This understanding is close to the concept of syndromocomplexes, frames, set containers in programming, but it is used in a specific for us application area, in representating the phenomena of anthropotechnosphere.

Results or responses of interaction or RI can be reflected in symbolic as well in digital form and can be described with the help of corresponding containers. We must point out that the digital form allow us to use not only semantic and logical analyses, but to use detailed methods of applied mathematics (including the grammar of various degrees predicates). Then using the analogues of syndrome-based approach and the theories of fussy sets a contained can be presented as a linguistic variable. In this case the digital landscape is set through building a function or objective functional (heights)

prescribed on the digital components of containers of the base which reflect them into the digital containers of responses-results.

Digitalized landscape is an array of function representations Kont (SPxDT)→ Kont (RI), in which the response (vertical) is set by a traditional definite metrical axis. We should pay attention to the fact that the containers of the base and the response may have different dimensions and, generally speaking, we deal with the reflection of the multitude of different dimensions into each other which is the subject of catastrophism. For our purposes of visualization when constructing the landscape we usually observe the behavior of one parameter. If we are able to represent the base container as the direct product of containers in the taxon Kont (SP)×Kont (DT), we will get a typical image of a landscape in a three dimension system of coordinates. If in the containers of all the taxons there is a general characteristic (like levels of financing or popularity), we get a landscape imminently over the semantic matrix base.

The anthropological key of digitalization or the ontology of generalized embodiment

Let us now turn to thehuman-like parameters which are often badly formalized. They inevitably arise when estimating the anthropological and social risks and deformations when introducing this or that technology into the social practices. At the ground of the approach that we offer the idea of introducing the concept of "anthropological key" lies or, to be more precise, the functional ontologies of generalized human embodiment, which are the subject of digitalization and can characterize the degrees and the risks of human nature deformations. We should point out that such problem definition is offered in the book by B.Ju. Judin [8]. We suggest to use the original methodology of quantum synergetic anthropology mentioned above.

Any instants of human external activity or internal being are reflected in the functional bodies of the human and the society [9]. Let us introduce our system of generalized embodiment.

Somatic body is viewed by us as the description of the object at a minimum rate of stimulation when we abstract from its reactions. This is the description of the material body and its elements in the space.

Energetic body (vitality) describes the degree of body mobility itself, the speed of its elements' relative position change, the intensity (the ability to produce work) without external stimulations. This is the body of connections between the elements and the energy of these connections.

Reactive emotional body describes the simplest reactions of the body on the contact with the reality, perception from sensory organs, the ability of the body to localize the energy and the actions in response to particular stimulations. This body allows to resist the environment and support homeostasis (if the type of the reaction corresponds). The physical body together with the reactive body can be called the body of flesh or the body of desire. It is important to mention that in our classification a robot also possesses flesh (in the form of non-protein material). The emotional body(the second component of reflective emotional body) is connected with psychosomatic reactions and reflective processes.

Logical or algorithmic body is characterized by the reaction of the body to multiply repeated stimulations, on constant contact with the environment and the reactions it remembers. As a result behavior reflexes, logical bounds "if-then", algorithms formed by the environment are worked out. Logical or algorithmic body in its turn is activated by emotional and motif-based motives of the body of desire. That is why we can speak of the logical body as of the body of common sense. This body is most effectively developed and inherited in semiotic systems of human culture and is effectively modeled by the computer systems of artificial intelligence. Notice that the bodies described(1-4) have until present time been well modeled by the modern methods of nature studies an information technologies and have recently been fulfilled by the principles of synergetic and quant coherence.

The following bodies of high mental organization are impossible to understand without bringing in the synergetic and quantum holistic principles. *Intuitive creative body* appears in emergent acts of

valuable information generation such as imagination, recognition, insight, foreseeing which are not given in the forms of reflective or logical action and are not connected with search operations or mechanical imitation. In particular the intuitive body is responsible for changing the algorithms without long "transitive" procedures of working out a new behavioral pattern, which is an integral part of creativity. Sometimes it turns long logical stages into the act of insight or suggests you a "crazy" hypothesis. It gives us a ground to speak about a particular type of working with time, memory and forecast, converted knowledge. This body enables the system to be superadaptive in the new circumstances.

The complex of interaction of the emotional, logical and intuitive bodies is sometimes often called a psychomental body (sphere). It is particularly responsible for the perception and the recognition of our internal embodiment, for forming the image of remote body of culture and body of senses. The central body or reasoning, the monitor of being is the logical body, it includes the codes of recognition and the body of senses, the subject body after Husserl. From the mentioned above we can make a suggestion that the intuitive body can "connect with", communicate with theother systems, tune to them. It delocalizes and its boundaries are ambiguously larger than the boundaries of the physical body, which enables to read the specific, noosphere informational potential.

Coherent empathic body is responsible for the states of superopenness and unity with the other bodies, phenomena, parts of reality, people and world. For example they are the states of experiencing the love towards yourself, fellow human beings and the "oceanic" feeling of love for the whole world which is the peculiar feature of saint, spiritual people. However the feelings can be different, even opposite, for example, hate. The intensity of these states, their subsequences set the measure of coherence. It is also the state of empathy or the concentration on the object which has always been the basis of religion, art, science, in-depth communication, psychotherapy, concentration, hypnoses and magic. The mechanisms of realization of this body are the same as in the case of the intuitive body, i.e. holistic phenomena of dynamic chaos and the phenomenon of Podolsky-Rosen.

The body of will declares itself as an instant state of readiness, determination, potential of action and power. The body of will is an aspiration for the aim in all the bodies (apart from the physical one perhaps), i.e. beginning with the body of flesh. The power of will depends on the degree of coherence, sub bodies of will in the other bodies, that is why the body of will is delocalized as well as the intuitive and the coherent body and is described with the same transconscientious holistic mechanisms. It shows in the rigidity of the negative feedback while achieving the goal: in the body of reflex it is will for life, in the body of emotions it is will for pleasure, in the body of logic it is will for explanation. We must point out that the bodies of intuition, coherence and will are mostly transpersonal and transconscientious. They are often referred to as the spiritual body of the human. Here we followed our works [10, p.162-163] and [11].

In addition to the 7 functional bodes mentioned, in order to describe the social communication which is radically deformed in the age of digitalization, we will introduce 3 more bodies of communication. Communication can be easily measured if divided into three types.

The body of material reality communication (MRC) is the immediate communication with the other people eye-to-eye, with nature and with gadgets. Here we fully realize the processes of empathy and socializing, the communication channel here is straight, without mediation.

The body of virtual reality communication (VRC) is the communication in our imagination with people and nature, autocommunication, communication through art, books, television, radio, virtual digital game characters and so on. Here a great potential of upbringing, education and translation of cultural examples and knowledge, the language of science and creativity can be seen.

The body of augmented reality communication (ARC) is the communication with other people and material reality via technology, gadgets, navigators, internet of things, networks in the web, distance learning tools and so on. In this type of communication the information exchange goes with

tremendous speed, we can witness fast processes of social, political self-organization and manipulation, creating new actors of social development – digital platforms and social networks.

Conclusion

For the representation of sociotechnical landscapes the ontology of states built enables to represent the anthropological profile of personality rather structurally and vividly in particular activity states. The visual realization on the anthropological key can be conveniently pictured in the form of Cartesian orasterial diagrams of anthropological profile basing on 12 quantitative characteristics of activation mentioned above functional bodies. These may be for example states of involvement into different types of free time games, every day or professional activities. Such profile diagrams are a basic part of anthropological key that describes the influence of digital technologies of different social and personal practices and it enables us to introduce the criteria of their anomaly, possible risks and ways of managing them, compensation correction of the anthropological key.

Further on the ontologies and social and personal states reviewed should be completed by temporal activity aspects and to understand the reason and the tendency of the change in the state it is necessary to consider life processes, take into account the activity and environmental factor of human and society development. We hope to dedicate our next work to these problems.

Resumen

El presente artículo evidencia los resultados derivados del proyecto de investigación titulado Propuesta de una guía metodológica para consultoría empresarial y contable para las micro, pequeñas y medianas empresas MiPymes del sur de Bogotá Colombia; clasificadas así dichas organizaciones por su número de empleados y volumen de ventas y cuya actividad económica atiende los sectores económicos industrial, comercial y servicios; el proyecto ejecutado surge luego de haber diagnosticado en un estudio previo la problemática y necesidades en las áreas funcionales administrativa y financiera de las organizaciones objeto de estudio del proyecto, es decir de las empresas mencionadas en temas de asesoría y consultoría externa, pues a partir de los resultados obtenidos en dicho estudio, y después haber realizado una referenciación conceptual, teórica y legal, pertinentes con las categorías del estudio, se genera el interés de formular una herramienta de apoyo que atienda esas necesidades identificadas, siento esta, una guía metodológica de apoyo para que por un lado, los estudiantes y profesionales de ciencias empresariales implementen en sus procesos prácticos de asesoría y consultoría; y desde otro, los empresarios obtengan beneficios al recibir apoyo funcional y efectivo en la atención de sus requerimientos detectados. Se presentan en el documento, los aspectos inherentes al desarrollo de la investigación, su conceptualización y diseño metodológico, así como los resultados y conclusiones generadoras de futuras discusiones en la formulación de proyectos orientados a la generación de herramientas de apoyo a las gestiones gerenciales de una organización.

Palabras Clave: Guía metodológica, consultoría empresarial, consultoría contable, MiPyme.

Introducción

La generación de riqueza y de valor en un sistema económico se determina entro otros factores, por la creación y fortalecimiento de la estructura organizacional bajo figuras empresariales, de los diferentes sectores productivos. Por esta razón y desde las instituciones de educación superior IES y los programas de ciencias empresariales de las mismas en sus procesos de formación profesional, se hace necesario la generación de nuevas estrategias y herramientas que contribuyan al fortalecimiento del sistema productivo; orientadas todas ellas, al crecimiento, desarrollo y proyección de las organizaciones que lo componen, así como a la mejora en la gestión integral de las mismas.

Para la generación de dichas estrategias es necesario que de manera estructurada y en forma periódica se identifiquen las necesidades y problemáticas de las organizaciones en sus diversos niveles funcionales con el objetivo de formular alternativas de solución; siendo justamente la identificación de dichas necesidades el punto de partida para el diseño del producto final del proyecto ejecutado como lo es la guía de consultoría; para el logro de la misma se tuvo en cuenta el diagnóstico realizado

Cite this Article as: Manuel Ricardo REY ROMERO And Cliden Amanda PEREIRA BOLAÑOS "Diseño Y Estructuracion De Una Guia Metodologica Para Consultoría Empresarial Y Contable Para Las Mipymes Del Sur De Bogotá – Colombia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

en un estudio previo sobre MiPymes, , una revisión documental desarrollada sobre consultoría y temas relacionados así como un análisis de las actuales estrategias educativas de formación estudiantil y proyección social de las IES, como convenios, contratos, pasantías y práctica profesional, que buscan apoyar a alas empresas; la suma de todas ellas condujo a la creación de la guía metodológica de consultoría empresarial y contable para las MiPymes como herramienta de trabajo de los estudiantes y futuros profesionales en sus procesos de asesoría organizacional desde espacios como la práctica profesional y obviamente en el ejercicio ya pleno de su disciplina, atendiendo de esta manera al empresario y sus necesidades.

El desarrollo de la investigación desde su planteamiento se reseña en el siguiente documento, presentando luego de aplicar un diseño metodológico de enfoque cualitativo, de carácter descriptivo y soportado en la revisión documental y trabajo de campo (grupos focales y cuestionarios [2,3,4], los resultados alcanzados al diagnosticar funcionalmente las organizaciones así como las conclusiones al contextualizar y conceptualizar la guía metodológica diseñada como estrategia educativa a ser utilizada por las IES junto con otras alternativas existentes, para acercarse y fortalecer a las empresas; la guía es susceptible de ser aplicadas en cualquier contexto educativo siendo simplemente ajustada a las necesidades del mismo y al cumplimiento de las normativas institucionales y legales en materia educativa y laboral [1].

Como aspecto introductorio para abordar el proceso investigativo desarrollado, se evidencian los referentes teóricos y legales que enmarcan la actividad empresarial en Colombia, y se describen los conceptos conducentes a la definición de la guía como producto final, destacando la metodología empleada, así como los resultados y conclusiones generadoras de discusión en entornos educativos con relación al diseño de instrumentos como la guía propuesta. Finalmente y antes de continuar es importante mencionar que las pequeñas y medianas empresas objeto de estudio del proyecto, a nivel mundial se han convertido en un tema relevante en la actualidad económica para muchos países; los cuales, generan interés en la creación y fortalecimiento de empresas cada vez competitivas como motor de desarrollo de sus gobiernos [5] Dicho interés se refleja en el incremento porcentual que de manera considerable ha tenido el empleo, la producción y el comercio gracias al desarrollo de las Pymes [6]; razones todas válidas para entender que el sector educativo debe abordarlas investigarlas y proponerles soluciones desde su alcance.

Metodología

La investigación realizada fue de tipo descriptiva con un enfoque cualitativo, que permitió conocer el contexto general de las MiPymes en su gestión, como insumo para el análisis de su situación interna en los sectores de industria, comercio y servicio. Se realizó un análisis general utilizando la técnica de revisión documental con relación al estudio de las empresas y específicamente de las ubicadas en el sur de la ciudad de Bogotá - Colombia; para dicha revisión se consultaron fuentes secundarias de orden cibergrafico y bibliografíco tales como informes, investigaciones y estudios de carácter gremial, público y privado a nivel internacional, nacional y local de los últimos cinco años de vigencia. De la misma manera en el proceso investigativo se utilizó la técnica de Grupo focal para el trabajo de campo, pues esta permite identificar desde la fuente empresarial las necesidades de las MiPymes en la gestión organizacional para la búsqueda de soluciones; tal y como lo afirma [7] quien menciona que para el desarrollo de un producto o servicio, es útil probar el mismo en el contexto real; de igual es importante destacar que a través de los grupos focales se puede trabajar con instrumentos de análisis en profundidad y detalle, donde la discusión grupal se utiliza como un medio para generar entendimiento profundo de las experiencias de los participantes.[8] Para la recolección de datos de los Focus Group se trabajaron: memorias en audio, notas de campo durante la sesión donde se identifican las ideas principales y observaciones relevantes y grabación en video [9]

Para la selección de la muestra se utilizó el muestreo probalistico aleatorio simple en el cual, cada una de las pequeñas y medianas empresas tuvieron la posibilidad de ser elegidas del total poblacional de las mismas ubicadas en el sur de la ciudad de Bogotá- Colombia. Los participantes en este muestreo, son seleccionados porque tienen alguna experiencia en común en grupos homogéneos para que se produzcan fácilmente el intercambio de ideas. [10] Considerando lo anterior se determinó

realizar un total de 6 grupos focales abordando la problemática en cinco localidades del sur de Bogotá - Colombia, con el fin de conocer conductas y actitudes de los pequeños y medianos empresarios en cada sector y de acuerdo con la actividad económica que desarrollan. Adicional a los grupos focales se aplicaron encuestas semiestructuradas a los empresarios, para la recolección de la información de conocimientos explícitos necesarios para analizar las características socioeconómicas, laborales y empresariales; con el fin de complementar la información recolectada en la investigación cualitativa para un análisis con mayor profundidad. [11] Para el análisis de la información se toman los documentos relacionados con el tema, y los resultados obtenidos en el estudio; que tienen como objetivo documentar las experiencias de los empresarios en su gestión empresarial a partir de los aspectos administrativos, contable y financiero, de tal manera que permita desde la realidad elaborar supuestos que aborden la problemática. Una vez aplicados los instrumentos de recolección de información; se procedió a tabular y sistematizar la totalidad de datos recolectados para lo cual se utilizó la técnica de triangulación metodológica, en la cual y mediante la observación directa del investigador, el cuestionario semiestructurado y el grupo focal se generaron las conclusiones conducentes a identificar el contexto de gestión organizacional de las MiPymes analizadas. La aplicación de diversos métodos para obtener información que pueda ser comparada y retroalimentada entre sí como insumo para llegar a conclusiones. [12]

Resultados

Una vez sistematizada la información luego de haber realizado la revisión documental y el trabajo de campo establecido, se obtuvieron los siguientes hallazgos por categoría de contexto del proyecto, es decir desde la situación a nivel internacional de las empresas en su desarrollo funcional, hasta la identificación de necesidades en el ámbito local en los diferentes sectores económicos; como insumo para la generación de la guía. Los resultados fueron los siguientes:

Aspectos Relevantes De La Revisión Documental A Nivel Internacional

l

Varias organizaciones no gubernamentales adelantan estudios sobre el comportamiento de las MiPymes en los países, como es el caso del Grupo del Banco Mundial y la Corporación Financiera Internacional [13] quienes realizaron encuestas a 45.000 empresas en 106 países en desarrollado, en función de la medición basada en la percepción de indicadores ampliamente utilizados para la clasificación y calificación crediticia e inversionista a nivel internacional, estos resultados dan a conocer los principales obstáculos que atraviesan las Pyme en el sector privado; se identifican las 15 dificultades más relevantes: el acceso al financiamiento con un 16.5%, el acceso a la electricidad 13.5, informalidad con casi 12%, tasas impositivas 11.3%, inestabilidad política 8.2%, mano de obra calificada 8%, corrupción 6.5%, robo y crimen asociado 5.3%, reglamentos, licencias comerciales, permisos, transporte, administración de impuestos, regulación personalizada y laboral un 3% y tribunales 1% como se muestra en la Figura 1.

Resultados Significativos Por Sector Económico Caso Colombiano

Las MiPymes en Colombia constituyen un grupo sobresaliente de empresas, se considera que: "Su estructura productiva se caracteriza por la existencia de pequeños establecimientos que contribuyen significativamente a la creación de empleo, a la generación de riqueza y a satisfacer necesidades de mercados poco atractivos a las grandes empresas" [14, p.33]. Como se ha dicho en el mundo las Pymes representan un sector empresarial importante para la economía de cada país y requiere un estudio detallado para conocer su comportamiento. El sector empresarial de las pequeñas y medianas empresas, desempeña un papel importante en el desarrollo actual del país, ya que influye en el crecimiento de la economía; en cierto modo, este sector de pequeños empresarios es uno de los más vulnerables frente a las exigencias del mercado que los obliga a ser cada día más competitivos, enfrentándose a problemas como escasa capacitación técnica y empresarial, así como su gestión administrativa, financiera y operacional entre otros, son algunas de las dificultades por las cuales atraviesan las pymes actualmente, tal como lo afirma la Universidad Escuela de Administración de Negocios EAN en la investigación realizadas por el grupo de investigación en Pymes.

Según el grupo de investigación G3Pymes de la Universidad EAN, las pymes representan el 99,9% del total de las empresas en Colombia, cerca de 1,6 millones de unidades empresariales las cuales de igual manera han aportado cerca del 38% del PIB total, teniendo una importancia muy relevante en la generación de empleo. Sin embargo, el tiempo de sostenibilidad de las mismas es muy corta; solamente el 50% de ellas sobreviven el primer año y solo el 20% al tercero, debido a la poca importancia que le dan a la innovación y al conocimiento; lo que genera falta de competividad y permanencia en el mercado [15]. Entre las grandes debilidades de las pequeñas y medianas empresas que se han identificado en Colombia se encuentran: capacitación, programas de emprendimiento, falta de proyección operacional, desconocimiento legal para exportación, manejo logístico entre otros [16]. De igual manera las pymes colombianas presentan dificultad en la proyección de su negocio de manera global, muy pocas exportan porque cuentan con limitaciones organizacionales, financieras y técnicas, desconocimiento de normas de otros países para exportar rezagándolas al mercado local; las operaciones logísticas se considera otra limitante referente a canales de distribución y volúmenes de producción, De esta forma como lo mencionan Codina, Pagan, Brown, Carmona, Cursi, Dorsey del Ángel, Sandoval. (2005) citado en [17]. la administración de las Pymes demanda un profundo conocimiento de las áreas que afrontan problemas por la globalización, ya que no solo se trata de manejar empíricamente un negocio, sino también es necesario tener conocimientos de administración para enfrentar el mercado actual en las áreas de: gerencia y planeación estratégica, mercados, recursos humanos, comportamiento organizacional, análisis financiero y evaluación de proyectos y adopción de las tecnologías de la información y comunicación Tics. En este orden de ideas otros aspectos de la problemática de las Pymes son: obstáculos del entorno, problemas macroeconómicos, barreras institucionales de infraestructura y de servicios y dificultades a nivel empresa; limitaciones que impiden llevar a cabo procesos de fortalecimiento para su crecimiento económico [18]

En lo que respecta a la diferentes problemáticas que los empresarios enfrentan, se puede decir, que según un estudio de la Asociación de Emprendedores de Colombia ASEC, radica en la falta de capacitación en lo que se refiere al emprendimiento; tal estudio revela que el 56% de los colombianos consultados creen que en las instituciones de educación superior no se brinda suficiente formación en emprendimiento, lo que indica que el empresario busca la forma de crear un mercado más competitivo pero la falta de oportunidades en adquirir las herramientas suficientes para competir y obtener resultados a largo plazo, radica en las falencias en la academia.

Según el análisis de las experiencias de la gestión de los empresarios analizados en los diferentes grupos de enfoque y encuestas aplicados a los mismos se puede concluir que hay aspectos propios para cada actividad económica posibilitando identificar las principales necesidades de cada grupo de

empresarios dedicados al comercio, industria y prestación de servicios como se muestra en la Figura 2.

Figura 2: Aspectos relevantes de las necesidades según actividad económica de las mipymes de las localidades del sur de Bogotá

Fuente: Elaboración propia resultado de la investigación. Triangulación de caracterización económica, empresarial y laboral, Focus Group y encuestas

Así mismo y a partir de la información obtenida en realización de los Grupos focales, se genera una triangulación de dicha información junto con la revisión documental de orden internacional y nacional; evidenciándose las necesidades de los empresarios que predominan en cuanto a temas administrativos, contables, y financieros. Ver figura 3

Figura 3: Principales necesidades en gestión empresarial mipymes del sur de Bogotá

Fuente: Elaboración propia resultado de la investigación. Triangulación de caracterización económica, empresarial y laboral, Grupo focal y revisión documental internacional y nacional.

Bajo dichos resultados se puede concluir que las principales temáticas que requieren atención en la gestión del empresario obedecen a diversos procesos y procedimientos de carácter administrativo, financiero y legal, elementos claves en el momento de proponer los contenidos de la guía producto del proyecto.

La Guía Metodológica

Las guías didácticas o guías de estudio constituyen un recurso esencial utilizada para el proceso de aprendizaje de la educación superior fundamentada en el constructivismo. Las guías son técnicas utilizadas para la formación técnica, tecnológica y profesional de la modalidad virtual, semipresencial y presencial, puesto que constituyen herramientas para los docentes no solo para orientar sino también también contribuir a la estructuración del proceso de aprendizaje del estudiante y organización de su propio trabajo.

Estructura Guía Metodológica

Establecer la estructura de una guía metodológica no solo obedece a unos requerimientos definidos quizás desde un referente teórico, sino a las necesidades y particularidades de quien la diseña en función de sus prioridades, así como del usuario final de la misma.

Por lo tanto, no existe una única estructura recomendada o definida para elaborar una guía metodológica, sino que esta atiende los objetivos mismos de ella y la funcionalidad que se busca al elaborarla y aplicarla. Morales, Martínez y Carrillo, (2015) afirman que la consultoría indistintamente de su ámbito de aplicación, presenta una serie de fases de asesoramiento que buscan contribuir al logro de los objetivos de la organización que interviene. Aplicando técnicas y herramientas puntuales que contribuyan a su cometido; un consultor puede diagnosticar, emitir juicios, recomendar y proponer entre otras tareas, acciones concretas para contribuir a solucionar un problema específico dentro de la organización que lo contrata. Sea cual sea su tarea y alcance definido en el objeto mismo de la consultoría, es recomendable seguir un proceso claro y específico que permita desarrollar con éxito, la labor encomendada.

Dicho proceso constituye entre otras, una de las bases más sólidas para generar una guía metodológica de trabajo en consultoría, y en el caso puntual en las áreas empresarial y contable; constituyendo a la misma en un instrumento a través del cual el orientador o usuario de la guía sigue un procedimiento estándar paso a paso que le permite intervenir de forma clara, las áreas y necesidades de la organización, de manera planificada, organizada y direccionada hacia la obtención de lo que se requiere, a saber: la detección de un problema o necesidad, la identificación de un punto crítico, la generación de una propuesta de acción; o la implementación de una estrategia en algún área empresarial. Mediante una guía estructurada, el beneficiario final, es decir el empresario de la MiPyme podrá ser atendido en sus expectativas de manera ágil y objetiva; y encontrar respuestas que dependiendo de su interés y aceptación puede validar dentro o no dentro de su organización para el logro de los objetivos buscados.

Bajo esta apreciación, y atendiendo el desarrollo de la guía a estructurar, se puede mencionar de manera específica que, para el ámbito empresarial, se debe definir inicialmente un modelo de consultoría a seguir, pues existen varios de ellos, dependiendo de la disciplina y el objetivo de la misma; pensando en ello, se puede establecer pensar que aquel que puede aplicar, es el de Consultoría de Procesos; Shein (1998), lo define como "el conjunto de actividades del consultor que ayudan al cliente a percibir, a comprender y actuar sobre los procesos que ocurren en su medio o ambiente, se busca transferir prácticas y teorías al empresario" (p. 80).; pues caben dentro de los contextos organizacionales de una empresa. El modelo mencionado, se evidencia en el cuadro 1 bajo la denominación de procedimientos aplicados. Como se muestra en Figura 4.

Figura 4: Etapas de la Consultoría

Fuente: Kubr (1997)

Como se puede apreciar en el cuadro, los numerales 1 al 5 corresponden a las fases del proceso de consultoría, destacando en la columna de la derecha frente a cada etapa, las tareas a realizar en cada una de las mismas, iniciando estas, con un diagnóstico y finalizando con una evaluación integral de todo el proceso desarrollado; acotando en todo caso, que no se definen como tal los procedimientos a seguir en cada tarea, pues sería sin duda muy dispendioso hacerlo y muy detallado dependiendo de la naturaleza y complejidad de la empresa de la que se hable. Lo planteado permite entender que junto con el modelo de consultoría, es importante definir el proceso como tal, como insumos para acercarse a la estructura y desarrollo de una guía metodológica del asunto, pues sienta las posibles etapas que de carácter genérico se definirán para ejecutar un proceso de consultor; destacando de igual forma que las tareas vistas en cada fase pueden asimilarse a parte de las intervenciones a realizar en cada

una de las áreas de la organización que pueda ser objeto de consultoría; siendo también insumo final de la estructura a plantea

Componentes de la Guía Metodológica

En la figura 5 se aprecia la estructura básica de la guía diseñada, sus componentes en su estructura y los servicios que prestará, entendiéndose la misma como un documento estructurado en el cual se presentan los siguientes elementos:

1. Título de la guía.
2. Objetivo de la guía.
3. Contenido por área de gestión a atender.
4. Procedimiento a seguir en el abordaje de cada área de gestión.
5. Formatos de protocolos y procedimientos sugeridos en cada área de gestión a intervenir.

Figura 5: Estructura de la guía metodológica

Fuente: Elaboración propia resultado de la investigación. Triangulación de caracterización económica, empresarial y laboral, Grupo focal y revisión documental internacional y nacional.

Conclusiones De Discusión

Una vez analizado los resultados ya presentados de manera global, así como la estructura de la guía propuesta se puede concluir entre otros aspectos con relación al contexto del sector productivo evaluado, los siguientes elementos:

1.A nivel interno la problemática se genera principalmente por falta de apoyo de entidades financieras, que les permitan a las pequeñas y medianas empresas adquirir créditos para la ampliación de su negocio, debido a que no tienen capacidad de endeudamiento, respaldo o vida crediticia.

2. Las necesidades mencionadas en los resultados se basan en capacitación oportuna y asertiva en los campos relacionados con el área administrativa, contable y financiera, puesto que el principal interés de los empresarios se ha limitado a la comercialización de productos.

3. En aspectos financieros y comerciales se destacan como relevantes, la deficiente estrategia para la fijación de precios, así como la ausencia de gestión en mercadeo ventas y publicidad.

4. De igual manera la influencia del entorno externo como por ejemplo las políticas del gobierno en materia laboral, fiscal y tributaria, la competencia desleal, la incursión de productos extranjeros en el mercado colombiano entre otros factores ha generado disminución en ventas considerablemente afectando la estabilidad de sus negocios.

5. Las problemáticas son comunes en los diversos sectores económicos a los cuales pertenecen las empresas.

Finalmente, a partir de los resultados obtenidos se genera la necesidad de proponer estrategias de gestión para fortalecer la formación de los estudiantes universitarios de ciencias administrativas específicamente desde la visión de la práctica profesional en el sector real productivo; dicha premisa debe generar en la academia, la revisión de sus actuales mecanismos de acercamiento a la realidad empresarial de las organizaciones en las cuales se desempeñaran sus egresados, para conocer de mano no solo las necesidades de las mismas sino el interés y mecanismo que pueden preferir dichas organizaciones en el momento de ser abordadas para recibir procesos de consultoría y asesoría.

Qué mecanismos se convierten en los ideales para realizar dicha tarea debe ser el interrogante a resolver, máxime cuando estamos en la era de la transformación digital y el uso de las Tics, que obliga a indexarse al empleo efectivo de la tecnología en los procesos mencionados.

De igual manera para el académico e investigadores de las organizaciones empresariales es relevante el analizar cuáles serán las futuras necesidades a atender en las MiPymes en la era de la cuarta revolución industrial como insumo para genera nuevas habilidades y fortalecimiento de las actuales en tema de gestión en la consultoría empresarial.

Abstract

The perspectives of resource-producing regions are closely connected with the state of mineral resource base, which at present is deteriorating qualitatively and quantitatively, hence, in many strategic programs of socio-economic development particular attention is paid to the increase of exploration activities, development of the Earth sciences to expand the knowledge on poorly studied areas based on latest technologies and innovation. The article presents a comparative analysis of socio-economic aspect of exploration in strategic programs of the chosen countries, namely, Canada, Australia, and Russia, to reveal similarities and differences. The research has shown various approaches toward development of new areas and practices of stimulating exploration activities as well as similarities in socio-economic consequences of field prospecting, exploration, and development.

Keywords: mineral resource, strategic planning, stimulation of exploration, region, socio-economic development.

Introduction

In the international practice, planning of exploration is performed at two levels. At the level of production companies interested in resource replacement to maintain long-term sustainable production, and at the governmental level to provide mineral resource safety to sustain socio-economic development.

It should be noted that in the scientific literature efficiency of exploration is often considered as growth reserve rates as compared with current oil and gas production that can be achieved with high costs, but the efficiency [1, 2], in authors' opinion, should be considered not only from the standpoint of proper choice of trends in exploration, but also with regard to sustainability of regional socio-economic development [3].

In the modern condition of deteriorating qualitative and quantitative characteristics of resource base, this aspect is becoming of particular significance and reflected in the programs of mineral resource base (MRB) development.

The goal of our research is comparative analysis of different aspects in planning exploration activities in foreign and Russian practices in connection with the objectives of regional socio-economic development.

Materials and Methods

The basic research materials are statistic and official data from Ministries and Offices of the countries involved, namely: Canada, Australia, and Russia. The choice is conditioned by the fact that these countries are the leaders in both production and export of mineral resources and hydrocarbon

resources. The main research method is empirical one, which is in demand to reveal the major common and different trends in planning of regional socio-economic development with regard to the significance of exploration activities.

Results

The International Practice in Involving Exploration in Socio-Economic Development of The Regions

The significance of exploration for a country development is observed in the work by Ericsson M., Löf O. [5], where in the analysis of statistic data over the recent 20 years (1996-2016) one of the authors' chosen input indicators were prospecting and exploration costs along with extraction costs and government revenues, whereas output indicator were human development index, different governance indicators as well as the Governance and Inequality based on the GINI coefficient that allowed them to estimate MCI (Mining Contribution Index). The authors intentionally included geologic exploration expenditures since it enables to create working places and contributes to the GDP growth as well as increases geologic potential and expand the information on the national wealth of the country in addition to contribution to growing reserve recovery. The analysis showed that 10 economically underdeveloped countries with high MCI moved up on the rating list of World Bank in terms of per capita income over 20 years. Some countries, for example Canada, decreased their MCI. Besides, comparison of resource producing countries and those with underdeveloped mining and petroleum industries has shown that in the former the human development index grew by 48 %, whereas in the latter only by 24% within the period under consideration. Nevertheless, the authors are concerned about low costs of explorations, as a mismatch between supply and demand is expected as a consequence of growing demand for mineral resource in next supercycle of the third decade, hence, a negative effect on the rate of economic growth is anticipated in both countries and territorial and administrative divisions.

In many countries exploration is an element of strategic planning. For example, in Canada mining resource industry provides 634 thousand direct and indirect jobs, of which 16,5 thousand are taken by indigenous people.

A number of important strategic documents were adopted in Canada, for instance, the Canadian minerals and metals plan, the Geo-Mapping for Energy and Minerals (GEM), Targeted Mineral Exploration Incentive (TMEI), the Government of Saskatchewan's Mineral Development Strategy, the Emerging Resources Program etc. The following significant aspects should be underlined in strategic planning in the sphere of exploration and mineral resource production.

1. Considering indigenous people's interests to maximize socio-economic benefits, first of all, for increasing indigenous people's employment, which leads to changes in corporate and staff strategies and policy in relation to indigenous people, the key element of which is creation of educational centers.
2. Development of northern, remote, and isolated regions, where socio-economic effect of mineral exploration and development is particularly significant, as it was underlined in the Canadian minerals and metals plan [6]. For example, in 2019 in Saskatchewan province the mineral exploration costs were $ 264 mln.
3. Additional financing of geologic sciences and extension of international cooperation in the sphere of innovation in Earth sciences, since it is promoting economic development and fostering Canada's role as a global leader in mining and petroleum industry. Mineral resource base depletion results in growth of mineral discovery cost and the fact that exploration methods are more in demand for smaller and more hard-to-recover fields that would also allow meeting the demand for some minerals in Canada, which are necessary to provide engineering, environmentally-oriented development of the industry.
4. On the basis of modern microeconomic environment, tax policy needs to be corrected to maximize investment attraction in geologic exploration, in spite of the fact that in Canada, in accordance with the Geo-Mapping for Energy and Minerals (GEM) program of 2008, there are federal tax incentives

for mineral exploration in the northern regions [7]. Though, it is important to highlight a positive momentum of financing stimulating measures, as a result of which five Saskatchewan exploration companies got $50 thousand each for exploration drilling. In oil-producing province Alberta reduced royalty tax is used as a stimulating measure.

In Australia production of mineral resource complex (MRC) is more than 70 % of export. Its share in GDP of the country increases by 7% [8]. More than 234 thousand people work in MRC, but if we consider related industries, there are more than 1,1 mln people, including indigenous people. MRC underpins the nation's high standards of living, notably reflected in Australia's high-quality education and health services.

On the whole, the analysis of MRC development plan has shown that Australia has similar problems with Canada. Let us point out some facts.

1. Focus on the plans of developing regional sustainability based on maximizing the benefits of resource development and favorable geographic location of the Australian continent with respect to fast-growing countries of Asia-Pacific regions.
2. Extension of intersectoral cooperation as a factor of increasing international MRC competitiveness in the world market. To eliminate any errors in strategic planning in future taking into account previous experience, it is proposed to support local communities, discover new resources, and develop workforce skills.
3. Changes in approach towards exploration. While in previous years there was a trend for better exploration of brownfields due to companies' attempts to minimize investment risks, now it is also necessary to extend exploration and prospecting new fields in the underexplored regions (two-thirds of the continent remains unexplored) to discover new perspectives for investment attraction and improve the access to new and existing geoscientific data and advanced scientific research.
4. Promotion of the Australian resources sector as the best place to invest into mineral resource production taking into account the well-established MRC in the world market as the most state-of-the-art and innovation-sensitive one. In the resources sector, new technologies and innovative solutions are resulting in new jobs, skills opportunities, support services and infrastructure in regional and metropolitan Australia. However, it is important to be fully aware that the uptake of new and increasingly digital technologies is broadening public concern about the impact on jobs, businesses and communities.
5. Development of stimulation mechanisms in regional exploration and prospecting based on co-financing of geologic exploration to create high-quality resources base for future generations for the coming decades. In recent years, investments in exploration were mainly made at the cost of risk capital, but due to new research trends the government participation is requested. As a result, the task is set to more precisely capture and quantify true greenfield exploration expenditure and activity of government in the new fields, as the data from the Australian Bureau of Statistics (ABS) is used to feasibly study the field development, which over-inflates the spend in greenfield developments from the beginning.

Thus, strategic plans in exploration activities are inseparable from regional socio-economic development programs of the resource-producing countries. Their success depends upon the efficiency of exploration, prospecting and development of mineral resources.

Russian Experience in Incorporating Exploration Activity into Socio-Economical Development of The Region

It is worth noting that exploration planning was inextricably linked to socio-economic development of the region, and as a consequence was documented in national economic plans and corresponding legislative and executive orders.

The issue of exploration impact on socio-economical and sociodemographic development is of particular relevance with the growing imbalance of economic development of oil and gas producing regions of the RF and in the context of unfavorable demographic trends specified in the "Concept of

Long-Term Socio-Economic Development of the Russian Federation for the Period up to 2030". In accordance with the Concept, the number of persons over working age will change from 32.1 million people to 40.7 million people by 2030. As a result, there will be 831 persons of over working age per 1000 persons of working age [9]. In order to reduce the proportion, a set of various activities is planned, however, the Concept neglects the issue of population increase in scarcely populated areas of the West Siberia, precisely the right bank of the River Tom, Eastern Siberia and the Far East.

The issues of inhabiting sparsely populated areas, improving quality of life in these areas, and providing the staff required for exploration activity were of particular importance during the period of the planned economy. There was also a crucial trend to transfer the employers who expressed a desire to move to a permanent job in petroleum and geology engineering companies operating in oil and gas provinces located within West and East Siberia and the Far East. This, in turn, stipulated the growth of towns and settlements and allowed providing oil and gas fields with qualified personnel for the long term, even up to the present day. As a result, infrastructure and field facilities required for producing both hydrocarbons and minerals were constructed. This led to a road-building boom, construction of houses, communal, welfare and recreation facilities for the labors of petroleum industry. It is worth noting that improved housing conditions and welfare services was a priority task which was resolved by "developing social welfare infrastructure, particularly, significant growth in construction of houses and recreation facilities, improvement of health care, trade and consumer services [10].

Therefore, the exploration activity mainly contributed to the need for the personnel who lived in close proximity to the place of work. Due to the absence of direct correlation, the indirect factor of growing economic and production potential of the region is population and standard of living. At the same time, it decreases with the growth of socio-economic and technological development of the region. In addition to the exploration and production costs, the other factor that might be considered as indirectly affecting socio-economic development of the region in particular and country as a whole is production and work conditions, transport, consumption points, and opportunities to combine [11].

At the present stage of the Russian history the development of the regions and territories are stipulated by the adopted strategies and programs (Figure 1). Under article 11 of the Federal Law "On the Strategic Planning in the Russian Federation", the documents developed for a certain region and industry involve the sector-related documents of strategic planning of the RF, the strategies of spatial development of the RF and socio-economic development of macro regions. Under article 19, fuel and energy complex provides the general plans which specify the sector-specific and cross-sectoral strategies. They should include priorities, goals and objectives, as well as governance indicators of state and municipal authorities and principles of national security of the RF, the most effective ways to achieve the goals in a certain sector of economy, spheres of State and municipal governance, region of the RF, and municipal entity [12].

Fig. 1: Sector-specific and regional documents which may embrace socio-economic aspects of exploration activity

Source: compiled by the author

"The Strategy of Socio-Economic Development of the RF for Medium and Long Term Period" and "The Projections of Socio-Economic Development of the RF For and Long Term Period" contemplated with regard to projections are referred to the documents of strategic planning. When planning, state programs and land-use planning schemes of the RF are compiled. Table 1 presents the author's view on socio-economic aspect of exploration activity in the above-mentioned documents.

Table 1: impact of exploration activity on the socio-economic development of the region presented in the strategic programs and documents

Document	Socio-economic aspect of exploration activity
The Concept of Long-Term Socio-Economic Development of the Russian Federation for the Period up to 2020 [13]	✓ Emergence of new centers of socio-economic development, which is stipulated by the development of energy and transport infrastructure, and introduction of regional-production clusters intended to realize the competitive potential of the region. ✓ Establishment of regional growth centers both within new petroleum and mineral producing regions and well-known densely populated areas. ✓ Reduction of inequality in living standards and quality of life in the RF by means of social and regional policy interventions. ✓ Strengthening the system of strategic governance of regional development, improving integrity and sustainability of regional development and production force management.
The Projection of Long-Term Socio-Economic Development	✓ Emergence and development of new big oil-producing centers and corresponding infrastructure.

of the Russian Federation for the period up to 2030 [9]	✓ Fostering exploration activity within new sites located in the well-known regions.
Land-use Planning Scheme of the Russian Federation [14]	✓ None
Energy Strategy for the Period up to 2035 [15]	✓ Well-balanced energy development of the RF regions. ✓ Emergence of new fuel and energy complexes.
General Plan of Oil Industry Development [16]	✓ Enhancing the resource potential to assure sustainable oil production rate in 2017-2035 and beyond 2035. ✓ Promotion of small and medium-sized enterprises in the various sectors of oil industry including exploration activity and oil production. ✓ Insuring an increase in oil reserves per annual oil production at the level not less than 1.2 up to 2020 and 1.3 for the period from 2021 to 2035. ✓ Russian technologies and equipment used in exploration, oil production and transportation, refinery (in each sector of petroleum industry) should account for not less than 55% up to 2020 and not less than 80 % up to 2035.
Strategy of Geology Industry Development for the Period up to 2030 [17]	✓ Revision of socio-economic development programs of the regions in order to improve energy and transport infrastructure involved in the development of mineral resources.

The aim of the government to encourage population growth within the new oil-producing regions is worth noted. However, the initiatives to expand and inhabit the territories by developing industrial, transport, and social infrastructure are not laid down by the law.

The development of market relations has shifted regional exploration activity from socio-economic issues to the corporate social responsibility, with special attention being given to the industrial and environmental safety, the guaranteed social package for the employers, their families and pensioners, adequate working conditions, and social and economic support of the regions. In this regard, the socio-economic focus is mainly rooted in voluntariness, not in a set of laws, and financial support of the mineral-producing regions with well-developed transport infrastructure. The main implementation mechanisms are as follows:

a) agreements on socio-economic cooperation with the RF entities in order to "coordinate the selection and implementation of the construction and renovation projects for critical social infrastructure" [18];
b) own social programs.

However, despite the socio-economic focus of regional development, due to the difference between planned and market economies there is a discrepancy between the exploration activity and the strategic demographic objectives that concern population increase within the scarcely populated areas located beyond the Urals. Today, there is a trend to eliminate socio-economic aspects of exploration activity, which, in turn, may contribute to demographic imbalance between the European part of the RF and West and East Siberia and the Far East. It has been happening for the past 20 years. In addition, shift work policy of oil producers, which is based on the attraction of the staff from the other regions, increases the number of emergency situations. It can be explained by the fact that the oil-producing companies have to hire service companies based on the tender procedures. As a rule, these companies, located in the other regions, have no sufficient experience in mineral and oil production within the regions in interest. Another crucial point is free-riding attitude towards the environment which slowly suppresses the attentive attitude towards the territory and, as a result, there is no place for sustainable use of natural resources.

Conclusion

1. Socio-economic significance of exploration activity is more prominent at the first stages of territory development. The results of such impetus depend on the scale of the involved work. Subsequently, the impact of exploration activity declines due to socio-economic and geological factors. The increase in population, employment, and welfare is more rapid at the first stage, and then it slows down. The amount of explored reserves proved at the first stage of the territory development increases only due to further exploration which does not involve numerous staff. As a result, there may be stagnation in staff demand. In addition, industry, transport and social infrastructures have been already developed. In the absence of large and unique fields or in a case of undiversified economy, socio-economic indicators may improve slowly.

2. The state of natural resource base urges the countries to implement measures to attract investment into exploration sector in order to stimulate socio-economic development of the regions [19].
3. Russian and foreign experience are similar in the fact that the State defines the focus of prospecting and exploration activity, while business is free to decide what exploration programs to implement. In a case of adequate and attractive stimulating measures, it is possible to expect the implementation of regional socio-economic development programs in the medium-to-long term.

Abstract

The article defines the theoretical basis for the interoperability of payment systems, presents its structural classification. As part of the structural classification, levels, types, forms of interoperability for payment systems are specified. Interoperability of distributed ledgers is reviewed. One of the main tasks of the development of the payment services market is the integration of conceptual, technical, organizational, regulatory solutions into a unified project that allows for the successful implementation and development of interoperability. Recommendations are made to the regulator on the implementation of interoperability in the payment services market, the participants of which are both credit organizations and fintech companies, which will allow them to increase efficiency and reduce costs.

Keywords: Interoperability, Payment System, Fintech, Cashless Payments, Ecosystem, Mobile Payment, Mobile Account, Electronic Wallet.

Introduction

The purpose of this article is to determine the possibility and feasibility of implementing interoperability in the payment services market. Currently, most of scientific research on this topic focuses mainly on the technical aspects of this problem.

The scientific novelty of this paper is based on the following:

1. The theoretical base for studying the interoperability of payment systems has been developed, the conceptual apparatus used for unification and comparative analysis of the interoperability of payment systems both abroad and in the Russian market has been expanded, and a structural classification of interoperability has been proposed; we also reviewed the issue of interoperability in distributed ledgers.
2. A conceptual framework for the interoperability of payment systems has been formulated.
3. We have also analyzed the current state of the payment services interoperability as well as the prospects for its development, underlying trends.

Theoretical aspects of payment system interoperability

There is no single definition of interoperability. It is generally considered that the definitions given by official standardization organizations, primarily ISO should be used. But even ISO provides at least three definitions of interoperability:

- The ability of two or more systems or components to exchange information and to use the information that has been exchanged according to ISO/IEC 24765:2009 (2009).
- The ability for two or more Object Request Brokers (ORB) to cooperate to deliver requests to the proper object according to ISO/IEC 19500-2:2003 (2003).
- The capability to communicate, execute programs, and transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units according to ISO/IEC 2382-1:1993 (1993).

In Russia Government Standard (GOST) R 55062-2012 (2012) defines interoperability as a set of related terms: such as interoperability barrier, external enterprise interoperability, internal enterprise interoperability, interoperability Glossary, interoperability system, enterprise interoperability, organizational interoperability, approach to achieving interoperability, interoperability profile, semantic interoperability, technical interoperability, interoperability level, interoperability reference model.

A comparison of different definitions of interoperability is presented in Table 1.

Table 1: Comparative characteristics of the concept of interoperability

	ISO/IEC 24765:2009	**ISO/IEC 19500-2:2003**	**ISO/IEC 2382-1:1993**	**GOST P 55062-2012**
Subject of the determination	System or component	Object request Brocker (ORB)	Function block	Information system or component
Purpose	To exchange information and to use it	Delivery of requests to the desired object	Exchange of information, run programs, and transmit data	Exchange of information and use of information obtained as a result of exchange
Additional condition			The user does not need to know the unique characteristics of functional blocks	

Source: compiled by the authors.

Interoperability may also have different levels. The classification of those is shown in Table 2.

Table 2: Interoperability levels

Interoperability level	Characteristic
Technical	Ability to exchange digital and analog signals.
Syntactic	Ability to exchange data
Semantic	Ability to exchange information
Pragmatic	Ability to share information in the context of tasks
Dynamic	Ability to share information in response to changing operating conditions
Organizational	Ability to function in a coordinated manner based on information exchange
Conceptual	Ability to share information under conditions of the agreement of assumptions and restrictions
Based on an exchange	Ability to transform information to the needs of the consumer
Integration	The ability to create a space in which the consumer does not feel heterogeneity of the environment

Source: compiled by the authors using the data from Batovrin V. K. et al (2009).

Because modern payment systems are open systems and are closely integrated with information technologies, the infrastructure, standards, and legal documentation that all elements of the payment system depend on, are currently being actively developed. Additionally, 'legal' level of interoperability might be added. We also believe that it is appropriate to define another additional level of interoperability for payment systems – currency-related interoperability. Currency interoperability soon will play a significant role, both inside and between individual currency zones, as well as to ensure the interoperability of cryptocurrencies.

There are several different classifications of interoperability, but these classifications define and characterize interoperability in terms of unrelated groups of properties, so in addition to levels, we propose to distinguish types, degrees, and forms of interoperability.

The types of interoperability of payment systems are shown in table 3.

Table 3: The types of interoperability of payment systems

Type of interoperability	Definition	Characteristic
Systemic	Interoperability at the level of a single payment system	Banks and payment system operators, when connecting to a payment system, agree to comply with the rules, standards and interfaces established by this system
Networking	Interoperability between different payment systems	It is most often used for cross-border or interregional payments, which allows the cardholder to use this card in another country
Parallel system	Allows a merchant or agent accepting a payment from a customer to participate in multiple payment systems	Although the seller accepts payments in different payment systems, this is simple and looks like achieving some compatibility from the outside

Source: compiled by the authors using the data from Interoperability in Electronic Payments: Lessons and Opportunities (2012).

There are two main types of interoperability:

- horizontal interoperability - is the compatibility of competing products, services, or platforms, such as the compatibility of data networks or different payment cards.
- vertical interoperability - is the compatibility of products, services, or platforms with products and services that extend their functionality (related products).

Technically, some products may be fully interoperable or non-interoperable as well as there may be different degrees of interoperability, for example, with respect to the functionality of these products. In addition, interoperability and openness can be symmetrical or asymmetric (products from one platform can be used on another platform, but not Vice versa).
In addition, interoperability can take various forms, as shown in Table 4.

Table 4: forms of payment system interoperability

At the platform level	At the agent level	At the client level
Allows clients of one Payment System Participant (PSP) to send money to clients of another PSP	Allows agents of one service to serve clients of another service	Allows customers to access their account via any card of the subscriber identification module (SIM card)

Source: compiled by the authors.

Interoperability for Novel Technologies

Interoperability is relevant for such novel technologies as distributed ledgers as well. Technically, distributed ledgers are specific type of the database. While historically all distributed ledgers were isolated from each other, with the growth of technology the demand for interoperability is getting stronger. The case in point is Bitcoin: bitcoin users can exchange tokens between each other, but this system is effectively closed loop. In other words, if Bob holds bitcoins and wants to transfer value to Ethereum, he needs to use third-party exchanger. The same logic applies to most distributed ledgers: lack of interoperability has detrimental effect on added value.

There can be different froms in interoperability, as discussed in Koens T. and Poll E (2019):

- Interoperability between a distributed ledger and legacy systems. For example, Bitcoin and a traditional banking payment system.
- Interoperability between distributed ledger platforms. For example, between Bitcoin and Dogecoin (two permissionless ledgers), or Corda and Ethereum (a permissioned and permissionless ledger).
- Interoperability between two smart contracts within a single ledger. For example, between Corda apps, which are smart contracts on a single Corda ledger.

As seen above, interoperability between distributed ledgers extends far beyond payment functionality. Schulte S. et al (2019) defined, that this affects such functions as smart contracts as well: in other words, interoperability would evidently have a large impact since users could select and combine blockchains based on their current demands while not being locked-into one technology.

As in other sectors, distributed ledgers interoperability, according to McLean S. and Deane-Johns S. (2016), might require agreements “about data interoperability, policy interoperability and the effective implementation of the international standards”: hinting on the fact that ‘anarchic’ ledgers (where there is no entity managing the development of the technology) might find it more difficult to become interoperable.

For example, Meaning J. et al (2018) believe that central bank digital currencies (i.e. central bank issued tokens recorded on a distributed ledger) should be interoperable with the legacy system. This means that “any deposit account could make a payment to any CBDC account and vice versa”). In more

general terms, distributed ledgers (at least in payment functionality) follow the same logic as other payment infrastructures that tend to move away from being closed loop, favoring free flow of funds and information.

At this moment interoperability of distributed ledgers is primarily technical rather than legal challenge. Meiklejohn S. (2018) states, that although different approaches to ensure interoperability between ledger exist and some of them are being tested, there is still no definitive answer to whether they ensure appropriate level of efficiency and quality. It is unclear if interoperability of distributed ledgers will be anyway different from interoperability of centralized databases from legal or institutional point of view. This makes the analysis of interoperability even more important and relevant.

Problems of Interoperability

Although interoperability is expected to benefit consumers and the payment services market, its implementation faces several problems.

The first type of problem for interoperability's implementation is the need to define and enforce a common set of rules and standards in both the technical and legal fields. Typical problems of interoperability development are:

- lack of a definition of what it means to become interoperable. This leads to confusion in the industry, as different operators have different ideas about what interoperability is;
- the advantages associated with interoperability are not always immediately obvious, and its true impact on the payment services market can only be proven after its implementation;
- distrust of competitors can make it difficult for operators to work together, even if they understand the benefits of interoperability;
- understanding and coordination on a technical and commercial model for managing interoperable processes;
- a conflict of organizational priorities may be barrier to implementation of interoperability;
- introduction of adverse control modes for PSP and interoperability.
- the introduction of interoperability can have negative consequences because of the concerns over competition, and because of the differentiation of products in the same network. The cost of implementing and operating an interoperable network increases and this may lead to payment system providers trying to protect their existing business while remaining isolated.

From a market perspective according to the State of the Industry Report (2015), a significant challenge in creating a viable mobile payment ecosystem is to ensure strong network effects. In particular, it is necessary to overcome the typical network market problem: while there are not many users, the service is not very popular for other potential users, but once a certain critical number of users is surpassed, its attractiveness as well as the number of users, begins to grow rapidly.

Factors, that affect the development of interoperability, can be divided into 4 large groups:

1. Economic factors: participants of payment systems voluntarily develop interoperability to make a profit, but economic factors in any case are derived from the participants' business strategies, and not just from the wish to make a profit.
2. Regulatory factors: industry associations can contribute to the "voluntary" development of the Association members interoperability, especially if this development is supported by the regulator.
3. Using national payment systems for the development of interoperability.
4. Market monopolization by one or more participants: the dominance of a single payment service provider can slow down the development of interoperability (why should other participants develop interoperability if 90% of payments are made by a single bank).

Let us look at some of the factors that influence the development of interoperability in more detail. One of these factors is the influence of monopolies.

Payment System Participant (PSP), that have monopolized the market by introducing new technologies ahead of their competitors, are reluctant to open their network of clients and agents, even under government programs, because this reduces their competitive advantage. On the other hand, if in the short term the economic effect of implementing interoperability is negative for this operator, then in the medium-term interoperability brings advantages, especially if there is a large overall market growth potential. On the other hand, if the short-term economic effect of implementing interoperability is negative for this operator, that in the medium-term interoperability brings advantages, especially if there is a large overall market growth potential. It is better to be a less dominant operator in a large market than a dominant operator in a small one.

From the market point of view, the failure of interoperability by a major operator (such as the case of Safaricom in Kenya, considered by Dahlberg et al (2015) or Sberbank in Russia) may lead to a lack of competition. Thus, the rejection of interoperability can freeze the asymmetric market structure to the detriment of payment system customers.

Thus, the development of interoperability in the payment services market depends on several factors, such as: the level of the sector development, the current state of the market, the political and economic landscape, regulatory maturity of regulators, the level of implementation and development of technological innovations, etc. This also requires coordination between various regulators, such as, for example, the Russian financial sector regulators: The Central Bank of the Russian Federation, the Ministry of Finance, and so on.

International experience in implementing interoperability

Mobile payment services are most often offered by banks or mobile operators as independent providers. Also, in some countries, the regulator has proposed initiatives for «full integration» of mobile payments with the dominant mobile payment operator or partnership schemes. Examples of such initiatives are Peru, Japan and Kenya. For example, according to Pierre Biscaye et al (2015), the Association of banks of Peru (ASBANC) launched a national "ecosystem" of mobile money, inclusive of all banks and Telecom operators in 2014. Other examples of "full integration", described by Bourreau, M. and Valletti, T (2015), are Japan and Kenya, where a single operator controls mobile payment services for a large Agency network. However, these models remain relatively rare.

Let us look at the most successful examples of interoperability introducing.

In September 2016, Visa launched the mVisa app for smartphones. mVisa is a QR-based payment service operating in India, Kenya, Rwanda, Egypt, Ghana, Indonesia, Kazakhstan, Nigeria, Pakistan and Vietnam. The mVisa press-release (2017) shows that the mVisa mobile solution provides the benefits of simple and reliable digital Commerce to financial institutions, sellers, and buyers in emerging markets, accelerating the global transition from cash to electronic payments.

mVisa helps to solve trade infrastructure problems by enabling customers to use their mobile phones to make non-cash purchases in stores, pay bills remotely, and even transfer money to friends and family by linking their Visa debit, credit, or prepaid account to the mVisa app. It digitalizes the base account and allows consumers to transfer funds from their account to the merchant's account in a reliable and secure way by scanning a QR code.

In Europe interoperability has been developed in recent years by the European payments Council (EPC) (2019) by developing the SCT (SEPA credit transfers) system to SCT Inst (SEPA instant credit payment system) as part of SEPA initiatives. SCT Inst implements an instant payment system at the pan-European level, facilitating the integration of interoperable solutions developed at the level of individual countries. Italy and Spain have updated their mobile payment systems (jiffy and Bizum, respectively) to match the EPC scheme, while Portugal, France, Belgium and the Netherlands have developed new systems and CSM that match SCT Inst. However, at the end of 2017, only 1,000 banks complied with the SCT rulebook, which is only 20% of the region's banks.

As for mobile payment systems, at the end of 2019, the European Association of mobile payment systems (EMPSA) which included seven payment systems from various EU countries — TWIN (Switzerland), Bancontact Payconiq (Belgium), Bluecode (Germany and Austria), Mobile Pay (Denmark and Finland), SIBS (Portugal), Swish (Sweden), and VIPPS (Norway), was established. Later, Bancomat Pay and Plick (Italy), BLIK (Poland), and Flick (Slovenia) also joined the system. Thus, according to EMPSA Press release (2020), EMPSA currently unites 11 mobile payment systems and 45 million users.
The goal of the Alliance is to ensure interoperability between these payment systems, which will allow end users to make payments within the services of the member systems of the Association. In June 2019, as FINTECH Switzerland (2019) informed, Vipps and Bluecode have already created an Association with four other mobile payment operators and Alipay to allow payments using QR codes in their apps.

Summarizing the entire range of approaches to implementing interoperability in various markets, we can focus on Camner's (2012) proposals for implementing a three-step process to consider interoperability, which involves:

- identifying the perceived problem or market opportunities;
- understanding whether solving the problem benefits both consumers and operators;
- decisions on how partnerships and relationships can help achieve the goal.

According to these steps, when interoperability is implementing, the actual choice of interoperability mode is the last one.

The first step is to try to identify market opportunities and regulatory barriers which may slow down market development and the usage of implemented solutions by customers.

Conclusions and Recommendations

Currently there are three main options for implementing interoperability at least for mobile payments:

1. Voluntary implementation of interoperability through the conclusion of bilateral agreements.
2. Voluntary implementation of interoperability using the services of a national integrator.
3. Implementation of interoperability mandatory with the usage of the national integrator's services.

The first option was implemented in Indonesia, Tanzania and Rwanda ('Achieving interoperability in mobile financial services' (2015)). The second one was implemented in Pakistan and Peru. Finally, the third option was adopted in Ghana, Nigeria and Mexico. Thus, the way taken in a country may depend on the technical readiness of the existing financial ecosystem.

Regulatory intervention to ensure interoperability can have its advantages - each individual mobile payment system becomes part of one large network. But mandatory interoperability requires investments that must be justified, and the solutions proposed by the regulator are not always the most cost-effective. On the other hand, mandatory interoperability can hinder market development, reduce competition, and discourage technical innovation. In some cases, the implementation of mandatory interoperability forced several operators to leave the market (for example, some cases was reviewed in the ESRB Report (2016)).

Regulators do not use only two extreme approaches: complete non-interference or mandatory implementation of interoperability. There are a lot of compromise solutions. For example, it is possible to let the market's participants not only find an acceptable solution for everyone but to take measures to accept it and regulate tariffs independently. Regulators can also monitor the process of interoperability integration by market participants and intervene in this process only if it is necessary for development.

Two conclusions can be drawn from this. First, regulation should ensure that no one operator did not take actions that increase the cost of interoperability. Second, decisions made by the regulator should

be based on the degree of symmetry of the market. Probably in an asymmetric market, the regulator should play a more active role to introduce interoperability.

Among the key problems faced by new and established companies in the market of electronic payment services is to force different systems to interact with each other and quickly adapt to the new rules. Against this background, we can see two trends in interoperability development:
1. Development of proprietary APIs to simplify data exchange between market participants, as well as protect your own data.

2. Implementation of ISO 20022 as a common language for various financial organizations.
For the purpose of interoperability efficiency, it is necessary to combine 3 functional elements:

1. organizational management;
2. business model;
3. technical integration.

Unfortunately, in most countries, the focus is on technical interoperability and not enough on other aspects that are critical to the development of interoperability.

On the Significance of Physical Culture in Shaping Health. Implications for Social Security

Ilona URYCH

War Studies University, Warsaw, Poland
i.urych@akademia.mil.pl

Abstract

Observation the negative impact of the lack physical activity of people on their health and social security were the main motivation for undertaking the research. Therefore, the aim of this article is to diagnose and analyze the importance of physical culture in shaping health in the field of social security. The research goal was achieved by providing answers to the following questions: How should health in the field of social security be understood? What are the opportunities for developing health in the field of social security through the participation of individuals in physical culture? What is the relationship between physical culture and human health in ontogenesis? The methods used were deduction and induction. Health is a fundamental human value and social security is a fundamental human need to ensure survival and physical, mental and social development (1). Thanks to an individual's participation in physical culture, the opportunities for the development of social security are broad and concern in particular positive structural and functional changes in the human body, whereas limiting physical activity leads to negative health consequences (2). The basis for the development of health and social security in the whole personal development of a person is their active participation in physical culture, which in childhood primarily serves to support the development of individuals, and in adulthood to maintain the level achieved, and in old age to actively counteract involution (3). Therefore, the challenges of fostering social security should be met by a parents and teachers.

Keywords: Social Security, Physical Culture, Health.

Introduction

The elementary factors causing civilizational diseases include reduced physical activity and a passive lifestyle. Consequently, many students are characterized by deviations from proper health, including posture problems and obesity. On the other hand, in the case of adults, the more and more common cardiological problems and oncological problems, as well as the negative consequences of stress are a true plague.

Little wonder that prevention of lifestyle diseases with physical activity is a topic that is widely discussed among doctors, educators, teachers, and psychologists. Increased systematic physical activity can mitigate or eliminate many factors that lead to diseases. Physical work, practicing sports and tourism, recreation, as well as any daily physical activity are becoming a necessity. An excellent opportunity to provide an appropriate dose of movement to children and youth are physical education classes at school, as well as extracurricular sport and recreation classes.

The above observation the negative impact of the lack physical activity of young and older people on their health and social security were the main motivation for undertaking the research.
The aim of this article[1] is to diagnose and analyze the importance of physical culture in shaping health in the field of social security. The research goal was achieved by providing answers to the

[1] This content of this article is a revised and expanded fragment of the following monograph: I. Urych, *Kultura fizyczna w kształtowaniu bezpieczeństwa zdrowotnego*, ASzWoj, Warsaw 2018.

following questions: How should health in the field of social security be understood? What are the opportunities for developing health in the field of social security through the participation of individuals in physical culture? What is the relationship between physical culture and human health in ontogenesis? The research methods used were deduction and induction.

In order for the narrative goal to be achieved in this article, first, the understanding of health in the field of social security is given. Discussed next are the possibilities for developing health in the field of social security through the participation of individuals in physical culture. Because physical activity is an important element of human health in individual development as a whole, the subsequent part of this article will discuss the correlation of physical culture with individual health in ontogenesis. The article ends with a summary.

The understanding of health in the field of social security

The dynamically changing reality brings with it many dangers and challenges concerning nearly all dimensions of human existence, including health, and more broadly, health security.

Along with the development of medical science, the concept of health has also changed. Many different ways of defining health have been proposed. One of these was to define health as the absence of pathological changes occurring in the body. It was also believed that health is an indicator of the level of functioning in society. Dąbrowski (1979) it also defined as a state that is the opposite of disease. Next, health was based (as it is often still) on a biomedical model, according to which medicine cures the physical body, which is completely separate from the psyche, which is important because of the emotions and convictions, but which have nothing to do with the body. Over time, researchers have pointed to interactions that prove that the purely biomedical model of health is not confirmed by reality. For example, Gerring and Zimbardo (2009) have been proven that positive and negative events affect the functioning of the immune system, people tolerate the negative consequences of stress differently, and appropriate social support can reduce the risk of death.

In the book by Gerring and Zimbardo (2009) health is understood through the prism of a biopsychosocial model, in which *bio* is the biological component of health and *psycho* represents the psychological component. These complement the social dimension. This model combines physical health with the state of mind and the world around the individual. In other words, health is understood as a state of complete balance and social, physical and mental well-being, which allows a healthy person to achieve his or her life plans and aspirations. However, health psychologists highlight the dynamic and multidimensional nature of health. They also identify it with welfare, which encompasses the physical, spiritual, intellectual, social and environmental elements of human life.
World Health Organization (1998), in turn, defines health as a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity (disability). In a research study by Woynarowska (2007) such an approach is important in that it not only emphasizes the negative dimension, namely the absence of disease as had been done earlier, but also emphasizes the positive dimension of health, namely welfare. In other words, the commonly used definition of health accentuates its dependence on active human participation, links it with inner and social life, as well as with the personal care an individual takes his or her own physical and mental condition. Health is a term referring to the general state of the body and mind, characterized by vigor and strength.

In the discourse surrounding health, one should also refer to the broader category of health security. Skrabacz and Sulowski (2012) pointed out that this in turn constitutes the foundation of social security and is also defined differently. On the one hand, it may refer to actions of the public authorities aimed at coordinating the diverse elements of health care, social and rehabilitative care, accident compensation, pensions, sickness benefits, employee health and other benefits in order to meet the needs of health services and living expenses. On the other hand Supranowicz et al. (2012) mentioned that health security can be considered from the perspective of individuals who consider the available health care services to be sufficient and treatment costs to be well-adjusted to their financial capabilities and trust that in case of a loss of the ability to earn a living, they will have

secured financial resources enabling them to lead a dignified life. Ruszkowski (2010) notes that the lack of health security corresponds to the subjective sense of danger faced by individuals in the event of illness. "We can regard the reduction of this feeling as much as possible as the achievement of a kind of well-being – a sense of full health security" – wrote Ruszkowski (2010, p. 6). Therefore, the level of health security may be determined by both access to health care and the ability to use it to such an extent as to satisfy health needs. This egalitarian point of view, originally formulated by the British Labour Party, has been successively adopted in contemporary Europe. As Sanecki (2011) although access to health care has become a civil right, it still depends on need and the citizen's ability to benefit from the opportunities offered by the system.

Cianciara and Wysocki (2006) draw attention to two closely related aspects, which are essential for the analysis of health security objectives and related terminology, i.e.: protection against the risk of illness and health loss, as well as protection against the effects of illness and loss of health. The first type of health security includes elements of financing and delivery of preventive and curative services. It therefore refers to the organization, mobilization and accumulation of financial resources, the purchase and delivery of services, as well as the development of human and physical resources, the knowledge capital and the management of the whole system. Ensuring health security is one of the tasks of public administration and, as a result, all citizens should have access to adequate services. Understood in this manner, security is discussed from the perspective of protection against global health threats, with a particular focus on terrorism or new communicable diseases. Safeguarding against disease and loss of health includes "the coordination of diverse elements of health care, prevention, social care, rehabilitation and occupational medicine services, and the payment of sickness, accident and disability benefits to meet the regular individual needs for a variety of health services and income earned" – wrote Cianciara and Wysocki (2006, pp. 79-80).

A definition of health security also needs to address three theoretical conceptions of health: biomedical, behavioral and socio-environmental health. The biomedical approach focuses on groups at high-risk for the diseases in question and on disease detection and treatment. The behavioral conception refers to high-risk attitudes and behaviors and is geared towards the development of educational programs to support changes in behavior. According to the socio-environmental approach, however, attention should be directed toward psychosocial and economic living conditions that pose a high risk to health. The socio-environmental conception therefore focuses on adapting individuals and groups to specific conditions and on improving their living conditions. While the first two approaches are geared towards individuals (particular persons), the third concept is geared towards communities and structural conditions. However, health is still commonly regarded as the absence of disease, and in a more sublime sense as a resource and the strength needed for everyday life. Meanwhile, the means used to achieve public authorities' health policy objectives, policies relating to the preservation and improvement of health, will come down to the concept of public health. As Opolski (2011, pp. 16-17) notes, public health is at the same time an art - the art of solving the health problems of individuals or communities. According to the World Health Organization (1998), public health can be considered as the art of applying science so as to reduce inequalities in health and ensure the best possible health for as many people as possible. Winslow (1920) of Yale University Medical School in the early part of the twentieth century also understood public health as both science and the art of preventing disease, prolonging life, and promoting physical health and fitness.

The discussion above shows that there is no holistic definition of health in the field of social security in the literature, and therefore Urych (2018) shall adopt own understanding of the term, according to which health in the field of social security is the shaping of optimal conditions to ensure the survival and development of a person in terms of his or her physical, mental and social health. Such an interpretation of health in the field of social security indicates that it is a process in which a person strives for biological, psychological and social wellbeing that allows him or her to function multidimensionally and to achieve his or her life plans and aspirations. Health is the highest value here, focused on the active participation of the human being in various forms of physical culture. Autotelic actions within the framework of the creation of one's own health are all the more necessary

today, when lifestyles in a globalized society are conducive to passive behaviors. These behaviors are decisive in the emergence of many diseases, referred to as lifestyle or civilization diseases.

It is equally important in the context of defining social security to refer to security culture. According to Cieślarczyk and Filipek (2017), security culture not only entails the body of knowledge characteristic for a given subject, but also the ways of thinking about security, as well as the related ways of feeling and achieving it. The components of security culture include a range of sectors corresponding to its subject areas, particularly, in this context, information security, cultural security, political security, ecological security, economic security, military security or public security. One of the components of security culture is health security, which is underpinned by health culture. At its root are the values and norms that guide a person acting to ensure his or her security. If the next few decades are accompanied by an increase in the level of risk in various spheres of human activity, i.e. in various areas of human security, the level of security culture, which to a significant degree is determined by health security, must also be raised in individuals and in social groups. As a panacea for satisfying the health needs of particular segments of the population, this should be guided toward the concordance of entities participating in building the health care system, and holistically, of entities creating a broadly understood health culture. In a research study by Kuczabski (2018) such actions are all the more justified in preparing for a possible crisis situation in which the protection of the life and health of citizens is essential.

The possibilities for the development of health in the field of social security through participation in physical culture

The health of contemporary people is determined by many factors. Yet the important connection between movement and human health has long been noted by many scholars. Its primary importance was pointed out by in antiquity by the philosopher: “Movement is life”. Physical activity is necessary for every process of creation, regardless of what it concerns. Movement creates and perfects the human being, enabling not only motor development, but also intellectual development. Human beings develop in motion and through movement. The great value of this was also noted by orthopedist Alfons Senger, who claimed that “Movement is life – life is movement”. Another philosopher, Arthur Schopenhauer, professed the principle: “Life is about movement and movement is its essence”. The importance of active participation in physical culture for shaping health was aptly expressed in the sixteenth century by Wojciech Oczko, physician to Polish kings, who pointed out that “Movement can replace almost every medicine, but all medicine taken together cannot replace movement”. In this statement, he emphasized that in order to maintain health, a person should engage in physical activity, which is the best medicine ever discovered.

The health of contemporary people is affected by many factors which may have both negative and positive effects. Drabik (1996) includes among those having a positive influence physical activity, proper nutrition, weight control, coping with stress, only moderate use of stimulants, not smoking, and an appropriate amount of sleep. Observance of all these pro-health recommendations will, in Drabik’s view, guarantee the maintenance of good health, a slim and healthy body, and will prolong lifespan as well. It is worth noting that Drabik (1996) lists physical activity as the factor with the most significant positive affect on human health. The researcher supports this position with the fact that active forms of recreation help to control weight and keep the body in good condition. Proper nutrition, providing nutrients in the right proportions, determines proper functioning. Also important is the ability to cope with stress and the strains of everyday life, as well as limiting or abstaining from the use of any kind of stimulant and not smoking. On the other hand, a sufficient amount of sleep allows the body to rest and regenerate.

Starosta (2003) called these pro-health factors “the spiral of life”, recommending for contemporary people a lifestyle based on systematic physical activity, rational nutrition and a hygienic lifestyle.
According to Starosta (2003), a healthy and fit person, thanks to systematic physical activity, a hygienic lifestyle, rational nutrition and living in an ecologically clean environment, permanently improves the fitness, efficiency and resistance of his or her body. Moreover, by means of physical activity of increasing intensity with elements of sports, the health and psychological resilience of the

person is improved. The high level of psychomotor efficiency and efficiency achieved helps to maintain normal body weight. On the other hand, properly organized short and long periods of rest extend biological youth, which results in an optimistic attitude towards life, satisfaction with life and with oneself, and consequently a successful and healthy life.

Starosta (2003) argues that the opposite of the "spiral of life" may be the "spiral of death", when a person, as a result of an inappropriate, sedentary lifestyle, enters into hypokinesis. The lack of movement results in pathological processes in organisms deprived of movement, which then grow ill and age more rapidly. This deficiency, together with other negative factors, causes many lifestyle diseases (e.g. hypertension, overweight, spinal deformations, flattening of feet). The accumulation of these leads to irreversible changes and consequently to many illnesses and premature death.

According to Starosta (2010), technological progress has deprived most people of the possibility perform physical labor. People stopped moving and began to lead a sedentary lifestyle while consuming too much food. According to scientists, the motor activity of the average person in the hundred-year period 1864-1964 decreased by 93%. The effects of reduced motor activity, excess calories and laziness were summarized by the World Health Organization, indicating that in 2007 there were 1.6 billion overweight people, and by 2017 this number was expected to increase by up to 40%. In this race for the top, the United States is the leader, with over 75% of its population being overweight, and Poland is approaching 50% of its citizens being overweight or obese. Recognizing this dangerous developmental trend, the World Health Organization tried to brake it by proposing a simple physical activity that could be used in any circumstances, namely in the form of a number of steps to walk: 10,000 per day for blue-collar workers, and 15,000 a day for white-collar workers.

Numerous studies by Grabowski (1999) have shown that even a short-term reduction in motor activity leads to far-reaching structural and functional changes in the human body, such as decalcification of bones, muscle atrophy, decreased efficiency, increased response time, etc. The results of these studies are presented below. There are also reasonable grounds to assume that the pace and intensity of involutionary processes (aging) in the body depend to a large extent on lifestyle, and especially on the role of motor activity. It was found, for example, that passive and sedentary lifestyle leads to the appearance of signs of motor aging already at the threshold of maturity, while physical activity allows one to maintain (and even periodically restore) physical fitness and bodily efficiency until late old age. Moreover, the effects of technological progress are not only more convenience in life and an increase in prosperity, but also the development of lifestyle or civilization diseases, such as atherosclerosis, hypertension, obesity, discopathy, etc., that are directly or indirectly related to the lack of physical activity.

On the basis of what is known about the main causes of death in highly developed countries, which are mainly associated with lifestyle diseases such as heart disease, cancer, stroke, obesity, or depression, Gerring and Zimbardo (2009) were formulated recommendations for human health in the field of social security:

1. Regular physical exercise.
2. Consumption of nutritious, well-balanced meals (high in fruits, vegetables and grains, low in fat and cholesterol).
3. Maintaining proper weight.
4. 7-8 of sleep per night; some rest and relaxation each day.
5. Fastening seat belts in a car and wearing a helmet when bicycling.
6. Not smoking and not using drugs.
7. Abstinence from alcohol or drinking in moderation.
8. Practicing safe sex with proper protection.
9. Regular check-ups with a GP and a dentist; following doctor's instructions.
10. Developing an optimistic view of life as well as maintaining friendships with others.

In this classification as well, the basis of health in the field of social security is physical activity as part of participation in physical culture. This is all the more important because, as research by Starosta (2010) has shown, the element of lifestyle determines 53% of human health.
The health benefits of systematic physical activity are comprehensive. Physical activity in the book by Starosta and Wangryn (2012) increases the range of joint motion, makes bones more flexible and less susceptible to decalcification and more resistant to fractures; it improves the use of lung capacity, improves the circulation of blood and lymph, prevents the formation of atherosclerotic changes, normalizes blood pressure,, improves the regulation of blood glucose levels, supports better elimination of waste products from the metabolism, improves concentration and intellectual functions.

Urych (2014) indicated that systematic active participation in physical culture, at 30% of maximum exertion, improves the health of both children and the elderly. The results of physiological, motor, epidemiological and other studies prove that physical exercise is an important factor shaping the structure and functions of the body. Movement is also irreplaceable in primary and secondary prevention of many non-infectious diseases, called lifestyle or civilization diseases, as well as in geriatric prevention (Urych 2014, p. 78-87).

The significance of the role of physical culture in shaping health in the field of social security is why scientists point to what is known as the minimal physical activity, which is a vital necessity, even a biological imperative or also a moral and social duty that individuals work toward their own health. The minimum physical activity indicates the amount of daily exercise necessary per week to maintain well-being. World Health Organization (1998) guidelines indicate that amounts to daily 30-minute endurance-building workouts, at an intensity of 40-60% of maximum exertion. Other authors define it as 10-15 thousand steps a day in the form of intensive walking or burning 1200-2000 kcal per a week in physical exercise. At very least, the preventative aspect of physical activity is an essential element a healthy lifestyle.

The essential promotion of health in the field of social security occurs not only in the primary educational environment of a child, such as his or her family home, where such activities are undertaken with varying degrees of diligence, intensity and frequency, but is also taken up in schools. In 2008, a team of experts appointed with Wiynarowska leader (2009) by the Ministry of Education in Poland decided to include a health education module in the core curriculum of physical education in middle and high schools. An important task of the school is also to provide health education, carried out by teachers in many subjects, whose aim is to develop students' ability to care for their own and other people's health. This statement places a high priority on health education among the tasks given to schools.

The leading role in the implementation of the health education module has been assigned to the core curriculum of physical education, which is "saturated" with content on various aspects of health (especially physical education), to a much greater extent than before. This completely new approach makes physical education the leading subject in the implementation of school health education. Thus, the appeals that had been made for many years by scholars of physical culture have been met. At the same time, it is a solution that is simultaneously one of the models recommended by the World Health Organization (1998), which singles out a leading subject (physical education) and the inclusion of health-related content in many other subjects.

The health education module in Poland is implemented in physical education classes which are compulsory for all pupils and are taught at each stage of education for one semester, i.e. approximately 30 hours. The decision regarding in which year and semester they take place is made by the school administration. These activities have been a clear success, extending the scope of health education to include psychosocial aspects of health, with particular emphasis on life skills (personal and social). However, it should be understood that schools and teachers cannot left to cope with a new task on their own. Health security should be developed primarily in the family environment, which still often remains little more than wishful thinking.

It should be pointed out that owing to participation in physical culture, not only is there a development of an individual's health in the field of social security, but also of their national awareness, identity and patriotism. Urych (2017) pointed out that patriotic attitudes can be shaped in the context of physical culture by, among other things, conscious and active care for the development of fitness, health and personality in various forms of physical culture, and by the student – especially during physical education classes.

The Relationship Between Physical Culture and Human Health in Ontogenesis

Over the past several decades, we have witnessed dynamic advances in science and technology that have made human life more productive. However, technological progress is also accompanied by phenomena that are detrimental to human life, such as the elimination of physical exercise and physical work, which adversely affects human health and physical development. The conveniences of contemporary civilization, means of transportation, automation, and computerization all reduce physical activity to a minimum. The growing popularity of passive leisure time activities with the use of mass media, especially television and the Internet, also contributes to a reduction of meeting a natural need of the human body, movement. The effect of these changes is the spread of lifestyle or civilization diseases (mainly cardiovascular, diabetes and neuroses), as well as negative social phenomena among youth and adults (alcoholism, nicotinism, drug addiction).

Daily physical activity is essential for the achievement, maintenance and improvement of human health. This is evidenced by the fact that it accompanies every human being at ever stage of their personal development or ontogenesis.

In the book by Gerring and Zimbardo (2009) in the human life cycle, the following periods can be distinguished:

- infancy (from birth at full-term do 18 months),
- early childhood (from 18 months to 6 years),
- late childhood (6-11 years of age),
- adolescence – (11-20 years of age),
- early adulthood (20-40 years of age),
- middle adulthood (40-65 years of age),
- late adulthood (over 65 years of age).

Urych (2014) mentioned infancy is a period of relatively slow motor development. The movements of the child are mainly uncontrolled and involve only large muscle groups. Congenital (unconditioned) reflexes, which are characterized by their reliability, invariability and instantaneity of occurrence, are predominant. In a research study by Dega (2003) unconditioned reflexes include saliva secretion, pupil constriction, respiratory reflex, yawning, sucking, the Babinski reflex (after stimulating the appropriate area of the foot, the big toe is stretched out and the others are spread), the Moro reflex (upon a proper stimulus, the child makes a clasping motion with hands and feet). As a result of motor learning, unconditioned reflexes become conditioned.

Gerring and Zimbardo (2009) pointed proper motor development in this period is as follows:

- 2 months – lifts up head,
- 2.8 months – turns over sideways,
- 4 months – sits with support,
- 5.5 months – sits without support,
- 5.8 months – stands with support,
- 7.6 months – stands up independently,
- 9.2 months – walks holding on to furniture,
- 10 months – scoots and crawls,
- 11.5 months – stands independently,

- 12.1 months – walks independently.

Moreover, the most rapid physical development in all periods of human ontogenesis takes place in infancy. Intentional movements, and above all the adoption of a vertical posture, are a signal of transition to the next period of motor development.

Based on research by Dega (2003)we know early childhood is characterized by a child learning to walk, climb, run, jump, throw and grasp. Walking can already take place in different ways, controlled forms of running are beginning to appear, the first signs of being able to help oneself are developing and jumping and throwing skills are emerging. The child starts to carry different objects, which is related to improving balance, and thus the ability to balance one's own body. At around 16-18 months of age, it is possible to overcome small obstacles. In the third year of life there the beginnings of a combination of, for example, running and jumping, as well as gripping and throwing are observed, which are the basis of the advanced motor skills used in sports and play.

The development of motor skills in this period is closely related to the mastery of speech and a gradual transition from concrete-image to abstract thinking. At the turn of the second and third year of life, praxis appears, i.e. deliberate movements using an object for its intended purpose. Nevertheless, children often have problems with actions that require more precise hand movements, e.g. buttoning, tying shoelaces, or eating independently.

The pre-school period in early childhood is conducive to the dynamic development of all motor skills. Research conducted by Denisiuk and Milicerowa (1969) shows that agility increases particularly in this period. It is also the time when various forms of movement are acquired, and functional games become imitation games. Because strength, speed and endurance are as yet underdeveloped, there are often difficulties in catching an object. The child has a biological need for movement but gets bored easily.

Sexual dimorphism in motor skills, although already distinct, is not yet as strong as in later periods of life. Boys show a visible advantage in running speed, throwing and jumping, while girls show superior flexibility and manual dexterity.

Late childhood begins when the child starts school. The shock of a sudden change in living conditions has an impact on the child's physical activity. According to Przewęda (1981), the following can be observed in children in the first years of primary school:

- a quite rich range of simple movements (these are generally harmonious, rhythmic, fluid, flexible),
- little development of motor skills, with the exception of high flexibility and considerable agility, and often a particular kind of speed,
- understanding the content of movements, which allows exercise to move from forms of play to forms of learning in the strict sense,
- increasing strength,
- enriching the variety of types of activities involving movement, which allows the teacher to shape the student's athletic interests.

Denysiuk, Milicerowa (1969) pointed visible ontogenetic changes can also be observed in capabilities regarding strength and speed. With the growth in mass, height and the changing proportions of the body, the relations of these parameters to the amount of the absolute force change. As a result, both girls and boys find it difficult to exercise. The changes taking place in the system also have an impact on the increase in the capability for speed during this period. Moreover, in the late school period there is a phase in which the assimilation of complex new movements comes with exceptional ease.
The process of maturation influences the propagation of developmental lines of motor activities that are characteristic for women and men. In the first phase of puberty, significant changes in body proportions take place, and sexual maturity is also accompanied by psychological anxiety. This

affects the development of motor skills and a certain stagnation in the development of the coordination of movements, as well as a slower increase in physical fitness.

One can observe the differences in the physical development of girls and boys, as well as the intensive development of individual interests. Young people often avoid active participation in physical culture, and there are also difficulties in teaching physical activity. In addition, changes in the cardiopulmonary system are not conducive to exercise requiring endurance, after which, however, an increase in endurance follows.

In a research study by Przewęda (1981) An important measure of motor development in adolescence is the level of agility. Research has shown that boys in the age range of 7-10 improve their agility very quickly. This process continues to be discernable up to the age of 18, but it does proceed more slowly. Girls, on the other hand, after a notable improvement in results at the age of 12-15 years, show a tendency to stagnate at that level.

Whereares Denysiuk and Milicerowa (1969) added at the stage of adolescence, there is a certain stagnation of motor skills, as well as sexual and individual differences. Boys in this period are much more proficient than girls. There is a growing interest in physical activity. There is a great increase in strength in boys and an improvement in their ability to sprint. On the other hand, girls improve their dexterity and agility. Endurance peaks in girls aged 15-16 years and in boys between 18 and 22 years of age.

Early adult age (20-30 years of age) is characterized by a relative stability of motor skills and increased intentionality and economy of movement in men. This is the period of peak performance in sports Middle adulthood is characterized by the fact that the motor activity of a person appears to be lower, although these movements are still agile and economic. Those who train regularly maintain high motor and physical fitness. The possibility of learning new motor activities decreases. The frequent loss of fitness around the age of 40 is not the result of biological aging, but of neglect.

Late adulthood in an adult who does not engage in any sport is characterized by involutionary processes in physical fitness, and a decisive decline in speed, strength and endurance

Conclusion

The aim of this article has been to identify and analyze the importance of physical culture in shaping health security. The research methods used were deduction and induction. It should be noted that the article does not constitute an original contribution either in the field of physical culture or in the field of health in the field of social security. Instead, it is to serve as introduction to the subject, the knowledge of which – in the author's estimation – may help contemporary and future theorists and practitioners in education or security to augment their knowledge and understanding of the essential function of various aspects of physical culture in the creation of health in the field of social security. It is also an attempt to broaden the awareness of the audience, especially parents and teachers of physical education, about how important it is to address contemporary educational needs through actions that develop health in the field of social security in and through physical culture.

The preceding analysis allows the following conclusions to be drawn:

1. Health is a fundamental human value and social security is a fundamental human need to ensure survival and ensure physical, mental and social development.
2. Participation in physical culture ensured that the potential for the development of health in the field of social security is multifaceted and mainly regards positive structural and functional changes in the human body, whereas restriction of physical activity leads to negative health consequences.
3. The foundation for the development of health in the field of social security in all areas of personal development is active participation in physical culture, which in childhood serves

primarily to support individual development, in adulthood to maintain the level of fitness, and in old age to actively counteract involutionary changes.

These considerations lead to the general conclusion that the building of health in the field of social security should be achieved both through the immediate meeting of the needs of children and youth, in particular in terms of their somatic and motor development (because it is impossible to make up for negligence in this respect) and through preparing them to maintain and improve these abilities later in life (because they do not constitute lifetime capital). These activities fall in particular within the scope of such forms physical culture as school physical education and extracurricular athletic activities.

The harmonious achievement the development of health in the field of social security through physical culture is very difficult due to the variability in how its processes impact both the body and the personality. The effectiveness of these may sometimes even be reduced, however. It is possible, for example, to increase bodily efficiency using methods that will simultaneously lower a given individual's level of motivation to exercise. Capacity - as a physiological category - depends mainly on the intensity and regularity of training, and motivation - as a psychological category - on the social climate in which the process of physical education takes place.

The task of shaping health in the field of social security can be met only by a conscious and thoroughly prepared parent or teacher, who is prepared both for physical training and to teach how to develop a personality able to work independently on their body, who is able to develop every area of the personality of children in their care, not only physically, but also mentally, morally and aesthetically. Meeting this task will enable the educator to focus not only on short-term goals, but also on long-term ones. This is manifested not only in the development of the physical abilities of the students who show outstanding physical fitness, but also in the development of the knowledge, skills and attitudes all young people need to take care of their own body, health and physical fitness throughout their lives.

Abstract

This paper examines the mediating role of behavioral intention on the relationship between the three determinants of technology adoption and actual use of e-learning. Therefore, a quantitative method was used and the data was collected from the Higher Colleges of Technology (HCT) in the United Arab Emirates particularly from the HCT Abu Dhabi campus. Hence, out of the 490 questionnaires administrated, a response rate of 82.9 percent was reported, corresponding to a total of 406 respondents that participated in the study. Findings from the analysis revealed that performance expectancy and effort expectancy had a positive effect on students' actual use of e-learning. However, the results revealed there is a negative correlation between social influence and the actual use of e-learning. In addition, the result shows that behavioural intention mediates the relationship between performance expectancy, effort expectancy, social influence and actual use of e-learning.

Keywords: Unified theory of acceptance and use of technology; E-Learning; Higher Colleges of Technology; UAE.

Introduction

Although the United Arab Emirates launched the transition from the country's largest national education system to e-learning, distributing approximately 14,000 electronic device computers to federal college students (Mostafa et al., 2016). However, the students using smart electronic learning face issues such as interactivity and connectivity (Zahran Khaimah, & Pettaway, 2016). Recently, the solicitation of electronic technology in the ground of education has aroused great interest, although the technology is still developing (Kamali, 2013). According to Alhebsi et al. (2015) in the Gulf region, the UAE played a leading role in developing high-end electronic devices for students teaching (Ati & Guessoum, 2014). However, the effectiveness of the e-learning system still not reached its expected position due to the lack of awareness on perusing students to adopt the e-learning in the education environment, and with the increasing integration of electronic learning in the community, there is a strong need for practical guidelines and recommendations to promote and provide an effective teaching and learning environment for income generation (Iran, 2011). Similarly, Universities in UAE are investing for many years in e-learning systems in order to improve the quality of student's education. Nevertheless, the utilization among students has not fulfilled a satisfactory level (Salloum, & Shaalan, 2018). Hence, the slow-paced adoption of e-learning by students in UAE's HEIs is worrisome, given that the infrastructural requirements for operating a robust e-learning system are in place. Thus calls for an investigation into the factors or determinants that enables the successful deployment and adoption of e-learning.

The developed nations are successfully implementing the e-learning technology besides realization of its massive benefits. However, the developing countries have failed, either fully or partially, to implement the e-learning technology. For instance, in United Arab Emirate, one of the developing countries, a growing number of universities are investing for many years in e-learning systems in order to improve the quality of education. However, their utilization among students have not achieve it is expected desire (Salloum & Al-Emran *et al.,* 2019).

Research Questions

The following research questions were formulated in line with the objectives of the study to guide the inquiry. They include:

1. What is the effect of social influence on HCT students' behavioural intention to use e-learning?
2. What is the effect of effort expectancy on HCT students' behavioural intention to use e-learning?
3. What is the effect of performance expectancy on HCT students' behavioural intention to use e-learning?
4. Does HCT students' behavioural intention to use e-learning mediates the relationship between their actual use of e-learning and the three dimensions of the unified technology acceptance model (i.e. social influence, effort expectancy and performance expectancy)?

Significance of the Study

This study was driven by the need to address the issues surrounding the adoption of e-learning by students in the UAE HEIs. The literature of e-learning is still an emerging one, and prior studies have investigated issues relating to e-learning adoption in general business setting as well in a western and developed country context, but there is need to focus on aspects such as higher education and in a developing nation context. Hence, the overall significance of this study was to provide a clearer understanding of the determinants that influence the acceptance of e-learning technology from a student perspective faculty in selected HEIs in the UAE. The findings will be an addendum to the body of literature by reporting the direct and mediating effects of the determinants of e-learning adoption and the actual use of the technology as well as provide a strong foundation that can be used to develop strategies for management and other stakeholders who are interested in successful implementation of e-learning that students can quickly adapt and use.

This research is of significance to the field of information systems and educational management as insights into the direct effect of the determinants e-learning adoption and the behavioural intention as well as the mediating effects of student's behavioural intention to use e-learning and their actual use of e-learning. Also, this study will enable the development of an adapted model of acceptance and use of technology, which in turn can be used to better enhance the deployment and implementation of e-learning systems across HEIs in the UAE.

Likewise, the research will be beneficial to higher education stakeholders, university management and faculty members in providing the feedback needed to design efficient e-learning systems that curb the inhibiting role of language, culture, improperly designed user interfaces as well as accessibility issues. With this, effective e-learning systems can be created to allow the students to tap into the enormous potentials and benefits it has to offer. It can provide university management with the necessary insights needed to formulate e-learning policies and standards for more efficient implementation. On the part of faculty members, findings from the study can be used to plan for effective integration of e-learning and contemporary teaching and learning, taking note of the significant determinants of e-learning adoption from student's perspective.

Literature Review

Unified Theory of Acceptance and Use of Technology

Numerous studies had used the Unified theory of acceptance and use of technology (UTAUT) to measure technology acceptance, adoption, intention or willingness to use, and many other technology-related topics specifically e-learning. For instance, Anderson *et al* (2006) used UTAUT in their in study titled "The Drivers for Acceptance of Tablet PCs by Faculty in a College of Business". Similarly, Jairak *et al* (2009) adopted Unified Theory of Acceptance and Use of Technology (UTAUT) model to determine the factors that influence the students' intention to use m-Learning in Thailand. The results show that the acceptance level of students on m-Learning is in the high level. Likewise, another study from Thailand done by Pinpathomrat & Gilbert (2013) who also applied Unified Theory of Acceptance and Use of Technology to investigate the factors that affect a Thai student's decision to take up and continue using E-learning.

In addition, previous studies from Arab countries had also used UTAUT model to measure technology acceptance. For example, Nassuora (2013) examine the possibility of acceptance in mobile learning (m- Learning) and study main factors that affect using m- Learning that focus on higher education students in Saudi Arabia. He Nassuora (2013) used UTAUT to determine the factors that influence the students' intention to use m-Learning. Furthermore, Emmanuel Awuni Kolog *et al* (2015) used Unified Theory of Acceptance and Use of Technology model to ascertain students' behavioral intention to adopt and use e-counseling in Ghana. The results of the research suggests Performance Expectancy and Social Influence as the influencing constructs (factors) towards students' behavioral intention to adopt and use e-counseling, Facilitation Condition and Effort Expectancy had no significant effect on the behavioral intention of students to adopt and use e-counseling in Ghana (Emmanuel Awuni Kolog *et al.,* 2015).

Moreover, Olatubosun et al (2015) utilize the modified versions of the unified theory of acceptance and use of technology (UTAUT) model in explaining e-learning adoption in higher education in a developing country and evaluate the size and direction of the impacts of the UTAUT factors on behavioral intention and use behavior to adopt e-learning in higher education. The results suggest that, it is well established that the latent variables significantly explain the UTAUT model in Nigeria. Also, Abdekhoda et al (2016); Ngampornchai & Adams (2016); Sarabadani et al (2017); Mostafa & Rachid (2017); Radovan & Kristl (2017); Zawaideh (2017); Soedarto et al (2018); Alasmari & Zhang (2019) all these authors used Unified Theory of Acceptance and Use of Technology model to examine the adoption of e-leering.

Empirical studies on E-learning

Grabinski *et al* (2020) investigate the benefits and drawbacks resulting from the implementation of e-learning in accounting modules among educators. They used survey questionnaire to collect the data among 79 accounting lecturers, employed by the leading Polish economic universities. Although they have found that the most important benefits of the e-courses included the enhancement of efficiency and flexibility of the teaching process. However, the survey has shown that e-learning is not widely used by accounting academics in Poland Grabinski et al., (2020). Furthermore, Al-Emran & Teo (2020) stated that studying the factors that affect the e-learning adoption is not a new research topic. However, exploring the effect of knowledge acquisition and knowledge sharing on e-learning adoption is a relatively new research trend that has not been featured in the existing previous studies. Therefore, they Al-Emran & Teo (2020) conducted s atudy to build a new model by extending the technology acceptance model (TAM) with knowledge acquisition and knowledge sharing to examine the e-learning adoption. They have distributed a total of 403 questionnaires to students enrolled at Al Buraimi University College (BUC) in Oman. The collected data was analysing via Partial Least Squares-Structural Equation Modelling (PLS-SEM) to evaluate the proposed model.

Another study conducted by Al-Fraihat *et al* (2020) aims to investigate the factors that are considered for the evaluation of e-learning system success and has led to the development of an e-learning success model that incorporates these factors. To test the model, an empirical study was conducted. Thus, the model of the study has been empirically validated by fitting the model to data collected from 563 students engaged with an e-learning system in one of the UK universities through a quantitative method of Partial Least Squares-Structural Equation Modelling (PLS-SEM). According to Al-Fraihat *et al* (2020) the determinants of e-learning perceived satisfaction are information quality, technical system quality, support system quality, learner quality, instructor quality, service quality and perceived usefulness, which together explain 71.4% of the variance of perceived satisfaction.

Alqahtani (2019) the usage of E-learning in the Kingdom of Saudi Arabia (KSA) academic institutions is still in its early stage and its impact is insignificant. In Saudi Arabian universities, there is a need to improve the understanding of how to deal with the new technology, how to meet the staff and student's requirements for teaching and learning, and how to tackle students' lack of motivation concerning independent learning. Alqahtani (2019) identify the main issues that are hindering the use of modern techniques of E-learning in Saudi Arabian educational system effectively, such as personal factor, and learning attributes. This study provides an initial framework that can be used as a detailed, structured E-learning roadmap by stakeholders in Saudi universities, as well as those in developing countries (Muhammad Ali et al., 2018).

An interesting study on COVID-19 and emergency e-learning done by Murphy (2020). The COVID-19 pandemic quickly led to the closure of universities and colleges around the world, in hopes that public health officials' advice of social distancing could help to flatten the infection curve and reduce total fatalities from the disease. Likewise, Murphy (2020) used Copenhagen school securitization theory and analyzing 25 declarations of emergency e-learning at American universities, Murphy (2020) argue that in addition to COVID-19 being framed as a general threat, face-to-face schooling was also presented as a threat through these policies. He (Murphy) concludes that securitization theory is an important tool for educators not only for observing (and understanding) the phenomenon of emergency e-learning, but also for supporting the de-securitization of schooling after the COVID-19 crisis passes (Murphy, 2020).

Theoretical Framework and Hypothesis of the Study

The unified theory of acceptance and use of technology (UTAUT) identified performance expectancy, effort expectancy, social influence and facilitating conditions as some of the factors that may influence the behavioral intention and actual use of a technology. The propositions of the UTAUT model have been severally tested in western and developed nation context, but there exist inadequate empirical validations of the propositions of the UTAUT model in non-western context as well as in countries categorized as developing nations. Thus, this study has only focus on the three dimensions of the independent determinants of UTAUT model; the facilitating conditions has been excluded in this study; hence, figure 1 shows the framework of the study that tested in the UAE context.

Figure 1: Framework of the study

H1: Social influence has a positive effect on Actual use of e-learning.
H2: Effort expectancy has a positive effect on Actual use of e-learning.
H3: Performance expectancy has a positive effect on Actual use of e-learning.
H4: Behavioural intention has a positive effect on Actual use of e-learning
H5: Behavioural intention mediates the relationship between effort expectancy, performance expectancy, social influence and actual use of e-learning.

Methodology

The purpose of this study was to determine student's views of the factors of e-learning adoption in higher education institutions in the UAE, by scrutinizing the effects of performance expectancy, effort expectancy, social influence on behavioural intention, as well as the examine the mediating role of the behavioural intention on the relationship between the three determinants of technology adoption and actual use of e-learning. Therefore, a quantitative method was used and therefore the data was collected from the Higher Colleges of Technology (HCT) in United Arab Emirates particularly from HCT Abu Dhabi campus. In addition, the survey consists of 5 different sections; each variable has five (5) items. The questions were adopted and adopted from Venkatesh et al. (2003) with further adjustment to fit the scope of this study. Actual use of e-learning was referred to as the physical and mental acts associated with the use of e-learning by students. This was measured using five items also. All scales in the questionnaire were structured on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Therefore, out of the 490 questionnaires administrated, a total of 406 valid data was used. Therefore, to display hypothesized relationships between variables, the study determines, estimate, analyse and present the model in a causal path figure. Similarly, the research assessment model present must be validated using the PLS-SEM technique. Assessment of conceptual or theoretical models for the purpose of validation in PLS-SEM; thus the validation includes a two-staged approach that begins with the assessment of measurement model followed by the assessment of the structural model. The essence of validating the model using this approach was to empirically measure it performance with existing criteria that support the validation of measurement and structural models.

Results

The data analysis was presented in line with the main research objectives of this study. Thus, after data collection, a response rate of 82.9 percent was reported, corresponding to a total of 406 respondents that participated in the study.

Convergent Validity and Reliability

According to Hair *et al.* (2014) convergent validity can be assessed using the factor loadings, composite reliability and the Average Variance Extracted (AVE). Therefore, to succeed convergent validity, each construct should have an AVE of ≥ 0.50, and the factor loadings should be preferably greater than 0.70. Although Byrne (2013) suggest that factor loadings of 0.50 are acceptable if the summations of the loading results in high loading scores contributing to AVE scores of 0.50 or greater.

Table 1: Convergent Validity and Reliability

Variable of the study	Cronbach's Alpha	Composite Reliability	Average Variance Extracted (AVE)
Actual Use of E-Learning	0.791	0.855	0.544
Behavior Intention	0.776	0.847	0.529
Effort Expectancy	0.795	0.861	0.557
Performance Expectancy	0.788	0.855	0.546
Social Influence	0.798	0.824	0.515

The results of the cronbach alpha and composite reliability scores exceeded the minimum threshold values as recommended by George and Mallery (2003); all the Cronbach's Alpha values were excellent as shown in Table 1. Similarly, composite reliability values were above 0.7 and therefore, it is acceptable (Bagozzi & Yi, 1988; Hair *et al.*, 2014).

Figure 2: Research Measurement Model

Byrne (2013) suggest that factor loadings of 0.50 are acceptable if the summations of the loading results in high loading scores contributing to AVE scores of 0.50 or greater. Figure 1 shows the factor loadings of each of the items in the study. All factor loadings ranging 05.72 to 0.847 as shows in the measurement model. Therefore, none of the item was deleted as no item had to factor loadings less than 0.5.

Discriminant Validity

According to Ramayah *et al* (2016) Discriminant validity is the degree to which indicators differentiate across constructs or measures distinct concepts by examining the correlations between the measures of potentially overlapping constructs. Thus, the significance of conducting a discriminant validity test is to assess whether the constructs are distinct from others in the measurement and structural models. Therefore, Table 2 shows the results of Discriminant validity using Fornell and Lacker Criterion.

Table 2: Discriminant validity using Fornell and Lacker Criterion

	Actual Use of E-Learning	Behavior Intention	Effort Expectancy	Performance Expectancy	Social Influence
Actual Use of E-Learning	**0.737**				
Behavior Intention	0.708	**0.727**			
Effort Expectancy	0.587	0.499	**0.746**		
Performance Expectancy	0.160	0.534	0.226	**0.739**	
Social Influence	0.322	0.386	0.185	0.178	**0.698**

The factor loadings criterion was also used to evaluate discriminant validity. Table 2 shows that all indicator loadings loaded highly on their own respective constructs compared to other constructs. Thus, there was no issue of high cross-loading between the latent variables. Hence, discriminant validity is established.

Table 3: Heterotrait Monotrait ratio criterion

	Actual Use of E-Learning	Behavior Intention	Effort Expectancy	Performance Expectancy	Social Influence
Actual Use of E-Learning					
Behavior Intention	0.785				
Effort Expectancy	0.716	0.595			
Performance Expectancy	0.228	0.698	0.285		
Social Influence	0.250	0.367	0.197	0.257	

In addition, Heterotrait Monotrait (HTMT) ratio criterion was also used to support the establishment of discriminant validity. As Table 3 the discriminant validity is established since all the ratios were below the threshold values of HTMT .90 as indicated by Gold, Malhotra, & Segars (2001) and Kline (2015).

Path Coefficients

The path coefficient or estimates from the structural model relationship have standardized values that typically range between -1 and +1, with path coefficient close to +1 representing a strong positive relationship while those close to -1 represents a strong negative relationship according to Hair *et al* (2016). In this study, bootstrapping of 500 subsamples to ascertain the t-values for 0.05 significance level was used to determine the path coefficients. Table 4 shows the results of the bootstrapping significance analysis for the structural path model coefficients, *t*-statistics and *p*-values.

Table 4: Significance test for the Structural model path coefficient, t-value and p-values

	Std β	Std Error	*t* Statistic	*p* Value	Hypothesis
Social Influence -> Actual Use of E-Learning	0.050	0.036	1.385	0.167	H1 Not Supported
Effort Expectancy -> Actual Use of E-Learning	0.296	0.039	7.562	0.000	H2 Supported
Performance Expectancy -> Actual Use of E-Learning	-0.286	0.036	8.056	0.000	H3 Supported
Behavior Intention -> Actual Use of E-Learning	0.694	0.036	19.474	0.000	H4 Supported

There are three direct path coefficients of which 2 (effort expectancy and performance expectancy) were significant with t-values exceeding the t- Statistic value of 1.96 and p-values value less than 0.05 as recommended by Hair *et al* (2016). However, social influence was not significant as the results shows that the t- Statistic value and p-values value less the required values. Therefore, Table 5 presents the results of the mediating role of behavior intention on the relationship between expectancy, performance expectancy and social influence and actual use of e-learning.

Table 5: Mediating Role of Behavior Intention

	Std β	**Std Error**	***t* Statistic**	***p* Value**	**Hypothesis**
Effort Expectancy -> Behavior Intention -> Actual Use of E-Learning	0.251	0.028	9.032	0.000	H5a Supported
Performance Expectancy -> Behavior Intention -> Actual Use of E-Learning	0.284	0.035	8.186	0.000	H5b Supported
Social Influence -> Behavior Intention -> Actual Use of E-Learning	0.171	0.026	6.512	0.000	H5c Supported

The result shows that behavior intention mediates the relationship between expectancy, performance expectancy and social influence and actual use of e-learning. This implies that in an e-learning content, student's behavior intention to use e-learning influences their actual use of e-learning when performance expectancy, effort expectancy and social influence are high.

Figure 3: Research Structural Model

Also, the results of the path coefficient and t- Statistic value is shown in Figure 3, the structural model of the study.

Discussion and Conclusion

Venkatesh *et al.* (2003) described performance expectancy as the extent to which an individual believes that using a system will help him or her attains gains in job performance. In the context of this study, performance expectancy was described as a student's belief that using e-learning will be beneficial and interesting in achieving high performance in learning. Thus, findings from the analysis revealed that performance expectancy had a positive effect on students' actual use of e-learning. Therefore, positive perceptions of the gains of e-learning will ultimately result in the intention to adopt it, whereas a negative perception of the gains of e-learning will result in student's intent to reject it as part of their learning activities. This finding is in line with previous empirical results of Alsumait & Al-Musawi (2013); Chauhan & Jaiswal (2016); Lowe & Boucheix (2016); Luzón & Letón (2015); Stebner *et al* (2017); Suki & Suki (2017); Tosuntaş *et al* 2015). Therefore, (H3) Performance expectancy has a positive effect on actual use of e-learning is supported.

Similarly, the findings from the study revealed that there was a positive linkage between effort expectancy and actual use e-learning. Venkatesh *et al.* (2003) described effort expectancy as the "degree of ease" associated with the use of a system. In this study, effort expectancy was conceptualized as students' belief that using e-learning in facilitating their learning will be easy for them, i.e. it will require little effort. This, therefore, indicates that effort expectancy is a strong determinant of the behavioral intention to adopt or reject e-learning. This finding is consistent with those of the original UTAUT model by Venkatesh *et al* (2003), as well as most of the studies reported in e-learning studies. For example, Dečman (2015); Raman *et al* (2014) Tosuntaş *et al* (2015); Yakubu & Dasuki (2019). Therefore, hypothesis (2) Effort expectancy has a positive effect on actual use of e-learning is supported.

However, the results revealed there is a negative correlation between social influence and actual use of e-learning. Venkatesh *et al.* (2003) described social influence as the degree to which individuals believe that significant others expect the individual to use the system. In the context of this study, social

influence was described as the extent to which student perceive that significant others (i.e. friends, social cycle, university management, academic administrators, educators etc.) expect them to use the e-learning system. This, therefore, implies that social influence is not satisfactory based on the behavioural intention to use e-learning among the Higher Colleges of Technology's students. However, this result is not corresponding with some of the findings reported in the literature (Dečman, 2015; Raman *et al.*, 2014; Suki & Suki, 2017; Yakubu & Dasuki, 2019).

Lastly, the mediating effect of behavioural intention in the relationship between the three UTAUT dimensions (i.e. performance expectancy, effort expectancy and social influence, and students' actual usage of e-learning. Hypotheses (H5a,b,c) were formulated to test the mediating role of behavioural intention. Therefore, the results show that behavioral intention mediates the relationship between performance expectancy, effort expectancy, social influence and actual use of e-learning. This finding is consistent with the findings of several studies reported in the literature (Chauhan & Jaiswal, 2016; Isaac *et al.*, 2019; Suki & Suki, 2017; Tosuntaş *et al.*, 2015; Yakubu & Dasuki, 2019).

Recommendations for Further Research

Future studies can include more variables such as culture, language and other contextual variables to study the effects of the determinants of technology adoption on students' use of e-learning systems. This will be particularly interesting if the role of culture and language can be explored in e-learning adoption. Such a study would lead to the development of a more comprehensive model for e-learning adoption that highlights the role of contextual variables such as culture and language. Also, there is a need to also examine the integration of several theories in order to come up with a unified and holistic overview of e-learning adoption. Several models and theories exist in technology acceptance, therefore integrating these models to test hypothesized relationships and factors can better improve our understanding of e-learning adoption. Finally, this study considered only the perspectives of students in establishing the findings of the study. It would be interesting to explore a comparative view of a faculty member and student's views regarding e-learning adoption. Factors crucial to both faculty members and students could be well understood if such a study was conducted.

Abstract

Data is probably the most valuable resource of our time, similar to what represented oil a century ago. Technology giants built their competitive advantage on the huge amount of data they are dealing with to drive the biggest societal changes. Cybercrime became a threat not only for the processes of the organizations but also for individuals as unethical data use can change people's attitudes and behavior not only towards the products and services, they are buying but also their political views and values. The purpose of this paper is to assess the dimensions of data security, ethics, and compliance in the context of new regulations.

Keywords: Technology, People Behavior, Data Security, Data Compliance, Regulation

Introduction

There are 2.5 quintillion bytes of data produces by us every day especially generated by internet, social media, communications, digital photos, services and the internet of things [1]. Impressive statistics regarding the main sources of data:

- More than 4.5 billion people use the internet [2], so about 60% of the entire population.
- On average, there are more than 40,000 searches on Google every second, so more than 3.5 billion searches every day [2].
- More than a third of the world's population is active on Facebook monthly [2].
- Every minute on Facebook there are 510,000 comments posted, 293,000 statuses updated, and 136,000 photos uploaded [3].
- Every minute we send 16 million text messages [2].
- In 2017, there were 4.7 trillion photos stored [2].
- Every minute there are more than 45,788 uber trips [2].
- There will be more than 20.4 billion connected things by 2020 according to Gartner [4].

Moreover, the systematic progress makes the technology even more affordable even free when it comes to services such as GPS, camera, news, banking all being integrated today in our mobile phone without any cost associated. Freemium, the combination of "free" and "premium" is a new business model especially for app developers who design the app adding premium features but make it free so as to attract a considerable user base while the source of revenue is coming from in-app advertisement or from a small portion of users which is paying for some additional features [5].

On the other hand, all this data reveals precious information about us from our usage behavior to what are our preferences, interest, opinions, and hobbies. These insights are the fuel for the brands and organizations to make data-driven decisions to design customized products or services according to

our needs and interest. Personalized products or services are becoming a significant part of our life because of their applicability and usability in different areas, allowing us to monitor our health and personal finance, shop online, play games, listening to the favorite songs and taking online courses to grow the skills we are interested in. But this is the mechanism of generating more and more data about us, data that makes the algorithm proficient in predicting our preferences and expose us to advertising that fits our desires and lifestyle.

At the same time, companies are looking for new ways of making sense of the huge amount of data to enhance the current products and services, to innovate in new areas, but also to optimize and automatize the business processes. This is why a new set of tools to analyze structured and unstructured data had been developed recently and there are some new skills in demand on the human resources market. Data guru, so the person who knows how to extract data, analyze it and look for patterns - skills that can improve the use of resources, value chains, managerial operations, industry knowledge, and growth opportunities, is a type of employee the companies are looking for [6]. Moreover, data scientist is one of the most promising jobs in 2019 [7].

According to McKinsey, data, and analytics not only changed the business practice, but data monetization is becoming another source of revenue by adding new services to current offerings, developing new business models, joining with similar companies to create a pool of related data that can benefit all of them [8].

Knowing what the main sources of data are, how this data is generated and the technological premises, it is quite easy to imagine that the process of producing, analyzing and integrating data in the main sources that generate them is intensifying continuously its peace.

Technological trends impact data collection and processing

Technology is rapidly shaping the way companies work and how we interact with the world. Specialists encourage to closely look over five new areas: Artificial Intelligence, Augmented Reality, Blockchain, Automation and Internet of things [9].

Artificial Intelligence (AI) is a computer area which has as the main purpose to mimic how people acquire the necessary knowledge, resonate, solve problems, perceive, learn, plan, manipulate and move objects. Machines can act and react as humans only if they have enough information to be used by its algorithms to identify patterns [10].

Augmented Reality (AR) is the technology that overlaps the virtual objects in the existing environment, as a result, the information addon creates a new artificial reality. Many augmented reality apps have been developed recently to enhance different industries from gaming to constructions, this technology having the potential to influence even more our lives [11].

Blockchain is a huge distributed database that runs on millions of computers and it is open source, so anyone can access the code to see what any structured information from banking transactions to information about who married whom or who owns what land or what light bought power from what power source. This is a way of proving the truth through mass collaboration establishing a source of trust in a world of distrust [12].

Automation is the process that increases efficiency and reliability by replacing manual operations or increase the speed for repetitive tasks. The potential of automation is huge, its impact in manufacturing is already known by decreasing the workforce in this industry but now it moves to more sophisticated jobs replacing the car drivers, pilots, public sector jobs or teachers [13].

Internet of Things (IoT) is the concept of connecting any device through the internet such as smartphones, coffee makers, washing machines, lamps, wearables or any other objects including components of different machines. The purpose of having all these objects inter-connected is to make

life much easier, for example, if the alarm clock is set for a specific hour, it can be linked with the coffee maker to have coffee prepared in the morning [14].
These trends are connecting with the data generation or processing. While IoT is the main source of data and AR is bringing data from a different reality, AI and automation bring new opportunities to process data and drive actionable insights and Blockchain collects data in an immense database.

Technology came with many risks associated to data

The expansion of data volume has many risks associated as the data protection regulations and the set of tools that ensure security doesn't keep the same pace with what we produce every day. Risks include applications, users or devices.

There are a few famous examples of data breaches. Cambridge Analytica is a name that resonates with the USA elections and the Brexit campaign because of its involvement as a data analytics firm that accessed 87 M of Facebook profile to build an algorithm that was able to predict an influence vote choice. This was the biggest data breach that involved the tech giant. Everything started with a group of thousands of Facebook users that were incentivized to take a personality test and agreed to have their information collected for an academic purpose. Not only their personal information was collected, but also their Facebook friends which allowed the algorithm to learn from more data and to improve the prediction accuracy and microtargeting with the customized campaign messages. Facebook denies that the harvesting of the Facebook profiles was a data breach as Cambridge Analytica and the companies they worked with got access to the information legitimately, the only rule breaker was the fact that the information was used for third parties. Cambridge Analytica, Facebook, and the other companies are investigating by the British Information Commissioner's Office for the Brexit campaign, by the Electoral Commission for the role played in the EU referendum and by many US institutions from House Intelligence Committee to FBI. The only price paid by Facebook so far was the drop in its share value [15].

There are other examples of the sensitive data that has been exposed over the last years [16]:

- About 15 Bn. of data records have been lost or stolen since 2013.
- Only 4% of breaches were secure, the data were encrypted to be useless
- 86% of the incidents occurred in North America.
- There are 6.5 M of data compromised every day, so 75 records compromised per second.
- 42% of data breaches are caused by hackers or criminals while 29% are caused by system glitches.
- ¼ of the incidents is caused by the employees.
- In the US the main data breaches were in Business (45.9%) and Medical (29.2%) sectors.
- Top 3 data breaches from the last 15 years were generated by American Online in 2013 impacted 92 M screen names and email addresses, Yahoo in 2013-2014 compromised all 3 Bn. accounts and Target in 2013 impacted 110 million accounts [16].

With the new technological advancements, there are many ways to use the technology to process apparently inoffensive personal data to create algorithms that are able to manipulate every choice we make not only regarding the brands we buy or use but also regarding the political options or the general opinions and values. Hacking humans is the ultimate risk for our data as a deeper understanding of the human decision-making process; the algorithms become more reliable at these types of tasks, at the same time making us less reliable. After the human operating system is hacked, a precise kind of manipulation, advertisement and propaganda will follow [17].

For 2020 companies there are ten risks when it comes to data privacy [18]:

- **Accidental sharing**, so the company's employees share sensitive information with someone outside the organization.
- **Overworked cybersecurity teams**, as the incidents number increases, and the security specialists are quite rare.

- **Employee data theft** means the insider threat which is coming mainly from employees who are not in leadership positions.
- **Ransomware attacks** that are designed to block a computer system until a sum of money is paid are on the rise, in 2019 the cost of a ransomware attack more than doubled.
- **Bad password hygiene** as some of the login credentials are already compromised by previous data breaches or other employees that have redundant or easy to guess passwords.
- **Bribery** of the employees to expose the company's data or to plant malware on the network.
- **Too much data access** as data is one of the main resources of the company, each employee should access only what he or she needs to know for that position.
- **Phishing emails** are on the rise, the technology makes the attack even more sophisticated.
- **Fraud** by taking the email addresses and passwords that enable even more elaborate attacks.
- **Denial** of the companies to understand the risks associated with the data to be equipped and train the employees to avoid the risks [18].

The biggest challenge of the companies is the sense of losing control over data that comes with utilizing third-party solutions for cloud, data management and analytics [19]. Moreover, according to a survey of 250 C-level leaders in the UK, data breaches and hacking attacks is the new reality for the companies [20].

Data security and cybersecurity

In this context with many risks associated with data, there is a focus on big data security market which is expected to register a CAGR of 17% between 2019 to 2024, concerns associated with data exposure being both for on-prem and on cloud systems [21]. New threats related to data privacy emerge and it is impossible to invest in eliminating them, but there are some preventive practices to help companies protect their data and their clients' data such as [22]:

- **Strong security policies and practices** and here everything starts with the efficiency of the data collection to have the optimal amount of data that can be manageable, but also the strategy for the incident response and backup recovery and the employees' familiarity with the procedures.
- **Access control** is related to giving the employees access only to the part of the network necessary for their activity.
- **Network Protection** through antiviruses, firewalls, and proper maintenance.
- **Encryption** which assures the data privacy even if the data is stolen because encrypted, it becomes useless [22].

Going even further, Gartner identified top security trends for this year and beyond that should be monitor over time to see the traction they get [23]:

- **Risk Appetite Statements Are Becoming Linked to Business Outcome**: IT strategies are aligned to business goals, security and risk management is gaining importance in the business decision.
- **Security Operations Centers (SOCs) Are Being Implemented With a Focus on Threat Detection and Response**: the focus in security shifts from prevention to detection and this involve building SOCs that will be able to integrate threat intelligence, consolidate alerts and automate response.
- **Data Security Governance Frameworks (DSGF) Will Prioritize Data Security Investments**: DSGF identifies data and defines data classifiers and data security policies, information that can be used to select technologies that minimize the risk.
- **Passwordless Authentication Is Achieving Market Traction**: authentification through Touch ID OR face recognition is becoming more popular and it increases both usability and security.

- **Security Product Vendors Are Increasingly Offering Premium Skills and Training Services**: Vendors' security services range from partial to full support to complement the unfulfilled cybersecurity roles.
- **Investments Being Made in Cloud Security Competencies as a Mainstream Computing Platform:** the shift to the cloud brings even more discussions related to security as it is the cloud customers' responsibility to keep it secure [23].

Data security is a growing area that fulfills the growing need of protecting the huge amount of data. Still, there is still a need of changing the paradigm to prevent the data breaches by simplifying the business processes, but also of developing easy to use security solutions that are abe to quick response to attacks and the stringent need of covering the skills gap on data security.

Data Protection Through Regulations

Data protection and ethical use of personal information is not only the company's responsibility, but it is also necessary to have a uniform standard applied by the governments or other types of institutions to protect citizens' personal data. Recently European Union came with regulations on both general data protection and also on artificial intelligence, the technology that uses a big volume of data to learn and develop dynamic algorithms based on the input data to take accurate decisions in different fields.

General Data Protection Regulation (GDPR) came into effect starting with May 2018, it applies only to the EU and it affects every company that stores and processes customer data from tech companies to marketers and research agencies that connect them. The directive is giving the individuals more power over less data, at the same time the companies that collect data and use it for the monetary purposes have less power. GDPR is giving to individuals 8 basic rights: to access their data; to be forgotten in the case they are not clients anymore or withdraw their consent; data portability, so the right to transfer their data from one provider to another; to be informed before data is gathered so the consent is necessary not implied; to have the information corrected; to restrict the processing; to object, to stop processing for direct marketing; to be notified in 72 hours in case of data breaches [24].

Moreover, the tech companies updated their politics to comply with GDPR, for example, Facebook created privacy options to put the users in control over their information to find and delete specific information on the site. Apple revealed its privacy dashboard while Google quietly updating its products and privacy policies [25].

On April 2019 European Commission's published the Ethics Guidelines for Trustworthy Artificial Intelligence (AI) designed by a set of experts and followed by a piloting program to collect feedback on how the guidelines should be implemented. The guidance sets key requirements to achieve Trustworthy AI: human agency and oversights; technical robustness and safety; privacy and data governance; transparency; diversity, non-discrimination, and fairness; societal and environmental wellbeing; accountability [26].

US lawmakers have introduced a bill – the Algorithmic Accountability Act planned for the companies with a large volume of data to assess the algorithms behind the automated systems to be sure these are not discriminatory or pose privacy or security risk [27].

Acknowledgement

This paper was co-financed from the Human Capital Operational Program 2014-2020, project number POCU / 380/6/13/125245 no. 36482 / 23.05.2019 "Excellence in interdisciplinary PhD and post-PhD research, career alternatives through entrepreneurial initiative (EXCIA)", coordinator The Bucharest University of Economic Studies".

Conclusion

Data is one of the most valuable resources of this century but, at the same time, it can make us as individuals extremely vulnerable to manipulation, propaganda or impact the business processes or resources of the companies. Data can be an easy target as it can be compromised in different stages of the process from data collection to storage and analysis. On the other hand, the cyberattacks are becoming more sophisticated with the technology progress; this is why the security industry is developing new tools and skills and the authorities design regulations to better protect data.

Evaluating Technologies for The Development of Open-Source Component-Based Educational Software

Irina-Miruna RADU

Bucharest University of Economic Studies, Romania
miruna.radu@outlook.com

Abstract

The current social distancing context of COVID-19 makes a huge impact on the way people are living. Systems and procedures are forced to move into online to be able to continue. The educational system makes no exception. This paper proposes to find the best tools for implementing open-source component-based educational software by evaluating the most popular web frameworks that are structured on the concept of component development. To achieve the goal, this paper identifies and analysis different evaluations of the three chosen frameworks through a two-step selection process. As a result, the evaluation criteria and the winner highlighted by the authors of the sources are emphasized in a table that can be easily used in future decisions. This way, the paper offers an overview of how the chosen software tools are perceived by the market with the recommended utilization purposes. It also proposes one of them for the development of open-source component-based educational software.

Keywords: Component, Component-Based Software Development, Education

Introduction

Our world is unfolding in a rapid rhythm, trying to evolve and create a better life than yesterday for its inhabitants. To help with achieving this goal, the programming world is trying every day to come with better strategies and technologies. The actual context of COVID-19 where currently, more than half of the people of Earth have experienced a form of lockdown and social distancing (WorldHealthOrganization, n.d.), has forced the people to move most of their daily tasks into online. This unfolding of events has accelerated even more the development of solutions and increased the significance of new technologies and innovative ways of thinking.

The domain of education was not a lucky one and it was pretty affected by this crisis as none of the actors involved in the process of education were prepared for a fully online process. And when primary education is the topic of the discussion this is where the things are even harder. The teachers did not have the knowledge and the right tools for this situation, the parents were not prepared to become all of a sudden an important pawn in the learning process of their children and the inspectors did not know how to lay a stable path to follow that would not upset the other actors.

This crisis has drawn attention to the fact that the word needs to innovate and bring solutions faster to market. The insights exposed by Stack Overflow's 2019 survey (Stackoverflow, n.d.) have shown that the developers have already concentrated their attention to technologies that help them develop easier and faster. Having a look at the result the most popular programming language was JavaScript, with its two web frameworks that encourage the component-based architecture, React.js and Vue.js, being the most loved ones. When it comes to the web frameworks that are used at this moment the top 3 include jQuery, React.js, Angular/Angular.js. These findings suggest a shift from object-oriented programming to the component reuse paradigm, where small items that can be put together like Lego pieces are developed to help in building different applications. The survey also unveiled the developer profile, a developer that cares about the community with more than half of professional developers on Stack Overflow contributing to open-source projects once a year or more.

The purpose of this paper is to analyze which web framework would be best to use for the development of open-source components for education. Having components will help the education system in creating personalized applications based on the needs of the curricula, teachers' wishes and

Cite this Article as: Irina-Miruna RADU "Evaluating Technologies for The Development of Open-Source Component-Based Educational Software" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

children learning paths. The web frameworks that will be analyzed are the ones that were on top of the Stack Overflow survey (Stackoverflow, n.d.) and that are known for introducing components as part of the implementation: Angular/Angular.js, React.js and Vue.js. To have a better evaluation, articles that compared the three frameworks were analyzed and their learnings were quantified to create a view on how they are seen on the market. As a result, the outcome of this analysis can offer the developers a view on the advantages of each one of the frameworks, helping in choosing the right one.

The rest of this paper is organized as follows. Section 2 provides the background and related work in regards to this research. Section 3 describes the frameworks. Section 4 presents the methodology and how the study was conducted. The findings are presented and discussed in Section 5. The final section presents the conclusions of this study.

Literature Review

More than fifty years ago, the Component-Based Software Engineering methodology arisen when McIlory (McIlroy, 1976) proposed to the world the idea of developing little pieces of software that can be used in different projects, an idea borrowed from the industry of commercial component production. As the years passed by, the idea grew and got traction in the programming community as in 1991, software reuse was seen as the (only) realistic approach to gain the productivity and the quality that the software industry needed (Mili, et al., 1995).

The domain of software reuse is still wrapped in some mystery as the latest trends study (José L. Barros-Justo, October 2019) has identified more than 120 proposals for future work. While identifying the gaps the authors of this paper have brought to light that two points stand out as recurrent in several topics: the need for more tools to support the development and the need to run more empirical studies.

When it comes to open-source software, the authors of (Papamichail, et al., 2019) observed that with the increased number of demands the open-source community faces, the developers' strategies shifted from doing everything on their own to relying more on reuse to minimize the cost and the time of the development. The article also provides a methodology of evaluating the reusability degree of software components which is based on metrics for five different properties: complexity, cohesion, coupling, inheritance, documentation and size.

In the matter of technical debt of components, one study encourages developers to perform open-source code reuse, as the technical debt is not a problem and it can be managed (Feitosa, et al., 2020). Furthermore, the paper provides evidence that reuse is a promising technology for preventing the accumulation of technical debt.

On the subject of whom application domains contain the most reusable-friendly software projects, the author of (Paschali, et al., 2017) proposed a list. At the top of the list there are domains such as Science and Engineering Applications and Software Development Tools. The Home and Education projects are on the bottom as they present the worst level of complexity and quality. This suggests that the identification of tools to improve the development of open-source components for education is necessary.

With regards to the impact component-based software development has on the education domain, in (Radu, 2019) it was concluded that component development can help through its' advantages (reducing development time, reducing costs, increase quality, increase reusability) with the current problems that the education system faces (lack of funds and teacher empowerment, lack of access to resources, curricula updates and personalized learning paths), only when keeping in mind the challenges this methodology has (choice of components, updates, maintenance, testing).

The Chosen Web Framework

To complete the goal of this paper, the chosen web frameworks are the ones that are the most popular in the Stack Overflow survey (Stackoverflow, n.d.) and that are known for introducing components as part of the implementation. The chosen ones are: Angular/Angular.js, React.js and Vue.js.

A. Angular

Angular (Angular, n.d.) is an open-source TypeScript-based framework powered by Google and released in 2010 as Angular.js. This version lacked a lot of essential features due to the changing trends of the markets (Casey, n.d.). So, in 2016 Angular 2 appeared and they dropped the "JS" part from the name. Even though AngularJS (version 1) still receives updates, the evaluation will concentrate on Angular.

In regards to the known projects that use Angular, there can be listed names as Google, Forbes, Telegram, healthcare.gov.

B. React

React (React, n.d.) is a JavaScript library developed by Facebook and released in 2013 which has a large community of users and developers around to maintain it. It was a competitor of Angular and in November 2019, it surpassed it, by recording the highest number of downloads.

The most known projects that are relying on React are Facebook, Instagram, Uber, Netflix.

C. Vue

Vue.js (VueJs, n.d.) is the youngest solution on the market from the list. It was released in 2014, by former Google employee, Evan You. It appeared from the need to have a lighter framework. Nowadays, this framework is rapidly growing in the hearts of developers.

Even is newer on the market, big companies like Alibaba, GitLab, Baidu trust Vue.js with their projects.

Research Method

To accomplish the goal of this article, the research method included different stages: searching for articles that compared the chosen technologies, evaluating their information, determining which ones are relevant for this paper and drawing conclusions.

First of all, searches were conducted with keywords as "Angular.js vs React.js vs Vue.js", "Angular vs React vs Vue" , "Angular vs React vs Vue.js for building components". After, the articles were read entirely to see if they are relevant for the study. Taking into consideration that the topic of this study is concentrated around specific technologies, most of the sources that responded to the search criteria are web sites and certain blog pages of experts from the field. Their opinions are valuable as they are familiar with these technologies and have insides from a practical point of view because they are using them every day.

For the paper, the quantitative approach was used. The articles that did not compare all the chosen technologies or that did not state clearly what criteria of comparison they used or what the ranking is, were excluded from the analysis. From 32 articles obtained in the first step, only 11 were selected for the review. For each one of them, the evaluation criteria and the winner were marked down. The results are presented in Table 1.

Results

From Table 1 it can be easily observed that the main advantage of Vue.js is the learning time, while React has a great community and nobody can contradict the level of maturity Angular has achieved.

On the subject of performance and flexibility the writer in (Martin, 2019) concludes that Vue.js and React give the user better performance and flexibility which makes them suitable for light-weight applications while Angular helps with large UI applications as it offers possibilities for routing, templates and even testing. The topic of performance is also the main subject that the author of (Borrelli, 2019) indicates. However, he is still able to provide an overview to offer a better understanding of the advantages and the challenges each of the analyzed frameworks has to offer. He recommends using Angular when working on very large applications with very dynamic content and React for applications that necessitate speed, versatility and an international audience. According to him, Vue.js seems to be good with lightweight applications that require speed and international audience. The same opinion is shared by the writer of (Kumar, 2018), who concludes that Vue.js is ideal for beginners to be used in small teams and small projects. For bigger applications he recommends looking into React when searching for flexibility and JavaScript and into Angular for object-oriented programming and TypeScript.

Regarding the job market (Refai, n.d.) shows that the Angular and the React job offers are very similar, but when comparing the average income of a developer from the USA, React is paid better, 64.10 $ hourly, while 59.85$ Angular.

The interaction of the audience through the comments can unravel other insights that can help in creating a clear picture. The author of (Daityari, 2020) was noticed by the audience that should have pinpointed a winner or at least explain in which context each technology can bring benefits as a comparison must give a result. When choosing a solution the majority of people who commented in the dedicated section of this article, choose Vue.js as a solution because it is easy and fast to develop in. The second best in their opinions was Angular because is architecture driven and generates good code quality. There were only few people that were on React side pointing out that big companies are using it and it has support for building mobile apps. Even though the author of (TechMagic, 2018) did not draw a clear conclusion of which framework to choose between the three of them, the article presents the pro and cons of each of them separately increasing the engagement of the audience. It had the biggest number of comments from all the analyzed articles. 52% of the responders in the comment section showed appreciation for Vue.js, while for Angular and React, the audience was equal. (24%)

Table 1: Assessment on how component-based technologies are seen

Criteria	Angular	React	Vue.js
Popularity	(Binariks, 2019)	(Binariks, 2019); (Duomly, 2020); (Refai, n.d.); (Sumon, 2020); (Casey, n.d.); (Kopilevych, n.d.); (IntelegainTeam, 2020)	(Daityari, 2020); (Sophia, 2019); (Kumar, 2018);

Maturity	(Daityari, 2020);		

Conclusion

When it comes to finding good results, combining multiple sources of data together can be a plus, as multiple sources mean an improvement of the robustness of the analysis. This was the idea that guided this paper. In the context of COVID-19 social distancing it is important to find fast solutions for moving processes into online environment. As the schools should restart, it is necessary to find outside the box solutions for the development of software for education. In this context, the creation

of open-source reusable components is important as it can help with many of the problems the educational system faces. This study proposes to analyze tools for developing these components through a quantitative method. The developers' perspectives are considered by searching studies that are comparing these technologies and quantifying into a list the results of their observations. Taking into consideration the point of view of the developers, this study concentrates on the 3 most popular web frameworks: Angular, React and Vue.js. The results show that the developers do not see a clear solution when choosing a web framework and it all depends on what is needed to be developed and the experience of the people working on the project. Angular is the mature one that helps developers in having a better structured code, with respect for patterns and tools to help with templates, testing or routing. Though the years, Angular gained contributors and a devoted public. React came fast from behind and managed to sway the public and gain popularity. Even if is just a web framework and you need different libraries for routing and testing, developers enjoy the flexibility it offers and the structure of component building functionality. Vue.js has its public that helps it evolve even though it does not have a big company behind the development. Developers love how easy it is to learn and the size and performance it proposes. The overall indications are that Angular is ideal for complex applications and an organize code, React is ideal for applications that need versatility and speed, while Vue.js is ideal for beginners and light weighted applications.

When it comes down to choosing the framework there is no right or wrong decision. It is all depending on the people that work on the project, what is the purpose of the project and what resonates with the goals of the organization. From my point of view, for building open-source component-based educational software I would choose React because of the big community and popularity. This means that more developers are willing to work on this kind of project. Having a big demand for job offers for this technology implies that more people are willing to build up skills and experience and working on open source projects it is always nice to have on the resume. Furthermore, the gained points for the building components features from the analyzed articles recommend it for this job. The flexibility and the performance that were mentioned through the evaluations enhance the idea that React is a good choice for this kind of project.

Abstract

The purpose of the article is to analyze scientific publications, assessing the risk of anthropogenic pollution of aquatic landscapes and its environmental and economic consequences. **Results.** Theoretical and practical aspects of calculating the amount of economic compensation for the effects of anthropogenic pollution of water bodies are considered in the article. It is shown that in conditions when it is practically impossible to eliminate or reduce the level of environmental pollution to harmless biocenoses, economic compensation of losses necessitates the search for alternative and additional sources of funding for contaminated regions. Adequate and accurate forecasting of the amount of economic compensation plays an important role. At this stage, the legislation approves the need for economic compensation for damage to the environment caused by its anthropogenic pollution. **Conclusions.** An economic mechanism ensuring the expanded reproduction of natural resources, their protection, regulation of rational use of nature, should be based on the principle of compensatory in terms of nature use system of appropriate payments. The main economic tool of it is the payment for natural resources and environmental pollution.

Keywords: water body, ecological condition, water quality, economic damage.

Introduction

In the twentieth century the use of natural resources became so intensive and environmental pollution so great that there was a need to charge payments for their use and environmental pollution. Ukraine joined this process in 1991. Introduction of such payments is justified by the need to accumulate funds to replace the used natural resources and to restore the environment. But natural environment in Ukraine and the world is constantly deteriorating. Domestic economy of environmental protection and nature management is legally formed simultaneously with the incipience and development of environmental legislation and the management system of environmental activities and nature management. This process is not complete yet and has not reached the level of world and European requirements. The legislation defines the structure and content of the economic mechanism of

environmental protection and rational use of nature but the regulatory framework ensuring effectiveness of these provisions is still imperfect and needs development, especially in the field of financial and incentive mechanisms. The legislative process of economic compensation for damage to human health and the environment from emissions and discharges of pollutants has gone through several stages, namely: the process of creating a legal framework began in 1991 - 1992, first of all, there was a transition from free use and natural resources pollution to a paid one.

One of the first ecological and economic instruments of environmental protection was the mechanism of payment for environmental pollution, introduced by the Cabinet of Ministers of Ukraine from 13.01.1992 № 18 "On approval of the Procedure for determining charges and payments for environmental pollution" (Resolution, 1992). Considering the crisis in the economy, the amount of payments for emissions and discharges of pollutants and the disposal of waste attributed to production costs did not exceed 5% of total taxable income in the reporting year.

Modern state policy in the field of environmental protection from pollution is based on the principle of "a polluter pays". This principle reflects the policy of making polluters responsible for all actions that harm the environment. The "polluter pays" principle was substantiated by the Organization for Economic Community and Development in 1972 for the first time at the international level. Since then, this principle has been actively used in the legislative practice of European and other countries (Boreyko, 2010). In Ukraine, the "polluter pays" principle was introduced in 1991 by the Law of Ukraine "On Environmental Protection" of June 26, 1991 № 1264-XII, which established (Article 3) that in Ukraine there is payment for environmental pollution. The mechanism itself for determining and charging the payment for environmental pollution was regulated by the Cabinet of Ministers of Ukraine "On approval of the Procedure for determining charges and payments for environmental pollution" from 13.01.1992 № 18 and the relevant resolution of the Cabinet of Ministers of Ukraine "On approval of the Order norms of the fee for environmental pollution and charging of this fee "from 01.03.1999 № 303 (Resolution. 1999). Payments were charged from enterprises regardless of ownership and departmental affiliation. Payment for pollution does not exempt companies from complying with environmental measures, as well as from paying penalties for environmental offenses and full compensation for damage to nature (Antonyuk, 2013).

The purpose of this work is to analyze scientific publications, assessing the danger of anthropogenic pollution of aquatic landscapes and its environmental and economic consequences.

Results and Discussion

Freshwater ecosystems are crucial for social development (Naiman, 1998) but rapid socio-economic development within watersheds as a result of human activities has negative environmental consequences for ecosystem's structures, processes and functions (Western, 2001). Human activities in the watershed can lead to the loss of key species and functional groups, nutrients, low self-healing capacity and loss of productivity for aquatic ecosystems. Therefore, it is necessary to restore them based on understanding of the relationship between catchment changes and the corresponding impact on the aquatic ecosystem. The relationship between a society and ecosystems should be harmonized on a watershed scale, and the water body and watershed ecosystem and society should be seen as integrated systems (Kramer, 1997; Roe, 2002).

Water quality problems of surface water bodies are caused by many different point and non-point sources from urban and agricultural areas (Conley, 2009), (Wittmer, 2010). Pollution of environmental components is caused by various substances, including nutrients, heavy metals and organic pollutants in microquantities (Ippolito, 2015; Destouni, 2017; Spycher, 2018; Pospelov, 2019). As surface water can only be effectively managed on a catchment scale and in an integrated manner, all sources of pollution and substances must be considered for (cost-effective) decisions in water quality management. Such decisions require an understanding of the catchment extent and should take into account future changes due to factors outside the scope of water quality management, such as climate change and socio-economic development in catchments. Ideally,

management alternatives should be selected according to their contribution to improving the overall quality of water in catchments, their cost and possibly other relevant public objectives.
The implementation of environmental measures is reflected in the costs and consumption of living and social labor, quantitative and qualitative impact on the production and use of consumer values in the national economy, as well as on the process of reproduction in general.

Indicators of damage are expressed in value terms. The damage includes monetary actual and possible losses, caused by environmental pollution to the territorial organization of society, as well as additional costs for compensation of all environmental damage. There are costs associated with prevention of pollution, formed at the source in order to reduce harmful emissions. There are three types of expenses:

- construction and operation of specialized systems and facilities - various types of treatment and disposal facilities and devices for sources of harmful emissions, as well as the creation of protection zones around these sources;
- development and implementation of closed (low-waste) technological processes, ensuring integrated use of all components of the material and energy flow with minimal inflow of harmful emissions into the environment;
- creation of a control and management system of environmental pollution, including subsystems of automated control of air and water pollution, industrial emissions control in periods of dangerous hydrometeorological situations and a subsystem of control and regulation of air pollution *(Karaeva, 2014).*

These expenses are aimed at reducing the total amount of economic damage and can not be classified as damage: costs incurred as a result of compensatory losses. There are actual and potential damages. The first characterizes the actual damage or additional costs associated with elimination of environmental pollution consequences. Potential damage is determined by the current state of the environment and the costs that society may incur in the future due to complex ecological condition of the territory. Socio-economic consequences of environmental pollution are manifested in four main forms:

- deterioration of the "quality of life", which consists in the deterioration of public health, violation of working and leisure conditions in contaminated areas;
- loss of working time associated with increased morbidity of the population due to environmental pollution which reduces the efficiency of labor resources in the region;
- reduction of national economic value of natural resources as a result of falling productivity of agricultural and forest lands in polluted areas, increased costs for water treatment by industry and communal services, reduction of fish productivity of reservoirs, their recreational value, etc.;
- intensification of corrosion processes in the polluted environment, increased pollution and clogging of technological equipment, leading to accelerated depreciation of fixed assets in the pollution zone.

The above consequences also cause economic losses from environmental pollution.

Economic losses consist of the total major local losses. The value of economic damage depends on three factors.

1) the amount of pollution and the degree of impact of a component of the environment.
2) elements of impact, which are all sorts of objects that take the negative influence of pollution.
3) elements of the state reflecting the level of regulatory economic indicators. These include the amount of produce manufactured by the staff during the working day, all sorts of hospital payments within the working day per employee, etc. (*Karaeva, 2014).*

All of the above factors form the total damage and are inextricably linked. The size of economic damage without one of them is unthinkable.

A number of foreign publications have assessed the economic costs of water pollution of water bodies.
The article (*Garza-Gil, 2006)* assesses the short-term economic losses from oil spills in the Galician coastal sectors for fisheries and aquaculture. The areas that received more oil spills suffered the greatest economic losses. The oil spill can be considered one of the worst in recent years, the amount of oil spilled (59.000 tons) and a wide area of influence: almost the entire coast in northern Spain and southwestern France.

The publication *(Reddy, 2006*) estimates the economic costs of water pollution in rural communities in terms of agricultural production losses, human health and livestock. Cost estimates are based on detailed primary data collected from an intensive study of two villages - one is affected by pollution and in the other pollution is less intense. The villages are located in the industrial zone in South India. The cost estimates show that the impact of industrial pollution on rural communities is very large in monetary terms. The document states that the principle of compensation can work if the damage estimates are realistic.

The article (*Douglas, 1999*) examines the economic losses from marine pollution associated with recreational activities in New Jersey and assessment of economic losses from the long-term fish pollution. During the summer seasons of 1987 and 1988, marine pollution and leaching occurred almost simultaneously in New York and New Jersey, leading to the closure of beaches, reduced use of beaches and reduced sport fishing. According to economic estimates, the total economic losses from pollution and floods in 1988 in New Jersey ranged from $ 379.1 million to $ 1,597.8 million (1987). In addition, the mouths of the Hudson River and New York Bay were contaminated with toxic substances (PCBs, DDTs, etc.) found in fish products.

Payment for the recycling of food waste on the basis of the "polluter pays" principle are widely recognized as a way to alleviate the financial stress associated with solving the problems that arise from water pollution (OECD, 1992). Environmental spending is also of growing concern due to the introduction of stricter quality standards for pollutants discharged into water bodies *(Maalouf, 2017).*

Economists James and Lee presented a concentration-pollution curve that shows that the relationship between the concentration of pollutants and the degree of contamination hazard demonstrates functional characteristics of the S-type *(James, 1971).* Many scientists have used this method to assess the degree of pollution risk caused by pollutants and the environmental and economic costs of water pollution (*Miural, 1990; Xu, 2013; Ofiara, 2001).*

In Ukraine, the main initial data for calculating compensation for the amount of damage caused to fisheries may be acts, reports, notices, memos, photographs, film, video and other documents. These are prepared by officials authorized to exercise state supervision (control) over compliance requirements of the legislation on protection, use and reproduction of aquatic bioresources or persons who directly observed cases of loss of aquatic bioresources, pollution of reservoirs and other damage to fishery reservoirs, direct calculations and measurements, results of control catches, and official data of competent research organizations of aquatic bioresources, including fish resources of this water body.

Damage is calculated on the basis of formulae (1-10), separately for each species (or a group of biologically related species), for each stage of aquatic bioresources development, followed by the compilation of these results (Order, 2011).

First, the total losses of fisheries in kind are determined, then - in the value at the current retail market prices of the region at the time of calculating the amount of compensation (UAH).

The amount of damages to fisheries caused by pollution of the reservoir is calculated on the basis of direct losses and losses from the loss of offspring.

Direct losses are calculated by the number of dead aquatic bioresources, including fish, juveniles *, larvae and eggs ** per unit of area, its average weight and the area of negative impact on aquatic organisms according to formula 1:

$N = P * S * M + (P_1 * M * S * K_1)/100 + (P_2 * M * S * K_2)/100,$

(1)

Where:

N - losses in kind, kg;

P - average number of dead fish, pcs / m2;

P1 - average number of dead larvae, pcs / m2;

P2 - average number of dead eggs, pcs / m2;

S - area of negative impact of damage, m2;

M - average weight of an adult, kg;

K1 - coefficient of industrial return from larvae,%;

K2 - coefficient of industrial return from caviar,%.

* - young fish are taken as mature fish.

** - larvae and caviar in the calculations are accepted as mature fish, taking into account the coefficient of industrial return for the period of their development to the adult.

For aquatic plants according to formula 2:

(2)

Pk2 = p * Z

where Pk2 - the amount of damages for the death or illegal harvesting of plants (UAH);

p - total mass of dead or illegally harvested plants (kg);

Z - cost of products made from 1 kg of raw materials, at current retail market prices in the region at the time of calculation of losses (UAH).

Calculation of damages for the loss of offspring is based on the number of dead fish, female fertility, spawning rate, the rate of industrial return and the average weight of fish according to formula 3:

N = P * Z / 100 * Q * C * K / 100 * M, (3)

where:

N - the amount of losses in kind, kg;

P - the number of dead fish, pcs .;

Z - share of females,%;

Q - average fertility of females, thousand pcs. eggs;

C - multiplicity of spawning (times);

K - coefficient of industrial return from caviar,%;

M - average weight of an adult, kg.

Losses from death of forage organisms are defined:

a) for plankton according to formula 4:

N = (S * H * P * p / b * K1 * A) / 100 * K2, (4)

b) for benthos according to formula 5:

N = (S * P * p / b * K1 * A) / (100 * K2) (5)

where:

N - losses in kind, kg;

S - area of damage, m2;

H - depth of the reservoir, m;

P - average concentration of forage organisms, g / m3 (for plankton) and g / m2 (for benthos);

p / b - conversion factor of biomass of feed organisms in products;

K1 - indicator of the maximum possible use of feed base by fish,%;

K2 - feed ratio for the conversion of feed organisms into fish products;

10-6 - conversion factor of grams into tons;

A - 10-6.

Coefficients for the feed base (feed organisms) of fish are given in Supplement 2 of the methodology [28].

Losses from spawning are calculated depending on the availability of initial data according to formulae 6 or 7:

a) on fish productivity of spawning grounds by formula 6:

N = S * P, (6)

where: N - the amount of losses, kg;

S - area of damage, ha;

P - average fish productivity of spawning grounds on industrial return, kg / ha.

b) from the loss of offspring according to formula 7:

N = S * P * Z / 100 * Q * C * K / 100 * M, (7)

where: N - the amount of losses, kg;

S - area of damage, ha;

P - the number of broodstock in spawning grounds, pcs / ha;

Z - share of females,%;

Q - average fertility of females, thousand pieces;

C - spawning rate (times);

K is the coefficient of industrial return from caviar,%;

M - average weight of an adult, kg

The amount of damage caused to the caviar, larvae and young fish in the refill of the dredge is determined by formula 8:

N = P * V * R * K / 100 * M, (8)

where:

N - the amount of losses, kg;

P - the number of caviar, larvae, young fish of each species, pcs / m3 of water;

V - volume of selected soil, m3;

R - multiplicity of soil dilution with water;

M - average weight of an adult, kg.

Losses from fish productivity of the reservoir during blasting are calculated according to formula 9:

N = S * P, (9)

where:

N - the amount of losses, kg;

S - area of damage, ha.

P - fish productivity of the reservoir, kg / ha.

The final value of losses is taken as the maximum of the calculated values of losses from the death of fish or the death of food organisms. Addition of these values is not allowed.

The amount of damages is calculated by formula 10:

Nuan = N * G, (10)

where: Nuan - monetary losses (UAH);

N - volume (kg);

G - cost of production, per 1 kg, at the current retail market prices of the region at the time of calculating the amount of damages (UAH).

Taking into account the growing anthropogenic pressure on water resources, the state's influence on regulating the use of water resources should be significantly strengthened and associated not with expanding its scale, but with changing the role determined by the nature of interaction between the state, economy and politics. The basis for an economic mechanism, ensuring the expanded reproduction of natural resources, their protection, regulation of rational use should be the principle of paid, compensatory in terms of nature use with the creation of a system of appropriate payments. Its main economic tool is the payment for natural resources and environmental pollution. This charge

should be high enough to force companies to introduce resource-saving, low- and waste-free technologies into production, efficient treatment facilities, dust and gas cleaning devices, waste disposal (*Antonyuk, 2013).*

Discussion and Conclusion

1. Environmental payments carry a wide variety of burdens in the system of public relations regulation in the field of environmental protection - incentive, coordination, control and compensation. The stimulating side of the pollution charge is manifested in its impact on the economic interests of environmentally hazardous enterprises by increasing or decreasing the economic pressure on them depending on the volume of emissions (discharges) into the environment. The stimulating nature of payment for excess emission (discharges) of pollutants is the withdrawal from the profits of polluting enterprises in multiples of the fixed payments for limited emissions (discharges) and makes it economically unprofitable to exceed the permitted emissions (discharges). This plays the role of a financial sanction and a compensatory means at the same time.

2. The coordinating aspect of the pollution charge is in the fact that it determines the financial share of each polluter in ensuring collective efforts in the field of environmental protection from pollution (fee standards are set according to each ingredient of pollutants (waste), taking into account their degree of danger to environment and public health).

3. The controlling function of the pollution charge is in using it as a means of responding to the achievements of polluting enterprises in reducing pollution. Depending on these results, the controlling body may leave the fee unchanged or increase it, as well as partially or completely exempt from the fee for environmental pollution, if effective technological measures are implemented to reduce emissions (discharges) of pollutants into the environment.

Abstract

This paper undertakes the task of determining contemporary challenges of implementation of employees' aspects of knowledge management in the area of company logistics and answers the question whether the size of a company influences the level of perceived significance of the aspects of organisational procedures that are manifested in the logistic workers' know-how. The conducted analysis of the literature reveals the principles that govern the placement of the human capital concept with regard to knowledge management and exemplifies organisational conditionings of their impact on the efficiency of an organisation in the context of logistics as well as participation of companies in the supply chain. The revealed role of employees' tacit knowledge for the development of a company justified the conduction of a survey among the so-called logistics professionals (non-probability sampling, PSAQs, n=197). The analysis of the results obtained revealed that, from the point of view of respondents, company's acknowledgement for employees' behaviour consistent with the procedures as well as employee's acquaintance with and understanding of organisational procedures increases together with the size of a company which is measured as the number of workers. The presented article broadens and offers a new perspective on the description of the issue of organisational procedures. Their description that has been present in the literature on the subject so far was related to employees' point of view and relationship between organisational procedures and achieved job satisfaction.

Keywords: Logistics, Employees, Knowledge Management, Know-How.

Introduction

The linkage between the issue of knowledge management and logistics in a company occurred still in the 1990s. Originally, this linkage was considered in the context of operations management and the significance of the concept of knowledge management for managers at this management level (Wiig, 1997; Armistead, 1999). This approach quickly exposed the problems in the flow of knowledge between the departments of a company. It also made it possible to reveal the lack of tools for the assessment of knowledge exchange within a company (Wijnhove, 1998; Ahmed et al., 1999). The results of further studies led to the statement that knowledge management solutions in companies should be regarded as the ones that support the whole organisation and the whole personnel (including individual employees) as well as the application of IT systems. From the perspective of logistics, it was also assumed that all and any applied and planned knowledge management tools should be designed in order to support logistic processes in a company (Neumann, and Düring, 2008). As a consequence, the development of logistic skills in a company occurred which over time was more and more frequently regarded as a competitive advantage factor (Morash et al., 1996; Wong and Karia, 2010). However, maintenance of this advantage required the ability to obtain and exploit knowledge to become a part of the company's business activity (Esper et al., 2008).

Cite this Article as: Marcin KOMANDA and Edyta KLOSA "Logistic Workers' Know-How as a Component of Knowledge Management in Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

While referring to the aforementioned issues, it should be mentioned that progressive orientation of the researchers' deliberation towards the strategic aspect of the executed logistic processes (Sum et al., 2001) was related to the increase in significance and broadening of the economic role of supply chains. Therefore, the context of cooperation between economic entities appeared (Juga, 1996; Pfohl and Buse, 2000). As a result, it was quickly noticed that the issue of knowledge management in the field of logistics is, to a larger extent, dependent on the situational context of the company and logistic processes related to it (Stentoft and Halldorsson, 2002). The context, especially in case of the flow of information, included also relationships with clients (van Hoek, 1998; Zhao et al., 2001). Therefore, paying particular attention to the issue of action integration and coordination in supply chains (which again emphasized the role of obtaining and exploiting knowledge) was postulated (Stadtler and Kilger, 2002).

The importance of exploited knowledge resources also comes from an ever greater complexity and dynamics of the business environment and an increasing diversity of logistic problems within companies (Neumann and Tome, 2006). In order to tackle the uncertainty that is connected with running a business, companies should not only develop their skills and competences within the scope of logistics, but also knowledge management since they have a positive relationship with the human capital (Cooper, 2016). The role of the human factor is, in turn, emphasized with regard to the dynamics of contemporary business environment and its influence on the generation of profits from the collaboration with cooperating parties (Bode and Müller, 2013).

Transformations in the area of execution of logistic processes and the context of their course in companies led to an observation that contemporary comprehension of these issues is much broader than the traditional understanding of the issue of logistics (Niine and Koppel, 2014). It results in the fact that logistic workers in the company are expected to have broader professional competences than before. There is also a positive attitude towards having additional formal education (from outside of logistics) or even managerial experience (Kotzab and Wünsche, 2015). This issue creates also specified challenges that companies have to face and that regard such issues as planning, organising and conducting employees' trainings, motivating employees and engaging them in the development of skills (Mohamad et al., 2020) as well as building job satisfaction (Kim and Kim, 2020). Questions about the purpose of trainings as well as the selection of their methods appear in this context (McKinnon et al., 2017). From the perspective of operating activity, the major objective is to ensure effectiveness and efficiency of task performance which may also result in training needs depending on the placement of a worker in the company, including his or her placement within the framework of logistic processes (Klosa, 2016). The objective of the paper with regard to the outlined issues is as follows: (1) to recognise contemporary challenges of knowledge management implementation in the area of logistics of the companies in the context of human resources; (2) to determine whether the size of a company influences the level of perceived significance of the aspects of organisational procedures that are manifested in the logistic workers' know-how.

Employees' context in knowledge management implementation into business logistics

While defining the relationship between knowledge management skills of the company and execution of logistic processes, it should be stipulated that these issues can be considered from the perspective of a single company or a supply chain (system of cooperating companies) (Pérez-Salazar et al., 2019). However, it may be assumed that knowledge management skills of a company have a positive influence on the practices implemented within the framework of the supply chain as well as on the results obtained by the company (Bahar et al., 2020). It is also emphasized that reaching a competitive position as a result of reduction of costs of conducting a business activity depends both on the appropriate exploitation of knowledge resources and technologies applied (Karia, 2018; Bahar et al., 2020). This technology refers both to logistic processes and the issue related to knowledge resources. Therefore, in a conceptual and planned way it must also encompass the issues related to the flow of information in the company/between companies, their forms (form of organisational documentation and databases) (Kivits and Furneaux, 2013) as well as the aspect of employees' access to them and skills of their creation and exploitation (Komańda, 2019). Relationships of this kind explicitly indicate also the issue of the situational context of the implementation of knowledge management solutions.

It is emphasised that contemporary logistic workers should therefore possess skills within the scope of supply chain management, handling of technological solutions as well as interpersonal and managerial skills, including especially communication skills (Gammelgaard and Larson, 2001). These skills seem to be of key significance for shaping behaviours of entities within the framework of the supply chain. This is, in turn, a significant issue for the integration of the chain itself (Yang, 2013) as well as for the development of relationships with clients (Marra et al., 2012) for the purposes of offer modification with regard to their expectations (Del Giudice et al., 2016). Taking also a broad spectrum of stakeholders into consideration in the studies in the analysed problem area (at least both suppliers and clients) makes it also possible to capture, in a more visible manner, the relationships between knowledge management and business results achieved within the framework of the supply chain (Wowak et al., 2013).

The arrangements made make it possible to state that human resources are one of the main factors shaping the development of logistics, and therefore also conditioning the possibilities for the implementation of knowledge management solutions in this area of company's business activity to a large extent (Durst and Evangelista, 2018). Human resources, however, keep a dynamic relationship with the remaining pillars of knowledge management which are also important for the performance of logistic tasks in a company. These are the processes and technology applied (Schniederjans et al., 2020). It is worth stating that the potential of technological solutions is wholly implemented only with their proper combination with the solutions in the area of human resources management (Andreeva and Kianto, 2012).

However, in this context certain incompatibility appears which is related to practical application of knowledge management solutions in the area of company logistics. On the one hand, a positive relationship between knowledge management application and operating efficiency and organisational results is emphasised (Fugate et al., 2009). It results in the pursuit of implementation and exploitation of knowledge management solutions. On the other hand, some research results point out that in spite of the existence of the aforementioned benefits from the implementation of knowledge management solutions, there is a lack of proper understanding of this subject among decision makers. They frequently lack knowledge about how to do it in a way adjusted to their own needs (Neumann and Tome, 2009). Unfortunately, the issue of barriers in the implementation of knowledge management solutions in the area of company logistics and the supply chain has not developed with due dynamics in the literature (Cerchione and Esposito, 2016).

The outlined conditionings for employees' development (including logistic professionals) working in the companies that frequently function within the framework of supply chains make it possible to state that the implementation of new technologies and training on how to use them will not suffice (Kianto et al., 2018). The attention should also be paid to individual competence gaps and training needs. This entails the introduction of properly prepared evaluations within this scope as well. They should take into consideration the individual employees' context that impinges upon the scope and level of indispensable competences (Klump et al., 2019). Moreover, two significant aspects should be taken into consideration. These are the aspects that shape prospective solutions within the scope of knowledge management and that, as a result, translate to the possibility of proper support of the course of logistic processes in the company and supply chain. Firstly, it is postulated that, as a consequence of conducted researches, a challenge of taking into account both formal and informal flows of knowledge in the knowledge management should be undertaken. The latter are frequently reduced in the conducted analyses. However, due to organisational culture dominating in a given company, informal flows of knowledge may play a very significant role in efficient knowledge exploitation as well as in obtaining business results (Blome et al., 2014). Secondly, the knowledge that is subject to exchange either within the framework of a company or the supply chain, can be diversified with regard to its substantial content and managerial problems it concerns (Done, 2011). It may also represent diverse forms which, depending on the accepted knowledge classification model and implemented solutions within the scope of information policy as well as technological solutions, will be a part of specific interpretative and design framework (Sudhindra et al., 2014). It requires the assumption that individual employees play different roles in the processes of knowledge creation and use (Dziubińska, 2017).

Following the Japanese knowledge management model, at the level of individual employees it may be assumed that their personal knowledge (referred to as tacit knowledge) is expressed in two dimensions. The first one is a cognitive dimension which is related to personal convictions, personal perception of reality and ideas and values the person believes in. The other dimension is the so-called technical component that concerns practical expertise and skills, known, above all, as know-how (Nonaka et al., 2000). It should be emphasised at this point that it is the tacit knowledge that is perceived as an element which will influence the results obtained by supply chains with ever greater power (Schoenherr et al., 2014). It also means that the tacit knowledge of logistic professionals employed in the company can be of key importance for the efficiency and effectiveness of the activities conducted by them.

It should be noticed that in the context of developmental perspectives of companies as well as employees themselves, a certain regularity can be observed in case of the organisation of employees' trainings. Companies of a higher level of procedure formalisation are willing to implement employees' trainings regarding documentation and databases of a higher level of organisation (that is of a specially dedicated subject matter for a selected group of employees, conducted regardless of performed professional duties) (Komańda, 2019). This relationship, however, may point out a more general trend related to the issue of the company size and implemented knowledge management solutions. Not only do large companies know more potential knowledge management solutions but also implement their broader set. Smaller companies may possibly search for knowledge about such solutions by getting involved in cooperation with other companies (Hörisch et al., 2015). The scope of implemented solutions related to sharing information in order to manage risk can be an example of such result concerning companies operating within the framework of the supply chain (Komańda and Klosa, 2020).

Methodology

The issue of know-how regarded as an element of tacit knowledge of logistic employees in the company became a key element of the research aim. Simultaneously, an organisational perspective towards this issue was assumed. The questions concerned determination of the role of manifestation of organisational procedures in the workers' know-how for the company. The project is a result of combination of two aspects resulting from the literature review. Firstly, it results from the significance of tacit knowledge for efficient operations of the companies that function in the conditions of supply chains (Schoenherr et al., 2014). Secondly, from the necessity to popularise organisational and technological solutions within the framework of the supply chain (Stadtler and Kilger, 2002). The size of a company, also as a result of the literature review, became the control variable (Hörisch et al., 2015). Therefore, the following hypothesis (H) was formulated: The significance level of manifestation of organisational procedures in logistic workers' know-how in respondents' opinions depends on the size of a company.

The specified variables concern an opinion expressed by the respondents about the significance, from the perspective of the company, of manifestation of organisational procedures in logistic workers' know-how in the following aspects: *behaviour consistent with procedures*, *acquaintance with procedures*, *understanding of procedures*. The respondents expressed their opinions on a five-point scale.

The invitation to participate in the research was aimed at persons who met the condition of being employed on the position that made it possible to qualify them as the so-called logistics professionals (they performed the functions of a logistics manager or a logistics specialist). The companies represented by them operated on the territory of Poland. The respondents were obtained for the research by means of convenience sampling (therefore, it was a non-probability sampling determined by the availability of participants). They answered questions independently using a paper questionnaire (Paper Self-Administered Questionnaires).

Fig 1. The main activity of the companies represented by the respondents

The answers of 197 persons each time representing another company operating on the territory of Poland were altogether qualified for the research. At the same time, the companies participated in supply chains. The respondents indicated production (44.7%) as well as trade (22.8%), logistic services (20.3%) and other services (12.2%) as the main activity of the company represented by them (Fig 1).

Fig 2. The size of the companies represented by the respondents

While analysing the size of companies represented by the participants (measured by a number of employees), it should be stated that microenterprises (employing up to 9 persons) constituted 14.72%, small enterprises (employing from 10 to 49 persons) 23.86%, medium-sized enterprises (employing from 50-249 persons) 24.37%, whereas large enterprises (employing at least 250 persons) constituted 37.05% (Fig 2).

Results

The Cronbach's alpha coefficient of the respondents' indications regarding an opinion about the significance of manifestation of organisational procedures in logistic workers' know-how for the company equalled 0.866. It is therefore at a high level. The values of mean, median and standard deviation are shown in table 1.

Table 1: Value of descriptive statistics

Variables	Behaviour consistent with procedures	Acquaintance with procedures	Understanding of procedures
Mean	4.0355	4.1218	3.8832
Median	4.00	4.00	4.00
Mode	4.00	5.00	5.00
Standard deviation	0.9917	1.0027	1.0746

It should be noticed that the values of medians for the variables are the same. The values for the mode *behaviour consistent with procedures* equals 4.0, whereas for the two remaining variables (i.e. *acquaintance with procedures* and *understanding of procedures*) they amounted to 5.0. It may therefore be stated that the respondents' indications expressing high significance of these aspects of logistic workers' know-how in the light of manifestation of organisational procedures were the most popular. The highest value of standard deviation and the lowest value of the mean is characteristic for the variable *understanding of procedures*. Therefore, it may be assumed that the respondents' answers differed most in case of this variable.

In order to verify the hypothesis made, the Kruskal-Wallis test was used. The results of the test are presented in table 2, whereas its ranks are shown in table 3.

Table 2: The results of the Kruskal-Wallis test for the variable grouping the size of a company

Statistic values	Behaviour consistent with procedures	Acquaintance with procedures	Understandin g of procedures
Kruskal-Wallis H	9.837	8.067	10.271
df	3	3	3
Asymptotic significance	.020	.045	.016

Table 3: Kruskal-Wallis test ranks for the variable grouping the size of a company

Variables	Workforce size	N	Mean rank
Behaviour consistent with procedures	Up to 9 persons	29	78.81
	10-49 persons	47	89.24
	50-249 persons	48	101.63
	At least 250 persons	73	111.58
	In total	197	
Acquaintance with procedures	Up to 9 persons	29	79.28
	10-49 persons	47	91.62
	50-249 persons	48	101.75
	At least 250 persons	73	109.78
	In total	197	
Understanding of procedures	Up to 9 persons	29	75.64
	10-49 persons	47	89.65
	50-249 persons	48	106.77
	At least 250 persons	73	109.19
	In total	197	

While analysing the test results, it should be stated that the hypothesis (H) made can be verified positively. The respondents' answers for three variables depend on the size of a company they represented (level of statistical significance $p \leq 0,05$). While taking into account the test ranks, it should be noticed that for the variables *behaviour consistent with procedures*, *acquaintance with procedures* and *understanding of procedures*, together with the size of a company, the significance of these issues increases in the respondents' indications.

Discussion

The hypothesis that the significance of manifestation of organisational procedures in logistic employees' know-how in respondents' opinions increases together with the size of a company was proven. The rank and role of organisational procedures results from the popularisation of methods of operation and applied organisational solutions in areas of business operations or in dimensions of its cooperation with other entities. Popularisation of these procedures favours effectiveness and efficiency

of employees' actions which results in the fact that they find themselves in the context of organisational processes and structure. It is more important if the scope of business operations is more diversified and conducted on a greater scale. The confirmation of this hypothesis completes previous findings within the scope of the role of organisational procedures since there are opinions expressed in the literature that organisational procedures regarding employees' activity favour their emotional and normative engagement (Valaei and Rezaei, 2016). In case of the presented research, however, it was possible to take into consideration the point of view of a company on this issue, although only in the dimension of know-how (which is more related to a normative engagement).

The literature review indicated that appropriate shaping of the human capital aspect is the main challenge of implementation of organisational solutions both within the scope of knowledge management and logistics as well as supply chain management. It is the human capital aspect that conditions proper exploitation of the implemented organisational solutions and efficient execution of organisational processes. It should be highlighted that properly planned and conducted personnel trainings constitute a significant element of knowledge management that translates, as a consequence, to building organisational competences. What is more, these trainings may and should also concern a broader set of problems than those resulting directly from the scope of employees' duties. It means that individual workers' knowledge (including logistic employees) should be shaped more broadly. This necessity frequently results from the participation of a company in the supply chain. As a consequence, these trainings may not only translate to the development of workers' know-how but also their level of motivation and engagement (Barrett, A. and O'Connell, 2001).

Conclusions

The conducted research meets a series of limitations. Above all, the non-probability sampling and the way of answering questions can be mentioned among them. It should also be noticed that only the companies that operate on the territory of Poland participated in the research. It means that generalisation of the obtained results should not be made freely onto broader groups of companies both within the scope of the Polish and international markets.

The results obtained as a consequence of both literature review and conducted analysis of the respondents' answers can, however, outline further directions of studies. Firstly, due the fact that the role of employees' tacit knowledge in the development of a company is raised in the literature, a research may be designed that will at the same time concern both its components, i.e. know-how and cognitive dimension. It may be tempting to state that know-how will be, above all, connected with the operating dimension of business activity, whereas the cognitive dimension significantly more with strategic aspects. Secondly, in the light of the survey results pointing out the dependency on the size of a company, it would be worth examining the existence of potential dependencies of the age of a company, since it may be assumed that not only smaller companies but also younger ones search for knowledge management solutions as well as logistic aspects that are suitable for them (especially if they already are a part of the supply chain). This situation can, in turn, also translate to the way they perceive the importance of the implemented organisational procedures.

Abstract

Rapid development of information technologies and the need to implement their achievements raise the issue of digitalization of education. As universities and colleges are preparing for the remote learning and teaching in the 2020-21 academic year, we focus on such challenges as academic staff prepositions, respective collegial governance processes, and collective agreements. The article aims to study the peculiarities of e-learning organization using remote learning technologies in secondary vocational and higher education in self-isolation mode, caused by COVID-19. The study identifies the peculiarities of e-learning in the transitional period at the Theater College of the Crimean University of Culture, Arts and Tourism, and the Sevastopol State University. It defines the concept of "remote learning" and describes the legal documents for its implementing. The method of analysis, generalization, and classification was used to process information about current and expired legal documents to design the algorithm for implementing e-learning and remote learning technologies. Assessing the quality of the regulatory framework allowed developing proposals aimed to create the educational environment characterized by individual educational technologies and independent curriculum. They correspond to the goals of the Russian education system reform focused on the development of the digital educational environment to provide multiple opportunities for quality education of various categories of students at the national and international level. The experience of using e-learning and remote learning technologies during self-isolation mode makes it possible to analyze its positive aspects, mistakes, regional and national specifics, "professional" peculiarities of educational institutions for further optimization of the educational process

Keywords: E-Learning, Remote Education, Remote Learning Technologies, Self-Isolation Mode.

Introduction

In materials of the Meeting of the Presidium of the presidential Council for strategic development and priority projects (2016) the new challenges were mentioned: rapid development of information

Cite this Article as: Nataliya SAMOYLENKO, Ludmila ZHARKO, Alexandra GEORGIADI And Maria SHEVCHENKO " Remote Learning and Teaching in Self-Isolation Mode: Challenges, Perspectives" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

technologies in the era of globalization and the need to use the world's achievements "here and now" have led to raising the issue of digitalization of education. In the reform of the Russian education system, special attention is paid to the digital educational environment, since it will contribute to creating conditions for providing multiple opportunities for quality education of various categories of students, not only at the national level, but also at the international level.

In research studies by Krasnova G. A., Mozhaeva G. V (2019), Zharko L. N. (2018), Samoylenko N. B. (2018) the issues of organizing e-learning and using distance learning technologies are highlighted as the subject of active discussion in the scientific world.

On May, 12 UNESCO Institute for Information Technologies in Education released Guidelines on Distance Education during COVID-19 (2020). The document encloses practical directions for the use of distance education tools pointing out the key elements of effective design and delivery of a distance learning program: learning resources (content design to support self-learning), pedagogy (sound pedagogical principles of guided-didactic conversation), learner support (psychological and emotional support of learners in academic interaction), and administration (management on the part of an efficient and accountable administration). As an industrialized form of teaching and learning, effective distance learning is characterized by the division of labor, where governments, educational institutions, academic and support staff, students and student bodies, parents as well as quality assurance/accreditation and academic recognition bodies become active participants contributing to the joint success.

After the outburst of COVID-19 pandemic lack of time and need for concrete actions resulted in the development of road maps by governments, ministries and educational institutions. The adopted solutions were to be implemented by the academic staff who faced the challenges of the disrupted teaching/learning process in their daily interaction with administration and students. The increased workload, working days of unfixed duration, lack of experience in remote teaching have provided the experience to reflect on so that to take more effective solutions in cooperation with administration and students in future.

Decree of the President of the Russian Federation dated (2020) proclaims that on the eve of the forthcoming academic year 2020-21 as universities and colleges are preparing for the continuation of remote instruction either fully or in part, the analysis of the solutions can provide new valuable knowledge.

As universities and colleges are preparing for the remote learning and teaching in the 2020-21 academic year, we focus on some studies concerning remote teaching during COVID-19 (2020) challenges: academic staff prepositions, respect collegial governance processes, and collective agreements.

We agree that academic staff associations should seek to protect the following core principles: academic decisions, including those involving changes to the mode of delivery of courses, should be made through normal collegial processes; academic staff should determine how best a course or program might be delivered remotely and maintain copyright over the course materials they produce; academic staff associations should be vigilant in protecting the work of the bargaining unit from outsourcing; extra time required for the preparation and delivery of remote courses should be recognized and compensated.

In March 2020 many countries have decided to close their higher education institutions because of the Coronavirus (Covid-19). Most of these institutions try to keep up to the normal schedule by switching to online teaching in self-isolation mode. Apart from using the institution's Learning Management System (e.g. Moodle, Blackboard, etc.), there are many other tools you can use for teaching from home. The following list does not contain everything that is out there. We have collected just a few ideas, tools and articles to make it easier to teach in these challenging times.

Purpose and Objectives of the Research

The article aims the study of the organization of e-learning using distance learning technologies by the implementation of educational programs in the educational institutions of secondary vocational and higher education in the self-isolation mode; the analysis of the organization of e-learning using distance learning technologies by the implementation of educational programs in the self-isolation mode.

The purpose of the work is the analysis of the experience of organizing e-learning with the application of distance education technologies when implementing educational programs during self-isolation mode.

The objectives of the paper included:

1) analysis of the national legal and regulatory framework with a view to ensuring effective educational process under the new conditions;
2) description of the decisions taken by educational institutions authorities to organize education during self-isolation and their implementation;
3) analysis of possible emergency situations when operating systems fail and the teacher / academic has to make solutions on the fly to sustain the teaching/learning process.

The research questions are:

1) What are the features of e-learning in self-isolation mode? Are there any challenges which are only for such a period?
2) What are the legal and regulatory problems of e-learning? The review of existing problems, and proposal of new solutions, an assessment of the quality of the regulatory framework in the organization of e-learning.
3) What is the algorithm of the educational process and the description of the set of actions for entering and working in the educational information system of the university.
4) E-learning problems in self-isolation mode, research and comparison with other educational institutions, with various information systems.
5) How to take advantage of the opportunities offered by the remote learning environment and how to make the next transition to remote education?

The paper highlights the main regulatory framework of implementing e-learning and organizing the educational process using distance learning technologies; analysis was conducted and prepositions for improvement of the regulatory framework of implementing e-learning and organizing the educational process in the higher education institutions are designed.

Literature Review

In UNESCO Guidelines on Distance Education during COVID-19 (2020) remote learning is viewed as “an emergency measure, which attempts to replicate the classroom teaching and learning process in an online mode and can also be considered a form of distance learning”.

Before conducting the course we work out how to evaluate. For this we need to know the purpose of evaluation (the key questions); the most appropriate methodology; how to carry out an evaluation.

Analyzing information about online Learning Strategies, we investigate the work of the Centre for Teaching Support & Innovation (CTSI). It provides leadership in teaching and learning at the University of Toronto and provides support for pedagogy and pedagogy-driven instructional technology for all teaching staff and teaching assistants (primarily through the Teaching Assistant’s Training Program) across the university’s campuses and divisions (https://teaching.utoronto.ca/).

Harrison, L. et al (2016) offered in Online Learning Strategies some elements of Online Learning & Teaching.

Online Course Observation Template consists of such sections:

Section 1. General Course Overview and Introduction**:** Setting the stage for learning and preparing students successful participation in the course activities.

- Does the instructor provide a thorough description of the course as well as introduce students to the course and the online format?
- Are the learner requirements such as basic technology needs and/ or participation expectations described?
- Are practice use of tools and/or community building activities included to prime the students for learning?

Section 2. Assessment of Student Learning: Alignment of activities and assessments with learning outcomes is evident in the course design.

- Are learning outcomes communicated?
- Is there a variety of activities and assessments?
- Is there alignment of learning activities and assessments with learning outcomes?
- Are formative and summative assessment opportunities part of the design?
- Are assignments clearly described, including grading scheme or rubrics?
- Is student workload appropriate to course level and duration?

Section 3. Instructional Design: A clear path to learning opportunities for students is provided, including interaction with the content, their peers, and their instructor.

- Are there opportunities to interact or seek guidance from the instructor?
- Are there opportunities to participate in community activities or peer-to-peer sharing?
- Is learning scaffolded, guiding students toward increasingly independent learning and/or application of relevant skills?
- Are there opportunities for student reflection on learning and/or feedback to the instructor?

Section 4. Online Organization and Design: Instructor's design and choice of technology effectively delivers course content and supports learning processes.

- Overall, is the navigation and structure of course easy for students to follow?
- Do the tools and media formats selected support the course learning outcomes?
- Are guides and protocols for use of the course tools provided?

Considering the course as a whole, provide feedback on the following:

- What aspects of the course do you see as strengths that will contribute to effective student engagement and learning?
- Are there any strategies or resources that you would recommend to enhance the design of this course?
- Final comments or observations?

Pearson collated research on effective online teaching and found nine strategies used by successful faculty:

1. Know the technology
2. Create and maintain a strong presence
3. Set clear expectations for the course
4. Establish a sense of comfort and develop a community of learners
5. Promote reflection and communication through quality asynchronous discussion
6. Have a good balance of active leader and active observer

7. Request regular feedback and be cognizant of misinterpretation
8. Regularly check content resources and applications
9. Expect the unexpected and remain flexible.

(https://www.pearsoned.com/9-strategies-for-effective-online-teaching/).

Methodology

The study was conducted at the Theater College of the Crimean University of Culture, Arts and Tourism, and the Sevastopol State University. This research is supported by the grant "Methodology and methods of using information technologies in training and support of teachers-facilitators' professional activities" registration number 48/06-31, 06.04.2020 Sevastopol State University. The method of analysis, generalization, and classification was used to process information about current and expired legal documents and to design the algorithm for implementing e-learning and organizing the educational process using distance learning technologies. The oral questioning, conversation, observation were used as the empirical methods.

Firstly the regulatory framework of implementing e-learning and organizing the educational process using distance learning technologies analysis was conducted.

Our paper presents the results of the experience where we have trained higher education teachers for the online course designing in the process of teaching and learning.

The main goal of the research was to present the organization of e-learning using distance learning technologies by the implementation of educational programs in the educational institutions of secondary vocational and higher education in the self-isolation period.

Results

The algorithm of implementing e-learning and the algorithm of the educational process itself using distance learning technologies are described.

The final result of its implementation in the educational process will be the creation of the educational environment with the designing of individual educational technologies and the independent curriculum.

Following the Russian Federation Laws (2012), the Order of the Ministry of education and science of the Russian Federation (2014), the first stage of the digital educational environment development, in our opinion, was the possibility of implementing educational programs using e-learning and distance learning technologies.

Moreover, according Recommendations of the UNESCO policy in the field of mobile learning. UNESCO (2015) E-learning involves the mandatory use of the Global Internet and / or local network of educational institutions and multimedia. Distance learning, in our opinion, is the implementation of the educational process at a distance.

Legal support for the implementation of e-learning is one of the challenges.

We started our research on this issue by analyzing the legal framework (table 1).

Table1: Legal support for the implementation of educational programs using e-learning and distance learning technologies

Level of document approval		Regulatory document	Date of adoption / approval	Articl, part №	Summary of document / article
		Federal law No. 273 "On education in the Russian Federation".	29.12.2012	16	Provides an opportunity to implement educational programs using e-learning and distance learning technologies.
				18	Describes printed and electronic educational and information resources.
	Federal Executive authority	On the priority projects in the field of education. Materials of the Presidium of the presidential Council meeting for strategic development and priority projects.	24.08.2016		Describes the development of the digital educational environment.
Acts of the Ministry of education and science of the Russian Federation and other ministries and departments		Order of the Ministry of education and science of the Russian Federation No. 816 "On the approval of the procedure for the use of e-learning and distance learning technologies by organizations engaged in educational activities in the implementation of educational programs".	23.08.2017		Describes the procedure of using e-learning and distance learning in implementation of educational programs.
Local acts of educational institutions		Regulations, orders, and bylaws of an educational institution on the use of e-learning, distance learning technologies in the implementation of educational programs.	As necessary.		Regulate the mechanism of e-learning and distance learning technologies implementation in the educational programs of an educational institution.

Obviously, the implementation of educational programs based on the use of e-learning and distance learning technologies is the focus of attention at all levels. The analysis of the legal framework promoting the use of e-learning and distance education programs has shown the possibility and approximate procedure for its full/partial use, as well as possible mechanisms for its regulation. Meanwhile, only odd bits of information have been found on the issue of degree programs where the use of e-learning is not possible even partially due to objective reasons and the specifics of the discipline taught. Thus, there is a need for an order at the level of relevant ministries to outline a list of specialties (with codes and names) where the use of e-learning is impossible, as well as guidelines for conducting remote classes in corresponding disciplines in force majeure conditions, for example, self-isolation.

The transition period to e-learning in self-isolation mode lasted 2 weeks.

The introduction of the general self-isolation regime due to the spread of a new coronavirus infection (COVID-19) has significantly accelerated the transition of educational institutions to e-learning. In our opinion, this transition did not always proceed in an orderly manner and at a high level, since not

all educational institutions were in equal conditions, and there was no preparatory stage, or it was short (1-3 days).

The paper describes the transitional period experience of the Theater College of the Crimean University of Culture, Arts and Tourism (fig.1) and the Sevastopol State University.

Fig. 1 Algorithm for the transition to e-learning

The Theatre College administration issued "An order on the temporary transition to the implementation of educational programs with the use of e-learning and distance learning technologies in special circumstances". By the order, the director was put in charge of the educational activities, and the working hours of the staff were established in accordance with the academic load, as well as the plan of methodological and educational work for the 2019-2020 academic year. The teachers were asked to update the calendar and thematic plans for the academic disciplines. The teachers and students were informed about the remote communication channels: the Skype and closed groups in the Vkontakte social network were offered as the training platform. A responsible consultant was appointed to assist teachers in the use of e-learning and distance education technologies. A report form, which teachers had to provide on the day of classes, attaching a screenshot of the lesson, was developed to control the conduct of training sessions (table 2).

Table 2: Report on the implementation of educational programs using e-learning and distance learning technologies during the period of self-isolation

№	Name of the discipline, Full name of the teacher	Date of the session	The theme of the lesson	The type o the lesson	Self-study work	Year	Number of students present

Lesson report

Teacher's name	Subject/ Discipline	Group	Date	Student	Lesson report using resources
Samoylenko N.B.	English for academic purposes	Phil/м -19-1	11.06 11.50 - 13.20	10/10	Topic: Unit 6. Research Papers. Key Words. Introduction Sections 1)Video: Research Paper Introduction https://www.youtube.com/watch?v=tSkb7KZ5yw0 Key Words. Developing Keywords for Your Research https://www.youtube.com/watch?v=PCUjnPS2_1g (present recommendations for writing research paper introduction and key words); 3) Preparing mind maps for theoretical material: 11. Research paper: general structure 12. Research paper: structure of introduction section Platform Big Blue Button https://bbb.is.sevsu.ru/b/fd3-v6q-9ke.

The students were informed that they had to continue their learning in the new mode to be admitted to their term or final exams (but for cases of legitimate excuses).

According to Order of the Ministry of education and science of the Russian Federation "On approval of the list of professions and specialties of secondary professional education, implementing educational programs which are not allowed using only e-learning, distance educational technologies" (2014) there are educational programs which are not allowed using only e-learning, distance educational technologies. That is why at the initial stage, there were difficulties with the academic disciplines of purely practical character, requiring additional equipment ("Solo singing", "Stage movement and fencing", "Dance", "Make-up", "Acting").

Aged teachers, in our opinion, did not overcome the psychological barrier when switching to e-learning, since they did not have enough knowledge of the technical tools of e-learning and it took them longer to adapt. It should be noted that the teachers' working day was no longer standardized.

The Regulation "On the Electronic Information and Educational Environment (EIEE)" defines the purpose, structure and procedure for the functioning of the electronic information and educational environment in SevSU.

To ensure the functioning of EIES at SevSU, the following information and telecommunication technologies are used: official e-mail (https://mail.sevsu.ru), a file server, webinar tools (Mirapolis Virtual Room, BigBlueButton, Discord, etc.), tools for videoconferencing (Skype, Zoom, etc.), remote communication information system (https://chat.is.sevsu.ru).

To inform the participants of the educational process, a community the VKontakte social network (https://vk.com/sevsu.online) was launched on. In the group news and teaching materials for organizing the learning process in a digital environment are quickly posted. Methodological materials, lecture notes and practical lessons, video instructions for teachers and students are posted and periodically updated on the website org.sevsu.ru in the folder "EES and DL Distance Learning SevSU" (https://www.sevsu.ru/novosti/item/7621-gde-najti-informatsiyu-o-distantsionnom-obuchenii).

Operational information about direct communication and feedback ("learning -teacher", "student - administration", "teacher - administration", "student, teacher, administration - technical support service") is located on the SevSU page of the official website in the "Education" section.

The educational process is carried out according to the following algorithm (table 3).

Table 3: Algorithm of the educational process in SevSU

Learner	Tutor
• Login / password verification, possibility of entering EOES "SevSU. RU". • Login to http: //test_moodle. sevsu.ru / • Search for the direction of training, course, group of students. • Choice of discipline according to the schedule. • Completing assignments, participating in online classes. • Sending completed assignments to the teacher for review.	• Login to http: // test_moodle. sevsu. ru / • Search for the direction of training, course, group of students. • Choice in the section "Course" of the name of the taught discipline. • Download PD, lecture notes and / or practical classes, presentations, assignments for independent work, links to online courses, additional resources if necessary. • Description of instructions for different types of work. • Determining the timing of assignments, time for online classes

Thus, the participants successfully pass all stages of training following the considered algorithm of the educational process.

Teachers were offered webinars from the educational platforms Yurayt, Lan. The ELS team "Lan" together with the St. Petersburg "Center for Educational Services" conducted an intensive online course "Technology for creating e-learning courses based on LMS Moodle", including a series of webinars (https://www.youtube.com/watch?v=-VM8elNM7-U&feature= youtu. be).

However the university administrators foresaw the problems that teachers could face in the distance learning in self-isolation period in the previous algorithm of the educational process at SevSU. The office of educational programmes SevSU has developed the course " Basics of Working in Moodle"

for methodological support of the distance learning organization (https://testmoodle.sevsu.ru/ mod/page/view.php? id=45750&forceview=1). The aim of the course is to help teachers develop their e-learning resources based on e-learning templates. The content of the course is presented with the guidebook.

The course offers to listen to the recording of the webinar "Implementation of electronic educational resources in the Moodle LMS" aimed to train teachers for the academic year by designing electronic course templates.

The structure of the course "Basics of Working in Moodle" includes a number of steps.

Step 0. Introduction
In this section, the system administrators of SevSU made a video instruction which is offering to get acquainted with the structure of the course home page, with a template, to make personal settings for a personal profile, and to study the stages of the structure of the electronic training course.
Step 1. Course setup
This video contains a detailed algorithm for setting up a course, informative sections of a course template, principles of course editing.
Step 2. The Section "General"
This step describes the structure of the section "General", the content of each element of the section "General" (abstract, forums, curriculum-thematic plan, and list of basic and additional literature, attendance) and the principles of its editing are described.
Step 3. Webinars
This section presents the possibilities of simultaneous classroom training in the form of webinars in the system "SevGU. Conference" based on BigBlueButton.
Step 4. Lecture materials
The video shows the organization of the presentation of theoretical material in e-course templates in two formats: in the form of lecture elements and in the form of file resources (lecture notes or presentation). The placement of theoretical material in the format of a lecture summary and presentation, settings the element "Lectures" and editing it in the author's course template is described in detail.
Step 5. Workshop
The organization of practical tasks in e-learning templates is presented in text format, the possibilities of working with the elements "Assignment", "Forum", "Seminar", "Test" and their editing methods are described.
Step 6. Other Moodle Elements and Resources
The teacher is offered a wide variety of resources and course elements that can be used for creating authoring courses in a distance learning environment. A separate part of the section is devoted to the electronic element of the course – "Chat". The algorithm of "Chat" creation and edition, its features, as well as its capabilities in synchronous written communication of course participants in real time are considered.

The last step of the course consists of the video instructions and text instructions for the guideline in Moodle.

Each step of the course ends with an anonymous survey of teachers, where they are asked to rate the usefulness of the content of the sections, indicate what incomprehensible material was in the sections and what other information they would like to receive on the studied sections.

After the end of the course teachers will learn how to create e-courses, design them in accordance with the requirements, place and organize educational materials in the course elements, and work with the course users.

Over the first weeks after the transition to remote learning, partially due to the lack of LMS experience of work on the part of academics, and for such technical reasons as LMS upsets, popular solutions taken by the university authorities and the staff included application of social network

VKontakte (Russian social network analogue of Facebook) and Skype. Although the platforms are not secure in terms of information and communication protection, they provided the necessary opportunities for conducting lectures and practical sessions online.

The popular decisions in the organization of lectures were basically live broadcasting (with or without the audiovisual recording) or group chats with downloaded texts and tasks to them.

The use of live broadcasting was very similar to the real-life lecture but conducted on the internet platform it got an additional tool in the form of a chat where students could ask questions and discuss the material. However, this kind of interaction was not very effective. Following the conversation and delivering the lecture simultaneously was time-consuming for the lecturer and could be ineffective and distracting for the students if interrupted by strangers.

The potential of group conversation based on learning material from the downloaded text was found more interactive if it was presented in portions with pre-reading, while-reading and after-reading questions discussed in the chat synchronically and followed by summative thematic tests. This feature was also appreciated by the students who for some reason missed the lecture but could read the conversation in self-study format.

Real practical classes and seminars were held in virtual classrooms on university's LMS or in Skype. The platforms offered opportunities both for implementing online resources enriching and diversifying the content of the disciplines, and, supplying teachers and students with interactive tools available across the Internet.

Thus, immediate decisions taken to compensate the lack of real interaction varied, but they all tended to fulfill the requirements of the educational process. Still, the experience proves their application has serious limitations which include security and copyright issues, technical and financial availability, as well as organizational potential for university, academic staff and students.

Georgiadi A.A. et al (2017) mentioned that the criteria for selecting a web resource from the position of a teacher can be availability, safety, reliability and functional compliance with the tasks of teaching a particular discipline with regard to the needs of the student audience. The main discipline content in the form of interactive abstracts, lecture materials, monographs, textbooks, that are copyright objects, should be stored and used on a secure platform with the limited access (for registered users). It can be a learning management system (LMS) such as Moodle or free cloud services that allow regulating access to the materials. Automation of learning control requires selection and acquisition of a test platform. The use of such a product in its turn requires a web resource with specific technical characteristics. Test platform performance can be ensured by adequate learning management system (LMS) or a web site. The area of creative interaction between teacher and students is associated with transformation of educational activity forms (classroom, extracurricular, independent and individual work). In this context, access to open cloud services is inevitable.

In the book Distance Teaching Syrvival Kit (2020) we studied the materials and documents:

1) Collections of tools recommended for online teaching

Many universities implement the flipped classroom, which is characterized as an instructional strategy and a type of blended learning that reverses the traditional learning environment by delivering instructional content, often online, outside of the classroom. *We recommend to study such resources:* https://www.heacademy.ac.uk/knowledge-hub/flipped-learning-0; https://flippedlearning.org/.

Discussion

E-learning is one of the components of the improvement system, both in the providing educational services and in receiving them. The end result of its implementation in the educational process will be, in our opinion, the expansion of the boundaries of the educational environment with the ability not only to design individual educational technologies and trajectory, but also designing the curriculum independently; creation of a unified information space in a separate educational institution; unification of information spaces within the domestic specialized educational institutions with the possibility of reaching the international level; providing the opportunity to repeatedly study the covered material; use of the latest information in the field of the taught discipline, will make the learning process more visual.

Conclusion

The experience of implementing educational programs using e-learning and distance learning technologies during the period of self-isolation made it possible to analyze the positive aspects, take into account the made mistakes, the regional, national specifics, "professional" features of educational institutions for further optimization of the educational process, for designing specialized training programs, approving the relevant standards; generating a unified communication format within the educational process. Although the forecast of UNESCO, the World Bank, and other organizations about increasing inequality in access to distance education is quite realistic, since not all students can cope with connecting to video broadcasting independently; not all students have technical means; Internet connection is not available everywhere.

In general, the research results confirm the need for full/partial implementation of e-learning and distance learning technologies for educational programs realization. The experience of using e-learning and distance learning technologies during the period of self-isolation makes it possible to analyze the positive aspects, take into account the made mistakes, regional and national specifics, "professional" peculiarities of educational institutions for further optimization of the educational process.

Abstract

The authors of this study have managed to explain in what way the methods of strategic analysis can be used to build a personal brand development strategy. To solve this problem the authors have identified the features of each method of strategic analysis and its application for the formation of a personal brand development strategy. The promotion method proposed by F. Kotler within the framework of the concept of marketing development of 4C was successfully transformed and applied to such an object as a personal brand.

Keywords: Personal Brand, Promotion, Development Strategy, Content Plan.

Introduction

The term "personal brand" was first coined by Tom Peters in 1997: "Big companies understand the importance of brands. Today, in the age of the Individual, you must be a brand. To be in business, our main job is to be a marketing Director who manages a brand called YOU" (Piters, 2012). Over the past 20 years, the term has migrated from business to almost all areas and the development of digital technologies and, in particular, social networks have had a great impact on this process. Today, personal branding is one of the key trends in the field of PR, since the concept of H2H (human-to-human) is increasingly coming to the fore in all areas (Marranco, 2015). Regardless of the market or professional activity, interaction is always carried out not between companies, but between people. Internet technologies replace people, but they also give the opportunity to actively develop and find their target audience to those who previously had almost no chance of doing so. The same rules apply to a personal brand as they apply to product brands. Information must be created as part of a content plan that is subordinate to solving specific tasks for creating a personal brand of the Manager. The rule for generating content is one – there should be enough of it so that the Manager is interesting to the target audience, but also does not spam it with dozens of posts a day (Hall, 2018). At the same time, if possible, the Manager should try to communicate with subscribers not only in social networks or through the site, but also to meet people in person. Knowing about the Manager personally, in the future, if a person needs a service as part of the professional activities of the Manager, they are more likely to give their preference to him, rather than to those with whom they have only communicated on the Internet or seen only in videos (Long, 2018). Of course, the person who creates a brand must constantly maintain contact with their potential customers, because their opinions and location are extremely important to them (Davydenko, 2009). The authors of this study aim to analyze the features of a personal brand and develop a strategy for its promotion.

Research Methodology

The authors conducted an empirical study aimed at identifying opportunities to using methods of strategic analysis to build a personal brand development strategy, presented a list of methods that are appropriate to use for these purposes. The following hypotheses are supposed to be tested:

- Strategic analysis methods can be used to develop a personal brand development strategy.
- The use of strategic analysis methods in relation to the development of a personal brand has its own characteristics.

An in-depth interview method was used in order to confirm the hypotheses (Glock, 1987). The results of an in-depth interview of individual entrepreneur who are dealing with organizing online conferences allowed to draw following conclusions:

- When developing a personal brand promotion strategy, traditional methods of strategic analysis are quite applicable, which allow analyzing the internal and external environments of brand development and promotion.
- In the course of the research, research directions were developed for building a personal brand development strategy (see Table 1).
- Table 1

Table 1: Methods for building a personal brand development strategy

N	Method	Features of method application in personal branding
1.	SWOT - analysis (Andrews, 1987)	Internal factors: analysis of the brand's strengths and weaknesses relative to its main competitors. External factors: opportunities formed in the external environment – technology development, consumer ecosystem development, etc., as well as threats – industry and macroeconomic factors that affect the development of the brand.
2.	Analysis of the value chain (Porter, Kramer, 2019)	It is necessary to define the types of values that can be created by the brand. This can be on-line courses, lessons, practical recommendations on various issues, webinars, conferences, useful content on the site. Internal factors: analysis of relationships between values, assessment of the possibility and economic feasibility of using various marketing tools for each direction of marketing activities of the brand involved in creating value. External factors: analysis of the organization of relationships with partners, competitors and loyal users, assessment of the possibility of using additional tools to engage users and increase brand loyalty, creation of a user ecosystem.
3.	7S (McKinsey 7S)	If we consider this tool in relation to the promotion of a personal brand, it is obvious that in the process of its development, there is a need to develop a strategy, hire staff and resolve issues about team management.
4.	PESTEL	The method is aimed at conducting a comprehensive analysis of the company's external environment: the development of legislation, the tax system, technologies and innovations that can be used by the brand, the presence of relationships between competitors, etc. Using the method allows you to systematize all factors of external influence on the brand ecosystem, both at the industry and macro-economic levels.
5.	Analysis of Five competitive forces (Porter, Kramer, 2019)	The method allows you to study in detail the level of competition-the presence of personal brands in this industry, application of actual promotion tools, the demand for the offered values.
6.	Ansoff Matrix	The analysis performed using this matrix allows you to develop 4 strategy options, depending on the type of product being promoted and

		the type of market.Личный бренд сам по себе является новым товаром для рынка, кроме того, он предлагает новый контент.
7.	Technology analysis by Christensen (Christensen, 2011)	The method involves analyzing the technologies used by the brand, including "breakthrough" technologies that radically change the process of creating value.

Thus, using these tools, we assess the real strategic position of a personal brand and form an approach to developing a marketing strategy for its promotion.

Based on the step-by-step process of developing and implementing a content marketing strategy proposed by F. Kotler (Kotler, 2017) the authors proposed an algorithm that includes 8 steps for developing a strategy for promoting a personal brand:

1. Goal setting and formulating objectives to achieve it. The strategic goal is to increase brand awareness and increase audience loyalty.
2. Determining the target audience.
3. Drawing up a content plan.
4. Generating content. Content can be generated based on studying the requests of the target audience, personal brands of competitors, as well as directions for the development of partner Internet communities.
5. The distribution of content.
6. Amplification of content. Search for opinion leaders-influencers who have a serious influence and can connect to the distribution of high-quality content.
7. Efficiency evaluation. In accordance with the concept of Marketing 4.0, new metrics are proposed for evaluating the effectiveness of marketing based on 5A: Aware – visibility (A1), Appeal – relevance (A2), Ask – search efforts (A3), Act – evaluation of actions (A4), Advocate – frequency of recommendations to others (A5). The user of the brand content moves sequentially from A1 to A5, and the conversion between each two values is measured along the way.
8. Selecting the most interesting content for the audience as well as the most effective platforms for brand promotion and attracting new users.

Results of The Empirical Study

An 8-step algorithm for developing a personal brand promotion strategy was tested on a specific example of a personal brand of an individual entrepreneur-an organizer of online conferences. In the process of developing a promotion strategy, digital tools Buzzsumo, SimilarWeb, and SEMrush were used, which allow you to analyze the process of promoting a personal brand and its effectiveness not only for a specific personal brand, but also to compare it with competitors by a set of parameters. As a result of the research, recommendations were developed for using SMM to increase audience engagement and activity. To develop content marketing, taking into account the trend for on-line education, including in connection with the COVID-19 pandemic, the brand owner was asked to develop and launch their own online courses on digital marketing,

Conclusion

Traditional STP process (segmentation, targeting, and positioning) can be successfully implemented using digital marketing tools and, above all, the Business Intelligence platform that aggregates OLAP and Data Mining tools for managing consumer experience and conducting in-depth consumer analysis.

Abstract

This research aims to study the factors that affect "consumer buying behaviour" in the food industry in Jordan. The main objective is to know if there is any influence of different packaging elements on the behaviour of consumer buying method through investigating the influence of multiple independent variables on research's dependent variables, this study has been considered in Amman-Jordan, a questionnaire has been used to collect data. Moreover, for analysis purposes, SPSS software was used. The study sample consisted of a hundred respondents and tested the following packaging elements: "packaging material, packaging colour, packaging printed information, design of wrapper in packages, font style and innovation", it studied the extent of their influence on "consumer buying behaviour". According to the findings, the material of packs and the design of wrapper have an obvious influence on "consumer buying behaviour" in the food industry, while the other elements do not influence "consumer buying behaviour". Independent variables influence by a percentage of 45% on the dependent variable, this means other elements are influencing "consumer buying behaviour".

Keywords: Packaging Elements, Buying Behavior, Food Industry.

Introduction

Firms nowadays face pressure from different types of consumer behaviours, inside and outside the market, that each is specialized in, which make them more curious to know better about the tools that push the consumer to choose their product or service. Therefore, they started from tens of years from now to study "consumer buying behaviour", one tool that researchers found previously is packaging and how much positive or negative the packaging elements may give an impact on the business profits. Many marketers believe that packaging is the last "P" of marketing "4Ps" that are price, place, promotion and product. (Adam & Ali, 2014).

The research purpose is based on the hypothetical analysis of the elements of packaging and their impact on the buying behaviour decision of the consumer. The tentative study covers the features of packaging which have an influence on "consumer behaviour" in the case where there are many other choices available.

Cite this Article as: Shafig AL-HADDAD, Hala ABURADAHA And Esraa KHATER "The Impact of Packaging Elements on Consumer Buying Behavior in Food Industry" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Research Problem

The obvious effect on "consumer buying behaviour" by packaging elements has so much attention from scholars, previous researchers found that packaging can be a valuable tool in the marketing communication giving more details of its elements and the impact of these elements on the behaviour of the consumer (Raheem et al., 2014), the "consumer behaviour" various depending on the packaging colour, quality, innovation and many different packaging characteristics (Raheem et al., 2014), it has been found that "consumer buying behaviour" is affected by the material of the product package (Adam & Ali, 2014). Some researchers gathered the elements of packaging in seven categories; colour, attractiveness, printed information, beautiful background, transport and handling facility, style of the front and availability of wanted information on the packaging (Abdullah, & Akterujjaman, 2013), each one of the seven has a separate impact on the buying decision.

Researchers found that labels give a value to the product, the reason they mentioned for that is consumers can get the information of the product itself, the origin of it and the purpose of usage (Zekiri, & Hasani, 2015). The impact of packaging for getting a competitive advantage is higher than the impact of advertising, it reinforces the decision to purchase, furthermore, it affects each time the consumer uses the product not just when he buys it (Deliya, & Parmar, 2012). The packaging is an important part of strategic marketing decisions. Therefore, it is a crucial managerial implication (Rundh, 2016).

This study seeks to answer the following question: what is the impact of packaging elements ("packaging colour, packaging material, printed information, font style, design of wrapper', innovation") on "consumer buying behaviour" in the food industry in Jordan?

Research Objectives

-To investigate the impact of packaging on "consumer buying behaviour".
-To know the impact of packaging elements on "consumer buying behaviour".

Literature Review

Nowadays, with the high competition in different markets around the world to seize consumer attention and purchase products of a company, packaging should be under the spotlight of the company priorities to get a competitive advantage in the marketplace (Wells et al, 2007).

The "consumer buying behaviour" is considered as a group of decision-making and the concerned individual action process to buy. In addition to product usage (Sharma, 2014), the "buying behaviour" of consumer indicates the individual buying method of a Product which works to satisfy the consumer needs, desires and the usage way (Mitul& Bhavesh,2012).

Wrapper Design, Packaging Material and Printed Information Influences Consumer Buying Behaviour, these elements when they purchase Nestle products during short time period. (Ahmad, et al 2019)
The packaging is considered important in its meaning for the consumer to communicate with the trademarks, also works to identify the product and the organization, and works to protect the quality of the product (Silayoi & Speece, 2007).

The study (Raheem et al.,2014), investigated the influence of packaging on "consumer buying behaviour" through studying the number of the independent variables which are packaging colour, material, design of wrapper, and innovation, to show the influence of the dependent variable which is "consumer buying behaviour", the study has indicated at the presence of a positive relationship between packaging and "consumer buying behaviour", besides of, the packaging is one of the most crucial factors that work to influence consumers buying decision, and it is considered one of the most important instruments in the marketing communication. The study indicated the need for understanding the influence of packaging elements on "consumer buying behaviour".

"Consumer buying behaviour" depends on the packaging and its features, such as the "font mode, innovation, printed information", background image, and the cover design, since there is an increasing interest in the packaging part because of the change in consumers lifestyle, the packaging as a tool to enhance the "consumer

buying behaviour", moreover, the sale point packaging one Important factor That works to influence the "consumer's buying behaviour" (Mitul& Bhavesh,2012).

$H_{01:}$ There is no statistically significant impact of packaging on "consumer buying behaviour" at $\alpha \leq 0.05$.
Packaging colour is considered one of the most important factors to potential customers when the customer undertakes the process purchase decision for juices since the colours contribute to attracting the customers' attention (Raheem et al.,2014; Mitul& Bhavesh,2012). Moreover, colours have different Meanings according to consumer's perception. (Shah et al, 2013).

According to (Farooq et al, 2015), the colour of the packs is the packaging scope, the selection of the colour and the colour of the visual parts is crucial to give the consumer what he expects. Researchers discussed the importance of packaging colour in visual designs of being a tool to give the ability of marketers at the same market to act harmoniously with each other.

H_{011}: There is no statistically significant impact of packaging Color on "consumer buying behaviour" at $\alpha \leq 0.05$.
Packaging Materials are the used materials to protect the product (Raheem et al., 2014). Because the packaging material works for protecting the product from loss and damage (Shah et al, 2013). According to (Raheem et al., 2014), packaging material contributes to changing the consumers' purchase decision and influences the quality level and consumer attraction for juices.

The material of the pack makes an important element, (Shah et al., 2013) shows that the high-quality material attracts more consumers than the low-quality products, which in this case, increases the profit margin of the firm and gives them an advantage over their competitors.

$H_{012:}$ There is no statistically significant impact of packaging Material on "consumer buying behaviour" at $\alpha \leq 0.05$.
Font style plays an important role in packaging impact; successful companies are characterized by having Specialists in studying, selecting and innovating the best attracting font modes. (Mitul& Bhavesh, 2012; Shah et al, 2013).

To attract the customer, one basic element according to (Shah et al., 2013) is to choose the right and appropriate font style, firms that understand the importance of this element and use the best font style get to have a market success.

$H_{013:}$ There is no statistically significant impact of font style on "consumer buying behaviour" at $\alpha \leq 0.05$.
Generally, product design has a role in attracting customers, so the companies seek to design attractive packages for customers, from different ages. (Mitul& Bhavesh, 2012; Raheem et al.,2014)
Researchers at the same time showed that the design of the wrapper is a way firms can use to identify their product. And firms need to know carefully which market segment they are working in and based on that they choose the right product design, for example, the production of wrappers that are safe to the children and attracts them as well (Shah et al.,2013).

H_{014}: There is no statistically significant impact of wrapper design on "consumer buying behaviour" at $\alpha \leq 0.05$.
Printed information on the packaging contributes to promoting the product, enhances its trademark, and helps the potential customers in distinguishing it from other competing products. The consumer might undertake the evaluation decision based on this information (Mitul& Bhavesh, 2012), these printed information includes product price, description, quality and other features (Shah et al, 2013).

H_{015}: There is no statistically significant impact of printed information on "consumer buying behaviour" at $\alpha \leq 0.05$.
The packaging is more affordable when we put the element of innovation in (Farooq et al, 2015), when the product has a touch of innovation in it, even if it was a little, it brings the consumer the feeling of attractiveness and the need to purchase it again, which leads to customer loyalty and an increase in the market share.

To satisfy consumer's needs and desires in design, packaging should be done to increase the product value introduced to the customer, such as ease of carrying the product, the possibility for recycling, and ability to

store it (Raheem et al, 2014; Shah et al, 2013). The companies seek for innovation in the packaging to preserve their trademark and to create a competitive advantage for it with low cost (Mitul& Bhavesh,2012).

According to (Adnan & Ahmad, 2013), the background image is considered to be what is printed in the customer mind, helps him to distinguish the product trademark from other trademarks, also the image on the product works in building the familiarity relationship with specific product and increases interest in it.

H_{016}: There is no statistically significant impact of innovation on "consumer buying behaviour" at $\alpha \leq 0.05$.

Contribution of the study

Even of the importance of studying the impact of packaging on "consumer buying behaviour" in the food industry, there is no research that clears the factors that shows this impact in Jordan. Therefore, this paper covers this issue.

Research Framework

Fig.1: Research Model

This model has been developed by the researchers based on the previous researches; (Adam & Ali, 2014), (Raheem et al., 2014), (Abdullah,& Akterujjaman, 2013), (Zekiri& Hasani, 2015), (Deliya& Parmar, 2012), (Rundh, 2016), (Wells et al,2007), (Sharma, 2014), (Silayoi & Speece, 2007), (Mitul& Bhavesh,2012), (Shah et al.,2013), (Zekiri & Hasani, 2015).

Research Methodology

Sampling Technique & Sample

The study population consisted of consumers who buy food products in Amman, the sample has been selected to study the influence of packaging elements on “consumer buying behaviour”, a sample of 100 individuals has been taken to conduct the study, it was a convenience sample to generalize the result in the food industry sector.

Tools of Data Collection

To receive data relating to the role of packaging on the buying behaviour of the consumer, data will be collected regarding seven variables, through designing a questioner consistent of questions about all the variables they will be analyzed using SPSS software.

Measure

The questionnaire contained 23 questions to receive data relating to each variable. Each variable was measured through presenting between 2-4 questions for each one of the variables, a five-point Likert scale was used which consists of five points 5-1. Reliability statics table shows that the sample's variances value is 86% this indicates the presence of reliability for all variables together.

Results and Discussion

Items responsiveness was measured using a 5 points Likert-scale followed by strongly disagree to strongly agree, value 5 refers to strongly agree and value 1 refers to strongly disagree.

Reliability statistics table shows the number of items and the Cronbach's alpha value. The variance of the sample is 86%, which indicates that there is high reliability for all 8 variables together.
Regression Analysis

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.674[a]	.454	.419	.56787

The results of model summary show that there is no impact of all independent variables upon the dependent variable because R=.674, the independent variables has 45% impact on the dependent variable which means there are other factors that have an impact on it.

ANOVA

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	24.685	6	4.114	12.758	.000[b]
	Residual	29.668	92	.322		
	Total	54.352	98			

In the ANOVA table, it is obvious that the statistical model is significant because the value of significance is less than 0.05which means that there is a relationship between independent and dependent variables.

Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.747	.459		1.627	.107
	Packaging colour	.179	.109	.171	1.646	.103
	Packaging font	.154	.103	.147	1.487	.141
	Design of wrapper	.267	.129	.238	2.064	.042
	Packaging material	.306	.129	.271	2.367	.020
	Packaging information	-.199	.111	-.173	-1.799	.075
	innovation	.113	.099	.109	1.143	.256

The dependent variable is “consumer buying behaviour”.
The regression equation is:
$Y=A+Bx_1+Cx_2+Dx_3+Ex_4+Fx_5+Gx_6$
S= α+ β1 (PC) + β2 (PF) + β3 (FD) + β4 (PM) + β5 (PS) + β6 (BSH) .747+.179PC+.154PF+.267PD+.306PM-.199PS+.113PSH

The coefficient table shows that there are two independent variables has an impact on the “consumer buying behaviour” variable which are the design of wrapper (sig. = .042) and packaging material (sig. =.020), but other independent variables have no impact.

Discussion

Packaging colour results from the study have presented that there is no impact of this variable on the “buying behaviour of customers” (r = 0.179). This means that the packaging factor is not an important factor to affect the decision of the consumer to purchase the product in the food industry in Jordan and hypothesis 011 is accepted. In comparison with previous researches, the results in Jordan are not the same because they revealed that there is an important and strong impact of the colour of packages on “consumer buying behaviour”.

The findings of this study for packaging font represented a no impact of this factor on the dependent factor (r = 0.154). Therefore, hypothesis 013 is accepted. When these results compared with other scholars results in other countries than Jordan, it seems that there is a huge difference between them because their results revealed that the impact of this factor on “consumer buying behaviour” is positive.

Wrapper packaging design findings in this study presented that there is an impact of the design of food packs on “consumer buying behaviour” (r = 0.267) which indicates that hypothesis 014 is rejected. The previous studies revealed in the positive impact of wrapper packaging design on the “consumer buying behaviour”, the same as this study.

For packaging material, the findings were positive and there is an impact of this factor on the dependent factor (r = .306). Therefore, hypothesis 012 in this study was rejected. There is a similarity between this research that has been done in Jordan and other researches outside Jordan; they all found that the packaging material is a strong factor to impact positively on “consumer buying behaviour”.

The packaging information factor results are less than zero (r = -0.199) which means that there is no impact of this factor on “consumer buying behaviour” for food products in Jordan, in comparison with other countries based on scholar researches, there is a huge hole between them because previously studied in outside Jordan showed that there is a big impact of this factor on the “buying behaviour of consumer”. Therefore, hypothesis 015 is accepted.
Hypothesis 016 is accepted because there is no impact of innovation on “consumer buying behaviour” when they buy food product (r = 0.113). Studies that have been discussed in the literature review of this paper said that there is an impact of this factor on the dependent one, which makes somehow an opportunity to make more studies for the reason behind this.

After finding that there is a significant impact of two factors (packaging material and packaging design) included in this study, the researcher discovers that there is an impact on the "buying behaviour of consumer" in the food industry in Jordan (r = 0.674). Therefore, hypothesis 01 is rejected.

Conclusion

The study took place in Jordan to see if there is any impact on "consumer buying behaviour" by different elements in food product packs. No study in Jordan shows this impact. Therefore, this study has been done. The study has investigated the factors depending on the previous studies, and depended on six variables from different studies ("packaging colour ،packaging material ،printed information ،font style ،design of wrapper, innovation") the questionnaire was designed based on these variables and distributed to a sample consisted of 100 individuals, (SPSS) software was used to analyze the data. The study reached that product packaging has a clear influence on "consumer buying behaviour". The material of packs and the wrapper design has an impact according to the findings of this research, the influence of the independent variable was by (45%) this indicates that other factors are influencing "consumer buying behaviour" other than the variables that have been included in this research and these should be searched for and do research including them, there is the need for more interest-in packaging material and design of wrapper in the food industry because of the extent of their influence on "consumer buying behaviour".

Recommendation

- Researchers advise the companies and the units of marketing in the food industry to care about different elements in their products packs.
- Companies producing the food products are advised to pay more attention to packaging two elements; packaging material and packaging design of wrapper because of their effect on consumer buying behaviour when he buys food products. Also advised to set a strategy for packaging the products in the food sector and care about that.
- Among the other recommendations in the food industry, the packaging is not considered the single element influencing consumers' buying behaviour since other important elements need to be investigated and studied.
- The next step in this research field for future researches is to include more elements of packaging.

The Scale and Structure of the Online Gig Economy

Izabela OSTOJ

University of Economics, Katowice, Poland
izabela.ostoj@ue.katowice.pl

Abstract

The gig economy is a part of the platform economy, mediating the transactions of labour services. The online gig economy is its important element. This segment is experiencing global growth, crossing national borders. This leads to the emergence of markets that can be analyzed traditionally – both in terms of types of work performed and in terms of countries where contracts for labour services and bids from contractors originate. Their development can be monitored using data from the Oxford Internet Institute. The article aims to assess the scale and structure of the online gig economy. The analysis revealed the leading role of the USA on the demand side and its important position on the supply side, which is dominated by crowdworkers from Asia. In terms of types of activities, the global online gig economy is growing in the area of software development and technology the most dynamically.

Keywords: Digital Platforms, Gig Economy, Online Labour Index.

Introduction

The segment of the economy referred to as gig economy has been growing for the last decade. Nowadays, it is associated with the process of instantenous adjustments of many independent contractors to the demand for services through a specially created digital technological platform, which also regulates pay for jobs performed (Stewart and Stanford, 2017; Lepanjuuri et al., 2018; Hunt and Samman, 2019). Digital platforms act as intermediaries in the delivery of services online or offline. The first platforms operating in this way were Amazon Mechanical Turk for services provided online and Uber for services delivered offline. Their relatively short presence in the economy led to the emergence of a new segment of the economy and labour market. By the end of 2019, about 30 platforms operating either on a global scale or locally, but modelled on the global idea, were identified (Schwellnuss et al., 2019). The very term gig economy was coined earlier, during the 2007+ crisis, and referred to any occasional, task-based work, especially with payment for individual jobs, which emerged at that time (Minter, 2017; Cambridge Dictionary), but with the advent of digital platforms acting as intermediaries coordinating demand and supply, its narrower meaning was adopted in literature.

The growth of the gig economy has changed the character of the modern labour market. The possibility of crossing national borders for requesters and crowdworkers operating in the online gig economy became one of its important characteristics. It was then that studies into the emergence of the planetary labour market were initiated (Graham and Anwar, 2019). This new segment of the labour market is relatively underresearched. The article aims to assess the structure of the market of the online gig economy defined as a process within which labour services provided online are offered and acquired via global specialized digital platforms. This was achieved by identifying the countries or regions playing a major role on the demand side in different parts of this market according to the types of activities, as well as the main players on the supply side, i.e. those who deliver services. The Online Labour Index (OLI) and the data from the Oxford Internet Institute (OII) were used.

The online gig economy as the segment of the platform economy – literature review

Digital platforms constitute the basic element of the platform economy. Each digital business platform aims to directly or indirectly mediate between the parties who wish to complete a transaction. Parker et al. (2016) defined the platform as a business facilitating value creation through interaction between external producers and buyers, whom the platform provides with and an open, participatory infrastructure, which, at the same time, it also manages. The primary goal of the platform is to build conditions for the exchange of goods or services, thus creating value for all its participants. The platforms that intermediate in the exchange of services are growing particularly dynamically.

Stewart and Stanford (2017) proposed several classifications of digital platforms. In terms of the function of the platform, they identified: 1) matching platforms, i.e. platforms that allow contact between the parties to a transaction, e.g. buyers and sellers, or contractors and service users, 2) platforms that allow information analysis and sorting (e.g. referrals or reviews), 3) platforms that allow adding new value, as is the case of online work. Additionally, they distinguished the following platforms according to the subject of intermediation: 1) labour platforms, intermediating the performance of labour services (which are the basis of the gig economy); 2) capital platforms, intermediating the rent or sale of assets. They form the platform economy (Farrell and Greig, 2016; Radonjic-Simic and Pfisterer, 2019).

Based on the results of the studies conducted by Stanford (2017) and Florisson and Mandl (2018), several major characteristics can be attributed to platform-mediated work:

- contractors are mainly motivated by end users, usually consumers, sometimes firms; they imply a triangle of mutual relationships: contractor – end user – intermediary platform;
- the service is commissioned (contracted) by the buyer (company or consumer);
- a paid task is organized through the platform and often breaks down into separate subtasks;
- work is performed in response to the current demand; contractors work when their service is acquired quickly, with no guarantee of continuity;
- work is remunerated exclusively for single performed tasks and when it is approved by the buyer; payment corresponds to an individual effect, such as an activity, a task or a product, and usually does not depend on the time involved;
- contractors are responsible for equipping their own workplace, which applies both to the place where the service is provided – a flat – and other elements of equipment such as a telephone or a computer;
- the platform acts as an intermediary in commissioning a task, evaluating its performance and handing its outcome over to the end user, as well as paying out remuneration.

Howcroft and Bergvall-Kåreborn (2019) proposed a model typology of crowdwork platforms, distinguishing four types according to the actor initiating the performance of a service and the stability of payment. The first type offers online paid work performed at the request of the buyer; tasks are modular, they can be microtasks forming a part of larger projects, addressed to the waiting crowd, a classic example is the MTurk platform; it is the most common type of platforms for the provision of labour services. The second type combines the idea of work and entertainment. Work is initiated by the requester, while the concept assumes that it is possible to combine pleasure, creativity and autonomy and cross the borders between them if work can also be treated as a type of leisure. This work can be paid, but it also helps workers develop their skills. Threadless.com is an example of such a platform, as its platform community together creates unique T-shirt projects. Another one is InnoCentive.com, which mediates discussion and solving of a variety of research and practical problems (e.g. in the field of software development), where contributions to a solution are rewarded with money. The third type includes platforms for mediating offline services that are provided for remuneration and within a limited territorial scope. The initiating actor is the crowdworker in the sense that he prepares the assets necessary to deliver the service and declares his readiness to work,

usually via a relevant app. This is often referred to as the hiperoutsource model and it informs such platforms as TaskRabbit or Uber. The fourth type mediates the provision of online services by highly skilled freelance professionals. The initiating actor is the contractor, who makes a bid, while payment is difficult to predict and uncertain. These services include, for example, the development of mobile applications for Apple or Google platforms or those offering extensive collections of photographs, such as iStockphoto. The platform collects bids and provides access to a customer base, distribution and marketing on a global scale, which are not available outside the platform. The rate is not fixed in advance, but when a buyer expresses interest.

The typologies of platforms correspond with the classification proposed by Bogenhold et al. (2017), who distinguished: 1) platforms for online work – performed by crowdworkers, including freelancers; 2) platforms mediating offline services – performed by those working on demand via apps, but delivered in the traditional way, outside the Internet (De Stefano, 2016).

Platforms that intermediate labour services have already attracted intensive research, focusing mainly on their impact on the quality of work (Kessler, 2018; Prassl, 2018, Ravenelle, 2019; Hoang et al., 2020). The key issues remain the conditions in which work is performed and the extent to which competition between crowdworkers is possible, especially price-driven competition. This, in particular, concerns offshorable services, which can be delivered remotely without an adverse effect on their quality (Author, 2013).

The online gig economy is therefore a key element of the platform economy in the part concerning labour service transactions. Online services provided via platforms are of particular importance to the development of a global, or so-called planetary, market in which orders and services are formed irrespective of national borders (Graham and Anwar, 2019). Gradually, its structure is taking shape, with its main actors, sources of competitive advantage and the characteristics of the online gig economy revealed, which makes a worthwhile research proposition.

Methods

The evaluation of the structure of the market of the online gig economy was carried out based on the OLI indicator, developed in the OII, and partial data collected in the process of observation of its changes. Platforms mediating online work are defined here as enterprises via which the service provider and its end user conduct a transaction entirely digitally, so both the order is placed and the service (e.g. a project) is delivered online by the platform, moreover, payment is also regulated this way, so is the final product received (Kassi and Lehdonvirta, 2018). Based on observations and initial measurements of the performance of most types of activities (from the so-called piecework to projects completed by freelancers), the authors of the indicator selected a representative sample of five platforms: Upwork.com, Freelancer.com, Mturk.com, Peopleperhour.com and Guru.com. They identified the following types of activities and corresponding sample areas of tasks and projects (Kassi and Lehdonvirta, 2018): 1) software development and technology (data science, game development, mobile development, QA and testing, server maintenance, software development, web development, web scraping); 2) creative and multimedia (animation, architecture, audio, logo design, photography, presentations, video production, voice acting); 3) clerical and data entry (customer service, data entry, transcription, tech support, web research, virtual assistant); 4) writing and translation (academic writing, article writing, copywriting, creative writing, technical writing, translation); 5) sales and marketing support (ad posting, lead generation, search engine optimization, telemarketing); 6) professional services (accounting, consulting, financial planning, legal services, human resources, project management).

The OLI-based measurement has been conducted since 3 May 2016. The indicator was constructed and standardized in such a way that 100 points mean the average daily number of new orders placed online in May 2016, i.e. the month when the measurement was first made. Therefore, the assessment of changes in the size of the online gig economy is relative and is performed with reference to the value described above as the base one, while changes can also be expressed as a percentage. The

indicator is presented on the Oxford Internet Institute website so that its level can be observed by country of origin of the order, as partial components of the indicator.

To assess the scale and structure of the online gig economy, the data concerning different aspects of the OLI indicator were used, including data on orders and bids by types of activity, countries of origin, or world regions. The author calculated the market shares of its participants on the demand and supply side by countries and regions as well as by types of tasks, which allowed her to create rankings. The Oxford Internet Institute repository was also used to present the actual number of countries of origin of crowdworkers. The examination of the structure of the online gig economy adopted the date of the initial observation period – 19 September 2016 – and the dates of late February and early March 2020, a period when the long-term effects of the pandemic were not yet experienced and the indicator remained relatively stable, since the aim was to identify the permanent characteristics of the global online gig economy.

Results

The scale of the online gig economy

Adopting the OLI indicator at 100 on the first day of measurement, i.e. 3 May 2016, we could observe an increasing trend on an annual basis, but also its high volatility in particular months or even days. Taking into account the more stable version of OLI, i.e. a 28-day rolling average over the 7 days preceding the selected date, the peak levels in subsequent years were recorded in the weeks prior to 20 May 2017 – 139.9 points, 12 March 2018 – 137.8 points, 12 April 2019 – 139.7 points, 16 May 2020 – 172.3 points, which means that the indicator was approx. 40%-70% higher than at the initial measurement. The indicator recorded the lowest values for subsequent years during the weeks prior to 7 January 2017 – 96.7 points, 11 January 2018 – 108.5 points, 11 January 2019 – 109.7 points, 9 January 2020 – 120.1 points, so generally even in the weakest periods, usually at the beginning of the year, it was higher than the initial level in 2016 and in the preceding year.

During the COVID-19 pandemic, which spread globally in March 2020 and affected most regions most dramatically in April (with the exception of China, where this happened about 1-1.5 months earlier), the OLI indicator initially recorded a slight drop from 150.1 points to 131.3 points in the period of 10 February 2020 to 7 April 2020 (on average within 7 days from a given date). By mid-May the indicator recorded an increase to its maximum for the entire period of measurement, as it reached 172.3 on 16 May 2020. It can be assumed that the initial drops were associated with the pessimistic assessment of the future condition of the economies and a decrease in economic activity in most countries; later on, despite the overall economic downturn, the importance of remote work and orders delivered remotely increased, so it can be assumed that some companies and contractors made wider use of platforms mediating online services in their business activity and it is possible that the trend will continue due to a growing awareness of the risks associated with similar random events.

The characteristics of the demand side

An important breakdown in the analysis of the demand side of the online gig economy is the origin of orders by country. Table 1. shows the rankings of the twenty countries playing the most important role in generating online orders as of 19 September 2016 and 25 February 2020. The first five positions additionally include the share of the countries in the total number of orders for online services.

Table 1: The first twenty countries by the origin of orders for online services

19 September 2016	25 February 2020
USA (52%)	USA (41%)
United Kingdom (6.3%)	United Kingdom (8%)
India (5.9%)	Australia approx..(6%)
Australia (5.7%)	Canada (approx..6%)
Canada (5%)	India (approx. 6%)
Germany	Germany
Singapore	Singapore
Hong Kong	UAE
Philippines	France
Spain	Israel
France	Netherlands
Brazil	Pakistan
Izrael	Saudi Arabia
Switzerland	Switzerland
UAE	Spain
Belgium	China
Norway	Hong Kong
Malaysia	Russia
Denmark	Italy
Ireland	Ukraine

Source: own elaboration based on the Oxford Internet Institute data.

Apart from the USA, which plays a leading role by generating about half of demand in this market, the next five countries had a share below 10%, while the rest just about 1% or less. The rankings show a certain reshuffle among the countries generating the most orders via online platforms within a few years of the initial measurement date. New European countries joined, but in some cases (Russia, Ukraine) this may be related to the implementation of the intermediary model, while other countries, such as Denmark, Ireland or Norway, dropped out of the ranking. On the other hand, Australia, Canada, the AUE, and Israel grew in importance. This shows the emergence of a new balance of power, in which both the most developed countries and emerging economies play a role, although the major actors do not change.

Another important breakdown of the structure of the global online gig economy is presented by type of activity grouped in main categories. Initially, the OLI indicator showed the structure of demand by the type of tasks in the following way: approx. 36% of all ordered services were jobs related to software development and technology, less than 20% involved creative and multimedia tasks, approx. 17% – writing and translation, approx. 13% – clerical and data entry, approx. 9% – sales and marketing support, while professional services accounted for less than 5%. More than half of the orders came from the USA, approx. 16% – from Europe (as of 19 September 2016 according to OII data). Table 2. presents the structure of orders by type of activity and a share in their markets, the five leading countries in terms of ordering online services or their larger groups by continent as of 28 February 2020.

Table 2: A share of the five leading countries and groups of countries in terms of a number of orders for online services by type of activity in % (28 February 2020)

Type of activity and a share in the structure of services	USA	Other Europe	Other Asia and Oceania	United Kingdom	Canada	Australia	India	All Africa	Other Americas
Software development and technology (43%)	40.8	14.6	11.3	7.9	6.3	5.0	7.9	3.2	2.0
Creative and multimedia (20.5%)	44.1	13.5	10.7	8.1	7.2	8.0	4.4	2.7	1.0
Writing and translation (13%)	31.6	23.6	14.6	8.8	5.8	4.4	6.2	3.3	2.0
Sales and marketing support (12%)	45.4	12.6	10.2	9.0	7.6	6.9	5.1	2.2	1.0
Clerical and data entry (8%)	48.3	14.2	10.0	8.3	6.6	7.0	2.9	1.6	1.0
Professional services (3%)	46.0	12.2	11.1	9.0	6.8	5.8	4.2	3.1	2.0

Source: own elaboration based on the Oxford Internet Institute data.

The data show that software development and technology continued to hold the largest share, which increased further compared to the initial period. Sales and marketing support also grew in importance. The USA had the largest share of orders for online services in all the markets by type of activity, with a clear advantage over the "Other Europe" group; the positions of particular countries according to their share in all groups of activities were similar, only India had a higher position (5th) in the first and third category of activities than in others. The advantage of the USA is particularly visible compared with other individual countries included in the ranking, as their market shares were below 10%, i.e. several times lower.

Table 3. shows the structure of demand for online services delivered via platforms, reported from the main five countries or groups of countries – participating in the segment, by type of activity as of 28 February 2020 (their share approximated to the nearest whole number).

Table 3: The structure of demand for online services in a country/region of their origin by type of activity (%) (28 February 2020)

Country or group	Software development and technology	Creative and multimedia	Writing and translation	Sales and marketing support	Clerical and data entry	Professional services
USA	42	22	10	13	10	3
Other Europe	41	19	20	10	8	2
Other Asia and Oceania	43	20	17	11	8	3
United Kingdom	41	20	14	13	9	3
Canada	41	23	11	14	9	3
Australia	40	26	9	13	9	3

Source: own elaboration based on the Oxford Internet Institute data.

The structure of demand for services delivered via online platforms in all the countries and regions was dominated by orders for software and technology development; orders from India had by far the largest share. In Australia, on the other hand, creative and multimedia orders were relatively important, while writing and translation orders ranked highest in the European countries (except the UK). Orders for sales and marketing support came, to a slightly larger extent, from the UK, Canada and Australia.

The characteristics of the supply side

In some areas, phenomena measured by the OLI indicators are explored more comprehensively. This concerns in particular the number and structure of crowdworkers. The measurement is conducted on a periodically selected sample of contractors from the four main – for the survey – platforms intermediating online services, namely: Fiverr, Freelancer, Guru, and PeoplePerHour. Activity is recorder for each platform once a day, according to the country of origin of each contractor, type of activity and potential participation in a project. In the measurement, each contractor was treated as "currently active" if he performed tasks during at least the previous 28 days, which reduced fluctuations in a small sample. In 2018, approximately 3.5 million contractors were registered on the four platforms under examination. Out of this number, about 100,000 contractors worked at least once a week. The authors of the measurement concept assume that on a global scale these numbers are at least twice as high (Kassi, Lehdonvirta, 2018).

An important characteristic of the supply side of the online service market is the location of crowdworkers. The origin of contractors by type of tasks performed points to their irregular distribution around the world. Online work involving software development and technology definitely dominates worldwide, which is particularly clear in North America, Asia, Australia and parts of Eastern Europe. On the other hand, in South and Central America and some Western European countries (France, Spain, Finland) writing and translation are the main services provided, while creative and multimedia projects are important in South America, Algeria, Sweden; sales and marketing support dominate in Iceland, the UK, Germany, Norway and Morocco. Accordingly, particular activities can be mapped out in terms of their prevalence, with a definite advantage of software development and technology on a global scale (OII data).

Table 4. shows the rankings of countries with the highest number of online contractors as of 19 September 2017 and 02 march 2020. The share in the total number of online contractors was additionally given for the countries in the top positions. Contractors from other countries accounted for less than 2%.

Table 4: Leading countries by the origin of online contractors (%)

19.09.2017	2.03.2020
India (24%)	India (35.5%)
Bangladesh (15.5%)	Bangladesh (12%)
USA (12%)	Pakistan (11%)
Pakistan (8%)	USA (6%)
Philippines (6.5%)	United Kingdom (4%)
United Kingdom (6%)	Philippines (3%)
Ukraine	Ukraine
Canada	Russia
Romania	Indonesia
Egypt	Sri Lanka
Germany	Egypt
Russia	Australia
Kenia	China
Nigeria	Canada
Italy	Kenya

Source: own elaboration based on the Oxford Internet Institute data.

In both readings contractors from India ranked first. Their share increased compared to the first measurement date, so they further strengthened their dominant position. Bangladesh ranked second, yet their share decreased, as was the case of the US and the Philippines. Pakistan's share went up, so did Russia's and Sri Lanka's. The dominance of Asian countries was reinforced. New countries that found their way to in the second ranking were Indonesia, Australia and China. Countries such as Germany, Italy, Romania and Nigeria dropped out.

Table 5. shows the structure of contractors by type of activity in total and by continent.

Table 5: The share of online contractors from particular continents by type of activity

(2 March 2020)

Type of activity and a share in the total number of contractors	Asia	Africa	Europe	South America	North America	Oceania
Software development and technology (39%)	79.0	2.5	10.5	1.6	5.3	1.0
Creative and multimedia (32%)	72.2	3.2	12.7	5.6	5.1	1.2
Writing and translation (10%)	41.5	14.9	16.6	2.2	20.7	4.1
Sales and marketing support (10%)	68.7	2.1	17.5	1.5	9.5	0.8
Clerical and data entry (5%)	73.5	2.2	6.1	2.6	14.8	0.8
Professional services (4%)	38.4	4.7	31.5	0	24.2	1.2

Source: own elaboration based on the Oxford Internet Institute data.

The first two categories of crowdwork dominated among online contractors. In all groups of activities contractors from Asia had the largest share. On the other hand, contractors from Europe also held a significant position particularly in professional services, and so did crowdworkers from North America, especially in the area of writing and translation. The distribution of contractors by type of activity between the continents can be interpreted as very uneven. Service providers from South America and Oceania have the lowest share in all types of activities in the online service market globally.

Table 6. presents data on the share that contractors hold in the market by type of activity in the fifteen countries (TOP-15), ranking highest in terms of the number of online contractors.

Table 6: The structure of online contractors by type of activity in TOP-15 countries (2 March 2020)

Country	Software development and technology	Creative and multimedia	Writing and translation	Sales and marketing support	Clerical and data entry	Professio-nal services
India	59	21	3	12	4	2
Bangladesh	19	54	7	11	9	1
Pakistan	41	31	12	7	5	4
USA	24	15	23	12	12	14
UK	17	17	15	27	2	23
Philippines	12	41	8	8	24	7
Ukraine	45	36	6	8	1	3
Russia	59	27	3	5	0	6
Indonesia	10	71	1	6	8	5
Sri Lanka	19	66	2	5	5	2
Egypt	33	41	18	4	1	3
Australia	31	29	28	6	3	4
China	82	10	3	3	1	1
Canada	28	23	32	7	4	6
Kenya	7	3	82	2	3	3

Source: own elaboration based on the Oxford Internet Institute data.

These figures show huge differences between the countries where most contractors originate from when it comes to what types of activities they specialize in, expressed as the share of particular contractors in the total number of crowdworkers in a given country. The dominance of software development and technology is strong in India, China, Pakistan, Russia and Ukraine. The creative and multimedia category is the domain of contractors in Bangladesh, Philippines, Indonesia, Egypt and Sri Lanka. Sales and marketing support have the largest share among contractors in the UK, so do professional services. Clerical and data entry contractors have a relatively large share in the Philippines. Writers and translators are the main category of crowdworkers in Kenya. In Canada, Australia, and the USA no single type of activity has gained prevalence. This shows that some countries of origin of crowdworkers in the online gig economy, especially the less developed ones, developed specialization in certain types of activities, while in the most developed countries do not seem to specialize in one particular type of activity.

According to a reading from the Online Labour Index repository containing complete data on the number of contractors from all the countries whose activity was recorded on the platforms included in the project, crowdworkers from 133 countries were active on 24 February 2020.

Discussion

Graham and Anwar (2019) argue that the online gig economy is an imperfect planetary labour market because of incomplete access to information for workers. This does not change the fact that a new market is emerging. The balance of power on the demand and supply side, as presented above, determines the price of services and payment for workers. The scale and types of jobs are decided by buyers, usually enterprises, from the USA; they benefit from reduced labour costs. As estimated by Cherry (2016) and Rogers (2015), a shift from hiring employees to engaging independent contractors has reduced US labour costs by about 30%. The average hourly rate is about 2 euros, while pay for small jobs at Amazon Mechanical Turk, which is settled on a monthly basis for work of about 20-40

hours per week, ranges from 200-750 euros, which is very low (De Stefano, Aloisi, 2018). The supply of labour services is dominated by crowdworkers from Asia. This has an impact on the overall low level of pay for services, which is the result of oversupply of labour services for many platforms and workers' consent to undercut rates. De Groen and Maselli (2016) give the example of a rate for low-skilled worker of Amazon Mechanical Turk, which was lower than the minimum wage in the USA (it accounted for 74% of this amount at that time), yet still it was fourteen times as high as in India. Profit for the platform is estimated at 10-20% of the value of each transaction (De Stefano and Aloisi, 2018). The findings of the above analyses can be treated as preliminary, requiring the adaptation of research methods to the global scale of the market and significant dispersion of requesters and crowdworkers.

Conclusion

The results of the analysis reveal that in the online gig economy the USA plays the leading role on the demand side and an important, but not dominant, role on the supply side, which can be considered obvious given the origin of digital platforms. Demand for online services is generated mainly by highly developed countries. In the ranking of crowdworkers by country of origin, the first seven positions have not changed since 2016. The Asian countries dominate, while the USA and the UK are the only highly developed countries in the top 10. The specialization of crowdworkers from particular countries is becoming clear, especially software development and technology in India and China, creative and multimedia tasks in Bangladesh and Sri Lanka, writing and translation in Kenya. On the other hand, the most developed countries follow a different trend and tend not to develop specializations. As different types of activities form separate markets, the situation in these markets, including pay rates, will be influenced by workers from these countries. The dominance of Asian crowdworkers determines the low level of payment for services, which becomes a problem for those who earn their living in this market.

Abstract

The article has theoretical and empirical character. Its aim was to identify the importance attributed by purchasers to good mutual relationships with offerors and to identify the importance of the perception of offerors as entities listening to purchasers' opinions and profiting from purchasers' spontaneous willingness to cooperate with offerors. The results of the cognitive-critical analysis of the world literature indicate a cognitive and research gaps. In order to reduce them, empirical studies were conducted. The survey method was used to gather primary data. The collected data were subjected to quantitative analysis (including statistical analysis methods). Between the importance attributed to good relationships with offerors and the perception of them, a statistically significant relationship was identified for each of the three analysed groups of offerors. The perception of offerors turned out to be a feature differentiating respondents' opinions on the importance of good relationships with offerors for producers and traders. The perception of offerors turned out to be a feature differentiating forms of prosumer activity undertaken by the respondents for three behaviours of an inter-purchase nature. The results obtained have a significant cognitive and applicability value because the aspects presented in this article have not been analysed so far.

Keywords: Offeror, Image, Relationships, Final Purchaser

Introduction

The contemporary consumer market can be defined as a relationship-based system, in which the quality of interaction is largely determined by the perception of other entities. Relationships between final purchasers and offerors acquire an exceptional importance in this system. No offeror could function without purchasers exhibiting particular activities. Although the activities may be of different nature and scope, ranging from typical purchase, through communication to creation, each of its manifestations affects the activity of an offeror as it can either contribute to the development of offerors or constitute a destructive factor for their further market activity. The fact whether the activity will support the development or not depends to a large extent on the following factors: 1) the manner of assessing mutual relationships by purchasers, 2) the perception of offerors in various market roles, including the role of knowledge user and the spontaneous creativity of final purchasers.

On the base of the results of the world literature analysis, which are presented in the further part of the article, one can state that the dependencies between the two categories have not been analysed so far, and no attempt has been made to investigate the significance of the categories in relation to the extra-purchase activity of final purchasers. So there are cognitive and research gaps in this area.

That's why the starting point for the considerations presented in this study is the following research problems: 1/how do purchasers assess mutual relationships with offerors?; 2/how do they perceive offerors' activities as regards listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate?; 3/how significant is the perception of offerors as a factor shaping the prosumer activity of purchasers?

To solve these problems the aim of the study was to identify the significance attributed by purchasers to good mutual relationships with offerors and to identify the importance of the perception of offerors in relation to the specificity of the prosumer activity of final purchasers.

Literature Overview

Establishing a particular relationship with another entity is tantamount to entering into closer interaction with it, which allows a better understanding of it, each time associated with the acquisition of particular market experiences (Schmitt, Brakus, Zarantonello, 2015). This leads to specific arguments for a particular way of perceiving the entity, which results in its image. Of course, the perception does not have to be a consequence of one's own experience gained as part of a relationship with the particular entity. It may also be based on opinions provided by other people (Cheung, Thadani, 2012).

In relation to offerors, a particularly important role is played by opinions of people with authority (Litterio, et al., 2017) and people who set some trends. A purchaser's own experiences which accompanied him/her during previous contacts with a given offeror and were the consequence of these contacts are also significant. The sources of a specific attitude towards an offeror may therefore be internal or external. The attitude is characterized by two determinants (Maciejewski, 2018): mark and strength. As for the first determinant, one can speak of a positive, negative or indifferent attitude. In the case of the second determinant, a weak attitude and strong attitude are distinguished. The effect of a particular attitude is the perception of an offeror, leading to their specific image. In the case of a positive attitude, the image will be rather good, and in the case of a negative attitude it will be bad.

The image may be viewed in a wide or narrow perspective. In the case of a wide perspective, the overall image of an offeror is in question, whereas in the case of a narrow perspective, it is about the image of an offeror referring to the fulfilment of a particular market role, including the image of the supplier, the employer (Baruk, 2017; Moser, Tumasjan, Welpe, 2017; Coldwell, et al., 2008; Balmer, 2001), the social activist, that is a socially responsible enterprise (which is mentioned by Shwu-Ing Wu and Hsin-Feng Lin (2014); P. Mudrack (2007); S. Valentine and G. Fleischman (2008), etc.).

Each of the partial images determines the overall picture of an offeror, which is the resultant of these images. A good overall image is conducive to purchasers' behaviour favourable to the offeror. This applies to both purchase behaviour (re-shopping, more frequent purchases (Cachero-Martínez, Vázquez-Casielles, 2017), etc., and extra-purchase (expressing positive opinions, sharing ideas about products, etc.). In the case of the latter, a final purchaser becomes an active co-creator of positive material values (e.g. products) and / or intangible assets (e.g. image) which strengthen the marketing potential of an enterprise.

The literature on the subject rightly emphasizes that including all stakeholders in the process of joint value creation is the main factor of success (Grimonpont, 2016). This also applies to purchasers, without whom no contemporary offeror could effectively function. A bad overall image may lead to purchasers' behaviour unfavourable to the offeror, which concerns in particular purchase behaviour and communication behaviour. Not only can purchasers give up the purchase of products of a given enterprise, but they can also become active destructors (Bolton, 2016) of its potential, for example by giving unfavourable opinions about a offeror, which results in a deterioration of his image.

In the literature the focus is placed on the analysis of the overall image and the above-mentioned partial images, as well as on the image of the products offered by an offeror (among others Rijsdijk, Hultink, 2009; Petrescu, Petrescu-Mag, 2015). In the literature known to the author, however, the issues related to the perception of an offeror have not been analyzed so far through the prism of listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate. The significance of offeror image in this role has not been examined in the aspect of the importance attributed by purchasers to good relationships with offerors. The perception of an offeror has been mainly analysed as a determinant of purchase behaviour (Uddin, Parvin, Rahman, 2008; Hansen, 2005; Karmoker, Haque, Uddin, 2016), as a determinant of attitudes towards products (Karami,

Siahpoush, Olfati, 2013; Khan, Bamber, Quazi, 2012; Rodrigo, Khan, Ekinci, 2018), etc. The more so, the importance of the perception of offerors in the aforementioned role as a factor potentially differentiating forms of prosumer activity has not been examined. A simultaneous analysis of these issues in relation to three groups of offerors, that is, producers, traders and service providers, has not been conducted, either.

To reduce the cognitive gap and the research one the following research hypotheses were checked:

H1 - there is a dependence between the importance attributed to good relationships with offerors and the way they are perceived in relation to listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate;
H2 - the perception of offerors is a feature differentiating respondents' opinions on the importance of good relationships with offerors;
H3 - the perception of offerors is a feature differentiating forms of prosumer activity of purchasers.

Methodology

In order to check the formulated hypotheses, primary research was carried out in the third quarter of 2018 among 1,200 people representing Polish adult final purchasers. A total of 1012 completed questionnaires were qualified for statistical analysis. 61% of the surveyed population were women, which corresponded to the structure of the general population of adult Poles (http://www.polskawliczbach.pl/#ixzz4F3Nogl1N). Non-random selection of a quota-type sample was applied. The research was direct in nature, requiring the interviewer's personal contact with respondents. This made it possible to obtain a high return rate of completed questionnaires.

The scope of the research included: 1/the perception of offerors regarding their listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate; 2/the importance attributed to good relationships with three groups of offerors, that is, producers, traders and service providers; 3/15 forms of prosumer activity of final purchasers. These forms were selected on the basis of the literature analysis and on the basis of unstructured interviews which were carried out before the survey was completed. The use of the Likert scale determines the possibility of conducting a factor analysis.

The primary data were statistically analysed using the Pearson chi^2 independence test, V-Cramer contingency coefficient, Kruskal-Wallis test (KW), exploratory factor analysis. The statistical analysis was performed using the Statistica 22.0 package.

Research Results

In total over half of the respondents attributed at least great importance to good relationships with representatives of each of the three analysed groups of offerors (table 1). However, for each of them, a relatively high percentage of respondents believed that such relationships are of little importance or even completely invalid. This was particularly evident in relation to producers, in the case of whom over 41% of respondents considered good relationships to be invalid or of little importance. This percentage was more than 10% higher than for traders and service providers. This may have resulted from the specificity of contacts with each of the analysed groups of offerors. Purchasers' contacts with producers in practice are much less of a personal nature than in the case of contacts with traders and service providers. The percentage of indications reflecting little importance attached by respondents to good relationships can, however, be considered high also for these groups of offerors. Perhaps this results from the not very good perception of offerors when it comes to listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate. As many as 60.8% of all respondents believed that offerors do not listen to purchasers and do not want to take advantage of purchasers' expressed willingness to cooperate. Therefore, it seems worth analysing the importance of respondents' opinions about offerors in this regard in relation to the role attributed to respondents by good relationships with offerors.

Table 1: The dependencies between the significance of good relationships with offerors and the perception of offerors in relation to offerors' listening to purchasers' opinions and taking advantage of purchasers' spontaneous willingness to cooperate

The importance of good relationships with offerors		Offerors' listening to purchasers' opinions and taking advantage of purchasers' spontaneous willingness to cooperate (in %)				Total (in %)		Chi^2 test value	V Cramer contin-gency ratio	Level of signifi-cance 'p'
		yes		no						
with producers	totally unimportant	6.0	35.7	8.6	44.5	7.6	41.1	11.107	0.105	0.011
	of little importance	29.7		35.9		33.5				
	important	44.1	64.3	41.7	55.5	42.6	58.9			
	very important	20.2		13.8		16.3				
with trader	totally unimportant	3.0	22.9	5.0	31.3	4.2	28.0	8.981	0.094	0.030
	of little importance	19.9		26.3		23.8				
	important	52.9	77.1	48.1	68.7	50.0	72.0			
	very important	24.2		20.6		22.0				
with service providers	totally unimportant	3.3	23.7	6.2	30.4	5.1	27.8	7.983	0.089	0.046

	very important	27.2		27.2		27.2				

Source: own study

Similarly to the results obtained for the total of the respondents, both among those who positively perceive offerors as well as those who perceive offerors unfavourably, the majority of respondents attributed at least high importance to good relationships with offerors. It can be noted, however, that the proportion of such indications was noticeably greater among the respondents who had a good opinion of offerors. This was tantamount to the fact that respondents who unfavourably perceive offerors attributed relatively less significance to good relationships with offerors. This was clearly visible for each group of offerors.

Results of chi-square test confirm a statistically significant dependence between the aforementioned variables for each of the three analysed groups of offerors. For each of them, the significance level 'p' had a value lower than the adopted limit value 0.05 (table 1). The H1 research hypothesis is therefore valid for the respondents. However, the dependencies are not strong, as evidenced by the low values of the V-Cramer contingency coefficient. Relatively the strongest dependence can be noticed in the case of producers, for whom the value of the coefficient is the highest. It is worth recalling that in relation to producers, the largest part of the respondents attributed little or no significance to good mutual relationships.

The KW test was carried out in order to check possible differentiation between respondents' opinions on good relationships with particular groups of offerors according to their perception. Statistically significant differences occur for two groups of offerors (producers and traders). It is relatively larger in the case of producers. The difference wasn't identified in relation to service providers. The hypothesis H2 turned out to be valid for manufacturers and traders.

In the next stage of the research process, 15 forms of prosumer activity reflecting communication and creation behaviours were analysed. Statistically significant difference was identified for 4 forms of activity (table 2). Three of them had the nature of communication behaviours undertaken in the context of relationships with other purchasers (that is, as part of inter-purchase prosumption),

whereas one activity consisted in independent manufacture of products, which did not require entering into relationships with other entities. Statistically significant differences were not identified in relation to any form of activity undertaken as part of the relationship with offerors. The hypothesis H3 for respondents can be considered valid only for the aforementioned forms of activity.

Table 2: The significance of differences between respondents' answers regarding the demonstration of selected forms of prosumeric activity according to the perception of offerors related to listening to purchasers' opinions

Analysed forms	Sym-bol	Offerors' listening to purchasers' opinions	KW test value	Level of signifi-cance 'p'

Aiming to identify and compare the internal structure of the forms of activity undertaken by the respondents, a factor analysis was carried out for the total of the respondents as well as for the respondents who positively perceive offerors and for those who perceive them in a different way. On the basis of the Kaiser criterion, in each case 4 factors with an eigenvalue exceeding 1 were separated. The first factor explains over 45% of the total variability of the studied phenomenon both for the total of the respondents and for the respondents who positively perceive offerors and those who perceive them negatively. It is worth adding that in each case, the first and second factor together explain significantly more than half of the total variability. Variables having factor loadings with the value of at least 0.7 were taken into consideration (table 3).

Source: own study

In the case of variables such as people's attitudes and behaviours, the factors distinguished in the factor analysis method can be interpreted as referring to segments of people (Horn, Huang, 2018). For each of the three studied groups of respondents segments can be identified, whose representatives show analogous forms of prosumer activity (table 4).

Discussion

The results of the research conducted indicate that the majority of the respondents negatively evaluated offerors as entities listening to purchasers' opinions and taking advantage of their spontaneous willingness to cooperate. Although in the literature on the subject attention is drawn to a new business model based on the inclusion of purchasers as active contributors to the process of value creation (Dellaert, 2019; Sundararajan, 2016), the feelings of purchasers themselves deny the practical application of such an approach by many offerors. It is all the more worrying that offerors should constantly search for new ways of satisfying the growing expectations of purchasers by providing them with valuable values. This allows offerors to gain a competitive advantage (McAfee, Brynjolfsson, 2017). One of such values, which are difficult and even impossible to copy by other enterprises (Wernerfelt, 2014), is building and strengthening good mutual relationships. The formation of relationships turned out to be at least important for the majority of respondents, especially for those who positively evaluated offerors in the role, and moreover, statistically significant dependencies between the two analysed variables were identified.

The results of this research indicate that key segment of respondents distinguished for each of the three analysed groups includes people undertaking prosumer activity both on the Internet and beyond. The second group in each of the three cases, in turn, includes people with off-network activity. This confirms, therefore, that communication and creation behaviours are undertaken not only on the Internet, but also in the real world, and in the case of inter-purchase activity, behaviours undertaken in the real world are relatively more important than behaviours undertaken in the virtual world. Therefore, many authors' highlighting the fact that prosumer activity is undertaken only or mainly on the Internet was not confirmed (Frenken, Schor, 2017; Brodie, et al., 2013).

Another feature common for the representatives of the main segments selected for each of the three analysed groups of respondents is the fact that they are prosumers showing activity when inspired by offerors. The importance of attracting purchaser activity is also highlighted by other authors, including T. Haumann, P. Güntürkün, L. M. Schons and J. Wieseke (2015), or E. Martineau and Z. Arsel (2017), although the fact that the respondents negatively evaluated offerors in this respect indicates that offerors' actions are frequently not effective. The fact of identifying a group of respondents undertaking only inter-purchase activity may prove that the results obtained are part of the approach presented in the literature regarding the creation of values by purchasers for other purchasers (Grönroos, Voima, 2013). However, it does not take place only in the virtual world, for which it is often analysed (Chu, Manchanda, 2016), but also in the real world, as evidenced by the demonstration of prosumer activity by representatives of this group outside the Internet.

Conclusions

It can be concluded that the majority of respondents attributed at least great importance to good relationships with offerors. This was particularly evident in relation to traders and service providers. At the same time, over half of the respondents believed that offerors do not listen to purchasers' opinions and do not take advantage of their spontaneous willingness to cooperate, which is tantamount to the negative perception of offerors. Between the importance attributed to good relationships with offerors and the way they are perceived in the market role mentioned, a statistically significant dependence was identified for each of the three analysed groups of offerors. Hypothesis H1 turned out to be valid for the respondents.

In turn, the perception of offerors turned out to be a feature differentiating opinions on the importance of good relationships with offerors only for two groups, which are producers and traders. The H2 hypothesis is therefore valid only for both groups of offerors, and it is not valid for service providers.

The perception of offerors turned out to be a feature differentiating the form of prosumer activity undertaken by the respondents only for three behaviours of an inter-purchase nature. It can be said that hypothesis H3 in the case of respondents is valid only for these three behaviours. Both in the case of the total of the respondents, as well as in the case of the respondents who positively perceive offerors and those who perceive them negatively, four homogeneous segments were identified, and they were characterized by very similar differentiating features. In each of the three analysed groups, the relatively largest role was played by the group of respondents who can be described as prosumers inspired by offerors, showing activity on the Internet and outside it.

By reducing a cognitive gap, the results are a contribution to the theory of marketing and consumer research. They also have management and social implications. They can, among others, facilitate the development of good mutual relationships between offerors and final purchasers as important partners cooperating with offerors in the marketing process. As a result, it becomes easier to meet the growing expectations of final purchasers and to build a competitive advantage, difficult to imitate by competitors.

Conducted research has some limitations including: subjective scope (only adults), geographical scope (only representatives of adult Polish final purchasers), objective scope (selected forms of prosumer activity and one aspect of the perception of offerors). The pursuit to eliminate these limitations will guide the future stages of the research process, within which it is planned to extend the scope of research.

Abstract

Work performed in the building industry contributes to the formation of many threats for employees. Microclimate factors, working at heights as well as dangerous substances used in the building space may cause a negative impact on the worker's health. In order to evaluate the safety and comfort of work in the construction industry, a questionnaire consisting of closed and open questions was carried out. The aim of this paper was to assess the level of safety in the construction industry. The study was carried out on construction of buildings in the area of the Lower Silesia Voivodeship. A survey among construction workers was conducted. Based on the studies, a number of factors have been identified that affect the level of occupational health and safety at work. The functional relation between seniority, the employee's age and the length of breaks at work was determined. It turns out that a lack of sufficient breaks during construction works was the main reason for overloading of employees. According to the respondents, the most common symptoms of the neck and lower spine were related to the work performed. In connection with the above-mentioned circumstances, more effective methods of improving the organization and safety of work in this industry should be developed.

Keywords*:* building, load, muscle, safety

Introduction

The construction industry makes a large contribution to each country's gross domestic product (GDP) (Korkmaz et al., 2018). Work in the construction industry can be classified as one of the most dangerous professions (Ganah et al., 2015). The wide range of work carried out in construction means that many accidents are registered in this industry every year (Latza, 2000). Among the most common causes, organizational, human and technical factors were mentioned (Bust et al, 2005). Poor work conditions directly affect a level of occupational safety and satisfaction while performing the duties of construction workers. The specificity of the construction industry results from its diversity and conditions under which the work was performed (Haslam 2002). Safety is increasingly emphasized as an indicator of success in a construction project (Mahmoundi et al., 2014). Ensuring safety on a construction site is one of the most important elements of the entire project. In addition, providing an accident-free workplace on the level of occupational safety required the reduction of excessive physical and mental load among the employees (Hansson et al, 2004; Whysall et al, 2006). Current medical studies show that load on the musculoskeletal system is a common and social problem in many countries (Buckle et al, 2002). Many reports determine a wide scale of this problem and the causes of illnesses among manual workers (e.g. farmers) as well as white-collar workers Fabunmi et al., 2005). Musculoskeletal disorders are one of the most common health problems at work and affect millions of employees every year (Boschman et al., 2015). According to a study of the European Foundation for the Improvement of Living and Working Conditions in Dublin, the social costs incurred due to the reduction of diseases in the musculoskeletal system of employees amount to approx. 15% of the costs of accidents at work. It should be emphasized that about 33% of manual workers working in the European Union suffer back and spine pain, almost 23% of respondents complain about general fatigue, and about 13% feel overload of the hands. Employees in the construction industry were also surveyed (Jarosiewicz, 2006). In their case, the load on the musculoskeletal system may be higher by 16% compared to other professions (Boschman et al., 2015).

Due to the wide range of work performed by construction workers, repeatability of activities, uncomfortable body position and environmental conditions, construction workers are particularly exposed to musculoskeletal disorders (Stomberg et al., 2010). An important factor affecting the comfort and productivity of construction workers is the ergonomic factor (van der Molen et al., 2005). Proper employee awareness in the aspect of ergonomics lies primarily in the daily work with the use of tools, machines and devices that do not adversely affect comfort and safety at work. Ergonomics is an adaptation of the work environment in which a person works to his physical capabilities (Smith, 2015). It is mainly about designing working elements used on a daily basis to facilitate work as much as possible (Albers et al., 2005; Buckle, 2005). It is also important to reduce injuries as result of the use of construction tools (Sang, 2008). The disorders of the musculoskeletal system were described by (Bobick et al., 1995; Oude et al., 2011; Murphy et al., 1992) as a very serious social problem, which occurred in many professions. It was mainly observed in the construction industry, where employees were exposed to external loads (Bust et al., 2005; Latza, 2000). So far, many authors have described the methods to improve safety in the construction industry (Moir, 2000). Mobeda et al. (Mobed, 1998) paid special attention to the problem of seasonal workers working on US farms. Employees who lived in California often performed very hard work. They had low social status, often a lack of valid health insurance, and significantly limited access to professional healthcare. The work environment in relation to musculoskeletal disorders was described by the physical and psychological factors that accompany the generation of this group. The following elements are characteristic for many physical activities: high repeatability of arm and hand movements, uncomfortable body position during work and monotony of movements. In the Polish construction industry, over 1 million workers perform their tasks in an uncomfortable position, and about 0.6 million are exposed to high work monotony. Nearly 1.5 million are forced to carry heavy loads over distances of 10 m. From the presented results it follows that the scale of the occurrence of musculoskeletal disorders is high and therefore, as the authors suggest, more attention should be paid to the conditions in which people work. According to Occhipinti et al. (2007), musculoskeletal disorders may result from a performed task with high repetition frequency, accompanied by a small mass of the operated object. Marras and Schoenmarklin confirmed the thesis that, while performing

physical work with a high repetition frequency, a risk of wrist disorders occurs (Marras et al., 1993; Johnston et al., 2005; Sari et al., 2010; Osborne et al. 2007). The particularly high level of this risk concerns women. Particularly dangerous are loads resulting from lifting loads above the human shoulder line (Sluiter et al., 2001). Neck, back, arm and wrist strains are especially dangerous (Hales et al.,1994). Often disorders in the musculoskeletal system result in absence from work (Hansson et al., 2004; Oude et al., 2011; Roelen et al., 2007). They cause very high costs during the recovery of the employee (Szeto et al., 2009). In order to identify the causes of musculoskeletal disorders among construction workers more precisely, a survey was conducted in which the relevant information was obtained.

Methodology

This paper had qualitative and quantitative features, hence a standardized questionnaire was prepared to collect the needed information. The authors assessed the level of safety and comfort among workers who met some criteria while performing selected works in the building industry. These criteria included: working at least one year in this industry and performing a similar activity in this period. The total number of participants were 160 men. The study was conducted in the Lower Silesia Voivodeship (Poland) on four construction sites. During these studies the workers were asked e.g. about their age, work experience and type of workstation. Information received from the studies was used to develop work instructions and to creative preventive actions aimed at improving working conditions by reducing the possibility of hazardous situations in the work environment. The aim of the study was to determine the relationship between age, work experience of the workers and their suggestions regarding determining breaks at work. This approach can lead to improvements in effectiveness and safety during the working day.

The studies were conducted between May and November 2019 on basis of a prepared questionnaire, own observations and analysis of reports describing the health level of employees in the building industry. Main research problem in this study was to verify whether it is possible to improve work safety on the construction site. Prepared questionnaire included 17 questions (10 closed and 7 open). The collected items in the survey were: age, work experience, scope of tasks, effort and discomfort level, usability felt, complaints and disorders, time needed for rest within working day as well as body workload connected with a performed task. On the basis of the obtained data, eight groups of workers were selected: drivers (D), roofers (R), plasterers (P), carpenters (C), physical workers (Ph), machine operators (M), steel fixers (Sf) and pavers (Pa). Basic time at work was 8 hours.

An important issue of the studies was to obtain information from the respondents allowing the improving of working conditions and assessment of employee satisfaction obtained from daily work. On the basis of the collected data and relationships between age, work experience and time needed for breaks, an improved schedule of the working day was proposed. Each respondent was asked to assess a pain/dissatisfaction level (PDL) at work. Their evaluation ranged from '1' ("little pain") to '5' ("extreme pain"). Based on this information the (PDISSevalution) for each type of ailment was calculated. In square brackets, an average percentage of pain duration (PAINduration) during work shift was described. All participants were informed about the study aims, and they then declared their participation in this study.

For determining the breaks at work, the following procedures were used;

- For heavy work, the number of breaks should be greater than three during the working day,
- For one break, its time should be set about half of the working day,
- It is preferable to use more breaks, because the effectiveness of breaks decreases when their length increases.

The data were processed in Microsoft Excel. This program enabled the calculation of mean and standard deviation. The t-Student test was used to analyze the differences between workers' answers by means of the STATISTICA 12 program. It was assumed that the difference is

statistically significant where $p<0.05$ (p-value probability). The relationship between the effectiveness of surveyed workers on working time by means of the STATISTICA 12 program was calculated. The accuracy coefficient R^2 of the determined function was also determined.

Results

The structure of examined workstations was dominated by pavers (25%), steel fixers (21%) and machine operators (15%) (Table 1). The total number of surveyed workers was 160 men. The age of workers ranged from 20 to 60 years. Taking into account the age of workers, the most numerous group of workers were 30-39 years' old, as well as persons with experience between 2-9 years.

Table 1: Description of the surveyed workers

Number of workers									
	Age (years)				Work experience (years)			N=160

Table 2 presents disorders and complaints as the consequences of daily performed work by surveyed workers. A majority of the respondents indicated pains in the lower part of the spine as well as in the neck. The pavers reported nearly one third of symptoms among all questioned, whereas only nine of the drivers had experienced pain or disorders.

Table 2: Number of complaints reported by respondents. In brackets a mean pain/dissatisfaction level (PDISSevaluation) of the respondents was presented. In square brackets, an average percentage of pain duration ($PAIN_{duration}$) during the work shift was measured.

Type of aliments	D	R	F	C	Ph	M	Sf	Pa	Total numer of respondents

** respondents could indicate more than 1 answer*

On the basis of statistical analysis, it was found that the results including assessment between analyzed professions differ significantly from each other by p=0.0000004 ($p < 0.05$).

Assessment of body-posture load of the employees while performing selected activities in the building industry

Many different tasks performed during the working day as well as wide range of held postures was observed (Table 3). The most numerous workers held an uncomfortable bent and twisted position which resulted e.g. from laying paving stones (paver). The smallest group of men used a shovel during their work. Some workers maintained a different position during the working day; for instance they lifted heavy objects of various shapes and dimensions, while adopting an uncomfortable position, for instance standing or sitting without the possibility of changing body position.

Table 3: List of the tasks or workers' positions taken during working day

Task/Postures	**N**	**%**
Lifting	11	6
Pushing the object	4	2
Bending the torso	14	8
Digging with a shovel	1	1
Lifting heavy objects often in an uncomfortable position	6	3
Many hours work in a sitting position (without the ability to change position)	12	7
Many hours work in a standing position (without the possibility of changing the position)	10	5
Many hours work in the neck inclination	12	7
Many hours work in the kneeling position (without the possibility of changing the position)	11	6
Many hours work in the squat (similar position)	9	5
Frequent twist of the torso	17	9
Doing work in position with a bended or twisted torso	19	10
Work in a position with bend or pulled head	21	11
Work with arms raised above shoulder joints	8	4
Work with excessively bent or twisted wrists	18	10
Work with a high degree of repeatability (>5 times per minute)	11	6
Total	**184**	**100**

** respondents could indicate more than 1 answer*

Among the solutions that could reduce the level of disorders or complaints resulting from work activities, respondents most often indicated a need to use a 30-minute break in the middle of work time. Undoubtedly, such an approach including longer breaks could result in improved work efficiency (Fig.1).

Fig. 1: Estimated time for performing required tasks during work shift reported by workers.

As many as 48% of respondents declared that they perform a required task during one work shift (8-10 hours), another 26% for a given activity needs 8-9 hours, and 8% of respondents took 12-15 hours. Necessary time for the rest in the opinion of 48% of respondents should take 10-20 minutes, 16% confirmed that it should be longer than 30 minutes, or even 60 minutes (Fig.2).

Fig. 2: Time for the rest during shift work, expected by the respondents.

The minimum time for recovery depends on the age of the respondent and increases especially in the range of 48-55 years of age and differed from 60 to 120 minutes. Younger employees up to the age of 35, for a minimum regeneration time, declared nearly 20 minutes (Fig. 3). It increased particularly sharply among more experienced employees (over 25 years of work) and ranged from 60 to 90 minutes. It is more diversified among employees with an average length of employment (7-15 years) and definitely decreased among employees who had worked for up to 5 years and results in only 10 minutes per 8 hours.

Fig.3: Time for rest according to the workers' opinions in relation to their age.

Figure 4 (a-g) presents the courses of workers' effectiveness (a ten-point scale) at work resulting from time of work (range 1-8 hours) based on the opinions of the respondents in the building industry. From these figures it can be shown that comfort decreases during the next working hour. Poor effectiveness of work was observed between the fifth and sixth working hours, when starting work at 8.00 am. The highest comfort at work occurred from 10.00 am to 11.00 am. During an eight-hour working day, the pace was at its lowest. Based on this information, the organizational aspect of the work should be improved. The best solution could include a modified schedule of breaks during the working day.

Determining breaks during the working day

Among the solutions which could reduce the level of complaints and risk of disorders resulting from performed work, respondents most often indicated the need to use the right moment for a break during a shift. Based on these expectations and the author's own observations, it was proposed that there should be a schedule of the rests during the working day (1-8 hours) and during overtime.

Based on the circumstances as well as the procedures listed in the methodology chapter, the breaks were worked out. The schedules were presented in Figures 6 - 7.

Fig. 6: Proposed distribution of the breaks during the working day for all groups of workers.

Repetitive tasks as well as work organization required the preparation of some specific solutions. For instance, in order to reduce the monotony of steel-fixer workers it was proposed that there should be a 5-min break after each performed hour. Due to working at heights, three breaks for a roofer have been proposed. The basic rule in designing breaks was a period in which the effectiveness of workers decreased. A similar approach was used for workers who worked overtime. Usually, the physical workers were the longest at work, hence breaks after each hour at work were proposed.

Fig. 7*:* Proposed distribution of the breaks during overtime work for selected groups of workers.

The tasks of the building industry require the use of workers' physical force, hence in order to minimize a risk of musculoskeletal disorders or pain development it is obvious that it is necessary to ensure the right level of comfort of work and organizational issues during the working day.

Discussion

According to van Tulder et al. 1995 and Silverstein et al. 1997 (van Tulder et al., 1995; Silverstein et al., 1997), activities involving overcoming musculoskeletal disorders require high financial outlays. The health problems related to the overloading of construction workers also appeared in the Netherlands. The local Ministry of Social Affairs promotes activities to improve work safety on construction site (Arbo, 2006). As emphasized by Gillen et al., (2004) and van der Molen et al., (2005), very often employers do not have sufficient funds for preventive actions or do not engage in cooperation with entities that provide technical solutions in the field of safety and ergonomics of work in the market. Referring to the research conducted among Dutch masons, it should be noted that about 45% of them suffer from ailments in the lumbar region of the spine and, in the shoulder area, about 27% (van der Molen et al., 2005). In the conducted research, 25% of workers complain of complaints in the lower part of the spine, while about 5% complain of shoulder pain. The most frequent external load during such work was in the range of 1-6 kg. The total working time in an uncomfortable body position was over 4 hours a day. A significant external burden also occurs during surgeons' work, especially during operations on patients. This is mainly due to the lack of a break during the procedure (Slack et al., 2008). It is necessary to introduce breaks because it will avoid medical errors and eliminate mental and physical overload (Geurts et al., 2006). Research conducted by Hassan and Abou El-Soaud (1997) among physical workers in the IT industry confirmed that the areas most exposed to pain and musculoskeletal disorders are the shoulders and neck (66.7% of the subjects) and the lower part of the spine (33% of people). The authors pointed out that static loads combined with dynamic loads such as wrists are particularly dangerous because in many cases it ends with employee injuries. As a consequence, symptoms of dysfunctions of the nervous and circulatory systems of these employees often appear. According to the Authors if employees will follow the rules of working hours and breaks at work, the level of work safety will be satisfying.

Summary

Based on conducted studies in the real work environment, it was found that more frequent breaks for industry workers should be introduced. A positive correlation was prepared between the seniority of industry workers and the time needed to regenerate during described works. In the 48-58 age group, a reasonable break-time duration should total 120 minutes, hence 15 minutes after each work hour.

Workers aged 20-30 have confirmed that their time to regain their strength is 20 minutes over an 8-hour working period. Despite many organizational and technical solutions, as well as applied individual protection solutions, there are a number of risks in the industry space that impact negatively on workers' health and life, which result in disorders of the musculoskeletal system in the cervical and lumbar parts, which may lead to the development of occupational diseases and result in time off work. As demonstrated during twenty-four hours, industry workers performed their activities for up to 12 hours per day, which additionally affects overload of the musculoskeletal system.

Abstract

The research is aimed at identifying the specifics of spillover effects that occur in the economic system in the process of digital development, as well as developing conceptual principles for their assessment. The authors attributed the direct effect of investing in digitalization to the growth of the digital economy's share in GDP, increased labor productivity, expanded market volumes and additional profit, and increased exports of ICT products. The authors adapted the concept of the "spillover effect" to research on the digital economy. The authors revealed the specifics and systematized the spillover effects of the digital economy (spillover-the effect of changes in the labor market and employment, spillover-the effect of social and regional asymmetry in the use of digital technologies, spillover-the effects of information risks), and justified their positive and negative impact on the national economy. The analysis of approaches to evaluating spillover effects allowed the authors to formulate recommendations for their evaluation based on the statistical method of variance and mean square deviation.

Keywords: spillover effects, digital economy, labor market, unemployment, digital inequality, digital gaps, information risks, social and regional asymmetry

Introduction

Digitalization processes change the essence of production processes – digital technologies and information resources become the basic factors of production, and the process of creating goods and services becomes remote and integral (OECD, 2017). The mechanisms and nature of relations between

Cite this Article as: Evgeniya K. KARPUNINA, Natalia N. GUBERNATOROVA, Amira A. DAUDOVA, Zarema N. STASH and Larisa A. KARGINA "The Spillover Effects of the Digital Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

economic entities are changing, they acquire features of network and virtual interaction, most often reaching the global level.

The habitual human environment, as well as the consumption model, is being transformed. Multifunctionality, personification and intelligence become the determining characteristics of a product or service that define its position in the market (Molchan et al., 2019).

Such fundamental changes, on the one hand, require appropriate investments related to the introduction of digital technologies and the restructuring of the main socio-economic processes, and, on the other hand, provide the benefits of digitalization in the form of additional profits, increased productivity and accelerated economic growth.

Many authors, studying the effectiveness of the digital economy, note that the real economic consequences of digitalization are much broader and more multifaceted (Volodina et al., 2011). Companies that implement digital technologies receive both private benefits from investment and related benefits-spillover effects-for example, in the form of improving the reliability of services, increasing the company's competitive advantages, obtaining a wider set of technologies and opportunities for their flexible application (Kuzovkov et al., 2019).

The existence of spillover effects of the digital economy or “digital side effects” is stated in the report «Digital Spillover» of Huawei company and Oxford Economics (2017). The calculations presented in the report confirm that digital transformation affects not only an individual company, but also covers the supply chain, as well as related industries, which ultimately leads to a significant positive impact on the economy as a whole (United Nations, 2019b).

The related results of digital technology implementation often exceed direct results, however, they are currently little identified and practically not evaluated. In addition, the spillover effects of the digital economy are not always positive.

Thus, the study of spillover effects of the digital economy is currently relevant.

Methodology

The purpose of the study is to identify the specifics of spillover effects that occur in the economic system in the process of digital development, their systematization, as well as the development of conceptual principles for their assessment.

The authors conduct a theoretical analysis of approaches to understanding the spillover effects of the digital economy, systematizing them by the nature of their impact on the economic system (vertical and horizontal; positive and negative).

The authors suggest using the statistical method of variance (a measure of the spread of a value relative to its mathematical expectation) and the mean square deviation to evaluate spillover effects.

The authors propose to use the following formula to estimate the spillover effects by using dispersion:

$$\sigma^2 = \frac{\sum(x-\bar{x})^2}{n} \quad (1)$$

The average square deviation formula has the following form:

$$\sqrt{\sigma^2} = \sqrt{\frac{\sum(x-\bar{x})^2}{n}} \quad (2)$$

The initial indicators for evaluating the spillover effects of the digital economy can be: Unemployment rate (TakeProfit, 2020); Human Development Index (HDI), adjusted for inequality in access to technology (United Nations, 2019a); Cybersecurity Index (ITU, 2019).

Literature Review

A significant number of scientific papers have been devoted to the study of the digital development patterns. Thus, the attempt to determine a logic for the digital economy formation through the allocation of digitalization waves belongs to Katz (2017). Atkinson et al. (2009), Varian et al. (2002) , Gillett et al. (2006) focused on identifying the economic and social benefits that the economic system and society receive from the introduction of digital technologies. For example, increased productivity as a result of implementing more efficient business processes supported by ICT, as well as optimizing the supply chain, reducing overall costs.

Brynjolfsson and McAfee (2014), Katz (2017), and Gordon (2012) describe both the positive and negative consequences of digitalization (for example, the reduction of the medium-and low-skilled workforce as a result of particularly strong capital replacement, as well as a slowdown in labor productivity). However, the authors do not separate the main and side results of digitalization.

Meanwhile, the concept of "spillover effect" (that is, the manifestation of any economic activity that affects the activities of third parties that are not directly involved in the interaction process) is most often found in the innovation management theory (Pittaway, 2003), when assessing the intra-industry impact of foreign companies ' investments and identifying positive effects (Buckley et al., 2007; Wang & Zhao, 2008), analyzing the R&D sphere (Coe et al., 2009; Kim & Lee, 2004), as well as in the process of assessing the spread of knowledge (Kesidou & Szirmai, 2007; Wang et al., 2009).

In the process of innovation management, there are horizontal spillover effects (innovations are copied by other companies, which leads to raising productivity), vertical (increasing productivity when delivering goods and services along the supply chain) and internal (through training in practice) (Teece, 1977).

Researchers point to the emergence of spillover effects from foreign direct investment both within the industry and along the technological chain, as well as the likelihood of not only positive, but also negative side effects (Fedorova and Barikhina, 2015). The methodology for studying spillover effects in the process of knowledge dissemination is based on two approaches: 1) MAR Spillovers (Knowledge spillover) explains how the concentration of firms in one industry helps move knowledge between firms (Edward et al., 1992); 2) Jacobs Spillovers shows how the concentration of different industries in one place encourages innovation (Carlino, 2001).

Researchers identify the following causes of spillover effects: the economic effect of scale of production and consumption of services; the specifics of the production of goods and services and the formation of added value; the social consequences of the impact of scientific and technological progress on the quality of human life (Kuzovkov et al., 2019). These reasons can probably be the source of spillover effects in the digital economy as well.

Thus, the specifics of the spillover effects of the digital economy remain poorly covered and unsystematic

Results

Direct Effects of The Digital Economy

Considering the digital economy in terms of a resource approach allows to identify the resources and factors that make up its basis: 1) generated human knowledge and skills; 2) digital infrastructure resources in the form of Internet access and information use opportunities; 3) research and development as the basis of technological innovation; 4) digital technologies based on artificial intelligence, robotics, AR/VR and blockchain. Creating and managing these resources requires significant investment from individuals, businesses, and the state.

The education sphere is the base for the digital economy formation. Access to education for all categories of the population, as well as the level of professional competence, is largely determined by

the standard of living of the population in a particular country, their income level, as well as support from the state. Experts use the Global Index of Cognitive Skills and Educational Attitude to assess the effectiveness of national education systems (Pearson, 2016). It is based on a ranking on two groups of international indicators: cognitive skills and educational level (including the literacy index and the index of the total percentage of students receiving secondary and higher education). In 2016, the United States ranked first in the world (100 points), Switzerland was second (87.2), Denmark ranked third (84.2), and the United Kingdom was fourth (84.8). Germany (70.3) was on 16 positions, Japan (64.2) - on 20, China (51.8) - on 30, Russia (49.1) - on 34, South Africa (45.6) - on 37, Brazil (45.1) - on 38, India (45.8) - on 49. In turn, the effectiveness of the education system determines the opportunities for human development. Thus, in 2018 Germany (0.939), the United Kingdom (0.920), the United States (0.920), and Japan (0.915) were included in the group of countries with a very high level of HDI; Russia (0.824), Brazil (0.761), China (0.758) are middle-level HDI countries, while South Africa (0.705) and India (0.647) are classified as low-level HDI countries (United Nations, 2019a).

The formation of a digital infrastructure is a prerequisite for the digital economy development. The gap in Internet access between countries and regions of the world remains significant. For example, the values of the indicator "ICT access and usage by households" in 2019 are as follows: in the US-79.88% of households have Internet access from home (79.1% - broadband access), in the UK-96.85% (95.84%), in Germany-94.83% (93.93%) China – 59.6% (54.3%), in Russia -76.3 % (21.4%), in Brazil -71.4% (63%) (OECD, 2020). The level of access to the Internet and the use of digital technologies by business structures also differs significantly. For example, in the UK, 94.68% of business structures have fixed and mobile Internet connections, 23.87% of all business structures use ERP technologies, 30.51% use CRM services, and 17.85% of enterprises have connection speeds above 100 MB/s, while in India and a number of developing countries, the value of similar indicators remains low (OECD, 2020). The structure of R&D financing varies from country to country. For example, in the United States, Japan, European countries and China, a large share of all investments in the ICT sector is taken by businesses, while in developing countries such as Russia and India, government support is high (table 1).

Table 1: Expenses of some countries for the R&D sphere development

Country	GDP (current prices) /billion US$), 2019	Gross domestic spending on R&D, % of GDP	R&D spending by government, % of total R&D	R&D spending by Business, % of total R&D spending in PPP$	R&D spending by Universities and Private non-profit, % of total R&D	Number of researchers per million inhabitants	Direct government funding of business R&D and tax incentives for R&D, 2015
USA	21 427	2,7	11,4	71,5	17,1	4 205	0,13
China	14 342	2,0	15,8	77,3	6,9	1 089	0,06

Source: compiled by the authors according to OECD (2020), Unesco Institute for Statistic (2020), World Bank (2020)

For example, in the UK in 2016, the total amount of investment in R&D was 1.67% of GDP, including the amount of public investment was 0.67% of GDP, private investment – 0.86% of GDP, 0.34% of GDP accounted for other investments by private non-profit organizations from abroad, including business financing programs outside the UK and the EU. Thus, the British innovation Agency is the main source of funding for British public innovation (more than 8000 organizations received support), in addition, other organizations (regional agencies, the Fund for energy entrepreneurs of industrial strategy, the Royal Academy of engineering, etc.) have provided positive experience of public funding. The UK government plans to increase investment in this area to 2.4% by 2027, and in the long term - to 3% of GDP (Royal Academy of Engineering, 2018). At the same time, increased government funding will also require growing business investment and more R&D projects to achieve success.

According to IDC (2020), 4.7 trillion US dollars were spent on ICT technologies in 2018, including 4.0 trillion US dollars on traditional technologies and 0.7 trillion US dollars on new technologies. In 2019, ICT spending increased by another 5.5%. At the same time, traditional spending on hardware, software, services, and telecommunications is gradually losing its importance in overall ICT spending, as cost savings due to automation lead to a redirection of spending to new technologies such as artificial intelligence, robotics, AR/VR, and blockchain. The introduction of new technologies is uneven across the world's regions and countries, but enterprises in emerging markets, following countries with mature economies, have moved to adopt new technologies that provide a rapid return on investment for targeted industrial applications (for example, the introduction of IoT and robotic solutions by manufacturing firms in China and the rest of Asia). Governments in developing countries are encouraging investment in new technologies and initiating the creation of smart cities, thereby integrating ICT with economic planning. In any case, almost every country focused on achieving the goals of digital development has adopted a national strategy in the field of informatization, which reflects special steps to expand the digital infrastructure, increase the level of education and competence of specialists to serve the digital sphere, strengthen the industry of scientific research and innovation, and ensure cybersecurity. For example, Germany implements the concept of “Industry 4.0”, Japan - New Strategy in Information and Communications Technology, the United Kingdom - Digital Economy Act, the United States - Digital Economy Agenda, China – “ Internet +”. These countries are aimed at achieving an increase in the quality of life due to the intensive development of the ICT sector (Karpunina et al., 2019a).

The direct effects of investing in digitalization are the level of digital development that has been achieved. For its assessment, McKinsey Global Institute uses the indicator “the share of the digital economy, as a % of GDP” (Fig. 1).

Fig. 1: The size of the digital economy in 2016, as a % of GDP
(Source: compiled by the authors according to McKinsey, 2017)

Huawei estimates that the global digital economy was worth $ 11.5 trillion in 2016, or 15.5% of global GDP – 18.4% of GDP in developed countries and 10% of GDP in developing countries on average. Experts emphasize that the digital economy has grown two and a half times faster than global GDP over the previous 15 years, almost doubling since 2000 (Huawei and Oxford Economics, 2017).

The maximum volume of exports of ICT goods, as a reflection of the costs of digitalization, in 2019 was reached by China - 138,651 million US dollars, the second place in the world remains with the US-138,651 million US dollars (Fig. 2).

Fig. 2: The structure of ICT goods exports, million US dollars
(Source: OECD, 2020)

The direct effects of digitalization are estimated as productivity increases.

Jorgensen et al. (2005) assessed the impact of ICT on multi-factor productivity in the United States and concluded that there is a delayed social and economic impact of various digitization waves.

The digital economy removes scalability constraints (digital technologies create an increased need for factor resources and meet additional final demand) and allows traditional sectors to grow at a faster pace. Growth is reflected in increased revenue from expanding market coverage (Varian et al., 2002, Gillett et al., 2006).

Katz (2017) notes that using broadband Internet access increases the efficiency of business processes and services and reduces overall costs.

An increase in the index of the digital economy ecosystem development by 1%, (due to the development of e-Commerce, e-government, e-health), led to an increase in GDP per capita in Latin America by 0.13%, noted Katz and Callorda (2017).

Barefoot et al. (2018) argue that the digital economy is the engine of GDP growth in the US. Thus, in 2016, the real value added of the digital economy (adjusted for inflation) amounted to 1,302.2 billion dollars, which is 82.2 percent more than in 2005. From 2006 to 2016 the real value added of the digital economy outpaced the overall growth of the economy each year and mitigated the decline in GDP during the recession in 2008-2009.

Identification and Assessment of Spillover Effects of The Digital Economy

Potential spillover effects from digital investments also affect certain areas of social and economic life and the national economy.

The classification of spillover effects can be based on various features. Traditionally, the "nature of interaction of subjects" is used as a criterion for classifying spillover effects in innovation and investment activities. According to this criterion, there are vertical spillover effects that occur between companies that are in a relationship, and horizontal spillover effects between other companies operating in the same market. They also identify technological spillover effects that occur when technologies are diffused, such as assimilation of foreign technologies or productivity gains resulting from the use of more advanced technologies (Chengqi and Zhongxiu, 2008).

Researchers emphasize that spillover effects can be manifested in the form of providing the market with new products of high quality, diversifying product lines, increasing the efficiency of companies in terms of costs and profit margins.

In our opinion, we can distinguish the following spillover effects of the digital economy.

1) Spillover-the effect of changes in the labor market and employment.

Thus, in the first wave of digitalization, a positive spillover effect was obtained in the form of employment growth (Katz, 2017). For example, Crandall et al. (2007), Shideler et al. (2007) empirically proved that a reduction in resource constraints during this period led to an increase in demand for labor and job creation, usually in service industries (such as financial services, education, health, etc.), as well as in manufacturing. Katz and Callorda (2016) also confirmed that between 2004 and 2015, a 1 percent increase in the digitization of the consumption index resulted in a 0.07 percent decrease in the unemployment rate.

However, Akerman et al. (2015) indicates that digital technologies and automation contribute to the polarization of jobs in most developed countries due to the limited digital skills of the population. Low- and medium-skilled jobs are prone to disappearing due to the introduction of advanced technologies.

Fossen and Sorgner (2019) conducted a mapping of the impact of digitalization on professions based on the values of destructive and transformative digitalization. The calculation of median values of indicators weighted by the number of employees in the corresponding professions in the United States allowed the authors to conclude that the impact of digitalization on the profession can not be considered solely as destructive or transformative.

However, when experts study the impact of digitalization on the employment structure, they often focus on the destructive effects - the probability of replacing human labor with machines (Brynjolfsson and McAfee, 2014; Acemoglu and Restrepo, 2019).

Indeed, on the one hand, automation can reduce employment in certain professions (medium and low-skill), while work platforms can increase the number of non-standard jobs (short-term, part-time, or low-paid jobs), as well as widen the gender wage gap. On the other hand, e-services, in particular e-health, can help society solve the problems of population aging and increasing social expenditures (OECD, 2017). Therefore, it is advisable to distinguish positive and negative spillover effects of changes in the labor market and employment. In this case, changes in employment can spread both horizontally (within the industry) and vertically (supply chain effects) (United Nations, 2019b).

2) Spillover-the effect of social and regional asymmetry in the use of digital technologies.

This spillover effect is a manifestation of digital inequality resulting from uneven implementation and use of digital technologies within countries and regions (Reimer, 2016; Greenstein and Prince, 2006;Van Ark, 2014; Karpunina et al., 2019c).

OECD experts pointed to the emergence of digital gaps between individuals, households, businesses and regions in terms of access to the Internet and the use of digital technologies in daily life and professional activities. On the one hand, access to the Internet and its use, the nature of the technologies being implemented are determined by the level and quality of life of the population, income and material capabilities of business, as well as needs for the realization of human potential and targets for

long-term development, and, on the other hand, by the implemented state policy in the field of digital development (Ragnedda and Muschert, 2013).

Thus, there is both a social vertical (in the form of a gap in the realization of development opportunities) and a regional horizontal (in the form of differences in the level of socio-economic development of regions) asymmetry in the use of digital technologies, which can be defined as a spillover effect of the digital economy, which has both a positive and negative impact on the development of the national economy (Hargittai, 2002; Stiakakis et al., 2010; Novak and Hoffman, 2000).

3) Information risks as a spillover effect of the digital economy.

In the digital economy, information risks become an integral part of objective reality. They affect the activities of individuals, businesses, and the national economy. They cause direct economic and image damage (McKinsey and Company, 2018). The OECD report says that the digital economy development requires addressing the risk of failures in areas such as digital privacy, security and trust (OECD, 2015).

Individuals face information threats in the form of personal data leaks, bank card fraud, spam and virus infections, and unauthorized computer access. In 2018, 27.9% of users experienced problems with loss of information, violation of its integrity and confidentiality, and hardware failures (Kevesh et al., 2019),

Competition conditions provoke the emergence of cyber attacks and cyber espionage in the industry to steal business information through faulty nodes and information systems, access to web servers, the use of malicious software, phishing, and others. They cause direct financial damage or loss of business reputation of the business company (Molchan et al., 2019). Sobers (2019) notes that a significant portion of cyber attacks (31%) are committed against the operating technology infrastructure of companies. There is a high probability of infection with virus programs (for example, in 2017, the Wannacry virus affected 400,000 machines in 150 countries, and the total cost of damage was about $4 billion).

Information threats also affect public administration systems and create conditions for conducting large speculative transactions that disrupt the natural information structure of markets and lead to an increase in unproductive spending on creating security systems, as well as to the loss of GDP (Karpunina et al., 2019b). Information risks reduce the potential benefits of digitalization by spreading both horizontally and vertically.

Conceptual framework for evaluating the spillover effects of the digital economy.

The spillover effects of investment are estimated using a simulation method based on the Cobb-Douglas production function, which shows the functional relationship between the volume of effectively used factors of production and the output achieved (Javorcik, 2004; Stančík, 2007; Fedorova et al., 2016). Such calculations are performed at the level of an individual company, industry, or region.

The impact of the spillover effect of investment in R&D on the knowledge stock and economic growth is estimated using econometric modeling (Griliches, 1992).

The assessment of socio-economic efficiency of the use of ICT is carried out by an integral and expert method, which consists of a point evaluation of parameters and calculation of the integral efficiency coefficient (Adzhemov et al., 2015; Kuzovkov, 2016).

In our opinion, these approaches to the digital economy are not applicable due to the lack of statistical data for assessment on an international scale, as well as in the context of individual countries and regions.

In this regard, we consider it appropriate to use the statistical method of variance (a measure of the spread of a value relative to its mathematical expectation) and the average square deviation to assess the spillover effects of the digital economy. The initial indicators in the calculations are: Unemployment rate - to assess the spillover effect of changes in the labor market and employment (TakeProfit, 2020); Human Development Index (HDI), adjusted for inequality in access to technology

– to assess the spillover effect of social and regional asymmetries in the use of digital technologies (United Nations, 2019a); CybersecurityIndex - to assess information risks as a spillover effect of the digital economy(ITU, 2019).

The accuracy of calculations and the objectivity of the results obtained will depend on the accuracy of statistical data provided by national statistical agencies and international organizations.

Conclusions

The article reveals the specifics of the effects obtained from the digital economy development. The direct effects of investing in digital economy come in the form of GDP growth, increased productivity, expanded markets, and additional profits.

The authors studied the spillover effects of the digital economy. The specifics of the spillover effect of changes in the labor market and employment, the spillover effect of social and regional asymmetry in the use of digital technologies, as well as information risks as spillover effects of the digital economy are revealed. It is proved that spillover effects can have both positive and negative effects on the national economy.

The authors investigated approaches to estimating spillover effects and proposed a variant of their estimation based on the statistical method of variance and mean square deviation.

Abstract

In the current situation which is characteristic for the environmental pollution and increasingly evident climate changes, the sustainable development is becoming an imperative, and the sustainable consumption is turning into a relevant component of its achievement. The aim of this paper is to contribute to the better understanding of sustainable consumption by young Croatian people and to emphasise the gender-based differences in this sense. There was used the scale which takes into account the consumption process, that is, the phases of purchase, use and disposal of product; all the important categories of product are included (food, housing, mobility and clothing) in terms of the pro-environmental behaviour and also the social dimension. According to the results, young people reveal the sustainable behaviour to an average extent – they are the strongest energy savers, but their awareness of meat consumption is the weakest. Regarding the gender, as in the majority of other studies, the females practice the pro-environmental behaviour stronger in eight behaviours, while the males show a statistically significant difference in their preference towards online shopping. Young people are a reflection of social values and behaviour, so what should be emphasised is the importance of interaction between all stakeholders for achieving the stronger sustainable consumption and, consequently, the sustainable development.

Keywords: sustainable consumption, pro-environmental behaviour, social dimension of sustainability

Introduction

Problems concerning the environment and society with which the humankind is faced today in its unavoidable ongoing development, especially climate changes threatening to significantly alter the way in which people may live in the future, inevitably impose the sustainable development, which was recognised as early as in 1987 to be the ''development that meets the needs of the present without compromising the ability of future generations to meet their own needs"(United Nations, Our Common Future, 1987, p. 45). An important component of the sustainable development is the sustainable consumption of individuals as the subjects of social change who share their responsibility to sustainability (Luchs and Miller, 2017). In the context of attention recently paid to the environment and development, particularly after 2006, there has been an abrupt increase in research into the sustainable consumption, among other things, mostly associated with the term such as the consumer's behaviour. (Liu et al, 2017).

The aim of this paper is to contribute to the comprehension of sustainable behaviour by taking into account a series of individual sustainable behaviours. Although certain studies are focused only on some of the behaviours, for instance, recycling (Hornik et al, 1995) or categories of products such as

food (Vermeir and Verbeke, 2006), the current study – like many others – combines the different forms of behaviour (Liu et al, 2010; Wang, Liu and Qi, 2014; Roberts, 1996; Gatersleben, Steg and Vlek, 2002; Ukkena and Nkamnebe, 2017; Whitmarsh and O'Neil, 2010; Bulut, Kokalan and Dogan, 2017; Kaiser and Wilson, 2004).

As for its structure, the current paper first contains the definition and dimensions of sustainable consumption; sustainability is originally viewed through these three core dimensions: environmental, social and economic (Elkington, 1999). Then there is an analysis of some studies into the pro-environmental behaviour and behaviours related to the social sustainability, with an emphasis on the first dimension. The research has been modelled upon Geiger, Fisher and Schrader (2017), taking into account the three phases of consumption: purchase, use and disposal; each consumption area (food, housing, mobility and clothing) has been included to a different extent. A special aim of the study has been to determine gender-based differences in sustainable behaviours in particular, so some of the previous investigations are surveyed here. The current study has been focused on the population of young people, that is, students in Croatia. Its conclusions are preceded by the contributions, limits and potentials of the paper to consider for the future research.

Definition and dimensions of the sustainable consumption

The sustainable consumption, so closely related to the term of sustainable development, is regarded as "the use of services and related products which respond to basic needs and bring a better quality of life, while minimizing the use of natural resources and toxic materials as well as emissions of waste and pollutants over the life cycle of the service or product so as not to jeopardize the needs of future generations"(United Nations, no date, p. 1). Emphasising the system of individual consumption, the sustainable consumption behaviour can be defined as the "individual acts of satisfying needs in different areas of life by acquiring, using and disposing goods and services that do not compromise the ecological and socio-economic conditions of all people (currently living or in the future) to satisfy their own needs" (Geiger, Fisher and Schrader, 2017, p. 20). The sustainable consumption is mostly associated with the pro-environmental behaviour, and can be also recognised as the environmentally friendly behaviour, ecological behaviour, etc. (Kurisu, 2015). The pro-environmental behaviour refers to the "behavior that harms the environment as little as possible, or even benefits the environment" (Steg, 2009, p. 309). The definitions of the pro-environmental behaviour can be essentially purpose-oriented and fact-oriented. In other words, it is possible to achieve the environmental preservation when one is motivated, which may truly lead to the environmental preservation, but not necessarily; on the other hand, the motive can be different, e.g. the health preservation that actually results in a positive impact on preserving the environment. As Kurisu (2015) claims, what is acquired is the perception of pro-environmental behaviours like the ones that actually contribute, or are perceived to contribute, to the environmental preservation.

The concept of sustainability is usually seen with the help of the triple bottom line model uniting the ecological, social and economic dimensions (Willard, 2007). An interesting example of the conceptualisation of sustainable behaviour is given by Quoquab, Mohammad, and Sukari (2019) who, accepting the definition of sustainable development, determines the scale with 24 items and 3 dimensions: quality of life, care for the environmental well-being and care for future generations; however, they do not mention the social dimension. As for the categorisation of sustainable consumption, apart from three fundamental dimensions related to the mere perception of sustainable consumption, it is possible to discuss the phases and areas of consumption. The sustainable consumption is commonly viewed through the following phases: purchase, use and disposal (Geiger, Fisher and Schrader, 2017; Kurisu, 2015; Macinnis and Folkes, 2010). Numerous pro-environmental behaviours can be differently categorised according to the areas of consumption. Based on the UK Department for the Environment, Food and Rural Affairs (Defra, 2007), they are recognised as energy and water efficiency/usage in the home, waste and recycling, purchase of eco-friendly products and personal transport. Geiger, Fisher and Schrader (2017) confirms that, from the viewpoints of greenhouse gases, acidification emissions, tropospheric ozone and resource/material requirements, food, housing and mobility represent the relevant areas. In a review of the sustainable consumption in China, Liu, Oosterveer and Spaargaren (2015) consider this behaviour similarly by taking into account these categories: food, housing energy and transport. Household consumption can be also divided into

the consumption of food, clothing and housing (Kurisu, 2015). Since the issue of sustainable consumption is a mixture of the intent and the impact (Di Giulio et al, 2014), a tendency of consumers to commit to the environmental preservation is important in their choices, but the final effect is also important, consequently, displaying those behaviours with a stronger impact on the environment is of significance. For instance, changes in the frequency and ways of transportation have a stronger impact than consuming water in a more responsible manner or carrying your own shopping bag with you (Defra, 2007; Steg and Vlek, 2009). The component of sustainability which refers to the society is also important, but it is less emphasised and understudied in literature. It is considered differently and, apart from the ethical characteristic of a firm and the fair working conditions, it can also include the frugal consumption, which, nevertheless, means economic considerations at purchase events (Pepper, 2009).

Research into some pro-environmental behaviours

When it comes to the conservation and preservation of the environment, consumers can practice a variety of behaviours. Measuring the pro-environmental behaviours, researchers used many unidimensional or multidimensional scales which make the comparison between studies difficult. In the studies into the sustainable consumption, a larger number of researchers is focused on the determinants of sustainable behaviour, mostly considering lots of different behaviours in the unidimensional scale linked with the pro-environmental behaviour (Arzu, 2008; Biswas, 2017; Kaiser and Gutscher, 2003; Liu et al, 2010; Wang, Li and Qi, 2014; Roberts, 1996). Advocating a wide approach to the social responsibility, Roberts (1995) has developed the scale for measuring the socially responsible consumer behaviour based on 26 items, including the dimensions of socially conscious consumer behaviour and the ecologically responsible consumer behaviour, and determining the four clusters of consumers. Considering numerous behaviours with regards to the main aims of the environmental preservation and conservation, Kurisu (2015) divides even 200 pro-environmental behaviours orientated towards the environmental preservation into 12 categories: eco-house/building, energy saving, enhancement of low carbon society, appropriate transportation, appropriate combustion, avoidance of pollutant discharge to water, water saving, reduction of waste generation, avoidance of overexploitation, protection of biodiversity, purchase of environment-friendly products, endowment for environmental activities. Gatersleben, Steg and Vlek (2002) include a wide range of behaviours related to the following groups: home heating, preparation and storage of food, laundry washing, bathing, audio-visual entertainment, transportation and holidays; Gilg, Barr and Ford (2005) consider many different behaviours within the groups of purchase decisions, habits and recycling, including also the social component thanks to the purchase of fair trade products; Ukkena and Nkamnebe (2017) determine these groups: purchase decisions, recycle behaviour, renewable energy/transportation and waste management/reduction; Whitmarsh and O'Neil (2010) divide behaviour into two groups: purchase and installation of durable goods and many other behaviours that contribute to the environmental protection. A variety of the researched factors and categories can be additionally found in Bulut, Kokalan and Dogan (2017), who consider sustainable behaviours across four dimensions, putting them into the categories of environmental sustainability to measure the environmental consciousness of consumers, savings to measure the propensity to save when shopping, and reusability to measure the using of items multiple times or in multiple ways, also related to the environmental protection, and the specific unneeded consumption which measures redundant shopping. Kaiser and Wilson (2004), analysing the conservation (ecological) behaviour, take into account 50 conservation behaviours and categorised them into the following six groups in the six-dimensional scale: energy conservation, mobility and transportation, waste avoidance, consumerism, recycling and vicarious, social behaviours toward conservation. They think that the multidimensional model predicts data better than the unidimensional model. Some studies, e.g. the one by Tanner and Kast (2003), investigates the determinants of purchasing a lots of different no other than food products, also including fair trade products.

Research into a consumer relation towards the social dimension of sustainability

Firms generally tend to be socially responsible. According to Mohr, Webb and Harris (2001), so many respondents have a positive relation towards firms that acquire corporate social responsibility. However, for the majority of them, such activities are not a purchase criterion, apart from a smaller

group in which the socially responsible consumer behaviour is actively participated. One of the earlier studies into the social dimension within the socially responsible consumer behaviour, which also includes the ecologically conscious consumer behaviour, was conducted by Roberts (1995), using 8 items of the socially conscious consumer behaviour. Based on the comprehension of socially responsible consumption suggested by Mohr, Webb, and Harris (2001), also considering the measures suggested by Roberts (1993; 1995; 1996), Webb (2008) developed the scale of socially responsible purchase and disposal, which includes both social and ecological criteria. The social aspect of sustainability is described with the help of 13 specific dimensions with regards to purchase founded on the corporate and social responsibility of firms. The social aspect of sustainability encompassing 7 items is included in one of the most complete scales that measure the consciousness about the sustainable consumption, developed by Balderjahn et al (2013), with the environmental and economic dimensions along with the already-mentioned one. In the framework of social implications of consumption behaviour, attitudes of consumers towards fair trade products drew a special attention. Connolly and Shaw (2006), thus, consider the perception of fair trade within the context of green and ethical consumption, and voluntary simplicity. De Pelsmacker, Janssens and Mielants (2005) determine and define different groups of consumers regarding their beliefs, attitudes and buying behaviour in relation to fair trade products. More detailed results about the features of consumers buying fair trade products are by Ambrožova and Častek (2013) claiming that even 71% of respondents who buy fair trade products did not buy any product because they could not accept the production and distribution policy of producers, that is, 72% of them did buy fair trade products guided by moral principles or to support those in need in this way. They also confirm that the buyers of fair trade products are primarily young and more educated people.

Gender-based differences regarding the sustainable consumption

Although demographic features do not lead to final conclusions when the socially and ecologically responsible consumers are described (Roberts, 1995), it is generally thought that they are older consumers, well-educated, better paid, and females (Gilg, 2005). Young people are increasingly becoming a more significant segment of consumers; they develop the pro-environmental behaviour through the consumer socialisation (Yan and Xu, 2010). Gender-based findings are not consistent, but it is still largely believed that women show more concern about the environmental issues and are more included in green shopping, which is likely related to their household and family (esp. children) health care (Middlemiss, 2018; Rawat and Garga, 2012). Roberts (1993) investigates the influence of gender on the socially responsible behaviour and finds that women are more socially responsible than men. Studying the ecologically conscious consumer behaviour, Roberts (1996) concludes that women show such behaviour more strongly. Focused on the sustainable consumption across four dimensions, Bulut, Kokalan and Dogan (2017) claim that the level of the overall sustainable consumption behaviour and the dimension within this, related to the reusability behaviour, is significantly higher in women than in men. Liu (2010) states that women show more concern about the environmental issues and acquire the habit of green purchasing more than men. As for the purchase of sustainable food products specifically, Vermeir (2006) claims that young women have significantly more positive attitudes towards buying sustainable food products and higher intentions to buy them. Doing research only on the female sample, Azru (2008) finds out that women behave more carefully in those cases in which there are economic costs, so they turn off the lights in empty rooms, they also switch off TV sets and other appliances when these are not used; that is, they are more careful then in comparison to the behaviours only related to the environmental protection, e.g. they do not buy those personal care products that are harmful for the environment. This finding has not been confirmed by all studies, so Wang (2014), focused on rural residents, discovers that women are less active in their sustainable consumption behaviour, which is linked, however, with the higher level of education of men in rural settings. In their survey into the social aspect of sustainability, it is possible to mention the study by Ambrožova and Častek (2013), according to which the gender-based differences in purchasing fair trade products are neither statistically nor factually significant.

Research Methodology

Questionnaire Design

The entire study was orientated towards the two dimensions of sustainability: ecological and social. At designing the items of ecological dimension, the principle of phases of the pro-environmental behaviour was followed, so all the behaviours are put in the phases of purchase, use and disposal. The study is not focused only on one consumption area, but encompasses the items that are related to each consumption area: food, housing and transportation; it also includes one item with regards to clothes. Certain items have been chosen, as the author estimated, according to their frequency in the previous research and the likeability of their use by the population of young people.

Regarding the purchase phase, four items are related to the environmentally friendly products in the area of food: I buy locally produced food (Kurisu, 2015; Gilg, 2005), I buy fruit imported from the overseas countries (R) (Tanner, 2003; Geiger, Fisher and Schrader, 2017), I buy ecologically labelled food (Kurisu, 2015; Tanner, 2003), I buy food even if I think or know that it is genetically modified (R). The latest item is mostly under-represented in literature although Tanner and Kast (2003), for instance, examine the attitudes towards the genetically modified food. The following question also considers the purchase of environmentally friendly products: I buy cleaners, shampoos and cosmetics that are environmentally friendly (Whitmarsh and O'Neil, 2010). The energy saving is dependent on these choices of purchase: I buy energy saving devices (Bulut et al, 2017; Kurisu, 2015; Azru, 2008; Liu, 2010; Gilg, 2005) and I buy energy saving bulbs (Bulut et al, 2017; Roberts, 1996; Kurisu, 2015; Gilg, 2005) and. The reduction of waste generation is contributed throughout purchasing the following products and shows certain behaviours: I buy products made of recycled materials (e.g. paper) (Roberts, 1996; Liu, 2010; Gilg, 2005; Kurisu, 2015) and I prefer buying products in smaller packages (Roberts, 1996; Kurisu, 2015; Wang, 2014; Gilg, 2005; Whitmarsh and O'Neil, 2010). As for today's options, it is possible to choose to reduce pollution by avoiding means of transportation: I prefer shopping online to going to a distant shop (Whitmarsh and O'Neil, 2010). The behaviour that has an impact on the reduction of waste generation throughout decreasing the unnecessary use of plastic bags is reflected in this: I carry my own shopping bag with me (Kurisu, 2015; Liu, 2010; Gilg, 2005). The excessive consumption is so obvious with regard to many fashion products (Sheth, 2011) due to different trends, constantly requiring consumers to buy new clothes items and throw away those still functional, which does not reflect any thriftiness (Corral-Verdugo et al, 2011) and also increases the quantity of waste: Following fashion I buy new clothes and throw away old clothes (R) (Bulut et al, 2017).

Considering the phase of use, what has been researched is the pro-environmental behaviour in terms of eating habits since the production of meat has a negative impact on the environment and is also related to the ethical treatment of animals (Spiller and Nitzko, 2017): I eat meat (R) (Whitmarsh and O'Neil, 2010; Geiger, Fisher and Schrader, 2017). Mobility and transportation can have a high CO2 impact (Defra, 2008), so the following pro-environmental behaviours are important: I use the public transportation (Azru, 2008), I walk or cycle to cover shorter distances (Kaiser 2004), I share a car with others following a similar route (Whitmarsh and O'Neil, 2010). Consumers can also produce energy saving: I turn off the lights in rooms where they are not needed (Kurisu, 2015; Azru, 2008; Gilg, 2005; Whitmarsh and O'Neil (2010), I turn off the TV, the computer, etc. when not in use (Kurisu, 2015; Azru, 2008). Water saving has a low CO2 impact (Defra, 2008), but it is of significance as water is becoming a more critical resource, so the following items are included here: When I brush my teeth or use a soap, I turn off the tap (Kurisu, 2015; Azru, 2008; Gilg, 2005; Whitmarsh and O'Neil, 2010) and I save water by spending less time under the shower (Gilg, 2005; Whitmarsh and O'Neil 2010).

The items within the disposal phase include collecting and recycling: I recycle over-used packages (Gilg, 2005; Whitmarsh and O'Neil, 2010; Webb, 2008), I use the services of special recycling firms to take care of e-devices, which contributes to the reduction of waste generation (Kurisu, 2015). A decrease in particularly toxic influence on the environment has been researched via the following item: I leave batteries on the places specially designed for their disposal. The reduction of waste generation is also supported by long-time use: I rather fix devices instead of throwing them away (Kurisu, 2015; Wang, 2014; Whitmarsh and O'Neil, 2010).

No detailed division of items has been applied to studying the social dimension. The first item When buying some product I consider the ethical profile of its producer (Webb, 2008; Carrero, Valor and Redondo, 2020) is used here to examine the general relation of the respondents to the social responsibility of company; the second item specifically considers the working conditions available during the production of goods as well as the care about the environment: I buy products labelled "fair trade" (produced by taking into account the fair working conditions) (Kurisu, 2015; Gilg, 2005; Tanner, 2003; Balderjahn et al, 2013). The 1-5 point scale was used for all the dimensions of sustainable development (1=never, 5=always).

Sample

The study was conducted on the sample of 280 students at the Dr. Mijo Mirković Faculty of Economics and Tourism (all the study years and all the study programmes) in Pula from March to May 2020. The convenient sample was used, that is, only those students who were present in classes when the study was conducted were asked to fill in the questionnaire. Since 16 questionnaires could not be included in the analysis, the results are based on the total of 264 acceptable questionnaires. The sample comprised 70.83% females and 29.17% males, with the average age of 21.25 years.

Results and Discussion

Analysis of the sustainable consumption

Table 1 shows the means and differences across the items of sustainable consumption with regard to gender.

Table 1: Means of particular consumption behaviours and differences regarding gender

	$\overline{X}$	$\overline{X_F}$	$\overline{X_M}$	t-value

Following the means (average values) of sustainable development dimensions, it can be noticed that the respondents are more inclined to the pro-environmental behaviour (AVG=3.05), although slightly above the average, than to the social aspect of behaviour, which is lower or below the average (AVG=2.36). As for the consumption phases, they practice the pro-environmental behaviour during the phase of use most (AVG=3.35), and during the phase of purchase its practice is the least (AVG=2.87), although the values are above the average for each phase. Food is a product that is essential for human life with a significant effect not only on health but also on the environment. In Croatia it is largely possible to buy locally produced food, but the respondents take this particular opportunity a little (AVG=2.70). On the other hand, they do not buy a large quantity of fruit imported from the overseas countries, which burdens the environment because of transportation (AVG=2.97). In the food category, the respondents buy ecologically labelled food to the least extent (AVG=2.49), which may reflect their lack of consciousness about the environmental protection and their own health, but also a lack of such products. They mostly avoid the food that, they think or know, is genetically modified (AVG=3.29), which can show their relatively high consciousness about the harmful effects of such food on the ecological system and health. Further, only slightly above the average, they buy eco-friendly cleaners, shampoos and cosmetics (AVG=2.86), which may stem from a lack of the environmental consciousness, or they do not believe in the functionality of such products in comparison to classical products. Among all the product categories, they buy energy saving devices (AVG=3.23) and bulbs (AVG=3.32) most. Almost the least purchased products are those made of recycled materials (AVG=2.68), actually not quite on offer. The respondents also do not take great care of buying products in smaller packages (AVG=2.76). Unexpectedly for young people, they do not prefer on-line purchase (AVG=2.25), as opposed to their decision to travel somewhere in order to find a particular product. On the other hand, relatively well, they acquire the behaviour of carrying their own shopping bags with them (AVG=3.08). As expected for young people, they are not particularly prone to save when it comes to clothes, despite the unfavourable economic situation, so they mostly buy and throw away their clothes following the fashion trends.

In the phase of use, there is just one item closely related to food and it considers the meat consumption, showing a relatively high level of loyalty to the traditional nutrition including meat (AVG=1.75). A group of the transportation-based items reveals that the respondents use the means of public transportation averagely (AVG=2.57), but they are more inclined to share a car with others along a similar route towards more distant destinations (AVG=3.07). It is positive that, to a very large extent, they tend to walk or cycle in order to cover shorter distances (AVG=3.98). Regarding the electrical energy consumption in households, they are very conscious or economical, so they turn off the lights in rooms when they are not needed (AVG=4.45) or a bit less turn off the TV, the computer and similar

appliances when they do not use them (AVG=4.13). They are rather economical in terms of water consumption when they brush teeth or use soap (AVG=3.93), but they do not give up their desired way of using shower (AVG=2.93).

The disposal of products is within the average behaviour when the given phases are discussed (AVG=3.02) with the largest contribution of over-used package recycling (AVG=3.22), probably due to the currently available disposal systems in many Croatian cities. Although different firms collect e-waste and some shops take care of it, this is not much practiced (AVG=2.80), perhaps because of a lack of knowledge and efforts required to find such places. The respondents are more careful about regular battery disposal (AVG=3.07). The behaviour that regards the use of products and leads to huge quantities of waste refers to the disposal of existing devices and the purchase of new devices as opposed to their maintenance and mending. The value here is slightly above the average (AVG=3.00), probably reflecting the acquired habit of maintaining a product poorly to prolong its expiry date, which is contributed also by the activity of producing and selling different devices which encourages the purchase of new ones, in particular mobiles.

The purpose of studying the social dimension has not been to gain detailed insights into particular aspects. Therefore, the first item is here to examine whether consumers take into account the ethical characteristic of a company, which can actually include several aspects, with the result below the average (AVG=2.33). A similar value is recorded also in the purchase of "fair trade" products, with a slightly better result (AVG=2.39), perhaps because of an obvious scarcity of offer in shops when it comes to such products, and perhaps because of somewhat lower commitment to this aspect of social responsibility.

Analysis of the gender-based sustainable behaviour

When compared to the males, the females show a statistically more significant pro-environmental behaviour ($\overline{X_M}$=2.96, $\overline{X_F}$ =3.10, t=2.30, p<0.05), which is a reflection of higher means in the majority of items. This is in accordance with the majority of studies presenting females as more ecologically conscious; besides, they acquire the pro-environmental behaviour more strongly than males. There is a statistically more significant difference for the phase of use ($\overline{X_M}$=3.15, $\overline{X_F}$ =3.45, t=3.836, p<0.05) in which the females prove themselves as more responsible, which may be a reflection of their ecological responsibility, but also of their thriftiness. In terms of the social dimension, the value is equal for both genders (2.36).

Analysed across certain pro-environmental behaviours, statistically significant differences have been identified for 8 items. The obtained results show that the female respondents ($\overline{X_F} = 2.957$)purchased eco- friendly cleaners, shampoos and cosmetics more than their male colleagues $\overline{X_M} = 2.662$) (t-test = 2.20; p<0,05. This finding may reflect the consumption of such products, which is usually more present among females for the purpose of maintaining households, especially cleaners, but also a wider range of eco-friendly shampoos and cosmetics on offer, without neglecting neither the care nor tendency of women to buy natural products. Besides, the female respondents purchased energy saving bulbs more frequently $\overline{X_F} = 3.412$) than the male respondents ($\overline{X_M} = 3.117$) (t-test =1.718, p<0,10). On the other hand, the male respondents more frequently preferred shopping online than going to shops ($\overline{X_F} = 2.134$, $\overline{X_M} = 2.558$; t-test = -2.999, $p < 0.05$) ; the female respondents seem to be more orientated to traditional shopping. They also carry their own shopping bags more frequently than their male colleagues ($\overline{X_F} = 3.332$), $\overline{X_M} = 2.506$; t-test = 4.718, $p < 0.05$) , showing that they do care about the environmental protection when they go shopping, at which the males are probably less careful. In the phase of using different products, as expected, there is a statistically significant difference in the meat consumption ($\overline{X_F} = 1.866$, $\overline{X_M} = 1{,}468$; t-test = 3,364, $p < 0{,}05$) , which is more present in the males. It turns out that the females are more responsible in choosing transportation, since significantly more they use the public transportation ($\overline{X_F} = 2.770$, $\overline{X_M} = 2.104$; t-test = 3.875, $p < 0.05$), walk or cycle ($\overline{X_F} = 4.070$, $\overline{X_M} = 3.753$; t-test = 2.011, $p < 0.05$). This result may be explained by the general belief that males tend to buy a car earlier. The females show a statistically significant difference in water waste when they brush their teeth or use soap in comparison to the males ($\overline{X_F} = 4.086$, $\overline{X_M} = 3.571$; $t - \text{test} = 2.925, p < 0.05$) .

Contribution of the paper and its Limitations for Future Research

The contribution of the current paper is evident in making the sustainable behaviour of young people clearer through developing the original scale which takes into account the ecological and social components of sustainability; the ecological component has been analysed according to the phases of consumption experience: the purchase, use and disposal of products. The above-presented results have several limitations that can be a foundation for future research. The study is more general, that is, it is not focused only on a particular category of products or type of behaviour, but gives some hints about different sustainable behaviours, and, thus, represents a starting point for more detailed studies into particular dimensions. In order to enable us some deeper insights, research into the determinants of particular behaviours would be also useful in the future. Since the social dimension is not developed here in more detail, the future studies might include a more developed scale within the sustainable behaviour or a separate study only into the social dimension can be recommended. Apart from the above-mentioned dimensions, it would be also possible to include the economic dimension in some more comprehensive study.

Its additional value lies in the identification of gender-based differences in sustainable behaviour, due to which the current study also contributes to this group of previous studies. Besides, the obtained result can be a foundation for further research aimed at explaining particular behaviours, for instance, why male persons more significantly choose online shopping or female persons more significantly use the public transportation or walk to cover shorter distances.

The current study provides insights into the awareness and sustainable behaviour of young people, university students, but some further research could include the youth from different socio-cultural settings to show potential differences. Since this study was conducted with university students, some behaviours are excluded from the sample structure, especially pro-environmental ones that they unlikely practice such as the use of solar collectors, therefore, future research could be conducted on the population with different demographic characteristics, and with more different sustainable behaviours included.

Conclusion

The sustainable behaviour of consumers is a relevant factor of the environmental protection and fairer social relations on the Earth. With his/her own consumption choice, every consumer also makes producers to offer more sustainable products. In this paper, upon the analysis of many previous studies, 26 sustainable behaviours have been included and considered, of which 24 are related to the pro-environmental behaviours (obviously the most represented component in research on the sustainable behaviour of consumers); the rest of 2 items touches upon the social dimension. Based on the obtained results, it can be stated that the young people, university students, in this sample acquire the sustainable patterns of behaviour averagely, but they are more prone to the pro-environmental behaviour. It does not necessarily mean that they are less ecologically conscious; the better results in the phase of use compared to the phase of purchase may signify that eco-friendly products, practically not advertised in the national media, are less available. The average result in terms of the adequate sustainable disposal of products may indicate a lack of knowledge about this and a lack of options for such disposal of waste and over-used products. As in the majority of previous studies, it has been confirmed that the pro-environmental behaviour is stronger in females, in this study it refers to 8 behaviours, whereas males more significantly prefer shopping online to going to some distant shop. It is noticeable, therefore, that women prefer some behaviours, naturally, they are more engaged in maintaining the household (e.g. purchase of eco-friendly cleaners, shampoos and cosmetics). Compared to men, women are also traditionally supposed to make more efforts to find and choose products in shops, use cars less, so these are some of the issues that would be interesting to study in more details. Finally, it can be concluded that the respondents are not orientated to the sustainable behaviour enough, which reflects the awareness of sustainability in the society, but it does not need to be a reflection only of their values or attitudes but also a reflection of insufficient offer of sustainable products or their prices are not simply appealing to them. The goals of sustainable development can be accomplished only through the interaction of all stakeholders.

Is There A Link Between Corporate Rebranding Motives and Strategies? Evidence from The Warsaw Stock Exchange

Natalia K. WOJCIECHOWSKA

University of Economics and Human Sciences in Warsaw, Warsaw, Poland,
n.wojciechowska@vizja.pl

Abstract

Purpose: This study examines the relationship between the motives and corporate rebranding strategies. Such link was proved on Western markets. **Methodology:** The research was carried out on the sample of 121 joint-stock companies listed on WSE Main Market and New Connect in Poland. The chi-square test of independence was carried out for each combination of motives and strategies.
Findings: Statistical significance was proved for six pairs: micro- and macroeconomic factors and brand name shortening, acquisition and complete brand name change, merger and co-branding, acquisition and brand name shortening, strategic factors and co-branding, strategic factors and brand name shortening. The strongest effect was shown by Cramer's V for micro- and macroeconomic factors and brand name shortening. **Research & Limitations/Implications:** The results confirm that there is a link between motives and corporate rebranding strategies. Further research is required in terms of specific types of mergers and acquisitions and their relations with rebranding strategies. **Originality/value:** The research makes a notable input in terms of conceptual framework and systematization of definitions as well as new classifications of both rebranding motives and strategies. Empirical study investigates the relationship between corporate rebranding motives and strategies on the Polish market.

Keywords: Competitive Strategy, Motive, Corporate Rebranding, Joint-Stock Company

Introduction

Modern enterprises operate in an extremely competitive and turbulent environment. Challenges that organizations have to deal with include globalization process, technological progress, cultural and demographic changes as well as increasing competition (Rindell and Strandvik, 2010). The task of enterprises is to adapt to the rapidly changing environment on a micro and macro scale, especially in terms of their development strategy, including marketing (Chad, 2016). In the face of challenges companies devise miscellaneous strategies such as rebranding which may entail a brand name change. Harris and de Chernatony (2001) underline that a brand can be a source of a long-term competitive advantage of an enterprise.

The rising interest in the topic of rebranding observed in the last decade years results from several reasons. Rebranding is a salient phenomenon as it concerns a brand (Kapferer, 2012), which may constitute the most valuable intangible asset of an enterprise (Yeboah and Addaney, 2016). Choosing a brand name is one of the key tasks and challenges in marketing management (Turley and Moore, 1995). Furthermore, corporate rebranding is becoming increasingly common due to an increased frequency of sundry rebranding motives in the micro- and macro-environment of enterprises (Hatsu et al., 2016). However salient this phenomenon is, it still remains insufficiently researched, especially in Central and Eastern Europe.

Evidence from The Warsaw Stock Exchange" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Existing Conceptual Framework

The scholars who investigate rebranding refer to various management and marketing frameworks, such as, Prahalad's and Hamel's resource-based view (RBV) (Otubanjo, 2010), Porter's positioning school (Ohnemus and Jenster, 2007), Spence's signalizing theory (Goettner and Limbach, 2011), change management theory (Chad, 2016), Keller's CBBE model (Sarkar and Roy, 2015). The brand itself has recently been regarded also as a Teece's dynamic capability (Brodie et al., 2016).

In spite of the aforementioned, there are not many papers which analyze the theoretical framework of rebranding. Many researchers, however, touch upon other scientific disciplines, such as psychology or biology. For instance, Tevi et al. (2009) make references to Darwin's evolution theory by comparing a developing organization to a human organism. Peterson (2015) cites Loewenstein's information gap theory on curiosity when explaining consumer attitudes towards rebranding. Ing (2012) makes use of Anderson's information integration theory as he analyses consumers' manner of collecting information and shaping their own opinion.

In this paper I underline the strategic role of rebranding, particularly its corporate type, which can stem from – or lead to – crucial changes in and out of an organization. Hence, corporate rebranding can be analyzed from the perspective of change management theory as well as dynamic capabilities (of an organization) theory. With reference to the research question included in the article's title: Is there a link between corporate rebranding motives and strategies? – I assume, backed by the literature review, that indeed, such a relationship exists. The aim of this study is to check it empirically.

Rebranding

The essence of rebranding

American Marketing Association (AMA) does not explain rebranding perhaps because it explicitly refers to the word brand meaning "a name, term, design, symbol or any other feature that identifies one seller's good to those of other sellers" (www.ama.org).

Yet the lexical meaning of rebranding is not unambiguous. According to Merriam-Webster Dictionary to rebrand means "to change or update the brand or branding (of a product, service)" (www.merriam-webster.com). Rebranding, as stated in Collins Dictionary, is "the process of giving a product or an organization a new image, in order to make it more attractive or successful" , while to rebrand is "to present it to the public in a new way, for example by changing its name or appearance" (www.collinsdictionary.com). In a similar manner this term is explained by Oxford Learner's Dictionaries, i.e. "the act or process of changing the image of a company or an organization or one of its products and services, for example by changing its name or advertising it in a different way" (www.oxfordlearnersdictionaries.com). Cambridge Dictionary's definition focuses on the brand image as it reads "the act of changing the way that an organization, business company or product appears to the public" (www.dictionary.cambridge.org). Some of these explications seem incomplete as rebranding pertains not only to brand image or even only to the name itself. Aaker and Joachimstaler (2000) emphasize that image is one of the elements of brand equity.

In the management and marketing literature rebranding is defined in two distinct manners: from a broad and narrow perspective. According to the former view rebranding denotes any change in any element of the visual identity system or brand identity with or without a change in a brand name. In the latter view rebranding is predominantly a brand name change which may be additionally accompanied by a change in other elements of visual identity system or brand identity. This differentiation is shown in the tables 1 and 2 below.

Table 1: Broad perspective of rebranding

Author, year	Definition
Keller, 2002. (In: Tsai et al., 2015)	Change in name, symbol or design that can occur in any layer of a brand's hierarchy, including the corporate, business unit, or product levels.
Muzellec and Lambkin, 2006	The creation of a new name, term, symbol, design or a combination of them for an established brand with the intention of developing a differentiated (new) position in the mind of stakeholders and competitors.
Bradbury and Catley, 2007	A more radical strategy than revitalization. It is possible to rebrand a product or service and, in situations where corporate identity is strongly tied to the brand, to rebrand the organization itself.
Hankinson, Lomax, Hand, 2007	Rebranding is a strategy designed to signal change. Its most obvious signals surround its visual identity, its name, logo, strapline and colours either singlely or plurally.
Weissner, 2007 (In: Mutsikiwa, 2011)	The process of creating a product or service labelled with a given brand under a different identity through radical changes of logo, brand name, image, marketing strategy, advertisement, including brand or enterprise repositioning.
Perzanowski, 2010	Rebranding occurs any time a company alters an existing brand identity, creating a new name, symbol, or design associated with its offerings.
Khandy, 2011	Creating a brand anew or revitalizing the brand when it loses its market position.
Chawuruka 2011	The process of giving a product or an organization a new, more attractive image.

Dixon and Perry, 2017	A process for updating and building better experiences, more so than it is about launching a new ad campaign.

Even though I present only a selected number of collected definitions, the majority of them pertain rather to the broad rather than the narrow perspective, as in table 2.

Table 2: Narrow perspective of rebranding

Author, year	Definition
Ljumovic, Marinkovic, Milanovic-Golubovic, 2010	Creating a new brand name.
Goetner and Limbach, 2011	Major or minor name changes pertaining to a person, product or a company.
Delassus and Descotes, 2011	Brand name substitution.
Opuni and Baffoe, 2013	Changing an organization's name, targeting and repositioning the organization's offer to its customer and other publics. It is usually done to assign new meaning to an existing product or organization.
Collange, 2015	Changing brand names.
Collange and Bonache, 2015	Removing one brand name (the initial brand name) and replacing that name with another for a product, whether a good or service.
Agha et al., 2016	Brand name change.

This typology is distinct from the one of Muzellec and Lambkin (2006) as it does not include the aspect of time-span. I included it as a different kind of rebranding strategy (see next paragraphs).

This paper is limited to corporate rebranding only as one can notice a surge of attention to corporate brand in the recent decades (Fetscherin and Usunier, 2012). I refer to a definition of a corporate brand formulated by i.a. Ohnemus (2007), Ormeno (2007), Chailan (2009), Aaker (2010) and Keller (2011) who state that corporate brand is a brand which represents all or the majority of products offered by an enterprise and distinguishes them from the competitors' product offer.

Rebranding Strategies: Literature Review

Researchers analyzing rebranding strategies focus on four main aspects: developing a typology of rebranding strategy (Kapferer, 1992), identifying determinants of successes and failures of rebranding strategy (Coles, 2003), analyzing the relationship between rebranding motives and strategies (Gussoni and Mangani, 2012), and analyzing the relationship between rebranding strategies and both financial and non-financial enterprise performance (Gupta and Aggarwal, 2014).

The first typology of rebranding strategies was presented by Kapferer (1992) who distinguished the following four types which were later referred to by numerous researchers (Daly and Moloney, 2004). The researchers also indicate two basic types of rebranding strategies distinguished due to its scope: rebranding strategies without a brand name change (Singh et al., 2012; Tsai et al., 2015) and rebranding strategies including brand name changes. The second group is further subdivided into strategies with a partial brand name change (e.g. Goettner and Limbach, 2011) and strategies with a complete brand name change (e.g. Branca and Borges, 2011; Koku, 1997). Among the strategies with a partial change of the brand name, one can distinguish: co-branding (Basu, 2006), retention strategy, i.e. maintaining both brands, but also using them separately (Muzellec and Lambkin, 2008), shortening or extending the name by the number of letters that make up the brand name (Ferris, 1988) and shortening or extending the name by the number of words that make up the brand name (Mase, 2009).

Typology of corporate rebranding strategies

On the basis of the literature review presented above, I propose the following typology of rebranding strategies:

1. Brand name change strategies distinguished due to the scope of the brand name change:

    1.1. Rebranding with a complete brand name change
        1.1.1. Substitution – replacing the present brand with a new one (A → B).
        1.1.2. Retrobranding – replacing the present brand with a previous brand (A → B → A).
    1.2. Rebranding with a partial brand name change
        1.2.1. Modification – shortening or exteding brand name (Aa→A).
        1.2.2. Co-branding – new brand consists of two or more previously known brands or their elements (A+B→AB).
2. Brand name change strategies distinguished due to a brand's geographic scope:
        2.1.1. Brand localization strategy (global brand → local brand).
        2.1.2. Brand internationalization strategy (local brand → global brand).
        2.1.3. Counter-localization strategy (local brand → local brand).
        2.1.4. Counter-localization strategy (global brand → global brand).
3. Brand name change strategies distinguished due to the number of stages:
        3.1.1. One-stage strategy (A→ B).
        3.1.2. Multistage strategy (A → AB → B).

Rebranding motives

Literature Review

Rebranding motives are the subject of many studies. According to researchers, rebranding is a result of many different factors such as, for example, weaker brand performance in a given consumer segment (Ponnam et al., 2015), loss of brand market position, an outdated image or poor reputation (Le at al., 2014). Mergers and acquisitions are one of the most frequently mentioned reasons (i.a. Brophy, 2013).

According to the Institute for Mergers, Acquisitions and Alliances (IMAA, 2020), in 2019, the number of mergers and acquisitions in the world amounted to more than 49 849 transactions with a total value of over 3 701.4 billion USD. Although the value of transactions has decreased in comparison with the previous year, as well as compared to the peak years 2007 and 2015, the number of transactions has been growing steadily and continuously since 1985. Consolidation of entities can be also observed on the Polish market. The reports of IMAA indicates that the number of mergers and acquisitions in Poland has increased since 2014, reaching a record number of 792 in 2015 (IMAA, 2020). In 2019, 582 transactions worth nearly EUR 9 billion were carried out in Poland (IMAA, 2020). According to the data collected in this research, mergers and acquisitions are the most common motive for rebranding.

Gussoni and Mangani (2012) indicate that mergers, horizontal acquisitions, high value mergers or private equity mergers and acquisitions determine the use of strategies defined as innovative, i.e. when the target brand consists of the brands of both entities or is newly created. In other cases, the enterprises choose strategies called by the authors as conservative, when the brand of the acquiring or acquired entity is the target brand.

According to Ettenson and Knowles (2006), mergers and acquisitions determine as many as ten different types of corporate brand rebranding strategies. For example, mergers and acquisitions most often lead to the application of strategies 1) retaining all elements of the visual identity system, including the brand name only of the lead company (in most cases), 2) retaining name and other visual identity elements of the target company, 3) retaining name and visual identity system elements of the

lead company and only the name of the target company, 4) retaining only the brand name of the lead company, 5) retaining names and all elements of visual identity system of both brands, 6) retaining only names of both brands, 7) retaining name of the lead company and elements of visual identity system of the target company, 8) retaining both name and elements of the visual identity system of the target company and only the name of the lead company, 9) creating a completely new brand, 10) both brands still exist independently.

However, mergers and acquisitions are not the only motives for rebranding. The researchers enumerate other factors, such as diversification (Muzellec and Lambkin, 2006), repositioning (Weisnner, 2007) or mistakes in company management (Todor, 2014). Some researchers, such as Rhee and Han (2006) emphasize that apart from the abovementioned motives there occur others e.g. high expectations of consumers towards the company pertaining to reputation and compliance with corporate governance principles.

One of the more frequently mentioned motives for rebranding are image problems, regardless of whether it is outdated, inappropriate, misleading or in crisis (Luck, 2012). Changes in the target group are also widely described in scientific publications as one of the reasons for rebranding (e.g. Bradbury and Catley, 2007).

An increasingly important group of rebranding motives constitute market fashions concerning, e.g., the name of a corporate brand containing a reference to a currently popular technology. At the beginning of the 2000s, it was popular to add the word dotcom to an existing brand name or to replace it with another name by adding dotcom (Cooper et al., 2001). The latest trend regarding changing the name of a corporate brand (often identical with the company) is its change by adding the word blockchain (Zhao et al., 2018). This phenomenon was some time ago so ubiquitous that the US Securities and Exchange Commission (SEC) verified companies that decided to suddenly change company, corporate brand name and business profile due to a suspicion that the only motive may be a desire to quickly increase the valuation of shares of listed companies (Price, 2018).

A similar phenomenon has been described by Byun (2012) based on the research on a group of South Korean enterprises, where the name of the brand which was to evoke positive associations and ultimately increase the market value of enterprises was the name of the chaebol. Legal regulations to a trademark may also constitute a motive for rebranding (Perzanowski, 2010).

Muzellec and Lambkin distinguish four groups of rebranding motives: changes in a company's internal structure, changes in a company's competitive position, changes in a company's corporate strategy and changes in the environment. In turn Goi and Goi (2011) indicated several internal and external rebranding motives.

Typology of rebranding motives

On the basis of the literature review I developed a typology of rebranding motives.

Internal motives comprise of:

1) factors pertaining to the structure and form of ownership of an enterprise, such as: mergers, acquisitions, divisions, initial public offering, spin-offs;
2) factors pertaining predominantly to a company's strategy (at the level of an enterprise, strategic business unit or function, including marketing) or enterprise results, such as: brand results (e.g. loss of brand position or brand value), image (outdated, inappropriate, indistinct, broken, damaged, in crisis), reputation (problematic, weakened), organizational culture (inadequate), management mistakes, technology (obsolete), enterprise performance (poor, low market value, financial problems), separation of the value chain, change of company business activity, diversification, internationalization, location strategy (adaptation/standardization), infrastructure development, foreign market entry, changes in customer value proposition, brand repositioning, sponsorship, targeting new groups.

External motives include:
3) macroeconomic factors (political and legal, economic, socio-cultural, technological, demographic) such as: fiscal policy, legal obligations, development of technology, random disasters, new consumer preferences, regulations to a trademark, changes in market trends, changes in the economic legal environment, cultural trends;
4) microeconomic factors: target group (loss of trust, saturation, ageing, changes in demand, shrinking of a target group), competitors (market position, entry of new competitors, new strategies of competitors), intermediaries (contract termination, change of rates for services, conflict of interest).

According to the literature review, it can be concluded that the most typical internal motive pointed out by many rebranding researchers constitute mergers and acquisitions (Kapferer, 2012), and changes in ownership structures of enterprises (Muzellec and Lambkin, 2006). The most common external motives are consumer trends, inadequate or outdated image (Stuart and Muzellec, 2004,) and repositioning (Kaikati, 2003). Changes in legislation (Ljumovic et al.., 2010) and technology (Perzanowski, 2010) are rarely pointed out by the researchers.

Research Method

Data and sample

The quantitative research was conducted on the sample of 121 joint-stock companies listed both on the Main Market of the Warsaw Stock Exchange and its alternative trading system New Connect[1]. The research timeframe covers years between 2000 and 2015 for WSE Market and 2007-2015 for New Connect. In this 15-year period I identified 138 cases of corporate brand name changes, which means that some enterprises rebranded more than once.

The data concerning rebranding strategy and also main and detailed motives were obtained from the secondary sources – publicly available data of enterprises listed on the Main Market of the Warsaw Stock Exchange (WSE) or New Connect. In addition, I used the following sources of information: periodic information (annual and quarterly reports), current information (corporate), confidential information (e.g. mergers, divisions, separations, restructuring, reorganization, legal disputes, new patents and licenses, registered trademarks and other) and publicly available data posted on the websites of the companies being the subject of the study (e.g. press releases), industry reports and business intelligence reports, as well as interviews with CEOs and directors of marketing and corporate communications departments. The characteristics of the companies included in the sample is presented in table 3 below.

Table 3: Sample characteristics – number and size of enterprises, type of market and economic activity

Type of economic activity	No. of enterprises	Type of economic activity	No. of enterprises
Construction	8	Manufacturing	34
Finance and insurance	29	Transportation and storage	2
Information i communication	19	Real estate	4
Electricity, gas, steam and air conditioning supply	1	Professional, scientific and technical	2
Wholesale and retail trade	20	Public administration	2
Type of market			
Main Market	91	New Connect	30
Size of enterprise[2]			
Large	62	Medium	22
Small	37		

Number of cases of corporate brand name change per enterprise			
1 case	105	3 cases	3
2 cases	20	4 cases	1

The vast majority (91) of entities included in the survey that changed the name of the corporate brand were listed on the main market of WSE during the period considered, while 30 of the surveyed companies were listed on New Connect. The largest number of enterprises was represented by manufacturing (34), the finance and insurance (29), while companies in the wholesale and retail trade as well as information and communication sectors were represented in almost the same number (20 and 19 respectively). The least represented industries were: construction (8), real estate (4), as well as transport and storage, also professional, scientific and technical activities; public administration (2 companies each from each industry), while one enterprise operated in the industry of electricity, gas, steam and air conditioning supply.

Large enterprises constitute the majority of the surveyed population (62 entities), small enterprises – a smaller group (37 companies), while medium-sized enterprises are the least numerous group (22).

Measures

The empirical study included the following motives for changing the corporate brand name change: 1) mergers, 2) acquisitions, 3) strategic factors, 4) microeconomic and macroeconomic factors. In addition, the following rebranding strategies included: 1) complete brand name change), 2) co-branding, 3) extension of the corporate brand name and 4) shortening of the corporate brand name.

The study was testing following hypothesis: *H.: The type of the motive for rebranding differentiates the corporate rebranding strategy implemented by an enterprise listed on Main Market or New Connect on Warsaw Stock Exchange*

Fig. 1 : The relationship between the motives and corporate rebranding strategies of WSE companies

Independent variables constitute the type of the strategy: substitution, co-branding, extension, shortening and the type of the motive: mergers, acquisitions, strategic factors, macro- and microeconomic factors. In the chi-square independence test, both categorical variables were coded in words.

Research Analysis

In order to verify the hypothesis the chi-square test of independence was carried out – see table 4 below.

Table 4: Contingency table and chi-square test of independence for motives and strategies

			Motive				Total
			merger	micro- and macroeconomic factors	acqusitions	strategic factors	
Corporate brand name change	complete	Frequency	13	3	40	30	86
		%	50,0%	30,0%	72,7%	63,8%	62,3%
	co-branding	Frequency	4	0	4	0	8
		%	15,4%	0,0%	7,3%	0,0%	5,8%
	extension	Frequency	4	0	5	3	12
		%	15,4%	0,0%	9,1%	6,4%	8,7%
	shortening	Frequency	5	7	6	14	32
		%	19,2%	70,0%	10,9%	29,8%	23,2%
Total		Frequency	26	10	55	47	138
		%	100,0%	100,0%	100,0%	100,0%	100,0 %

	Value	df	Asymptotic significance (two-sided)
Pearson chi-square	27,507[a]	9	,001
Likelihood ratio	28,017	9	,001
N significant observations	138		

a. 56,3% cells (9) have expected frequencies less than 5. The minimum expected frequency is ,58.

The chi-square test of independence for the above variables gave the following results – chi square is 25,507 and df equals 9. The statistically significant results of the chi-square test suggest that the dominant type of rebranding motive is linked with the applied strategy type of brand name change. The contingency table indicates that the complete brand name change strategy was chosen most often chosen by enterprises which rebranding motive was acquisition and least often by enterprises which rebranded due to micro- and macroeconomic factors. Co-branding and brand name change extension are strategies which are more often applied in case of mergers and other motives, while brand name change shortening is the last choice of enterprises in case of acquisitions.

The analysis above is not yet fully credible due to a limited number in many cells in the cross-tab. The assumption in chi-square independence test reads that the number of cells for which expected frequencies are less than 5 should not exceed 20% of all cells in a cross-tab. In this analysis this value is 56,3%, which means that the estimated chi-square statistics might be exceeded. This, in turn, may lead to a higher probability of type I error (erroneous rejection of a true null hypothesis of independence of two variables). One of the solutions to avoiding this problem is sample expansion. In this particular case it is, however, impossible as I included all enterprises listed on WSE which rebranded in 2000-2015 in the sample. The only solution is to carry out individual chi-square tests for the pairs of variables referring to all 16 combinations of motives and strategies. These tests are shown in tables with four cells for partial frequencies (in the original table there are 16 of them), which makes it possible to increase expected frequencies and avoid rejection of the null hypothesis.

Out of sixteen individual chi-square tests six proved to be statistically significant – the results are discussed below. In all of the cases the null hypothesis of chi-square was not rejected as in none of the cells the expected frequencies was less than five.

The relationship between corporate brand name shortening and acquisition was checked in the second individual chi-square independence test – see table 5 below.

Table 5: Contingency table and the chi-square independence test for corporate brand name shortening and acquisition

			Acquisition		Total
			no	**yes**	
Corporate brand name shortening	**no**	Frequency	73	49	122
		%	73,7%	89,1%	79,2%
	yes	Frequency	26	6	32
		%	26,3%	10,9%	20,8%
Total		Frequency	99	55	154
		%	100,0%	100,0%	100,0%

Table 6: Contingency table and the chi-square independence test for corporate brand name shortening and strategic factors

			Strategic factors		Total
			no	**yes**	
Corporate brand name shortening	**no**	Frequency	89	33	122
		%	83,2%	70,2%	79,2%
	yes	Frequency	18	14	32
		%	16,8%	29,8%	20,8%
Total		Frequency	107	47	154
		%	100,0%	100,0%	100,0%

The results in the cross-tab (chi-square=3,334; df=1; Cramer's V=0,147) indicate that 29,8% enterprises which rebranded because of strategic factors applied corporate brand name shortening, while the majority of enterprises (70,2%) chose a different strategy. The relationship between the variables is also statistically significant though not very strong as p value is 0,068.

The next individual chi-square independence test analyzes the relationship between shortening of corporate brand name and micro- and macroeconomic factors (table 7).

Table 7: Contingency table and the chi-square independence test for corporate brand name shortening and micro- and macroeconomic factors

			Micro- and macroenomic factors		Total
			no	**yes**	
Corporate brand name shortening	**no**	Frequency	119	3	122
		%	82,6%	30,0%	79,2%
	yes	Frequency	25	7	32
		%	17,4%	70,0%	20,8%
Total		Frequency	144	10	154
		%	100,0%	100,0%	100,0%

The results in the cross-tab (chi-square= 15,739; df=1; Cramer's V=0,320) imply that 70% of companies which rebranded due to micro- and macroeconomic factors shortened its corporate brand name, whereas only 17,4% chose a different strategy. The link between these two variables is not only statistically significant as p equals 0,000 but also strong.

The relationship between corporate co-branding and merger was checked in the following individual chi-square independence test – see table 8 below.

Table 8: Contingency table and the chi-square independence test for co-branding and merger

			Merger		Total
			no	**yes**	
Co-branding	**no**	Numbers	124	22	146
		%	96,9%	84,6%	94,8%
	yes	Numbers	4	4	8
		%	3,1%	15,4%	5,2%
Total		Numbers	128	26	154
		%	100,0%	100,0%	100,0%

The results in the cross-tab (chi-square=6,595; df=1 and Cramer's V=0,207) imply that merely 15,4% of enterprises which rebranded owing to a merger decided to co-brand. Whereas up to 84,6% of enterprises chose a different strategy. In spite of being statistically significant (p equals 0,010), the relationship between the merger and co-branding is weak.

The fifth individual chi-square independence test verifies co-branding and strategic factors (table 9).

Table 9: Contingency table and the chi-square independence test for co-branding and strategic factors

			Strategic factors		Total
			no	**yes**	
Co-branding	**nie**	Frequency	99	47	146
		%	92,5%	100,0%	94,8%
	tak	Frequency	8	0	8
		%	7,5%	0,0%	5,2%
Total		Frequency	107	47	154
		%	100,0%	100,0%	100,0%

The results in the cross-tab (chi-square=3,707; df=1 and Cramer's V=0,155) imply that 100% of enterprises which rebranded due to strategic factors applied a different strategy than co-branding. None of enterprises which rebranded because of strategic factors applied co-branding. Therefore, the relationship between strategic factors and co-branding is statistically significant but weak as p value equals 0,054.

Table 10 shows the results of the chi-square independence test for complete change of corporate brand name and acquisition.

Table 10: Contingency table and the chi-square independence test for complete change of corporate brand name and acquisition.

			Acquisition		Total
			no	**yes**	
Complete change of corporate brand name	**no**	Frequency	53	15	68
		%	53,5%	27,3%	44,2%
	yes	Frequency	46	40	86
		%	46,5%	72,7%	55,8%
Total		Frequency	99	55	154
		%	100,0%	100,0%	100,0%

The results in the cross-table (chi-square=9,890; df=1; Cramer's V=0,253) imply that the vast majority of enterprises (72,7%) which rebranded due to an acquisition replaced their corporate brand name. The smaller group of enterprises (27,3%) which rebranded due to this motive decided on a different strategy. The relationship between these two variables is both statistically significant and strong as p value is 0,002.

Analysis Summary

To sum up all the analyses – the empirical data proved the hypothesis as there are statistically significant differences between the dominant motives and strategies of rebranding. It should be emphasized that not all motives differentiate all types of rebranding strategies. Statistically significant differences have been observed in 6 out of 16 pairs of motives and strategies. The strength of association between the nominal variables in each of the 6 pairs is presented according to the Cramer's V – see table 11 below.

Table 11: Cramer's V ranged from the highest to the lowest value for the pairs strategy of corporate brand name change and motive with statistically significant results of chi-square independence tests only

No.	Pair of strategy of corporate brand name change and motive	Cramer's V
1.	Shortening of corporate brand name and micro-and macroeconomic factors	0,320
2.	Complete change of corporate brand name and acquisition	0,253
3.	Co-branding and merger	0,207
4.	Shortening of corporate brand name and acquisition	0,181
5.	Co-branding and strategic factors	0,155
6.	Shortening of corporate brand name and strategic factors	0,147

The strongest effect was observed for the pair shortening of corporate brand name and micro- and macroeconomic factors. This means that the enterprises which rebranded as a result of micro- and macroeconomic factors were identified as these which more often chose the strategy of shortening the corporate brand name. Strong effect has been identified also for pair 2,3 and 4. This means that the companies which rebranded due to an acquisition were more often identified as these which replaced their corporate brand name. The enterprises which rebranded because of a merger were more often identified as these which co-branded. Moreover, the enterprises which rebranded as a result of an acquisition were more often identified as these which shortened the corporate brand name. A weaker effect was observed for pairs 5 and 6. The enterprises that rebranded due to strategic factors were more often identified as these which co-branded, while those that rebranded due to strategic factors were more often identified as these which shortened the corporate brand name.

Conclusions

This study made a notable input in the field of rebranding. The reason for this is twofold; first, this field is still underresearched in terms of conceptual framework and systematization of definitions, and second, the particular relationship between the motives and strategies also remains insufficiently researched. Moreover, the few researchers investigating this subject-matter (i.a. Basu, 2006, Ettenson and Knowles, 2006, Mangani and Gussoni, 2012) scrutinized only the correlation between mergers and acquisitions and rebranding strategies. This research included also strategic factors as well as micro- and macro-economic factors. I did not identify a similar research to be carried out on the markets of the Central and Eastern Europe.

The study confirmed the hypothesis that the motive differentiates corporate rebranding strategy. Basu (2006) claimed that various types of mergers and acquisitions lead to one of the four following strategies: retaining one brand, co-branding, creating a new brand, retaining both brands but each for a different market or situation. The results of this research are in line to some extent with results of Basu's study as among enterprises that rebranded due to an acquisition or a merger the majority created a new brand or co-branded. However, this study also proved that among the enterprises which rebranded as a result of an acquisition many of them chose the strategy of shortening the corporate brand name. It should be added, however, that I did not differentiate between various types of mergers and acquisitions. The results of my study are also partially in line with the results of the research of Gussoni and Mangani (2012) as mergers may lead to co-branding. Yet, in contrast to the researchers' results, this study proved that in case of the Polish joint-stock companies acquisitions may also lead to the so-called innovative strategies, such as complete brand name change (substitution). The results of the study conducted by Ettenson and Knowles (2006) indicate that almost 40% of enterprises that underwent M&A changed both the brand and other elements of the visual identification system of the acquired company. It is also confirmed in this study as one of the strongest correlations was identified between the complete change of corporate brand name and an acquisition.

Nevertheless, these are not only mergers and acquisitions that differentiate corporate rebranding strategies. Rapid technological growth is of rising importance. In this research this motive was included in the group of micro- and macroeconomic factors. Euromonitor International reports of 2010-2020 (Gordon et. al) indicate that at least five out of ten key consumer trends are primarily shaped by technological progress. Therefore, what is also backed by the research results, it has an undoubtedly significant impact also on brand management strategies, especially rebranding.

Limitations and Further Research

The data was collected only from the secondary sources. I included only one type of corporate rebranding strategies in the research which was distinguished due to a range of changes in the brand name. The sample is limited solely to joint-stock companies listed on Warsaw Stock Exchange Main Market and New Connect.

It is recommended to deepen the research on the relationship between the motives and corporate rebranding strategies, including diversification of variables (e.g. many types of rebranding strategies or types of mergers and acqusitions). What is more, a similar study could be carried out on other markets of CEE (or other markets in the world). Finally, a comparative analysis between various countries and markets would enable the scholars to deepen the conclusions and formulate universal managerial implications in this matter.

Endnotes

1. New Connect was established in Poland in 2007 for companies "*with large growth potential, operating in innovative sectors mainly with intangible assets, looking for equity between several hundred thousand and several million PLN and a possibility of an IPO in the exchange market in near future*", in: https://newconnect.pl/basic-info. (31.03.2020).

2. Microenterprise: less than 10 employees, annual turnover or balance below 2 mln EUR. Small enterprise: less than 50 employees, annual turnover or balance below 10 mln EUR. Medium-sized enterprise: less than 250 employees, annual turnover below 50 mln EUR or balance belowe 43 mln EUR." Long-Term Dynamics and Features of The Russian Arctic's Economic Development

Natalia A. SEROVA

Luzin Institute for Economic Studies of the Federal Research Centre "Kola Science Centre of the Russian Academy of Sciences", Apatity, Russia, nataleks13@yandex.ru

Abstract

This research aims at studying main trends in the economic development of the Russian Arctic region since 1950-2018. In accordance with the results of this analysis, the author has identified three conceptually different periods in the development of the Russian Arctic zones which involve an intensive economic development stage in 1950-1990; a nascent stage for market relations in 1990-1999; and a modern development stage or a re-development stage for the Russian Arctic region that started in 2000 and has lasted ever since. The paper also demonstrates major features of the Arctic zones' economic development at each stage.

Keywords: Arctic zone of the Russian Federation, Region, Economic Development.

Introduction

At present, the Arctic region is one of the most essential vectors in the Russian domestic and foreign policies on an assumption that the Arctic region is rich in natural resources and may guarantee its sustainable development and secure national safety in the 21st century. Due to the fact that a clear idea of the features and mechanisms to the economic processes typical of this region is necessary for the identification of priority trends and tasks in the development of the Arctic zones, this research was focused on studying parameters describing certain aspects of the Russian Arctic's economic development in 1950-2018 within the boundaries of an area which is defined as the Arctic zone of the Russian Federation (or the RFAZ) pursuant to Decree of the RF President No. 296 dated 2 May 2014 'Concerning Land Territories of the Arctic zone of the Russian Federation.'

Materials and Methods

The analysis was executed on the basis of official data from the Russian Federal State Statistics Service on the social and economic status of Russia and RFAZ regions over a period of 1950-2020, as well as on the basis of statistical data from the Historical materials project (http://istmat.info). Due to the unavailability of the major economic indices, the research included only main indicators of the industrial production and investment activities. Using the indices of the actual industrial output/capital investment volumes that describe the changes as compared to the previous year, the author has calculated relative indicators of industrial and investing dynamics which are the growth rates and increment rates, as well as annual average growth rates. For the first period (1990-1999), the year 1950 was applied as a base year (the year 1970 was used for the investing dynamics); the year 1990 – for the second period; and the year 2000 – for the third period.

The calculations of the growth rates were made by the following formula: $Tr = I_1 / I_0 \times 100$ where Tr is the growth rate, in %; I_1 is the index of the actual industrial output/capital investment volumes in the current period, in %; and I_0 is the index of the actual industrial output/capital investment volumes in the base period, in %.

The calculations of the increment rates were conducted by the following formula: $Tp = Tr - 100$ where Tp means the increment rate, in %.

The calculations of the annual average growth rates were executed by the formula of the geometric mean from the indicators of the indices of the actual industrial output/capital investment volumes for certain periods.

Results and Discussion

The second half of the twentieth century was marked by an increased economic significance of the Arctic territories in the USSR's national economy. Due to the discovery of large mineral deposits, the industry there developed faster than that on a national average value in a period from 1950 to 1990; a mean five-year increment rate in the RFAZ was +34.9% against a USSR's national rate of +31.9%.

The generalized view of the industrial production dynamics in the RFAZ is shown in Figure 1 as compared to the Russian national average values for a period of 1950-1990.

Figure 1: Dynamics of industrial production (1950 = 100%)

Source: author's calculations

The extensive exploration of the Arctic territories was mainly promoted by the development of navigation in the Northern Sea Route (or NSR) that connected the mining industry of the European and Eastern Arctic regions at a poorly available onshore traffic infrastructure. During the whole Soviet period, the NSR cargo carriage scope grew annually having reached its maximum in 1987.

In general, Leksin and Porfiriyev (2019) reported that the presently used economic and infrastructural resources in the Arctic macroregion were created for over 90% during the Soviet (socialist) time.

In the mid-1980s, the industrial production in the Arctic regions started demonstrating a clear trend of rundown. Thus, the average growth rate of the RFAZ gross industrial output in 1980-1985 was 31.0% and dropped down to 29.7% in 1985-1990. Upon the breakup of the USSR, the scaling back of the economic activities in the Arctic region became drastic, and by the late 1990s, the industrial output had reduced almost by one third. The most negative dynamics for that period was demonstrated by the Chukotka Autonomous District where the production output in 1999 was 38.6% of the year 1990 value. Kumo and Litvinenko (2016) assume that the downturn in the district's key branches related to the gold and tin mining became unprofitable because of the development of market relations and resulted in the shutdown of the largest mining and processing enterprises in Chukotka and dismantling of the majority of mono-industry workers settlements and townships.

The slump in production in the Arctic regions was accompanied by an abrupt diminution of investment inflows. It mostly affected Chukotka where the capital construction for the considered period was almost curtailed (the volume of investments to the region in 1999 was only 3.7% of the year 1990 value). The lowest recession was registered in Yakutia and on Yamal, but even in those regions the scope of investments at the end of 1999 was contracted by almost three fourths as compared to the year 1991 level.

The generalized view of the industrial production dynamics and actual capital investments to the RFAZ is shown in Figures 2 and 3 in comparison with the Russian national average values.

Figure 2: Dynamics of industrial production (1990 = 100%)

Source: author's calculations

Figure 3: Investment dynamics (1990 = 100%)

Source: author's calculations

In general, the investing recession to the Arctic regions was deeper as compared to the national average level (by the late 1990s, capital investments to the Arctic regions dropped by almost four fifths) and could not be compensated by a relatively more favourable situation in the oil-and-gas regions, for example, on Yamal. Moreover, a faster investment slump took place against the background of a less reduction in the industrial production as compared to the national average value. Thus, the Arctic regions 'became some kind of a buffer damping negative consequences of the national setback in production during the economic crisis, but faced a worse situation in terms of the conditions for the fixed assets reproduction' (Didyk and Serova (2005)).

At the same period, the whole Arctic transportation system started breaking up (Konovalov (2011); Selin (2002)). The discontinued public supply of materials and machinery to the High North and Arctic regions and abolition of the public administration authorities for these challenging territories led to the unprofitability of the majority of Arctic harbours, reduction in the number of polar stations, and decommissioning of a greater part of ice-class vessels (Ulchenko and Bashmakova (2018)). This also caused the closure of many civil aerodromes, ultimately, only branches of former combined forces were what had been left of the unified Arctic aviation system in 1993; afterwards, over 70% thereof ceased to exist.

With the breakup of the centralized Soviet system, all state programs aimed at the support of the High North and Arctic regions were aborted because the public policy was focused only on the reduction of costs in those regions (Lukin (2010); Ponomarev (2009)). It resulted in the degradation of the social sector, abrupt increase in life costs, growth of unemployment, etc. (Bradshaw (1995); Heleniak (1999); Shaparov (2019)), having caused mass depopulation of the Arctic regions. In general, the number of inhabitants in the RFAZ dropped by 9.7% in 1990-1999. The largest depopulation was faced by Chukotka (by 2.4 times), Nenets Autonomous District (-21.0%) and Murmansk region (-19.1%). The main reason for the arisen social problems lied in the breakup of the Soviet system

for the legislatively established mechanisms of attracting and fixing human resources in the Arctic regions that stipulated various allowances and increased locality pay factors (Oleinikov (2013)).

In the early 2000s, the Arctic territory became one of the priority trends of the Russian foreign policy. The giant resource potential of the (Gautier et al. (2009); Kontorovich, A.E. (2015)) region and emerging opportunities for the development of the strategically vital traffic routes (Smith and Stephenson (2013); Biev (2018)) have stirred up an unprecedented interest to the Arctic region from leading countries of the world and largest oil-and-gas and mining companies. This, in turn, had caused an acute necessity for the development of a conceptually new national public policy towards Arctic territories. Russian Federation National Security Concept No. 24 dated 10/01/2000 set a task to 'promptly design mechanisms for supporting the economic development of the Arctic territories.' Three months later, there was the Public Concept of the Support to Northern regions adopted and afterwards draft Fundamentals of the Russian Arctic public policy and Concept of the sustainable development of Arctic territories compiled.

The attempted measures along with the increasing prices at the global feedstock (oil, gas, nonferrous metal ores, and diamonds) market had promoted the economic growth and amplified the investment activities in the Arctic territories. Already by 2000, the scopes of investments to the RFAZ had grown by 76.5% as compared to 1999 while the mining industry became the main economic sector in that region. However such impressive investing growth indices should not be overestimated because no conditions for a sustainable investment process ensuring an extensive fixed assets reproduction on the basis of own regional resources, had not been created in the RFAZ at that moment and this created risks of an economic slack after a period of the investment boom. It is well exemplified by the Chukotka Autonomous District where the investing activities were boosted upon the election of the prominent businessman, Roman Abramovich, as a governor (capital investments grew 108 times in 2003 as compared to 2001). However after the expiration of his governor's powers in 2005, the inflow of investments to the region significantly reduced.

In general, an intention of the state to apply a comprehensive approach to the Arctic's development mainly distinguished the third stage from the second one of the development of the Russian Arctic territories. Despite the fact that social problems emerged in the 1990s still remain unsettled, in particular, that the trends of depopulation and declining living standards continued (Kiseleva and Gokova (2016); Shelomentsev et al. (2018); Rybakovsky and Kozhevnikova (2019); Korchak and Serova (2019)), exactly this period has marked the initiation of the RFZA institutional and legal framing.

In 2008, the foundation of the Arctic-related legislation continued with the approval of the Fundamentals of the Russian Arctic public policy in accordance with which the primary national interests included 'the application of the RFAZ as a strategic resource base ensuring the resolution of the issues related to the social and economic development of the country' and 'using mass-media as a national Arctic transportation communication.' Upon the approval of the above Fundamentals, dozens of federal law and strategic documents were published to directly or indirectly provide an insight into the RFAZ as an independent governmental unit (Skufyina (2016)). In particular, there was the composition of onshore RFAZ territories identified, the Strategy for the development of the RF Arctic zone development and provision of national security for a period till 2020 approved. As well, the State Program for the Social and Economic development of the RF Arctic zone for a period till 2020, and other documents were applied.

The economic development of the Arctic regions in that period was defined by sustainable growth trends of the industrial production and capital investments (Figure 4-5). Gadzhiyev, Akopov and Krestovskikh (2012) suggest that the major factors of the investment recovery included profits from an extensive export of raw materials, attraction of foreign low-interest loans by the companies and public financing. At a regional level, the Chukotka Autonomous District became an economic growth leader due to the started development of certain new gold deposits there in 2008-2012. Over the considered period, the regional industrial output increased by 8.2 times and an arrival of investments grew by 7.3 times. Due to large-scale investments to the oil-and-gas production, high growth rates of the industrial output (by 3.6 times) were also typical of the Nenets Autonomous District.

Figure 4: Dynamics of industrial production (2000 = 100%)

Source: author's calculations

Figure 5: Investment dynamics (2000 = 100%)

Source: author's calculations

It shall be noted that this stage of the Russian Arctic's development has not settled social issues. Korchak (2020) points out that the issues of poverty, unemployment, depopulation, etc. still remain urgent in the Arctic regions indicating a low efficiency of the public policy in the field of social development in the RFAZ.

Conclusions

The analysis has shown that the development of the Russian Arctic territories took place in three conceptually different stages defined by the intensity of their economic development, scales of public support and long-term interests of the national economy, and namely:

1) 1950-1990: an intensive economic development stage of the Arctic territories. It involves an economic growth in the regions where large-scale mineral deposits and oil-and-gas fields were discovered, mainly on Yamal;

2) 1990-1999: a nascent stage for market relations. In the course of domestic economic reforms, the Arctic regions fell into a profound crisis accompanied by an abrupt drawdown of investment activities, a reduction of industrial production output, a fall of living standards, and a mass exodus of the local population; and

3) 2000-present: a modern development stage for the Arctic territories which is characterized by an investment activity revival based on an active national policy related to the RFAZ development on the one hand, and by continuing negative events in the social sector on the other hand.

Abstract

Plastic is a very harmful material for nature. It is reported that 40 per cent of the pollution in the globe is happening due to plastic. Some of the reports (Patrick J Kiger, 2015; Claire Le Guern, 2019; Laura Parker, 2015; Erik Van Sebille, 2016) show that around 8 million tons of plastic waste are gone to the ocean each year which affects the marine life extremely. Plastic is not biodegradable material. In all dimensions, we can say that plastic is an adversary to the earth. It is very essential to reduce the use of plastic to protect our nature. Many of the countries have banned single-use plastic products such as water bottles, bags, straws, etc. by considering environmental issues. Kerala state in India banned the same from 1 January 2020. In this situation, bamboo products can be considered as an alternative to plastic products. The present paper tries to describe the environmental challenges of plastic and also the ecological and eco-friendlier importance of bamboo and its products in the period of single-use plastic ban in Kerala. The needed data is gathered by reviewing various literatures. The paper proves that bamboo has an inevitable role in environmental sustainability like soil erosion protection, conservation of soil and water, check dams, bamboo railing in river banks, carbon absorption, reconstruction of land, etc. It can be used for making many of the products instead of plastic such as household items, decorative items, bathroom products, musical instruments, ornaments, etc. due to its eco-friendly characteristic.

Keywords: Plastic, Bamboo, environment, eco-friendly

Introduction

Plastic pollution is one of the important environmental challenges that increase day by day and simultaneously there is an increase in the manufacturing of single-use plastic products. The globe is becoming incapable to deal with them. Plastic pollution can be shown in many areas of the globe even though it is mostly clear in African and Asian continents where the waste management system is not efficient. Plastic is made from fossil fuels for more than a century. Laura Parker (2019) demonstrates that, after World War II, the manufacturing and use of plastic are enlarged heavily so that the modern world is not identifiable without plastic. Plastic is used in many areas, but it has numerous dark sides. The single-use plastics have planted a use and throw culture among humans. So the usage time of its products is very less whereas the lifespan of the plastic waste in the environment is around a hundred years. According to Charles Moore (2020), plastic pollution is the accretion of plastic products in the environment and the creation of various issues to animals and humans. Many of the species in the land and ocean consume single-use plastic products by mistaken as their food. It may lead to the death of them or create health issues to the human by eating these species.

Cite this Article as: Ms. Sreelekha E K and Dr. Ambily A S "Ecological and Eco-Friendlier Importance of Bamboo in The Era of Single-Use Plastic Ban in Kerala" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

When we throw the plastic waste in the land, the soil also becomes polluted. It prevents the ways of rooting of the plant. Land becomes unable to save rainwater due to plastic waste. Plastic is harmful material to the environment in any way. By considering the fact many countries banned single-use plastic products. In India, some of the states are banned completely and the remaining states are in the way of a complete ban of single-use plastic products. Kerala government has banned the production, selling, storing, and transportation of single-use plastic products in the state from January 1, 2020. In this circumstance, bamboo products can be an alternative for plastic products due to its environment-friendly nature. The paper describes the environmental challenges that create plastic products. Along with this, the paper depicts the ecological and eco-friendlier significance of bamboo and its products in the epoch of single-use plastic ban in Kerala.

Statement of the Problem

Plastic pollution is an immense problem faced by the world nowadays. Plastic is a useful material for human but it involves abundant side effects on the environment. It can ruin the sustainability of the environment. So it is important to realize the downsides of plastic products and to reduce the dependence on them. Single-use plastic products are a powerful enemy to the environment. Because it is thrown to the environment immediately after use. It can create many problems for the environment and its species. Certain countries have banned the manufacturing and use of single-use plastic products. Kerala state in India has also banned it from 1 January 2020. In this situation, bamboo products can be used as a substitute for most of the plastic products. Bamboo is available in Kerala abundantly. The present paper narrates the drawbacks of plastic to the environment and also describes the ecological and eco-friendlier value of bamboo as an alternative for plastic products in the circumstance of single-use plastic ban in Kerala.

Objectives

Following are the objectives of the paper:

- To study the drawbacks of single-use plastic products by considering the environment.
- To understand the ecological importance of bamboo to protect the environment.
- To know the eco-friendlier value of bamboo products in the era of single-use plastic ban in Kerala.

Methodology

Secondary sources are used to collect the needed data for the study. Various research papers, articles, newspaper reports, magazines, government reports, etc. are reviewed for gathering data.

Plastic as an adversary to the environment

According to Prof. Mahendra Nath Roy (2019), the ages of man are categorized into four parts like stone age (man started to use the weapons and tools made from stone), bronze age (man used tin and copper to make articles), iron age (man-made items with iron) and last one is plastic age since 20th century. Plastic is a polymeric material that can be shaped or moulded into various articles by applying pressure and heat. Ferdinand Rodriguez (2019) mentioned that plastic is a raw material for a wide variety of products due to its properties of the low level of density, transparency, low level of electrical conductivity, and toughness. Anthony L. Andrady and Mike A. Neal (2009) reveal through their study that in the packaging sector plastic has a role especially to pack foods and drinks. The features of plastic like lightweight, durability, easy installation, easiness in removal and recycling, etc. are used in many areas.

In the industrial viewpoint, plastic has tremendous uses and benefits. But it has many of the downsides when looking to the environment side. Production and consumption of different kinds of plastic lead to pollution which affects the human, animal, and environmental health. Christopher J Rhodes (2018) emphasizes that the world has produced more quantity of plastic than the preceding half century since 2004. Along with this, the total quantity of pure plastic is calculated as 8.3 billion

tonnes which are largely made from crude oil and natural gas. In the period of 1950 and 2015 entirely 6.3 billion tonnes of plastic waste including primary and secondary was produced. Out of this almost 9% of the plastic waste is recycled, 12% are burned and the rest of 79% is either being kept in landfills or being disposed to the environment directly. Over the years, the quantity of plastic waste disposal in the earth and ocean is increased. Vietnam, Philippines, Indonesia, Sri Lanka, and China are the most plastic polluters in the world who produce 56 per cent of worldwide plastic waste.

UNEP (2018) says that plastics are not biodegradable. They slowly divide into small pieces which are called micro plastics and it remains in the earth. Plastic containers and bags are made from Styrofoam that needs around thousand years to decay in the land. The most commonly founded single-use plastic products in the environment are plastic drinking bottles, bottle caps, food packets, straws, plastic grocery bags, plastic containers, etc. These products are thrown in the environment immediately after use. Plastic waste can make plentiful problems when it is dumped in the environment. Plastic bag obstructs the path of water and increases natural calamities. When the drainage is blocked by plastic the mosquitos and other insects are breeds in that water, ultimately the transmitted diseases are increased. Many of the species like dolphins, turtles eat the plastic bag, etc. by misunderstanding them as their food. The toxic chemicals that added in the plastic bags at the time of production either kill the species or reach the human body by eating them. These chemicals can damage the lungs, nervous system and reproduction system. In many countries, the plastic waste is burned and it releases toxic emissions. It is very dangerous to the health of humans and animals. The plastic also creates economic damages. The dumbed plastic waste in the water affects fishing, shipping and tourist industries heavily. It needs to spend a high cost on maintenance due to plastic. There is also having an additional cost on clean beaches and coasts.

Various studies show that plastic bags are capable to make serious pollutions in the environment which also leads to animal and human health issues (Riyad Moharam and Maher Ali Al. Maqtari, 2014). There are 13 countries including United Kingdom, Taiwan, New Zealand, Kenya, Zimbabwe, Canada, France, Morocco, Rwanda, Antigua and Barbuda, United States, Bangladesh, South Korea banned single-use plastics to protect the environment. In India, single-use plastic ban is not yet completed even though some of the states are banned single-use plastic.

Table 1: Plastic banned states in India

Completely banned states	Partially banned states	Not banned states
▪ Jammu and Kashmir ▪ Himachal Pradesh ▪ Uttarakhand ▪ Punjab ▪ Haryana ▪ Rajasthan ▪ Madhya Pradesh ▪ Uttar Pradesh ▪ Maharashtra ▪ Karnataka ▪ Chhattisgarh ▪ Sikkim ▪ Arunachal Pradesh ▪ Nagaland ▪ Tripura	▪ West Bengal ▪ Goa ▪ Kerala ▪ Gujarat ▪ Odisha	▪ Manipur ▪ Bihar ▪ Telangana ▪ Tamil Nadu ▪ Assam ▪ Jharkhand ▪ Meghalaya ▪ Mizoram ▪ Andhra Pradesh

Source: Central Pollution Control Board

The Prime Minister of India Narendra Modi declared on Independence Day of 2019 that single-use plastic to be banned from 2 October 2019 which is the 150th birth anniversary of Mahatma Gandhi. He expects to accomplish the mission by 2022. Many of the states in India have already banned single-use plastic before this declaration. Sikkim is the first state which banned disposable plastic

bags as a first step to ban single-use plastic. In 2006, Sikkim banned packaged drinking water, Styrofoam, thermocol plates and cutlery to protect the state from plastic pollution (Vikaspedia).

In Kerala, the state government banned the activities of production, selling, storing, transporting single-use plastic products from 1 January 2020. It is declared by Chief Minister Pinarayi Vijayan on 21 November 2019 after considering the environmental issues faced by the state due to the plastic waste which is calculated as around 45000 tonnes per year (Rashmi Shrivastav, 2020). Kerala government banned the following single-use plastic products;

Table 2: Single-use plastic products banned in Kerala from 1 January 2020

Plastic carry bags irrespective of thickness	Non-woven bags
Plastic sheets which are used as table spread	Plastic flags and plastic buntings
Thermocol and Styrofoam cups and plates	Plastic water pouches, non- branded plastic juice packets
Decorative items made from Styrofoam	Drinking water bottles less than 500 ml
Single-use plastic plates, tumblers and cups	Plastic garbage bags
Plastic straw, fork, spoon, stirrer	PVC Flex material
Plastic coated paper plates, cups, bags, and bowls	Plastic cover used to pack vegetables and fruits

Source: Suchitwa Mission, Govt. of Kerala

Single-use plastic products are dangerous to the environment because it is thrown immediately after use. All of the banned items were useful to the man so that it is needed to make the items with other alternative materials. It is very important to keep in mind that the alternative should not be harmful to the environment. In this sense, we can use bamboo as a substitute for many of the plastic products. Bamboo is the everlasting evergreen flowering plant and it has enormous uses.

Bamboo and its uses

According to New World Encyclopedia, bamboo consists of more than 1200 species in the grass family of Poaceae, growing in tropical lands in Africa, America and Asia. The distribution of bamboo is more than 90 genera in the subfamily of Bambusoideae and the tribe of Bambuseae. Bamboo is a grass which has a commercial value. Bamboo can grow very quickly than any other grasses. It provides food to pandas, elephants, gorillas etc. and it is useful to humans for medicinal, ornamental, constructional and so on purposes. Bamboo is a symbol of culture in various countries.

There are many miraculous stories about bamboo plants and the popularity of it is growing day by day. The word bamboo is originated from the Malay word “Mambu”. Malay is the national language of Indonesia and Malaysia. Dutch named it “Bamboes” in the 16th century after it acquired the name “Bambusa” which is its Neo-Latin name. Some states that bamboo got the name due to its sound of an explosion when it is heated in the fire. Because it makes an “explosive bam-boom sound” in the fire.

Bamboo is grown in the tropical and subtropical regions of Africa, Asia and Latin America. It can be seen in five continents including Asia, Australia, Africa, South America and North America. Bamboos have in all continents excluding Europe and Antarctica. The majority of the bamboo species are grown in the climate of a warm atmosphere. But some of the species also can be found in various climates from warm tropical regions to cool mountainous regions. China has the first position in the production of bamboo in the world. India is the second largest producer of bamboo. In India, many of the peoples of different states depend on bamboo. Bamboo is useful for many of the purposes including medicines, food, construction, ornaments, and household and so on.

Means of Food Security

Bamboo ensures food security in the form of the shoot to many of the people around the world. According to Hossain M.F. (2015), when the bamboo shoot is reached about 15-16 cm height, it can be harvested. The shoots from the monopodial (running) and sympodial (clump-forming) bamboos

are mainly used as food. The tender portion of the bamboo shoot is used for cooking after avoiding the outer fibrous portion. These shoots can be used along with or without meat and vegetables to make soups or curry and even pickles. Divakar Prasad Nirala (2017) acknowledges that many of the food items can be prepared by bamboo such as bamboo shoot chutney, pakoda, pulav, bhaji, pickle, soup, beer, juice etc. Vinegar made from bamboo is utilized for bio insecticide. In the words of Hossain M.F. (2015), varieties of nutritional components are included in various species of bamboo shoots. This is used by the tribal communities as traditional way over many years. Bamboo shoot is a good source of dietary fiber, protein, minerals, amino acid and also contains low fat. From bamboo shoots, soft drinks and wines also can be made.

Act as Medicine

Bamboo is considered as medicine since ancient times. Various parts of the bamboo are used for different purposes as traditionally. P. Nongdam. (2014) concedes through his study that the bamboo shoot has the high potential to use as the healthy food due to its medicinal values such as proteins, carbohydrates, vitamins, minerals, amino acids and also contains less fat. It has the ability to control cholesterol and diabetes and it also helps to reduce hypertension, paralysis and sweating. Various parts of the bamboo have their own medicinal benefits. According to Hossain M.F. (2015), the root of the plant is used to treat the bleeding gums and arthritis. The bamboo shoot is helpful for digestion and the tender shoot of Bambusa bambos species is beneficial for birth control. Jun Panee (2015) says that it is used in traditional Chinese medicine to facilitate labour easily and discharge of the placenta. Bamboo is accepted as a calming, cooling and phlegm resolving plant. It is used along with traditional methods to treat stomach and lung heat, febrile illness etc. Bamboo leaf extract is useful for urinary dysfunction and eczema owing to a high level of heat. Hossain M.F. (2015) reveals that it also includes the properties of cancer prevention and helps to reduce cholesterol and blood pressure.

As a Construction Material

Thi Bich Van Ngu yen (2018) demonstrates that bamboo has the feature of texture which is greatly helpful to make distinctive designs for the interiors. Many of the designers use bamboo for making the unique design of furniture and they say that materials from bamboo are strong, flexible and highly powerful both internally and externally. Bamboo is highly resistant and durable than many other kinds of woods such as maple, oak etc. It has different finishes that encourage the interior designers to use bamboo for their works. Bamboo gives natural grace and utility of woods without environmental hazards. According to Asia-Pacific Network for Global Change Research, in construction, dependency on materials like timber, brick, cement etc. create environmental hazards like discharge of green-house gas at the time of production. Bamboo can be considered as a trustable material for construction because it uses less amount of energy for the production compared with other materials.

Ecological Impacts of Bamboo

Ramakrishnan M. (2018) acknowledges that bamboo can be found in various climatic situations and Korea, China, Australia, Japan and India consist of different types of species of bamboo. Bamboo has an important role in the environment because it protects from ultraviolet rays and assists in lower light intensity. It also has the ability to lower the rate of deforestation. Bamboo can decrease the pollution level by delivering more oxygen to the atmosphere and also reduces carbon dioxide up to 35%. Sijimol K (2016) celebrates the fact that bamboo can hide away carbon dioxide and convert it into oxygen. So that it can reduce Carbon dioxide which causes global warming and it doesn't leave back the carbon dioxide to the environment. According to H. Lalhruaitluanga (2009), some of the bamboo species absorb around 12 tons of carbon dioxide per hectare that leads to the existence of a high volume of fresh air in the atmosphere. It can also release 30% more oxygen than trees. Divakar Prasad Nirala (2017) shows through his study that bamboo is a rapidly growing plant around the world. A single bamboo can protect the soil up to 6 square meters. One hectare of the bamboo growing area can take 12 t of Carbon dioxide from the atmosphere and also it can keep 1000 t of water. Sijimol K (2016) considers that the colonization of bamboo has an inevitable effect on soil as biological, chemical and physical.

H. Lalhruaitluanga (2009) argues that bamboo can perform various ecological functions such as soil erosion management and water and soil conservation. Bamboo considerably reduces rain flow and averts enormous soil erosion by its expanded root system. The vast nitrogen consumption characteristic of bamboo reduces water pollution. It can also replace land which is degraded. So it is capable of preventing land degradation. The study of Sijimol K (2016) concedes that bamboo is helpful for the stabilization of the riverbank because it is mainly growing near to the river. It can improve the fertility of the soil in chemical and physical aspects by adding a large quantity of vegetation, dry stalks and culms to the soil. It also gives the survival for many of the species in the ecosystem.

According to Stephane Schroder (2012), bamboo can absorb a high quantity of carbon dioxide from the atmosphere. Scientific studies reveal that Guada Angustifolia species of bamboo can absorb about 21.41 tons per hectare in a year. One hectare of matured Guada bamboo has the capacity to generate 5.8 times extra biomass than most of the other trees. It is renewable as well as a sustainable resource because it grows continuously. So that it can develop a forest more quickly than other forest species can. Bamboo has the ability to regulate water in both qualitatively and quantitatively. It acts as a fence to manage the water flow in rivers. The widespread root system of Guada bamboo is helpful for the conservation of soil in the bank of the river. Bamboo can be planted in the areas where the chance for landslide has. Bamboo has a great capacity for water storage because it reserves the water in the soil and stems throughout the rainy season. Along with this, in the dry season bamboo gives back the water to the river and soil. Bamboo enables the scattering of raindrops by its leaves. It can prevent soil erosion. Bamboo also contributes a massive quantity of organic matter by its leaves and dry culms which lead to the increased fertility of the soil. Bamboo beautifies the nature with its wonderful leaves and culms.

Akwada D.R. (2016) reminds us that climate change is becoming rapidly as a global circumstance. The main reason for climate change is deforestation. Deforestation is happening mostly due to the use of timber in various industries which is slowly grown. The production and utilization of fast-growing plants such as bamboo are useful in industries as the best alternative for wood. The quality of the bamboo species in safeguarding soil and water is recognized by the government. Absorbed carbon dioxide is neutralized partly within a short period by products from bamboo. Dr. Jim Bowyer (2014) observes that the rate of timber production and harvest cycle in a forest area is normally managed to 80 to 100 years while the rate of bamboo production and harvest cycle is 4 to 6 years which reveal that the yield of bamboo is 7 to 10 times than hardwood. J.Atanda (2015) says that in construction, bamboo reduces the utilization of wood and it has a glassy surface which reduces the use of paint. So that it can eliminate the health problems arising from paints. Bamboo can be used as the reinforcement for concrete due to its good quality. It has the potential for decreasing deforestation and soil erosion. It helps to safeguard biodiversity and assist a sustainable environment.

Eco-friendly products from bamboo

Rushabh A. Shah (2013) explains that bamboo is an important fast-growing woody biomass non-timber forest product. It can be considered as a substitute for wood. Bamboo is one of the important construction materials and it is extensively available in India. It can protect the environment and also enhance the development of the economy.

Thi Bich Van Ngu yen (2018) argues that bamboo is recommended by its use, natural characteristics and also by its specialty of sustainable material. It is used in construction because it is a versatile plant and it is a replacement for wood. According to Asia-Pacific Network for Global Change Research, the demand for timber in the construction industry will be increased whereas the supply will be decreased in the future years. As per Planning Commission, the timber demand is approximated to 153 million cu m in 2020 while the supply will be 60 million cu m in 2020. It reveals that the price of the timber may be increased so that the products from bamboo get enough scope. Bamboo is eco-friendly because of its characteristic of fast production than wood.

Thi Bich Van Ngu yen (2018) agrees through his study that bamboo has the ability to protect our remaining forests. Planting this wonderful plant especially in the banks of the river helps to preserve

the dyke, lowering the breaking of dyke, reduces the effect of flood and also safeguards the environment. Bamboo is known as Green steel because of its properties of making environment-friendly products.

It is a great sustainable, natural material that has the characteristics of antifungal and antibacterial and also an environment-friendly like against plastic. Plastic is one of the most important origins of pollution around the globe. Bamboo has many of the good qualities than plastic. So that it is called as green gold. Our earth is becoming a trash bin for waste that is harmful to our environment. Plastic is the main reason for this situation. Wanda Thompson emphasizes that fossil fuels are required to make plastic which leads to the increased quantity of carbon discharge in the atmosphere. There have many reasons to use bamboo instead of plastic. Bamboo can grow without pesticides and fertilizers and it can also harvest within three to five years. Bamboo needs only less amount of water to grow so that no need of irrigation facilities.

According to Better meets reality (2019), bamboo is more sustainable than plastic under many of the reasons. It arises from renewable resources of bamboo fibre while plastic is a synthetic material that arises from a non-renewable resource. Bamboo is energy-intensive and eco-friendly than plastic. Bamboo products don't have synthetic contents and it is biodegradable. So that it never creates any harmful effects on the environment. On the contrary, plastic is not biodegradable and has a negative impact on the environment. Nidhi Sankar says that bamboo is antimicrobial. This is the reason for preferring the bamboo to make kitchen utensils and cutting boards in many countries. Bamboo properties can kill harmful bacteria and provides long-lasting safety.

According to Foundation for MSME clusters (2019), bamboo is one of the main alternative for timber, plastic, steel etc. It has the potential than plastic to lower the carbon and build a market opportunity. Plastic is produced from petrochemicals which pollute the environment while bamboo discharges 35% more oxygen and takes carbon dioxide from the environment. Bamboo products are not polluting the environment and not become an opponent to environment sustainability. It is totally ecological friendly so that bamboo can become a best alternative for many of the plastic products.

Table 3: Products that can make from bamboo

Household items	Decorative items	Bathroom products	Stationery items	Other products
* Basket * Trays, plates * Carry bags * Water bottles * Spoon, fork * Table coaster * Spoon holder * Chopstick * Skewers * Chopping board * Steamer * Curtain	* Flower vase * Flowers * Photo frame * Lampshade * Holding hand fan * Sculptures * Clock	* Tooth brush * Tooth brush holder * Liquid soap dispense * Tray * Tissue paper holder * Soap dish * Towel holder * Mat * Garment rack	* Pen * Pen holder * File rack * Phone holder * Shelves * Card holder * Exam pad	* Musical instruments * Agricultural tools * Garments * Ornaments * Furniture * Toys * Construction

Conclusion

Bamboo is known as "poor man's timber" and it has the capacity to provide livelihood not only to humans but also to animals. It has many uses and it is a good substitute for timber, steel and plastic. Bamboo helps to protect the ecosystem from many of the problems such as deforestation, soil erosion, decayed land etc. It beautifies the nature and discharges the fresh air to the atmosphere. Bamboo can grow quicker than any other plant so that in construction it can use instead of timber. Bamboo is more durable than many other timbers like oak, maple etc. The products made from

bamboo are eco-friendlier and it is not harmful to nature like plastic. Even plastic has many of the advantages to the human it is totally disadvantaged to nature. Plastic cannot be degraded in the soil or water and the smoke from the plastic is polluting the air when it is burned. By considering the negative effects of plastic products, single-use plastic is banned in Kerala from 1 January 2020. The manufacturing, selling, storing and transporting of single-use plastic products is punishable under the law in Kerala. In this situation, bamboo can be considered as an alternative to many of the plastic products. Bamboo especially Ochlandra Travancorica species is abundantly available in this state and it has been used traditionally for making many of the products. In this era of single-use plastic ban the artisans and industries that depend on bamboo can catch the market if it is utilised better. If the govt. and concerned organisations provide more support to the bamboo sector, it will be a great success in making and selling both traditional and modern bamboo products and ultimately reduce the dependence on plastic products. So through the use of the bamboo product, we can protect the environment from pollution.

Abstract

The present research aims to understand the perception of respondents pertaining to furniture made of Coir Composite Board. The study made an attempt to measure the strength of various attributes in order to get a better insight with regard to CCB as an environment friendly furniture stock. A survey was conducted through structured questionnaire for people who visited the International Coir Fest in Kerala, India 2019. Of the attributes chosen, the results highlighted the greatest strength of CCB furniture being 'environment friendly', 'good finish' and 'surface smoothness'. The research could aid the management and manufacturers to target their customers with proclivity towards Environmental-Economical-Societal Sustainability. With advent in its competitive price, the market potential of furniture made of CCB is to bring a major change in the panel board industry, the construction industry in totality.

Keywords: Coir Composite Board, perception, environment sustainability.

Introduction

World environment consciousness has been to the rise due to exorbitant environmental issues. An equitable and viable economy, a viable and bearable environment, an equitable and bearable society has been the key to sustainable development. 'It is indeed the development that meets the needs of the present without compromising the ability of the future generation to meet their own needs' (Brundtland Commission). It is a well-established fact that the current pattern of consumption will result in ecological unsustainability and that in order to mitigate the adverse effects of the same; different ways of living and consumption are adopted worldwide indicating environment sustainability as a very crucial work in today's date. A sustainable consumption is the key to foster the same. The United Nation's Environment Programme has emphasised on the need for 'sustainable consumption' as it is about consuming differently, consuming efficiently and having an improved quality of life. Environmental problems and its immediate and adverse impact on human health has become a relevant issue among academicians, governments and organisations (Haytko and Mutulich, 2008).This results in various issues pertaining to sustainability which implicitly brings about a major change in consumer demand and behavior (Mendelson and Polonsky, 1995). Though eco-friendly consumption called 'green consumerism' has been welcomed by developed nations, developing nations like India has been receptive about the same (Khare, 2015). Thus, it becomes all the more crucial and relevant for the marketers to have a better understanding of their consumers and consumption pattern. An antecedent to this could be to measure the perception level and preference of the consumers towards eco-friendly products.

Ambily "Elucidating the Consumer Perception for Coir Composite Furniture: A Move towards Sustainable Consumption" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

Coir products have always withstood the test of time and are well addressed for being eco-friendly in nature. 'Coir' is mere a waste material processed from the coconut husk. The Coir Industry has been a part and parcel of the Indian culture and tradition and has been an important cottage industry significantly contributing towards economic development and withstood as a sign of recognition on various international platforms. The country accounts for more than two-thirds of the world production of coir and coir products. The State of Kerala is the home of Indian coir industry, accounting for a major share in coconut cultivation and of coir products. A wide range of coir products are manufactured which not only meets the domestic demand so also the global demand, fetching huge inflow to the country. An innovative product of the industry, the Coir Composite Board, CCB often called Coir Ply, is paving way for an entry into the market. The Coir fibre and waste incurred at the time of processing the coir husk serves as the main raw material for the production of CCB. It is similar to that of any other panel board widely used in the furniture industry. The major competition of this product comes from the wood based panel industry, inclusive of materials like plywood, laminates MDF so also composites made of wood veneers. Wood based panel industry is facing a big gap in supply mainly in view of the restrictions imposed in sourcing of wood, the main raw material. This opens up a window of opportunity for Coir Composite based building and furnishing products, with added advantage of it being wood substitute and environment friendly. Holding the properties such as lightweight, corrosion resistance and other advantages, CCB will be an important composite material in building and civil engineering. It is ideal for home and office interiors, as an exact wood substitute and subsequently economic. Studies by Levitt (1980) and Bennington (1996) have all pointed out that inadequacy in market analysis is the main reason for failure of new furniture products. It becomes utmost important to develop customer-oriented products based on their needs and desires. Previous study by Chitra (2007), have stipulated that of the environment friendly products chosen, furniture was the only product that 11 percent of the respondents were not aware of being eco-friendly. It was based on these foundations that the objective of the study has been derived as to analyse the perception about CCB furniture based on intrinsic attributes.

Methods and Materials

A structured questionnaire was prepared to collect data from the attendees of The Coir International Annual Fair held at Alleppey district, Kerala in the month of December 2019. The questionnaires were administered to 100 respondents who visited the stall and agreed to take part in the survey. The stall was exclusively for the display of Coir Composite Furniture. Probability sampling was the technique initiated to select an adequate sample for the study. A real time perception of the customers was analysed and documented through the distribution of questionnaires. The questions chosen for the same were adapted from similar research work already published in similar context such as Ratnasingam, 2007; Shahsavar et.al, 2019; Ratnasingam et.al, 2009. All the 100 respondents who participated in the survey completed the questionnaire. The software of "Statistical Package for Social Sciences" (SPSS) has been used to analyse the data. This software is commonly used for much of the multivariate analysis used, which makes it suitable for the study. The research questionnaire developed contains eight attribute which describes CCB as a premier furniture material (Table.1). The respondents rated these attributes on a five-point scale: 1=Totally Disagree and 5=Totally Agree.

Table 1: Attributes of CCB as a furniture material

Environment Friendly
Cost
Attractive
Fashionable
Youthful
Strength
Surface Smoothness
Good Finishing

Results and Discussion

The analysis indicated the perception of the respondents based on the attributes of CCB furniture. It is a proven fact that consumers' perception can to a greater extent influence their decision making process. Perception is the process by which information inputs are well selected, organized and interpreted to create a meaningful picture of the world. Factor analysis has been the tool used to find the factors that influence the perception of respondents. It is indeed a technique used to determine the underlying structure among the variables considered. The Eigen values of the selected factors were greater than 1. A total of eight factors were extracted with a cumulative percentage marked at 52.25 of the total variance. The Kaiser-Meyer-Olkin (KMO) and Barlett's Test of Sphericity has been used to analyse the sampling adequacy and correlation among the variables. The test in the study is found to be significant with p=0.000. The KMO measure is an index used to measure the appropriateness of factor analysis. A value in between 0.5 to 1.0 indicates an appropriate result and a value below 0.5 indicates inappropriateness to conduct a factor analysis. The KMO value derived stood at 0.896 as shown in Table 2 which indicates the appropriateness. The Cronbach's α (Alpha) was run to test the reliability of variables considered. Generally an alpha value above 0.7 is considered acceptable (Hair et.al., 1998). The alpha value derived was 0.862 for the study which is in the acceptability range as shown in Table 3 in reliability statistics.

Table 2: KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.896
Barlett's Test of Sphericity	Approx.Chi-Square	306.318
	df	28
	Sig.	0.000

Table 3: Reliability Statistics

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
.862	.866	8

The mean value of most of the attributes was quite satisfactory. Though a variation occurred for variables like 'cost', 'fashionable' and 'youthful', it is high in terms of variables like 'environment friendly', 'surface smoothness' and 'good finishing'. This depicts that most of the respondents agreed to the statement that CCB furniture are environment friendly, has good surface smoothness and a great finish. As far as the cost consideration is concerned, the respondents showed varied opinions, though mostly disagreed to the fact that it is low on cost consideration. There were respondents who opined the fact that the product is innovative, environment friendly and has a great finish unlike any other furniture stock.

Table 4: Inter-Item Correlation Matrix

	Environment Friendly	Cost	Attractive	Fashionable	Youthful	Strength	Surface Smoothness	Good Finishing
Environment Friendly	1.000	.346	.418	.371	.218	.427	.432	.405
Cost	.346	1.000	.322	.327	.223	.419	.376	.387
Attractive	.418	.322	1.000	.507	.498	.551	.517	.657
Fashionable	.371	.327	.507	1.000	.551	.449	.427	.545
Youthful	.218	.223	.498	.551	1.000	.455	.442	.508
Strength	.427	.419	.551	.449	.455	1.000	.550	.639
Surface Smoothness	.432	.376	.517	.427	.442	.550	1.000	.547
Good Finishing	.405	.387	.657	.545	.508	.639	.547	1.000

The results of the study imply that CCB furniture could be the future of furnishing and construction industry. People showed a positive response towards the material for being environment friendly and good finish. Experts suggest that the furniture made of CCB are highly durable for it being water resistant, termite resistant, fungal resistant even after undergoing various treatments during the course of processing and production exerting the biggest strength of CCB. Cost consideration was perceived to be little unconvincing, but every effort should be made to reduce the cost of processing and production of CCB so that it can be made available to every class of individual. The furniture made of CCB is innovative and it is a thought process in need of further enhancement to rightly make it highly competitive in the market.

Conclusions

This study is one of the first attempts to analyse the market perspectives pertaining to CCB furniture. The furniture made of Coir Composite Board is perceived to be environment friendly which reasserts the title as, 'a move towards sustainable consumption'. Building a positive social, environmental and sustainable image of coir composite furniture will enhance the products value and this will tilt up consumer preference for the product and their intention to purchase it. The study is also a piece of valuable information to the furniture manufacturers, policy makers and environmentalists. The study helped to identify the very basic factors with positive as well as negative responses which should be incorporated into the design of CCB furniture. The findings will also allow the marketers of CCB furniture to device strategies for how to present the product to the consuming public. For instance, the environmental and societal benefits associated with CCB furniture can be used as leverage to increase the market share. Through better market strategies, the marketers of the product can target consumers who are pro-environmentalists in character, thus attracting a price premium on the product, Apart from all these there are limitations that need attention. Firstly, a small size sample survey was initiated which may caution the generalisability of the research. Secondly, the demographic background of the respondents was not considered limiting the findings to an extent. Thus, in future research endeavors the demographic factors need attention. Moreover, apart from the attributes there are a lot more other factors that can be put for consideration. So also the same can be brought under different conceptual framework exhibiting a better insight in the field.

Abstract

Innovative development is relevant for companies of any type, size and any specificity. Global trends, such as the emergence of new disruptive technologies, digitalization and accelerated product life cycles, are driving radical changes in most industries. Changing value chains, shifting profitability zones, emerging new players - and this fundamentally changes the balance of power in industries, significantly accelerating the introduction of new ideas and developments. Every year new technologies penetrate our life faster and faster, and companies have less time to implement them. As a result, the usual structure of industries is changing: the share of innovative companies in many sectors already reaches 10-20% and will grow rapidly in the coming years. Thus, a prerequisite for the leadership of companies in the market and the guarantee of sustainable competitive advantage is the need to use a wide range of innovative levers. Today, in order to gain a significant place in the industry, any company needs to comprehensively engage in innovations, applying all three of their main types - product innovations, process innovations and innovations in building a business model.

Keywords: Innovations, Innovative Development, Innovative Technologies, Global Trends, Investments, Economic Growth, Solar Energy, Ecology.

Introduction

There are industries in the Russian economy that are the most promising points for the introduction and development of innovations. Innovation requires large investments and large-scale sales markets. It is an industry using a scale of production such as oil and gas industry, energy, mechanical engineering, metallurgy. Such industries are becoming engines for the introduction of disruptive technologies.

Cite this Article as: Elena A. BORKOVA, Natalia V. Sopina, Elena A. MUTAREVA, Lina V. VATLINA And Tatiana N. RODIONOVA "Coordination of The Process of Creation, Implementation and Adaptation of Innovative Technologies by Russian Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

However, the rapid emergence of new technologies in the world today requires the company to radically change its approach to work and allocate a fundamental amount of investment for innovative development.

Innovations can also be created in small industries, for example, in certain promising niches in pharmaceuticals. In any industry there are promising areas where Russian companies can create value through innovation and accumulated competencies, thereby forming a platform for further development.

But for the large-scale growth of innovations in the country, coordinated interaction of big business, the state, science and technology entrepreneurs is necessary, since large companies and fundamental research with the support of the state become the sources of global innovation. Global innovation requires serious investment, which is often not enough for an individual company, so partnership plays a fundamental role for the successful commercialization of innovation.

The interest of the state in the innovation process can contribute to the inflow of new investments and the acceleration of the rates of development of industries. Since today the role of the state is not only in sponsoring R&D, but also in determining priority areas that can contribute to ensuring the necessary inflow of investments.

Innovation in The Modern World

New inventions and innovations have become an integral part of our daily life. The pace of development and innovation continues to accelerate, with business models emerging that were difficult to predict just 20 years ago. The speed of progress and the emergence of new solutions have increased many times, as a result, many companies that face new challenges of innovative development are forced to introduce new ideas and technologies in order to stay in trend.

New times require new solutions and management models. Today it is no longer so important who invented, it is important who quickly implemented and adapted his business and his products to the needs of the client. Therefore, the speed of decision making, the speed of bringing new products to the market, the openness of companies to interaction with the outside world, scientific organizations and other large companies are no less important than fundamental science and their own research.

In every industry, there are a myriad of examples of new technologies emerging, such as breakthroughs in genetic engineering in healthcare or the creation of ultra-strong alloys in metallurgy. There are also drivers of innovation common to all industries - the digitalization of industries and the introduction of Industry 4.0 tools, including robotization and automation of many processes, from the work of call centers to production.

The Relevance of Innovation for Companies

Each company is essentially unique and is at a certain stage of its development, therefore, the method of strategic decision and selection of projects is individual: for example, for a new company it will be premature to talk about the rapid achievement of any results in innovation, if the company has been successfully innovating for a long time. activities, then she must clearly track her results in order to understand the reasons for the failure to fulfill the previously established plans.

As practice shows, for the successful implementation of innovations, it is necessary to adjust the management model; for this, the company needs to determine the appropriate method of building it, appoint responsible employees, allocate resources, optimize or re-develop the processes for making investment, commercial and personnel decisions. In addition to the formation of an operational management model, it is necessary to provide employees not only with resources, but also with appropriate tools in terms of finding and implementing new technologies and solutions.

To achieve the required level of motivation of the company's employees, it is necessary to create a favorable corporate culture that is favorable to innovation. The key role in its formation belongs to the head of the company and the overall success of the implementation of innovative projects depends on him.

The creation of the correct corporate culture largely depends on the quality of the processes formed in the company, as well as on the tools used, among which 2 key ones should be noted: training (first of all, top and middle management), as well as the translation of the values of an external positive innovation culture through more active interaction with other participants in innovative activities (successful companies or startups). 94% of the surveyed top managers of companies singled out the development of corporate culture among their employees as the main driver and innovation (Pirogova O., Plotnikov V. 2020.)

Thus, a wide range of employees are involved in the implementation of innovative initiatives - from initiators of innovative ideas to supporting units providing financial and legal support. In this regard, for the successful implementation of innovations, it is important to understand the participants in the innovation process of the main goal, remove barriers and adapt current activities to the new needs of the company.

Focus on Innovation

Innovations are one of the key factors in the development of the company, which, during systematic work, has a significant socio-economic effect and affects both private business and state institutions, and society.

Fig. 1: Involvement of management in the implementation of innovations in the company (research by CB Insights, State of Innovation (2018)).

A deep understanding of the need for change at the level of all employees of the company will remove the barriers that prevent the introduction of innovation. At the same time, in order to achieve long-term sustainable development of the company, it is necessary to focus not on individuals, but on all employees involved.

The key factors in the implementation of innovation (leadership of the company leader and a clear strategy) are confirmed by the PWC study, see Fig. 2. (PWC, 18th Annual Global CEO Survey 2018).

Fig. 2: Key success factors for innovation.

In addition, during the research conducted in preparation for the article, it was revealed that companies that launch more than 10 pilots per year are more successful in innovation and receive significant or breakthrough effects from innovation. The survey of Russian companies during the study is shown in Figure 3.

Fig. 3: Impact of innovation, %.

Разные цели и намерения компании задают различную повестку для инновационной деятельности. Инновационная стратегия зависит от внешней среды и общей корпоративной стратегии компании и может быть ориентирована на работу с разными типами инновационных решений. Задачами инновационной стратегии компании являются формирование целей инновационного развития, формирования плана реализации стратегии, определение инструментов внедрения и подходов к управлению инновациями.

For companies whose goal is to improve operational efficiency, incremental and process innovations may be most relevant. As an example, the Russian company Evraz has launched the MineShed mine planning system. On average, for mining companies, the use of lasers and big data technologies to process its results can reduce annual costs by hundreds of thousands of dollars in each of the quarries (Union of mining engineers 2020).

Here is an example of a strategic decision made by another Russian company: Rostelecom's main market is traditional telephony, and when it began to decline by 10% per year, this led the company to decide to diversify its core business and enter new markets. This required significant organizational

changes and investments in new products and services, infrastructure development. However, the results justified the resources and efforts spent - today the company occupies a leading position in the Russian market of broadband Internet access and Pay TV services (Rostelecom, https://spb.rt.ru/b2b).

The company creates innovative solutions in the field of cybersecurity, cloud services, solutions in the field of healthcare, education and housing and utilities. The changes led to the fact that the share of revenue from communication services decreased due to the emergence of new flagship business segments.

It is important that the strategy for working with innovations is a consequence and continuation of the overall strategy of the company. This will allow synchronizing innovation activities with the strategic goals of the company and eliminating conflicts between innovation and operational tasks.

As an example, we will cite the practice of the strategy of PJSC Severstal, which has formulated the main priorities for the company's development (information from the company's website):

• "cost leadership" - to achieve significant cost advantages in terms of production of main products compared to competitors, while maintaining the global industry leadership in efficiency;

• "excellent customer experience" - providing unique offers in all target markets;

• "new opportunities" - access and successful application of advanced technologies and new business models that appear on the market.

• improving the corporate culture of the company.

These priorities were adopted by the company for 2018, and they largely determine the directions and tools for working with innovations.

Thus, corporations should remember that in the context of the rapid development of technology and technology, innovation becomes the key to a competitive advantage and the basis for the company's sustainable development. Disruptive innovation is the most important, as it carries the greatest risks for any company, so the company must pay special attention to its innovative development in the long term.

Three Horizons Model

To maintain competitiveness, a company must balance its innovation budget across three groups of innovation: incremental, radical, and disruptive. Following this rule, over the past decade, the following budget allocation for innovation has been extended among foreign companies: 70% - for incremental innovation 20% - for radical innovation 10% - for disruptive innovation.

From an organizational point of view, the formation of a portfolio can be carried out by dividing the corporate budget into innovations into three baskets. The largest budget basket for incremental innovation, the medium budget basket for radical innovation, and the smallest budget basket for disruptive innovation. This will eliminate competition between projects from different baskets (projects of different horizons): when incremental innovation projects are preferred because these projects, unlike projects of radical and disruptive innovation, are at a higher stage of readiness, have a sound economic and risk assessment.

The three-basket approach ensures that there is a budget and a corporate focus on radical and disruptive innovation (the basis for maintaining its competitiveness over the long term). According to a study by KPMG (KPMG, Benchmarking Innovation Impact 2018), over the past 7-8 years, there has been a significant shift in resource allocation priorities towards radical and disruptive innovation.

Fig. 4: Changes in the distribution of companies' investments in different types of innovations

The Role of The State in The Development of Innovations

Previously, the role of the state in the innovation process was to create an innovative environment in which all market participants could effectively develop and implement innovations, as well as to sponsor fundamental science and new developments. In the modern world, due to the large number of variables, the high degree of mutual penetration of industries and the growing speed of change, the role of the state becomes even more important.

The active position of the state in the innovation process can significantly accelerate the rate of development of individual industries. Pursuing a policy of innovative development of the country, including the development and implementation of a strategy for the development of industries, the state not only provides funding for strategically important promising projects, for example, in the military-industrial complex and fundamental science, but also directly affects how industries develop. Determining the most promising industries and niches, the state provides a wide range of service support to businesses in these areas, including technology brokerage and assistance in the export activities of innovative companies.

The state also stimulates cross-sectoral cooperation, bringing together stakeholders to build relationships and search for synergistic opportunities, promotes the creation of joint programs, including organizing platforms for dialogue between large businesses from various industries, science and start-ups to search for new ideas and work together on large-scale tasks.

Finally, the state identifies obstacles to the development of innovations (legislative, infrastructural) and actively works to eliminate them. In other words, the role of the state is important for the development of all five key factors for the success of innovation in a country: the demand for innovation, infrastructure, funding, competencies, and a culture of innovation.

• The state can act as a customer of innovations, ensuring the demand for new technologies and products.

• The state provides an environment and conditions for the development of innovations in the country, creating the necessary infrastructure.

• The state plays an important role in funding innovative research.

• The state supports the formation of competencies and technologies for the development of innovations in the country.

• The state promotes the development of an entrepreneurial and innovative culture.

A striking example of a successful domestic innovative company is «Transas», one of the world leaders in the production of high-tech equipment, software and system integration for maritime shipping.

«Transas» accounts for over 35% of the global electronic mapping and navigation systems (ECDIS) market, about 25% of VTS installations and over 45% of the global maritime simulator market. (http://www.transas.ru/about).

Ecology Issue

A separate important trend influencing many areas is increased attention to environmental issues and environmental awareness, the development of renewable energy sources and a change in the structure of the energy industry. Recently, the availability of natural gas worldwide has grown significantly as a result of the development of shale gas extraction technologies. This allows you to gradually replace less environmentally friendly and less efficient sources of raw materials. (Borkova, 2020).

China has set a strategic goal to switch its fuel and energy complex from coal to cleaner fuels, thanks to which in 2017 the consumption of natural gas in the country increased by 15% (National Development and Reform Commission, 2018).

In the field of alternative energy, there is also a significant increase in the use of solar and wind electricity, including due to a rapid decrease in its cost, over the past three years, the cost of building solar power plants has decreased by 68% and will continue to decline further. In India, it is cheaper even without government subsidies (Vedomosti 2020).

If 10 years ago solar energy accounted for less than 1% of the world's electricity generation capacity, then at the end of 2019 it was already 9%, according to the International Energy Agency (IEA). According to his forecasts, by 2040 the share will increase to 24%.

Much of the capacity is boosted by India, where the cost of building solar power plants has dropped 84% in eight years, according to the International Renewable Energy Agency (IRENA). Costs have dropped dramatically in Australia, the United States and China, and the cost of solar energy in these countries is now one of the lowest in the world.

In Russia, contrary to the commonly held opinion that there is no sun in the country, our country with its vast territory spread over different geographic zones has favorable conditions for the development of various segments of solar generation - from microgeneration for private households to large-scale grid stations. In about 2/3 of the territory from the southern to the Far Eastern parts of the country, the level of solar radiation allows solar power plants to operate with an installed capacity utilization factor (ICUF) exceeding 14%, which corresponds to, say, French and Spanish solar energy. For comparison: in Germany, where the installed capacity of solar energy is about 50 GW, the average ICUF of photovoltaic plants is at the level of 10% (https://www.ng.ru/ng_energiya/2019-09-09/12_7671_growth.html).

In addition to the construction of renewable generation, several plants to produce solar cells and other electric power equipment have appeared and are successfully operating in Russia over 5 years. Their total production capacity is 600 MW today and will reach 700 MW by 2020. Thanks to the domestic development of heterostructure technology, the efficiency of which in cells exceeded 23%, Russia entered the top-3 world manufacturers of solar modules in terms of efficiency. These results made it possible to start the first export deliveries of solar cells and modules to Italy, Switzerland, Finland, Austria, India, Thailand, and in 2019 Russian companies entered the Kazakhstan market - the current portfolio of solar generation projects to be built using Russian equipment is 238 MW. In the electricity economy, the main indicator that allows comparing alternative types of generation is the present value of electricity production (Levelized Cost of Electricity – LCOE).

LCOE represents the estimated cost of electricity generation over the entire design life of a power plant. It is calculated by dividing the reduced (discounted) total costs during the life cycle of the facility by the estimated volume of electricity generation for the same period.

According to the latest report from the International Renewable Energy Agency (IRENA) published in 2019 Renewable Power Generation Costs in 2018, solar and wind energy are the cheapest generation technologies in most regions of the world. According to the global IRENA database, more than four-fifths of solar photovoltaic installations, due to become operational in the world in 2020, will provide cheaper electricity than the cheapest new coal, gas and diesel generation facilities.

Energy storage technologies are rapidly developing - the cost of a lithium-ion battery has decreased since 2010, according to McKinsey, by almost three times. As a result of changes in this area, the architecture of the electricity industry could change dramatically. The development of innovations in several related industries, for example, in transportation (electric vehicles), industry (new materials) and construction (modular structures) also reduces the harm done to the environment.

At the same time, from a technical and technological point of view, a fast and capacious energy storage system is a useful device for integrating solar energy into a single power system. Russian generating companies began to implement energy storage systems in the infrastructure of grid solar power plants and to work out with the system operator joint actions of generating facilities in various modes. Bashkiria has become a pilot region, on the territory of which a solar power plant project using industrial energy storage will be implemented for the first time.

Power supply in this area is carried out by a single-circuit power transmission line with a length of 100 km with a dead-end substation. Two solar generation facilities with a capacity of 5 MW each will be equipped with energy storage systems with a capacity of 4 MWh. Batteries will allow the stations to operate both in parallel with the network and autonomously. Thus, solar power plants will provide electricity to the entire area, and in the event of an emergency shutdown or repair work on the power line, they will supply hospitals, schools, kindergartens with electricity in an autonomous mode. Such so-called island power plants continue to gain popularity today, due primarily to the demand for distributed generation facilities.

Conclusion

Thus, today the Russian economy is faced with a choice - what technologies to stake on so as not to be left behind the "innovative board" in the future. An increase in investment in innovation in the domestic market will create conditions for a natural increase in the production of equipment that is competitive in world markets and will allow Russia to be competitive in the global market. The Russian experience, like the experience of other countries, shows that the market can quickly "absorb" and adapt innovative technologies on the market.

Therefore, when considering the issue of state support for innovative projects, it is necessary to take into account not only money, but also the development of Russian innovative technologies, industrial development, global competition in world markets, as well as the impact of these technologies on the environment.

Abstract

Currently, the technology transfer process is being actively carried out in Russia. The direct participants in this process are scientific organizations and higher educational institutions of the country, which account for a large share of research and development. The work examines the legal status of scientific and educational institutions in the issue of the disposal of the results of intellectual activity for the implementation of technology transfer. The issues that hinder the growth of efficiency of technology transfer in education are considered. Measures are proposed to address these problems.

Keywords: Technology Transfer, Technology Transfer Centers, Scientific Developments, Intellectual Property, Innovations.

Introduction

Technology transfer is the process of transferring the results of intellectual activity and rights to them from one person to another. The purpose of technology transfer is the commercialization and scaling of technologies. There is an opinion that technology transfer is a process of transferring ideas that arise in the process of fundamental research and are implemented at the stage of development work (Rybkina E., et al. 2018). And in this case, it does not have the goal of earning income, which, from our point of view, does not correspond to reality.

Technology transfer should be viewed as a process of using the state's scientific potential. This process is one of the key factors in the development of the country and the world economy. How actively a country participates in the process of implementing the results of scientific activity determines the prospects for its scientific and technological development and the level of competitiveness. The goal of any state is to take a leading role in the emerging economy of a new type. A new type of economy

KUDROVA "Scrum Solo: Application in Projects with a Strong Integration Component" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

is an innovative economy. It is characterized by the constant development of science and technology, the growth of production and the transfer of high-tech products.

The issues related to the technology transfer process are considered by many authors. The works (Dudin et al., 2013; Luksha et al., 2009) highlight the theoretical concept and methodology of technology transfer. There are studies that note the role of technology transfer in the development of the country's innovative economy (Leholetov et al., 2017; Selishcheva et al., 2018). Many authors consider the problems that arise during the operation of infrastructure facilities of a technology transfer institute, such as technology transfer centers (Aleksandrova et al., 2015; Zharova et al., 2018). In their works, researchers often compare the level of development of the institution of technology transfer in Russia and abroad. But despite the large amount of research devoted to the study of technology transfer, there are still many questions to be considered.

The aim of this work is to identify the features of the implementation of technology transfer by scientific and higher educational institutions in Russia.

To achieve this goal, the authors used theoretical and empirical methods of scientific knowledge, the system-structural method, the method of analysis and synthesis, the comparative legal method.

Results and its Discussion

The level of the country's innovative development can be assessed using the global innovation index (Tab. 1). The main leaders in the field of innovation are European countries. The leading role among them is occupied by Switzerland, which has been in the first place in the ranking for 10 years. Switzerland ranks first in terms of both “entry” into innovation and “exit”. And this trend is typical for all countries that occupy the first positions in the ranking. The opposite situation is observed in Russia. Indicators characterizing the development of innovative activity have a better value than indicators characterizing its results. According to the index, one of the strengths for the development of innovative activity in Russia is the number of issued patents and developed utility models and the amount of payments received for the sale of intellectual property objects. All these indicators, in our opinion, characterize a positive result in the implementation of the technology transfer process in Russia.

The technology transfer system that has developed in the country has its own characteristics. In modern conditions, the innovation system and Russian legislation must resolve issues of ensuring the entry of Russian technologies into international markets. In countries with developed economies, the degree of development of the innovation component can be judged by the structure of exports and imports. So, mature technologies should prevail in exports, and new science-intensive technologies should prevail in the structure of imports. According to official statistics, Russia still acquires technologies to a greater extent, rather than sells them (Tab. 2). And only on scientific research export exceeds import.

Table 2: Trade of technologies with foreign countries on the transaction's objects in 2019.

The technology transfer system that is currently being formed dates to the Soviet period. The first stage of its creation can be attributed to the 1950s, when the process of integration between the university and academic environment began. Scientific, technical, and educational centers and laboratories began to be created in academic institutes. (Solov'eva Yu., 2013). In higher educational institutions, divisions appeared that were engaged in scientific research and development.

In the 1970s, the integration process intensified, and the institutional framework for innovation began to form. Interuniversity educational and production complexes were formed.

The 1990s became a turning point for the structures that were called upon to ensure the transfer of scientific results to the innovation sphere. Due to the destruction of production ties, and the reduction in the number of research organizations, imbalances arose in the institutional structure of science. The number of organizations engaged in the creation of new developments and research has sharply decreased from 1992 to the present time. But, since 2010, there has been an active growth in the number of departments in higher educational institutions of Russia and individual enterprises that have begun to carry out scientific and technical activities (Tab. 4). This process can be explained by the active policy in the field of innovations, which has begun to be carried out by the state.

Table 4: Number of organizations performing research and development

	1992	2000	2005	2010	2015	2018
Number of organizations total:	4555	4099	3566	3492	4032	3950

Compiled by authors from the https://rosstat.gov.ru/storage/mediabank/GOyirKPV/Rus_2020.pdf

The main participants in the technology market in Russia are government organizations and higher educational institutions, and not high-tech companies, as in other countries (Salitskaya E. 2018). Russian science, in this regard, plays an important role in solving the problems of technology transfer from the academic environment to the real sector of the economy, to ensure the innovative development of the state.

From a legal point of view, technology transfer should be considered as a process of making transactions related to the disposal of rights to the results of intellectual activity, which in general represent a new or improved technology for the production of products (rendering services, doing business) (Salitskaya E. 2018). In this regard, regulation of technology transfer is carried out by regulatory legal acts related to the results of intellectual activity. The results of intellectual activity are objects of intellectual property and are regulated by the relevant legislation. Since 2008, technology transfer has been regulated by articles of the Civil Code of the Russian Federation.

In Russia, there is a developed system of laws in the field of intellectual property, but legal acts directly regulating the transfer of technologies were adopted only in 2016 (Rybkina E., et al. 2018). Therefore, legal regulations in the field of technology transfer are relatively new.

However, the state, despite the lack of a legislative framework, implemented measures aimed at conducting fundamental and scientific research. In 2018 alone, the country's budget allocated 30 billion rubles for grants and 115 billion rubles in subsidies for research and development. Within the framework of the Strategy for Innovative Development of the Russian Federation, a direction is being implemented to form an innovative infrastructure and to create technology transfer centers. Today in Russia there are more than 100 technology transfer centers. And most of them work based on Russian universities. However, their territorial distribution is uneven (Zharova E., et al. 2018). Most of the technology transfer centers are concentrated in Moscow, St. Petersburg, the Republic of Tatarstan.

It is the state academies of sciences and state universities that carry out research activities in Russia. Here, such results of intellectual activity as databases, inventions, selection achievements, know-how, etc. are created. These institutions carry out most of the scientific and technical developments related to high technologies.

What is the legal status of these institutions? State educational institutions and scientific organizations, according to the current legislation, are budgetary and autonomous institutions, but at the same time they are non-profit organizations (Salitskaya E. 2018). The difference in legal status between budgetary

and autonomous institutions is as follows. For budgetary institutions, a list of governing bodies has not been established and there is a ban on placing funds on deposits and conducting transactions with securities. Autonomous institutions do not have such financial restrictions, but their activities should be carried out under the supervision of a supervisory board. And in general, autonomous institutions are more independent than budgetary ones.

Budgetary and autonomous organizations must carry out their main activities based on a state assignment, from which they cannot refuse. The state task is determined and formed by the founder. The Government of the Russian Federation acts as the founder. The difference arises when a state assignment is issued to conduct fundamental and exploratory research. In relation to higher educational institutions, in this case, the founder is the Ministry of Education and Science of the Russian Federation, in others the organization is the Federal Agency for Scientific Organizations.

The activities of state universities and institutes, scientific organizations can be divided into two categories. The first is the work that is carried out within the framework of the state assignment. The second is work that is performed more than the state assignment. This division is important from the standpoint of understanding who owns the rights to the results obtained during research activities. Since this directly affects the speed of the transfer of technologies that are created in universities or scientific organizations. When the work is completed within the framework of a state order, the owner of the rights to the results of intellectual activity will be determined by the contract. Otherwise, the contractor becomes the owner under a contract that did not provide for obtaining a scientific result.

There is a problem of determining the owner of the results of intellectual activity when it is carried out within the framework of a state assignment. There is no such provision in the documents regulating the implementation of the state assignment. In accordance with the current practice, the rights to the results of intellectual activity performed under the state order belong to the contractor. The executor is a university or scientific organization. In this case, the customer (state) has the right to demand to provide him or another person with a non-exclusive license for the results of activities.

Despite the existing shortcomings in the legislation, the general conclusion is as follows. When a university or scientific organization carries out research activities commissioned by the state, in most cases they will become the owners of the rights to the results they have obtained. But this right is limited by the legislation under a government contract when the customer can request a non-exclusive license free of charge. If the research work is not carried out within the framework of a state contract, then the exclusive rights to the results of intellectual activity belong to the performer. In this case, the customer can use the result obtained only in accordance with the purposes specified in the contract.

Consequently, scientific organizations and state universities have the exclusive right to the results of intellectual activity that they create in the performance of a state assignment, within the framework of a state contract and under R&D agreements, unless otherwise provided by additional agreements.

In order for scientific and educational organizations to dispose of the rights to the results of intellectual activity, they received the right to create appropriate economic societies. Small innovative enterprises have become the missing link between scientific institutions and the real sector of the Russian economy. Small innovative enterprises can apply a simplified taxation system, a reduced tariff for paying insurance premiums. The legislation allows scientific and educational organizations to contribute monetary funds and other property to the authorized capital, lease property belonging to them without holding a competition. But even in this case, universities or a scientific institution can use the right to the development carried out only with the permission of the founder. The state is most often the founder. And this is where the problem arises, since the process of negotiating a deal can be delayed. Therefore, for the commercialization of the obtained developments, it is not enough to find a buyer, which is also difficult in Russian realities. It is necessary that the buyer still agree to a postponement of the conclusion of the contract in connection with the approval of its founder. And most importantly, the buyer must agree to acquire the right, which is limited by the state's ability to require a license to use the results of intellectual activity.

It turns out that research organizations can transfer technology, but they have several limitations that can slow down the implementation of this process.

Today, in addition to imperfect legislation, other problems are observed in the implementation of the technology transfer process. First, there is a shortage of personnel, and secondly, there is a lack of funding. Since the institution of technology transfer is just beginning to develop in Russia, employees of scientific institutions do not have practical experience to bring the results of intellectual activity to the market. An obstacle is the low salaries of scientific specialists compared to the commercial sector, which leads to an outflow of qualified personnel. It should be borne in mind that the stages of technology transfer require the participation of not only scientists, but also marketers, lawyers, designers.

In addition to small innovative enterprises, technology transfer centers are opening at universities and research organizations. If the development is carried out within the framework of a state order, then the revenues of technology transfer centers come from the state. Moreover, developments created by the state are not always required on the market. In this case, the government's money was simply wasted. Therefore, technology transfer centers need to attract third-party customers, but at the same time, such orders may always be insufficient to ensure the work of all specialists. Today, almost every educational institution in one form or another is opening innovative departments that are engaged in scientific research. And if there are several such institutions in the city, then they simply cannot always provide themselves with work. Working only on government orders is not effective. That is, the supply of such services may be several times higher than the existing demand. Therefore, it is necessary to apply measures aimed at stimulating the demand for scientific products.

There are several solutions to this problem. It is possible to create large technology transfer centers in the region, which will coordinate the innovative activities of educational and scientific organizations. These centers can be specialized by industry, can concentrate human and financial resources. That will allow them to gain the experience and information necessary for the successful commercialization of developments. Such centers operate in France, Norway (Salitskaya E. 2018). However, the creation of such centers will require significant budgetary funds and will lead to the reform of the existing system of technology transfer. Which will entail significant economic and transaction costs. Therefore, in our opinion, the creation of such centers can be taken up by the universities and scientific organizations themselves. But for this, the state needs to create conditions for them to have a desire to create unified technology centers. This process will proceed progressively and will allow them to reduce costs and build a new system for organizing technology transfer. State assistance can be as follows. The first one is the improvement of the legal framework governing the transfer of intellectual property rights to the resulting developments in the transfer of technologies. The second is to provide direct government support to scientific organizations involved in technology transfer.

Conclusion

As practice shows, there are problems in the implementation of technology transfer. One of them is the weak regulatory framework on the disposal of rights to the results of intellectual activity in relation to educational and scientific organizations. This is essential, since it is they who carry out a large proportion of research and development, which can then be directed to the real sector. Another problem is the weak business interest in these developments. This leads to low commercialization of the results obtained. It should also be noted that the number of technology transfer centers in the intellectual property market far exceeds the demand for the services they offer. The creation of large technology transfer centers operating within the region can solve these problems.

From our point of view, in addition to creating unified technology transfer centers, to increase the efficiency of technology transfer, it is necessary to take measures aimed at:

– Increased demand for scientific products from business.
– Bridging the gap between science and business in the direction of creating new scientific developments.
– Increasing the level of commercialization of scientific developments.
– Taking measures aimed at developing innovative infrastructure in the field of technology transfer.
– Application of measures of state incentives for technology transfer.

The increase in the efficiency of technology transfer to the scientific and educational environment will contribute to the successful integration of higher educational institutions and scientific organizations with the national innovation system.

Abstract

In the context of growing business internationalization, values held by modern managers and their importance on people management in a multicultural environment are a topical and pertinent area of research. Values support managers in the realization of their visions, missions, and goals, all of which directly influence the effectiveness of the whole organization. Values play a significant role in multicultural environments, where they can act as a team bonding factor. The study described in the article is a mixed methods study: it combines traditional analysis of the subject literature and an empirical study. The results of the Corporate Values Index (CVI) study are described in the first part and used as the starting point for the preliminary study conducted by the authors of the article. The aim of CVI study was to answer the questions what values dominate in companies and how widely these values are incorporated in management. The next part presents the findings of the pilot study (8 telephone interviews) conducted by the authors, which they held with Polish managers working in multicultural environments. This pilot study is an introduction to a larger research project which will be conducted among managers working in international companies in Poland, Spain, and the Czech Republic. The article ends with the conclusion that the values held by managers are extremely important and affect a multicultural work environment. The main aim of the article is to demonstrate the role and significance of values held by managers working in multicultural environments.

Keywords: Values, People Management, Multicultural Environment, Managers

Introduction

The authors' decision to investigate values stemmed from their interest in this issue and the present crisis of values in business caused by companies' excessive focus on profit. Many people consider values to be uncountable, thus difficult to describe and measure and translate into measurable profit. This is a very interesting issue, especially because many organisations declare their willingness to manage by values, although, unfortunately, they do not put these declarations into practice (Le, Fuller, Muriithi, Walters, Kroll 2015). However, it should be emphasised that there are managers who attempt to build organisational culture on the basis of values shared by all or a vast majority of employees. This is due, among other things, to the development of such areas as motivation and employee involvement, which are used to increase the overall efficiency of an organisation. A widespread trend in contemporary business, called Motivation 3.0, assigns the role of motivators to various internal elements, including values (Pink, 2009). When it comes to the internationalization of business, Poland occupies an important place not only in Europe, but also worldwide, hence the issue of values and their influence on people management is of an increasing interest for Polish managers. For example, the Polish sector of modern business services intends to employ nearly 340 thousand

people in 2020. The increase in employment in service centres in Poland since the first quarter of 2016 amounted to 43%, which is why this sector is so important from the point of view of people management. Employment in the first quarter of 2020 is predicted to reach over 336 thousand employees (ABSL 2019). These data motivated the authors of the article to investigate values held by modern managers and their impact on people management, especially in a multicultural environment.

The interest in values in management is relatively young. The first study in this areas was conducted by Thomas J. Peters and Robert H. Waterman, who, based on observations of the American economy in the early 1980s, recommended that entrepreneurs create a value system that would become a vital element of their competitive advantage (Peters, and Waterman, 1982). This research trend was continued by Ken Blanchard and Michael O'Connor, who led to a change in thinking in business in terms of values (Blanchard, and O'Connor, 2003): while managers used to focus on hard elements in management, such as systems and structures, the new trend encouraged them to focus on the organizational culture, which, built on values, was to form the foundations for employee involvement.

The theoretical part of the article describes the concept of values and the role they play in people management, taking into account the multicultural context. Next, it discusses the results of studies carried out by the ECCO Network and the results of the authors' study (8 telephone interviews); the latter are of a preliminary nature and will serve as a starting point for an in-depth study on values among Polish, Spanish, and Czech managers.

The aim of the article is to demonstrate the role and significance of values held by managers working in multicultural environments. Bearing this aim in mind, the following research questions were formulated: Do managers employed in international companies in Poland are familiar with and understand the concept of values? What values do they hold? Do they manage by values in practice? Can managers identify the impact of values prevalent in a given enterprise on people management in a multicultural work environment?

Values in contemporary organizations - definitions and the role they play in people management

Values are present in all organizations and held by all managers, and manifest themselves in organisational artefacts, behaviours, processes, and structures (Schein, 2004). Without a doubt, values represent the deepest level of cultures (Alas, 2009). In this context, it should be remembered that an organisation, being an institution, does not have and does not create its own internal values (Stackmanet, Pinder, and Connor), as it is the people working in an institution who implement values in an organisation (Thomsen, 2004).

The subject literature offers numerous definitions of values. The authors of the article focus of those of them that facilitate the understanding of the role values play in an organization in the context of their impact on people management. One of the definitions that best reflects this meaning of values is presented by Pucik, Ticy, and Barnett (1993). In their opinion, values are broadly understood convictions, often unconscious and non-negotiable, about what is good or bad, beautiful or ugly, rational or irrational, normal or abnormal, natural or paradoxical, or decent or indecent. Yukl (2002, p. 190) describes values as "constructs representing generalised behaviours or states of affairs that are considered by the individual to be important". Another definition states that values are ideas and beliefs that influence and guide our choices and actions (Gini, 2004). Henderson and Thomson (2003) define values as the sum of our preferences and priorities; preferences are what we would like to achieve, while priorities indicate how important particular preferences are in relation to one another.

Analysing values from the business perspective, some researchers claim that values determine how an organization and the people who make it work (Lebow, and Simon, 1997). Moreover, suggestions to replace management based on traditional control with management based on values were already made some time ago (Pruzan, 1998).

Initially, values within management were presented as a simple and mechanical concept of management (Blanchard, and O'Connor, 2003). However, the attempt to manage by values at the organisational level is not clear or obvious (Speculand, and Chaudhary, 2008). One of the first definitions of management by values (MBV) was given by O'Reilly and Chatman (1996, paragraph 168): "[...] a combination of identifying strategically relevant values and norms, as opposed to irrelevant values and norms, and promoting agreement as opposed to chronic conflict among organizational members [...]". In management by values (MBV), the main role played by values is to regulate employees' behaviour in order to achieve maximum efficiency. This means that the effectiveness of MBV depends in part on the effectiveness of the defined values in value statements; in order to assess their effectiveness, different value categories should be analysed (Jaakson, 2010, p. 795).

People work effectively and efficiently when they share a common vision, mission, and goals. This sharing is achieved by a set of shared values, which is most often implemented by management. However, in order to skilfully manage people, managers should be aware of their own system of values and of the values that are shared and accepted in a given organisation. If these values are consistent with the expectations of the multicultural work environment in which a manager operates, and if they are actually respected, then management by values brings the expected results. It should be emphasized that a manager who is aware of the importance of values is able to integrate employees around shared values and convince them to apply these values in practice. If this happens, values contribute to employee involvement, which is of particular significance in international companies, in which work environments are based on cultural diversity (Barnett, and Karson 1989).

The authors would like to point out three main reasons which, in their opinion, have a significant impact on the growing role of management by values in business, especially in multicultural organisations. They are based on the aforementioned study by Thomas J. Peters and Robert H. Waterman, who already 40 years ago predicted that the creation of a cohesive value system shared by all employees will become a vital element of a company's competitive advantage (Peters, and Waterman, 1982).

First of all, the financial crisis that hit the world over ten years ago triggered an interest in values in business. At that time, managers were faced with a great problem of the market recession. The previous conviction about the need to build long-term relationships with customers turned out even more prominent; such relationships should be based on communicating to customers their benefits. At present, it is not the transaction itself and short-term relationships that matter most but long-term relationships with customers. Such an approach must account for the implementation of certain values in management (Dixon, and Adamson, 2011).

Second, the values prevalent in an organization make it possible to build its uniqueness and to increase its competitiveness. It is values that distinguish one company from other companies in the market. They are a key element of successful multicultural organizations, which owe their success to an ability to dynamically, flexibly, and quickly adapt to the changes in the market. It is vital to adhere to and promote those values that clearly indicate what is respected and appreciated in a given company, what all employees strive for, and what is crucial in building positive, long-term relationships with clients. Cherishing shared values helps, especially in a multicultural environment, to avoid misunderstanding, both in relations inside and outside the organization, and to achieve objectives, which is possible thanks to efficient team management.

Third, an appropriate set of values allows managers to implement effective knowledge management, which is indispensable in the successful functioning in the international market. If an organization fosters its employees' independence and creates conditions that allow them to develop their creativity and innovation, it will achieve success by increasing the effectiveness of its operations. It is worth mentioning that employees working in a multicultural environment have more experience and this experience is more diverse than in monocultural ones, while the possibility of sharing knowledge allows them to use it to increase the effectiveness of their company. "Creativity thrives on diversity" (Morgan 1989), which is a great asset of multicultural teams.

Multiculturalism in organizations affects managers' attitudes, behaviours, and the values they hold, such as openness, tolerance, and acceptance of employees' cultural differences (Knap-Stefaniuk and Burkiewicz, 2018). In addition, managers of multicultural teams should be empathic and sensitive to the values held in diverse cultures, and, at the same time, have a strong personality and charisma to face specific challenges posed by a multicultural environment (Knap-Stefaniuk and Burkiewicz, 2020). They should also try to create the appropriate atmosphere in the workplace, especially in view of work-related stress and mental strain (Knap-Stefaniuk and Burkiewicz, 2019), which is particularly important in a culturally diverse work environment.

It is crucial to hold and promote those values which clearly indicate what is respected and appreciated in a given company, what all employees strive for, and what is the most significant in building positive, long-term relationships within the company and with customers. This allows managers (especially those who work in international companies in which cultural differences are a part of everyday functioning in culturally diverse teams) to make the right decisions and to avoid conflict or misunderstanding (Świątek-Barylska, 2010).

Management by values motivates employees to work faster and better than traditional management. What is more, studies confirm that compatibility between employees' personal and organisational values and the transparency of these values increase the level of their organisational involvement (Posner, and Schmidt, 1993). Thus, shared transparent values are indeed of great importance (Blanchard, 2006).

It is not only the multiculturalism of an organization that influences what values are held and promoted in it by managers. Generational differences are also a key factor affecting people management, especially in organisations with employees from diverse cultural backgrounds.

Employees belonging to different age groups display different attitudes towards work and values (Pendergast, 2009). Currently four different generations are present in the labour market: Baby Boomers (born between 1949 and 1963), Generation X (born between 1964 and 1979), Generation Y (born between 1980 and 1994), and Generation Z (born after 1995 or even 2000), (Shephard, 2006). The oldest employees (Baby Boomers) primarily expect tolerance, stability, teamwork, and consensus. Generation X looks for stable employment and values low-stress and secure jobs that do not require facing new challenges and changes (Deverson, Hamblett 1964). Generation Y, called Millennials, is the first generation that is not afraid of change and appreciates freedom of speech, choice, and activity (Heaney, 2007). The same is true of Generation Z, which holds similar values in its professional and private life to Generation Y, but does not pay attention to long-term relationships with employers (McCrindle, 2014).

"As business leaders strive to accomplish great achievements in our global economy, it is important to always remember that values endure. They are absolute, unchanging and non-negotiable" (Dean, 2008, p.7). Values connect employees, bind teams together, support the achievement of goals and facing new challenges, shape employees' attitudes and behaviour, their relations with managers and contacts with clients. Values held by managers significantly affect people management, for example, communication between team members, motivating employees, resolving conflict, or, more generally, treating people and appreciating their work and achievements. In a multicultural environment managers' values are often the foundation that unites employees from diverse cultures around what is shared, acceptable, and understandable to all of them.

Summing up, it is worth referring to Rokeach's (1973) definition of a value: for him it is simply an enduring belief that is personally or socially preferable. Following this definition, values can exist at individual, organizational, and societal levels. At individual or organizational levels values act as a guide or a standard for people's behaviour. They represent the way in which people think and behave.

It should be remembered that, as the company develops, organizational values are shaped by all members of the organization and events that affect its functioning (Gorenak, Ferjan, 2015). Managers

and their values have a paramount impact on how effectively teams work and organizational objectives are implemented, especially in a multicultural environment.

Methodology

The research method adopted by the authors of this article is a mixed method based on the analysis of the subject literature and the discussion of the results obtained in the empirical study. The article first discusses the results of secondary studies conducted in a number of countries by the ECCO Network, an international network of advisory, consulting, and research companies, which were a continuation of the study devoted to business values carried out in 2003 only in France. Next, the results of the authors' study (8 telephone interviews with Polish managers working in international companies in Poland) are presented. This study is an introduction to a larger research project.

The first edition of the international study conducted by the ECCO Network in 12 countries (Poland, Germany, France, Italy, Hungary, the Netherlands, Spain, Finland, Norway, Great Britain, India and the USA) took place in 2006 an was named "Corporate Values Index 2006". It covered the employees of several thousand companies from fourteen different industries (ECCO Network 2006).

The second edition was carried out in 2009 and included over 3800 companies from the financial sector from 10 countries (including Poland, Germany, India, Spain, Great Britain, Ukraine, and the United States). It yielded over 18 500 different terms referring to the values held by employees of these organizations. For the purpose of the analyses, in the "Corporate Values Index 2009" their number was reduced to 89 values, which were subsequently used to compile a list of 10 values that were the most popular internationally, based on the frequency with which they appeared in respondents' answers (ECCO Network 2009).

The "Corporate Values Index 2013" was the third study of this kind conducted by the ECCO Network; it took place in 2013, covered 4300 largest companies representing 14 industries in 13 countries around the world and identified nearly 23,000 values (ECCO Network 2013). The questions regarding values were answered not only by top executives, but also by managers, employees, and customers. The ECCO Network did not reveal the research tool used in the studies, and the first and third editions covered companies from various industries, while the second edition focused on the financial industry.

The study conducted by the authors of the article was based on the interview method and telephone interview technique. Such a solution proved to be the most effective, taking into account the epidemiological situation in Poland related to COVID-19. The authors developed a short interview questionnaire with closed and open questions directed to managers; the questionnaire was based on the study carried out by the ECCO Network.

The key criterion for selecting respondents was their employment in managerial positions in international companies (with over 100 employees) located in Poland and their experience in managing multicultural teams (at least 2 employees of different nationalities in the team).

The interviews with 8 managers who had been holding managerial positions for more than 3 years (the authors assumed that 3 years is a sufficient period to acquire experience in managing a multicultural team) were conducted between July and August 2020.

Some respondents agreed to have the interviews recorded (3 people), while 5 did not, so the respondents' answers were written down by the authors. The answers to the interview questions were coded and categorised, and served as the basis for a short quantitative data analysis.

The respondents participating in the study were Polish managers (2 women and 6 men) aged between 35 and 49.

The results of studies on values held by managers working in multicultural environments

Studies on modern managers' values and their impact on people management in diverse cultural contexts have been conducted for some time. Searching a popular JSTOR digital library reveals the extent to which these studies have been undertaken internationally, for example, in India (Roy S., Dhawan 1984), Slovenia (Kovač, Jesenko, 2003), Iran (Alavi, Yasin, 2003), Kuwait (Ali Abbas J., Al-Kazemi, 2005), Turkey (Askun, Oz, Aşkun, 2010), USA (Posner, 2010), South Africa (Mayer, Louw, 2013), Iceland (Sigurjonsson, Vaiman, Arnardottir, 2014), Bulgaria (Petkova-Gourbalova, 2015) and many other.

To the best of the authors' knowledge, there are no Polish studies that in a practical way investigate contemporary managers' values and their influence on people management in a multicultural environment.

The first edition of the study conducted by the ECCO Network in 2006 revealed that at that time values became one of the leading trends in people management. A set of values held by a manager and their skilful implementation considerably facilitates the process of shaping employees' desired attitudes and behaviours. What is important, the results of this study indicated that values in management are an important step forward compared to e.g. management by objectives. The study demonstrated that the values that guided managers in shaping the strategy of people management and also enterprises in general, included: quality (listed by 38% of respondents), innovation (38%), customer satisfaction (37%), honesty (21%), care for the environment (18%), teamwork (18%), and know-how (17%). Interestingly, at that time as many as 77.5% of the companies analysed in the study applied the concept of management by values, while in Poland the percentage of such companies was only 21.5% (ECCO Network 2006).

In the "Corporate Values Index 2009" the analysed values were grouped by importance and category, which yielded 8 main groups:

- *professional values* are linked to the quality of the offer and the company's core business, company characteristics and products, all of which translates into customer trust and satisfaction,
- *combative values* are related to 'soft' abilities that are conductive to high competitiveness, including ambition and initiative,
- *behavioural values* describe the way in which a company and its employees operate, i.e. adaptability, freedom, and commitment,
- *societal values* define the attitude to the environment in which the company operates,
- *relational values* refer to the way in which a company communicates with its environment (e.g. accessibility, trust, and partnership),
- *fulfilling values* are linked to a company's attitude to employees' individual feelings and characteristics, such as humanism, personal development, or sensitivity,
- *moral values* concern a company's attitude to the principles of ethics, morality, and honesty,
- *social values* are the ones that are shared with society, such as democracy and equality.

The values most frequently indicated in the study were: quality (39%), innovation (39%), customer satisfaction (26%), honesty (19%), and environment (18%).

The 2009 edition of the study revealed values important for different nationalities. For example, the managers from Spanish companies appreciated social values and societal values the most, with social responsibility (39% of the respondents), responsibility (36%), and innovation (30%) heading the list. However, managers from other countries in southern Europe put relational values, including accessibility (38%), innovation (31%), cooperation (31%), and sharing (31%), on top. Honesty (34%) was the most important value indicated by the Italian managers. Vales rated the highest by the Germans were societal values, e.g. social responsibility (67%) and professional values, e.g. customer satisfaction, reliability, and work quality (29%). For the Austrians, social responsibility and health (38% each) were significant values. Professional values (e.g. customer satisfaction, 40%) and moral

values (e.g. honesty, 30%) were the top ones for the Dutch, while the Ukrainian managers most frequently indicated combative values (e.g. innovation, 96% and success, 81%), professional values (e.g. quality, 92% and know-how, 85%), and relational values (e.g. communication, 62%). In the UK, innovation and know-how were the ones most respected (60% each), followed by reliability (44%) (i.e. professional values), and combative values such as customer satisfaction (32%) and success (32%). The American managers most often pointed to professional values and combative values, i.e. trust (39%), customer satisfaction (33%), and innovation (28%). In the Indian companies, innovation (53%) (a combative value), customer satisfaction (42%) (a professional value), and reliability (39%) (a relational value) were rated the highest (ECCO Network 2009).

In the "Corporate Values Index 2013" study the most frequently chosen values were innovation (40%), quality (30%), customer satisfaction (28%), honesty (20%) and concern for the environment (17%). Also in this edition, values were divided according to the respondents' nationality. In the UK, the ones from the top included: honesty (62%), innovation (31%), and know-how (31%), in the USA: customer satisfaction (63%), competitiveness (53%) and honesty (47%), while in Switzerland: quality (43%), responsibility (38%), and innovation (29%). Managers from Norway valued: customer satisfaction (39%), ambition (24%) and innovation and flexibility (19% each), from Finland: customer satisfaction (70%), responsibility (25%), and teamwork (25%), and those from Australia: integrity (85%), service (40%), teamwork and customer satisfaction (35%). Crucial values for the French managers were: accessibility (34%), innovation (31%), efficiency and team spirit (25%), for the German ones: customer satisfaction (50%), quality (41%), and social responsibility (36%), whereas for the Spanish ones: innovation (52%), customer satisfaction (48%), and know-how (48%). In Dutch companies, the most important value indicated by respondents was customer satisfaction (35%), which was in line with the result obtained in the previous study. Also the Italians remained faithful to their values: honesty (35%) was again chosen as the most important value at work. The Austrians pointed to two values on the top of their list: innovation and quality (50% each).

Comparison of the values indicated by managers in the studies conducted in 2009 and 2013 is presented in the table below. Unfortunately, the studies did not include managers of all nationalities of interest to the authors, hence below only comparison of those nationalities that were included in both studies is given.

Table 1: Comparison of the most important values indicated by managers from the countries included in the study

The most important values indicated by managers from the countries included in the study		
Country	Corporate Values Index 2009	Corporate Values Index 2013
USA	trust (39%)[1]	customer satisfaction (63%)
United Kingdom	innovation and know-how (60% each)	honesty (62%)
Spain	social responsibility (39%)	innovation (52%)
Netherlands	customer satisfaction (40%)	customer satisfaction (35%)
Italy	honesty (34%)	honesty (35%)
Germany	social responsibility (67%)	customer satisfaction (50%)
Austria	social responsibility and health (38% each)	innovation and quality (50% each)

Source: own elaboration based on: ECCO Network 2009; 2013.

The questionnaire used in the study conducted by the authors of the article was based on the eight main groups of values identified in the ECCO Network study (professional values, combative values,

behavioural values, societal values, relational values, fulfilling values, moral values and social values). As the authors assumed that it is managers who determine what values are appreciated in a given company, they decided to focus on values held be managers who worked in a multicultural environment. It should be remembered that the study described here is a preliminary one; it will be continued on a broader scale in the near future.

The purpose of the interviews was to obtain information whether the managers who took part in it were familiar with and understood the notion of values, whether they were able to indicate what values they held (which of the above mentioned groups were the most important for them), and whether they managed by values in practice. Moreover, the authors also wanted to find out whether managers were able to determine the impact of values prevailing in their company on people management (in the teams they lead) in a multicultural work environment.

As was already mentioned, the respondents included 2 women aged 35-42 and 6 men aged 36-49. At the time of the interviews, all of them worked in international companies, in which they were in charge of multicultural teams (that consisted of employees of at least 2 nationalities), and had been working in managerial positions for over 3 years (between 5 and 14).

All the respondents (8 people) were familiar with the concept of values, which they defined as: convictions that allow people to determine what is good and what is bad, rational or irrational, decent or indecent (6 people), ideas and beliefs that influence and guide people's choices and activities (5 people), and as a sum of people's preferences and priorities (5 people). All mangers agreed with the statement that "values determine how an organisation and the people who make it work" (8 people).

When asked about the 8 main groups of values described in the ECCO Network study, the respondents' answers were as follows: professional values (8 people), combative values (6 people), behavioural values (6 people), societal values (7 people), relational values (5 people), fulfilling values (7 people), moral values (6 people), social values (5 people).

Most respondents indicated professional values, societal values, and fulfilling values as the vital ones. Only 4 of them declared that they implemented the concept of management by values in their work (and stated that this concept had been present in their companies for several years).

Managers were able to determine the impact of values prevailing in their company on people management (in the teams they were in charge of) in a multicultural working environment. The most important values they listed included: communication (7 people), innovation (7 people), quality (7 people), teamwork (7 people), responsibility (6 people), cooperative spirit (6 people), and customer satisfaction (6 people). The respondents declared that the values they held had a significant impact especially on such areas of people management in their teams as: efficient communication (7 people), shaping employees' motivation and involvement (7 people), cooperation in the implementation of group projects (7 people), building team relations – inside and outside the company (6 people), planning trainings for employees and their development (6 people), designing objective evaluation systems (6 indications), building relations with clients (6 people), sharing knowledge and experience (6 people), building the atmosphere of cooperation (6 people), and solving conflict (6 people),.

Discussion

The results of the studies carried out by the ECCO Network in the area of values in the organizations that participated in them lead to the following conclusions:

- the values in individual companies in 2006, 2009, and 2013 were similar,
- among the values indicated in 2006, 2009, and 2013, quality, innovation, customer satisfaction and honesty were the most frequently indicated,
- in 2006 the key values included quality, innovation, customer satisfaction, honesty, and care for the environment,
- in 2009 these were quality, innovation, customer satisfaction, honesty, and care for the environment,

- in 2013 it was innovation, quality, customer satisfaction, honesty, and care for the environment,
- in 2013 several new values were listed, including society, corporate spirit, global approach, reliability, customer satisfaction, and leadership,
- the studies confirmed that different values were significant for different nationalities.

Interviews conducted by the authors revealed that the managers who took part in them were familiar with the concept of value (8 people). Most of them defined values as convictions that allow people to determine what is good and what is bad, rational or irrational, decent or indecent (6 people). The groups of values they respected most included professional values (7 people), societal values (6 people), and fulfilling values (6 people). Only 4 managers declared that they applied the concept of management by values in their companies.

The respondents also listed the values that prevailed in their companies. These were: communication, innovation, quality, teamwork (7 people), and responsibility, spirit of cooperation and customer satisfaction (6 people each). The respondents indicated that the values dominant in their enterprises (in a multicultural work environment) had an impact on people management, especially in such areas as: efficient communication, shaping employees' motivation and involvement, and cooperation in group projects (7 people each). Other areas included building team relations, sharing knowledge and experience, building the atmosphere of cooperation, or resolving conflict. These areas are very important in managing employees who come from diverse cultures.

Limitations

The authors of the article are perfectly aware of the limitations that result from conducting a primary study with a small research sample (8 managers). Nevertheless, as mentioned in the Introduction, the study was an introduction to a larger research project that will investigate, among others, the role and importance of values held by managers working in multicultural environments that the authors intend to conduct among Polish, Spanish and Czech managers.

The primary study was conducted with the use of the interview method and the telephone interview technique, which was also a certain limitation. However, the authors made such a decision because of the situation related to COVID-19. Originally, the authors had intended to conduct in-depth individual interviews, which would certainly yield more insightful and detailed results.

The results obtained in the study allowed the authors to signal the role of values held by managers on the area of people management. The authors are aware that this is an area of research that requires a more in-depth approach in further research projects.

Conclusion

In the authors' opinion, values are absolutely essential for effective people management, especially in companies where multiculturalism of employees is a widespread, permanent element of the manager's daily work.

Therefore, it should be emphasized that the results of the studies conducted by the ECCO International Communications Network in 2006, 2009, and 2013 revealed a growing role of values for managers and organizations; it can be even said that nowadays values are becoming a "must have" in business. When companies implement certain sets of values, they 'prompt' their managers to use these particular sets for proper communication and cooperation with employees.

Managers who are able to implement a flexible work culture based on shared values, especially in a culturally diverse work environment, are highly effective in utilising the potential of multicultural teams, e.g. their innovation, creativity, knowledge, and experience sharing. Tolerance and acceptance for diversity should be on top of the list of values held by managers who work with employees from diverse cultures.

Modern organizations, if they want to develop and be competitive, must hold values on the basis of which managers will be able to effectively manage employees and build well-tuned, efficient teams. The values that managers hold are particularly pertinent in environments characterised by cultural diversity, as they allow them to unite people from various cultures around what should be transparent, shared, and accepted by all employees.

The authors believe that the values held by contemporary managers exert a great impact on people management, also in Poland, where the sector of modern business services is developing very dynamically. Therefore, it should be emphasized that in the future not only technological development and its consequences, such as robotic process automation (RPA), machine learning (ML), and artificial intelligence (AI), will pose a challenge for managers working in an international environment. An equally challenging area they will have to face will be skilful management by values and the continuous improvement of human capital in order to direct employees towards values shared in a multicultural working environment.

Summing up, it should be emphasized again that respecting shared values – by managers and employees – is conductive to, especially in an intercultural work environment, developing innovation and team spirit, avoiding misunderstandings and difficult situations, and thus to effectively achieving team and organizational goals. Values held by managers are particularly important in such environments, as they influence the attitudes, behaviours, and values of employees. They affect various areas of management, especially people management.

The in-depth study the authors are planning to conduct in the near future will investigate values held by managers in Poland, Spain, and the Czech Republic. Further studies in this area should examine whether the values held by managers are consistent with those held by employees. Additionally, it is worth analysing whether and to what extent the values held by different generations active in the labour market at present differ, especially in the context of cultural diversity of work environments.

Notes

1.The number expressed as percentage indicates the percentage of managers of given nationality who have indicated this particular value as significant in their daily work.

Abstract

The paper presents the results of a study of the features of manifestation of nomophobic behavior and its interrelationships with perceived stress in junior medical students from two countries with different cultures. The anonymous survey using the FIE-Stress Inventory and Mobile phone use related anxiety questionnaire was attended by 292 students in the first two years of study - 210 students from Ulianov Chuvash State University in Cheboksary and 82 -from Bukhara State Medical Institute. The data on the similarities and differences among students of Russia and Uzbekistan in the level of stress, manifestations of nomophobic behavior and their interconnections which can be taken into account when planning preventive work with students at a medical university were obtained.

Keywords: medical students, stress, nomophobia, Russia, Uzbekistan.

Introduction

The topic of smartphone and digital media overuse is attracting the attention of an increasing number of researchers. Such behaviors are widespread among those in the digital age (Scott et al., 2017) and are closely associated with mental health problems (Nikolaev and Kulygina, 2020), especially among students (Cain, 2018).

Nomophobia is a relatively new and insufficiently studied psychological phenomenon arising in the process of human-smartphone interaction, the clinical consequences of which are widely discussed today (Yildirim and Correia, 2015). First described in 2010 (King et al., 2010), this condition is characterized by anxiety arising in a mobile phone user, anticipating a situation in which he may be left without access to his phone (Yildirim et al., 2016). Researchers find in nomophobia traits of both social phobia and addictive behavior (King et al., 2013) which can be considered in the frame of compulsive use of online social networking sites (Kuss and Griffiths, 2017).

Medical students are known to be at high risk of mental health threats (Voltmer et al., 2008), incl. due to the specificity of attitudes towards death and suicide (Chistopolskaya et al., 2016; Chistopolskaya et al., 2017). Among them, problematic smartphone use is also widespread which not only negatively affects

health but is also associated with academic failure (Prasad, 2017). Scientists believe that this problem is becoming more and more urgent for medical students (Farooqui, 2018) and is already gaining socially significant character (Basu, 2018).

The aim of this study is to study the features of the manifestation of nomophobic behavior and its interrelationships with perceived stress in junior students studying medicine and living in countries with different cultures - in Russia and Uzbekistan, in order to identify the extent of similarities and differences in the consequences of smartphone and digital media use.

Method

The study was conducted on the basis of Ulianov Chuvash State University, UCSU (Cheboksary, Russia) and Bukhara State Medical Institute, BSMI (Bukhara, Uzbekistan). The anonymous survey involved 292 medical students in their first two years of study - 210 students in Russia and 82 - in Uzbekistan.

The average age of students of the two medical universities did not differ statistically ($p>0.05$) and amounted to 19.63±1.32 years at UCSU and 19.59±1.51 years at BSMI. The sex composition of the surveyed at UCSU was 41.43% of men and 58.57% of women, in BSMI - 43.90% of men and 56.10% of women. These ratios in the two study groups of students also did not differ statistically ($p>0.05$), which made it possible to carry out a quantitative and qualitative comparison of the groups.

The level of perceived stress was determined using the FIE-Stress Inventory which made it possible to establish both the severity of the general level of stress and its three components - physiological, informational and emotional (Ivanova, 2008). To establish the severity of nomophobic behavior, students filled in a 35-item Mobile phone use related anxiety questionnaire (Nikolaev et al., 2018).

Mathematical processing of the results was carried out using basic statistics and correlation analysis (with a significance level of $p<0.05$).

Results

The results of the study showed that the general level of stress among Russian medical students was significantly higher than that of their Uzbek peers ($p<0.0001$). Evaluating the qualitative structure of stress it can be noted that Uzbek medical students in comparison with Russian medical students had a lower severity in all of its components - physiological, informational and emotional stress ($p<0.0001$). In other words, Uzbek students were less likely to report general somatic symptoms (headache, sleep disturbances, poor appetite), less often felt a lack of time, information overload, impairment of memory and thinking abilities, less experienced various negative experiences (fear, anxiety, irritation, uncertainty, dissatisfaction).

In the Russian group, students with varying intensity of stress were represented in different proportions - more than half of the students (58.57%) had an average level, every fourth (26.19%) had a high level, every seventh (14.76%) had a low level, and one person (0.48%) - a very high level of stress. In the Uzbek group, only two levels of stress intensity were presented - an average level (63.44%) and a low level (36.56%). At the same time, the significance of differences between the groups was determined only in relation to the low level ($p<0.0001$) - medical students from Uzbekistan were significantly more likely to have a low intensity of stress than students from Russia.

An analysis of the results of filling in Mobile phone use related anxiety questionnaire revealed both similarities and differences between Russian and Uzbek medical students. In particular, students from

Russia and Uzbekistan with the same frequency ($p>0.05$): prefer that the phone was always within the field of view; keep it next to them in a bag, pocket or hand; put the phone closer to the bed at night so as not to miss a call; do not part with him in the bathroom, shower or toilet, as well as for food; check the phone to find out if messages have come, if there have been calls; return home for the phone, even if it threatens to be late; worried and fussed if the phone suddenly disappears; get angry and have poor control over themselves if left without a phone; when the phone is off, they feel anxiety; experience anxiety when they are out of the coverage area of the network for communication; feel anxious if the connection is lost, or if the phone is turned off; nervous and angry when it is not possible to turn on the phone; carry a charger with them in case the phone battery runs out; are afraid of stealing their phone; try to browse social networks in their free time; trying to update the phone; follow the novelties in the world of mobile technologies and purchase new accessories for the phone; feel a phantom vibration or a phantom call from a phone, incl. when it is off.

Uzbek medical students reliably more often than Russian students enter the necessary information into the phone instead of memorizing or writing down ($p=0.0037$); turn off their phone ($p=0.0169$); are afraid of losing their phone ($p=0.0208$); waking up in the morning, first of all, they pick up the phone ($p=0.0445$); after a temporary stay without a telephone, they immediately clarify whether there were calls or messages ($p=0.0493$).

Russian medical students are significantly more likely than Uzbek peers to carry two telephones with them at one and the same time ($p=0.0018$); envy those who change their phone more often ($p=0.0081$); get annoyed and answer rudely when there is no way to check the phone or if someone is distracting ($p=0.0083$); being on a visit, they try to follow the telephone and communications (whether there is a connection, whether calls or messages have been received) ($p=0.0107$); consider that sometimes “digging” in the phone is much more interesting than communicating with relatives or others ($p=0.0316$); do not spare money to buy a new phone model or accessories for it ($p=0.0372$).

To clarify the nature of the relationship of the studied parameters, a correlation analysis of the obtained results was carried out separately in the Russian and Uzbek samples.

Two pairs of significant correlations were common for both samples. The first positive relationship is between the student's age and the frequency of switching off the phone ($r=0.20$ and $r=0.23$). The second is between the level of informational stress in the student and the feeling of vibration of the phone for no real reason ($r=0.25$ and $r=0.22$).

Negative correlations between the student's age and the following symptoms became characteristic only of the Uzbek sample: phantom call syndrome ($r=-0.31$), phantom vibration syndrome ($r=-0.31$), placing the phone next to the body ($r=-0.41$). The latter practice, in turn, positively correlated with the level of emotional stress ($r=-0.28$) and the average level of general stress ($r=-0.23$).

More significant correlations were found among Russian students. The older students had a lower level of information stress ($r=-0.16$). Boys turned off their phones more often ($r=-0.27$), girls more often feared theft ($r=-0.16$) or loss of their phone ($r=-0.20$) and more often had a higher physiological level ($r=-0.22$), informational ($r=-0.23$), emotional stress ($r=-0.24$), and general stress ($r=-0.26$). Russian students of both sexes also showed positive relationships between the general level of stress, its various forms (physiological, informational and emotional stress) and anxiety symptoms associated with the use of a mobile communication device, including phantom vibration syndrome and phantom call syndrome.

Conclusion

In this study of the features of nomophobic behavior and its interrelationships with perceived stress among medical students from two countries it was found that the level of general stress among Russian students exceeds that of Uzbek students who are more likely to have low stress intensity. Most of the manifestations of nomophobic behavior occur with the same frequency in students from both countries. The frequency of phantom vibration syndrome corresponds to a higher level of information stress in them, and the frequency of switching off the smartphone corresponds to an older age.

Among Uzbek BSMI students, there is a higher willingness to use a smartphone as a storage device and turn it off at night. In older students phantom call and phantom vibration syndromes are less common. Younger Uzbek medical students are more likely to place their smartphones next to their bodies and have higher levels of emotional stress.

Among the Russian students of UCSU, the guidelines for the possession of several phones and the desire to change them more often were noted. All forms of stress are interconnected with the frequency of phantom ringing and phantom vibration. With age, the frequency of information stress among Russian medical students decreases.

The obtained comparative data can be refined using a larger sample of students from different universities in the two countries. However, they can already be taken into account when planning preventive work with undergraduate medical students.

Agriculture in Poland And the Protection of The Natural Environment. Results of Expert Studies

Arkadiusz PIWOWAR

Wroclaw University of Economics and Business, Wrocław, Poland
arkadiusz.piwowar@ue.wroc.pl

Abstract

Agricultural activity has a considerable impact on shaping of the natural environment. It is directly associated with the consumption of natural resources and changes in the spatial development, and hence it becomes necessary to take into account environmental issues in the agricultural economics in the macroscale, mesoscale and microscale (in agricultural policy, analyses of economic effectiveness in agriculture in specific spatial ranges, ethical dimension of the economic activity, social responsibility of farmers, etc.). The article presents the opinions of experts regarding the causes of problems related to the threat to the natural environment in rural areas in Poland and the proposed remedial measures. The survey was conducted at the turn of 2017/2018 and concerned current problems in the studied subject area. The main objective of the research was to identify the reasons why farmers did not take actions aimed at protection of the environment, as well as to indicate the measures (at the central and local levels) that could improve this situation. The experts indicated many possible actions that may contribute to an improvement of the condition of the natural environment in rural areas in Poland.

Keywords: Rural Areas; Agriculture; Environmental; Protection; Tag Cloud

Introduction

Production activity in agriculture, especially in the open-field crop cultivation and grazing livestock farming, is inseparably associated with the nature. Agriculture is a very important element of the landscape and it fulfils many non-production functions related to protection of the natural environment. The industrial model of agriculture, which is characterized by a high degree of chemicalization and mainly economic measures of productivity of agricultural holdings, creates many threats in the ecological sphere (Babin et al. 2019; Balsalobre-Lorente et al. 2019; Ren et al. 2019; Englund et al. 2020; Chen et al. 2020; Bereznev et al. 2020; Möhring et al. 2020). The use of a combination of expenditures that allows obtaining the highest income, which is characteristic of the industrial agriculture, is not optimal from the social point of view. In agriculture, negative external impacts are mainly of environmental character (Lanz et al. 2018; Hou and Hou 2019; Rose et al. 2019; Ahmad et al. 2019; Armstrong and Stedman 2019; Zhu et al. 2019; Piwowar 2020; Balogh and Jámbor 2020). They include reduction of biodiversity, disturbances in the natural circulation of nutrients, pollution of soil, water and air, as well as excessive consumption of water resources. The internalization of negative external impacts of agricultural production is a challenge of the present times – both in the theoretical and practical sphere (Van Grinsven et al. 2015; Hsianget et al. 2019; Pravia et al. 2019; Zheng et al. 2019; Gong et al. 2019). Currently in Poland there is a relatively high level of mineral fertilization. The use of pesticides, especially herbicides, is also relatively high (Piwowar 2018b; Zalewski 2020). Environmental side effects, which result from the livestock production activities, also concern emissions of pollutants into the soil and air (Piwowar 2018a). In addition, the issues related to the emission of pollutants, caused by grass burning, spot soil contamination during preparatory work associated with the use of agrochemicals, etc., are also important from the point of view of shaping the low-emission economy in the agriculture (Van den Berg et al. 2020). There are also many other challenges in rural areas associated with the protection

Cite this Article as: Arkadiusz PIWOWAR "Agriculture in Poland And the Protection of The Natural Environment. Results of Expert Studies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of the natural environment, such as reduction of low-altitude emissions (Adamczyk et al. 2017; Samsonstuen et al. 2019; Piwowar and Dzikuć 2019; Kaczmarczyk et al. 2020).

The issues at the point of contact between the environmental protection, ecology and agricultural activity are very often taken up in the Polish literature of the subject. The interactions between the agricultural production and preservation, protection and shaping of the diversity of agroecosystems were presented inter alia by Marks and Markowski (2012), and Anderson et al. (2020). There are also studies conducted at the point of contact of economy, agriculture and environment, but it is difficult to determine how and to what extent the agriculture can ensure an environmental balance while maintaining the current level of profitability (Robertson and Swinton 2005; Roesch-McNally et al. 2018; Dominati et al. 2019). The studies show that farmers' sense of responsibility for the state of the natural environment and their awareness in this scope are important here (Gołębiewska and Pajewski 2015). Legal regulations and acts play a significant role in the protection of natural resources and prevention of the loss of natural values (Janiszewska and Ossowska 2017). Institutional frameworks and the level of support for the agriculture under rural development programs should take into account the problems of environmental protection even to a greater extent (Gała 2017). In addition, implementation of innovations in agricultural holdings may bring positive effects for the natural environment (Kagan 2011; Piwowar 2017; Piwowar 2018a). The necessity of incorporating environmental aspects into the theory of production in the agriculture as well as into the measurement of productivity has been presented in the Polish literature inter alia by Góral and Rembisz (2017).

Environmental protection is one of the most important challenges of the present times in Poland. This paper presents results of questionnaire surveys and expert studies, which have been a part of the research concerning the problems associated with the low-carbon agriculture in Poland. The research project is funded by the National Science Centre. The main objective of the research was to identify the reasons why farmers did not take actions aimed at protection of the environment, as well as to indicate the measures (at the central and local levels) that could improve this situation.

Research Methodology and Characteristics of The Test Sample

The survey, the results of which are presented in this paper, was a part of the research process carried out under a research project in the area of basic research. The surveys were carried out in the period from November 2017 to March 2018. Along with the expert studies, there were conducted surveys among farmers (nationwide and representative; size of the test sample: 1101 agricultural holdings). The experts in the studies included primarily employees of agricultural advisory centers in the provinces, in which the surveys of farmers were conducted (Mazowieckie, Opolskie, Lubelskie, Wielkopolskie, Małopolskie and Pomorskie Provinces). The randomly selected territorial area of research well characterizes the diversity of agriculture in Poland, including the intensity of agricultural production. It is very important because the specialization of agricultural production, its scale and intensity largely determine the condition of the natural environment. For example, in the Opolskie voivodeship, high mineral fertilization is noted, it is an area with a dominant share of intensive plant production. On the other hand, the Wielkopolskie voivodeship is characterized by developed animal production, especially of pigs.

In each of the six randomly selected provinces where the surveys were conducted, at least 3 experts completed the questionnaire surveys. The agreement with the Agricultural Advisory Centers included clauses saying that the questionnaire surveys can be conducted among other experts in the analyzed material scope (not employed at the Agricultural Advisory Centers), recommended by the Principal. The questionnaire for the experts consisted of three thematic blocks:

1. general information about the respondent;
2. rural areas and protection of the natural environment in Poland;

3. quality of the natural environment in rural areas in the province (district) which the respondent represents and knows the conditions occurring there.

24 experts took part in the research, including 14 women and 10 men. The average age of the respondents was 36 years. The youngest participant in the survey was 29 years old, while the oldest – 65 years old. Almost all experts (23 respondents) had a higher education. The experts were characterized by considerable experience in the subject of agriculture development and rural development. 14 people indicated that they has over 20-year experience, 8 experts indicated the experience of 5–10 years, while only 2 persons indicated the experience of less than 5 years.

A traditional form of presentation (tables, drawings, descriptions) as well as a modern form of data presentation, i.e. a tag cloud, were used in this study. This modern form is more and more often used in scientific studies, also in the research in the fields of ecological economics and sustainable development (White 2013; Smółka-Dolecka 2016). Using a web application (Wordle tool for online data visualization), the statistics of the occurrence of individual keywords in the verbal descriptions provided by the experts (open-ended questions concerning opinions of the experts) were examined and the results were graphically presented in the symbolic structure of the cloud.

It is worth noting that the opinions expressed under this research project were provided by the people closely linked to the agricultural activity, who observe the work of farmers on a daily basis, help them to formulate plans (e.g. concerning crop rotation, fertilization, chemical plant protection) and elements of strategies of agricultural holdings, as well as complete application documents under the Common Agricultural Policy (CAP).

Results of The Research and Discussion

Two research questions addressed to the experts concerned their assessment of the current state of environmental protection in Poland and their assessment of this state in rural areas (Fig. 1).

Fig. 1: Experts' assessment of the current state of the environment in Poland in general and in rural areas in Poland

Source: own study based on questionnaire surveys (N=24)

As it results from the research, none of the experts assessed the state of the environment as "definitely good". Most of the respondents assessed the state of the environment as "rather good" (71% of the respondents surveyed in terms of the state of the environment in rural areas and 54% of the respondents surveyed in terms of the state of the environment in Poland in general). It is worth noting

that negative assessments (rather poor and definitely poor) of the state of the environment were declared by five respondents in each group.

In response to the question whether farmers in Poland disregard the problems of environmental protection, an affirmative answer was given by 7 respondents, 10 people answered "no", while 7 persons had no opinion on this subject. The respondents indicated (multiple choice question) the reasons why farmers did not take measures aimed at environmental protection (Fig. 2).

1.	Concern for financial costs of such measures
2.	Lack of faith in the effectiveness of individual actions
3.	Lack of motivation and interest in the problem of improving the effectiveness of agriculture in terms of environmental
4.	Reluctance to change habits in the scope of production technologies and techniques
5.	Lack of incentives from local authorities
6.	Persistence in the conviction that "others also do nothing"
7.	Lack of knowledge in the scope of modern, pro-environmental technologies and techniques

Fig. 2: Declarations of experts concerning the reasons why farmers did not take measures aimed at environmental protection in Poland

Source: own study based on questionnaire surveys (N=24)

The experts most often indicated that farmers were afraid of financial costs of measures aimed at the protection of the natural environment. In addition, a relatively high percentage of responses concerned the lack of faith in the effectiveness of individual actions taken by a farmer and the lack of motivation and interest in the subject of environmental protection.

The respondents also provided their opinions on the subject of emphasizing the negative impact of agricultural activity on the natural environment in the selected media. The results of this part of the analyzes are presented in Table 1.

Table 1: Declarations of the experts on emphasizing the possible negative impact of agricultural activity on the natural environment in the selected media, normative acts and other elements of communication in the society

Specification	Definitely yes	Rather yes	Hard to tell	Rather not	Definitely not
	[%]				
Legal regulations	8	63	17	13	0
Scientific publications	17	42	38	4	0
Popular science papers	8	58	17	17	0
Training programs for farmers	33	38	13	17	0
Discussions, public debates	0	33	25	29	13

Source: own study based on questionnaire surveys (N=24)

According to a vast majority of experts, the possibility of a negative impact of agricultural activity on the natural environment is emphasized in the area of legal regulations (8% of "definitely yes" answers and 63% of "rather yes" answers) and in the area of training programs for farmers (33% of "definitely yes" answers and 38% of "rather yes" answers) and thus consequences of such actions are determined. The lowest number of positive indications by the experts concerned public discussions and debates. Almost every third respondent stated that the importance of the above-mentioned topic rather had not been emphasized in them, while 13% stated that "definitely not".

The questionnaire also included open-ended questions that allowed experts to speak freely about the actions that should be taken at the central and local levels to improve the state of the natural environment in rural areas. The results of this part of the analyzes are presented in Figures 3 and 4.

Fig. 3: A tag cloud for the respondents' indications concerning the actions to be taken at the central level in order to improve the state of the natural environment in rural areas

Source: own study based on questionnaire surveys (N=24)

Fig. 4: A tag cloud for the respondents' indications concerning the actions to be taken at the local level in order to improve the state of the natural environment in rural areas

Source: own study based on questionnaire surveys (N=24)

Among the actions at the central level, the experts mentioned inter alia:

- informational, promotional and educational actions in the media in order to raise the public awareness and to increase the extent of use of modern technologies;
- development of nationwide programs concerning, inter alia, subsidies for soil liming;
- changing the legal regulations (e.g. in the scope of the obligation of analyzing soils in terms of nutrients content and preparing fertilization plans on this basis);
- co-funding of projects concerning support for low-carbon agriculture as a part of consortia that will be created, inter alia, by scientific units;
- rigorous enforcement of legal regulations in the area of environmental protection;
- increasing the expenditures under the Rural Development Program for the activities related to reduction of smog (inter alia, subsidies for replacement of coal stoves), increasing the expenditures on water supply and sewage systems; subsiding the investments in household sewage treatment plants (groundwater protection), subsiding the investments in solar collectors, etc.;
- introducing additional direct payments for agricultural holdings that conduct agricultural production in accordance with the integrated methods;
- changing the rules of agri-environmental programs in the scope of sustainable agriculture to more accessible to farmers;
- conducting training for farmers in the scope of low-carbon economy in rural areas; promoting and implementing precision farming techniques;
- conducting training in the scope of the use of fertilizers, plant health products, and agrotechnical treatments in the conditions of climate change, etc.

In turn, the actions at the local level proposed by the experts include:

- creating clear, transparent spatial development plans, taking into account the interest of investors and other residents of rural areas;
- local (communal, district) support for organic farming, inter alia, through organization of sites for selling organic products (without any costs for farmers);
- development of local programs in the scope of monitoring of the environment – air, soil, water;
- subsiding replacement of stoves from municipal funds;
- local initiatives in the scope of education (promoting good practices).

Summary

In conditions of intensive farming and an excessive extent of chemicalization of agriculture as compared with the needs, the environmental pressure increases and the degradation processes in the field and meadow-pasture ecosystems are strengthening. There appear potential threats to the sustainability and stability of the structure of the agricultural landscape as well as threats to the biodiversity. Despite the fact that environmental protection issues were taken into account in legal regulations and despite additional financial benefits for farmers for a minimization of environmental risks (especially for farmers implementing agri-environmental programs), the analyzed problems still constitute challenges for the agriculture.

According to the research carried out among experts, limited financial resources are the main reasons why farmers did not take measures aimed at environmental protection in Poland. Actions this scope (including replacement of heat sources in farmers' households, construction of household sewage treatment plants, thermomodernization of residential and farm buildings) are costly and thus support programs should be created both at the central and local levels. In addition, the experts indicated other reasons: the farmer's lack of faith in the effectiveness of individual actions, the lack of motivation and interest of farmers in the problem of improving the effectiveness of agriculture in terms of environmental friendliness, and farmers' reluctance to change habits in the scope of technology and production techniques.

The experts indicated many possible actions to be taken at the central and local level, which can contribute to an improvement of the condition of the natural environment in rural areas in Poland. They pointed out, inter alia, the role of the state and the economic policy, with a particular emphasis put on the stabilization of incomes of farmers who conduct organic and integrated production, as well as indicated the actions that could be taken by local authorities. Education had a special place in almost all of the experts' opinions. Educational projects are necessary to eliminate the backwardness in terms of environmental protection. In addition, local governments in rural communes should head in the direction of new strategic thinking, where the low-carbon economy should be the central point of reference. Conditions conducive to realization of pro-environmental attitudes of farmers should be created. To a small extent, the respondents mentioned actions carried out or potentially initiated by the agricultural self-government. According to the experts, the issues associated with threats to the natural environment are clearly emphasized in various forms, in particular in legal regulations and training programs for farmers, and to a lesser extent – in scientific and journalistic articles. In the opinion of the respondents, this subject is insufficiently emphasized in public discussions and debates.

Acknowledgment

This study was conducted and financed in the framework of the research project "The state and prospects of the development of low-carbon agriculture in Poland and the behaviour of agricultural producers", granted by the National Science Centre in Poland, program SONATA, grant No. 2016/21/D/HS4/00087.

Paul CALANTER

Institute for World Economy, Romanian Academy, Bucharest, Romania, paul.calanter@yahoo.com

Abstract

Investments in renewable energy are considered a major objective of sustainable economic development all over the world as they are a driver of technological progress and a cornerstone in combating climate change. Our paper aims to present the progress made on investments in renewable energy globally, but also to highlight, through a comparative quantitative analysis, the impact of the COVID-19 crisis in the field. The research methodology is based both on a screening of the most relevant global reports, but also on the use of case studies presenting progress and challenges in two of the most advanced economies: US and China, given that prior to the COVID-19 crisis both states had ambitious targets for the development of renewable energy. The concluding part of the paper will present whether the pandemic crisis and its economic impact are an impediment to investments in renewable energy or may bring some opportunities for the future of these clean energy.

Keywords: Renewable Energy, Investment, US Economy, China Economy, COVID-19 Crisis

Introduction

It is now unanimously accepted that renewable energy represents a key element of sustainable economic development around the world, while some studies show that investment in renewable energy remains an indispensable factor for the technological progress, but also a guarantee of prosperity for the future generations (Aslani, 2013).

Although it is currently well known that renewable energy development programs are one of the most important challenges for both advanced economies and developing countries, numerous analyses (Aslani et al., 2012; Damon, Sterner, 2012; Filibi, Alonso, 2012) indicated that in all these economies the authorities are developing strategies for a greater involvement of the private sector in making investments in the field, thus being more likely to achieve the ambitious targets in the field. It is worth mentioning that according with Global Trends in Renewable Energy Investments 2020 Report (GTR, 2020), both governments and companies around the world have committed to adding some 826 gigawatts of new renewable power capacity in the decade to 2030, at a likely cost of around $1 trillion.

Considering the importance of involving private investors in renewable energy, our analysis aims to highlight the economic impact of the COVID-19 crisis in the field against the consequences of the pandemic, highlighting the pre and post pandemic situation in two advanced economies: USA and China. While COVID-19 crisis has slowdown deal-making in renewables in recent months, along with that in other sectors, it is undoubtedly that the pandemic economic consequences will affect investment levels in 2020. However, our research aims to highlight if the COVID-19 crisis may also enable governments to tailor their economic recovery programs to accelerate the phase-out of polluting processes and the adoption of cost-competitive sustainable technologies.

Investments in renewable energy in 2019 - global trends and challenges

According to the report "Global Trends in Renewable Energy Investments 2020" (GTR, 2020) in 2019, private investors have contributed massively to the financing of renewable energy globally, while supporting the energy transition to sustainable economic development. The report shows, in 2019, a net increase in global renewable energy capacity, which increased by a record 184 gigawatts (GW). However, in 2019, total investment costs were only 1% higher, amounting to 282.2 USD billion. Meanwhile, the full cost of electricity production has continued to fall for solar and wind energy, amid technological advances and fierce competition in the field.

In 2019, several of the trends highlighted in previous years in terms of investments in renewable energy continued. Thus, the overall level of investment amounted to 282.2 USD billion, an increase of 1% compared to 2018 with a continuous decrease in costs for solar and wind energy, and China remained the world leader in investments in renewable energy (Chart 1), although the US recorded the largest increase in these investments compared to the previous year (Table 1).

Chart 1: Global ranking of renewable energy investments in 2019 (USD billion)

Source: Authors based on the GTR 2020 Report.

Note on abbreviations: The EMEA includes countries in Europe, the Middle East and Africa, and the APAC includes countries in the Asia-Pacific region.

As can be seen from table 1, in 2019, Taiwan recorded the most spectacular increase in investment in renewable energy compared to 2018, while the first ranked (China) recorded a decline compared to the previous year.

Table 1: Investments in renewable energy in 2019, compared to 2018

Country	Investment in 2019 (USD billion)	Growth, compared with 2018
China	83.4	-8%
US	55.5	28%
Japan	16,5	-10%
India	9,3	-14%
Taiwan	8.8	390%
Spain	8.4	25%
Brazil	6.5	74%
Australia	5.6	-40%
Netherland	5.5	25%
United Kingdom	5.3	-40%

Source: Authors based on the GTR 2020 Report.

Even in the face of the economic difficulties generated by the COVID-19 pandemic, renewable energy have proved their resilience (Chart 2), but according to recent international analyses (Turk, Kamiya, 2020) future progress on investment in the field cannot be achieved without massive government support. Thus, according to official statistics (GTR, 2020), the growth of renewable energy sources will slow down towards the end of 2020, due to delays in the construction of new facilities caused by supply chain disruptions and social distancing measures. In this context, many projects, such as photovoltaic installations for businesses and households, could have a strong downward trend in the medium term, without government support.

This is all the more possible as, apart from electricity production, many renewable energy sectors have proved to be much less resilient. According to the GTR report, the production of biofuels for transport will be reduced by 13% in 2020, this being the first significant decrease in the last two decades. Also, the consumption of heat produced from renewable energy sources is likely to decrease in 2020, mainly due to low activity in the industrial sector. Adding to these difficulties, low oil and gas prices make biofuels and renewable thermal technologies less competitive.

Chart 2: New capacities for electricity generation through renewable energy in the period 2018 - 2021 (GW)

Source: Authors based on IEA data (https://www.iea.org/data-and-statistics/charts/renewable-electricity-capacity-additions-2007-2021-updated-iea-forecast).

Note: Data for 2020 and 2021 are estimates and forecasts based on current trends.

Challenges for the development of renewable energy in 2020

According to the latest international statistics (IEA, 2020) in 2020, the global demand for renewable sources has increased due to their use in the electricity sector. Even if the demand for electricity for end-use has fallen significantly due to the lockdown measures imposed by the health crisis, low operating costs of electricity based on renewable sources along with priority access to the grid in many markets have allowed renewable networks to operate almost at full capacity and even expand. However, supply chain disruptions, construction delays and macroeconomic challenges increase uncertainty about new investments in renewable energy capacities in 2020 and 2021.

A recent IEA report (2020) predicts that net renewable electricity additions in 2020 will be 13% lower than in 2019, due to delayed construction activity from supply chain disruptions, but also amid blockages and social distancing and emerging financial challenges. Hence, it should be noted that many of the renewable energy projects (whether in the field of solar, wind or biomass) are expected to face implementation delays in terms of the stages allocated for 2020, amid financial difficulties caused by the economic crisis, but also due to the new investment priorities of companies triggered by the new challenges brought by the pandemic.

Thus, the IEA report estimates that additions to photovoltaic capacity will decrease by 17% in 2020, compared to 2019, while for wind energy projects there is a decrease of 12%. Moreover, due to the forecast uncertainty for the projects that were to be financially completed in 2020 and become operational next year, it is estimated that total PV additions in 2021 will decrease from 2019 due to the slower recovery of distributed photovoltaic applications, because individuals and small businesses need to reset their investment priorities.

It is currently an undeniable reality that the pandemic has the potential to change the priority of government policies and budgets, as well as having a strong impact on companies' investment decisions on financing renewable energy in the coming years.

This new reality implies a high degree of uncertainty for the renewable energy sector, despite its rapid expansion over the last five years. At the same time, several countries are introducing significant stimulus programs to respond to the current economic development and support their economies. Some of these incentives may be relevant for renewables, especially in the context where competitive technologies developed for renewable energy can provide structural benefits such as economic development and job creation, while reducing emissions and encouraging innovation.

While capital expenditures for renewable energy increased moderately in 2019, by 1%, due to onshore wind energy and the fact that hydropower has surpassed solar energy, capital costs for some technologies have continued to fall. For example, solar installation costs for utilities have fallen by more than 10%, continuing a downward trend due to support policies (e.g., expanding competitive bidding) along with expanding implementation in large, lower-cost markets, such as India. Practically, nowadays, thanks to new technologies, with the same level of investments, much more renewable energy can be produced compared with the previous years. Thus, the necessary expenses for the production of 1 MW of renewable energy in 2012 allow the generation of 1.5 MW today.

The decrease in capital costs contributed to the reduction of the average costs of electricity production currently calculated taking into account the entire lifetime of the installation (leveled costs of electricity - LCOE), for solar energy and onshore wind energy, along with other factors, such as average load factors. For wind projects, for example, larger turbines and increasing the height of the hub means that wind farms are able to produce more energy with a smaller number of turbines. This trend also leads to reductions in operating and maintenance costs driven by efficiency gains from digitization. Financing costs are also a key component of the LCOE, and low average capital costs (WACCs) have been vital to expanding investment in renewables globally.

For example, applying a standard average WACC of 8% to a US solar project in 2019 would produce an LCOE of about 80 USD / MWh in 2019. The LCOE for the same project with access to lower cost financing (4% on average) is just over 50 USD / MWh. The actual return required depends very much on the degree of risk from the associated market. The involvement of public finances has been key to reducing the cost of capital in emerging markets, such as India, which on average face higher financing costs (given higher risks to the country, technology and revenue).

In terms of loans, financing conditions have improved globally. This is due to lower base interest rates and lower debt risk premiums. For example, according to the IEA (Clean Energy Investment Trends, 2019), lower risk perceptions have contributed to improved availability and pricing of project financing in India for solar photovoltaic and wind projects in 2014-2018. The risk premiums applied to loans decreased by 75-125 basis points for both technologies during that period, with banks wishing to provide longer-term loans. In terms of equity, their expected returns have also declined globally, as support policies and growing market experience have helped reduce risk perceptions for investors.

The result is that LCOE for utility installations and wind turbines have fallen to levels between about 35-55 USD / MWh in China, Europe, India and the United States (assuming low-cost financing). Even lower prices have appeared in the tenders for the capacities that will be put into operation in the coming years, e.g. prices below 20 USD/ MWh in Brazil, Mexico, Portugal, Qatar and the United Arab Emirates.

To stimulate growth, central banks are likely to keep interest rates low. However, some emerging countries may face challenges as sovereign risks increase and there are signs that commercial banks could increase lending margins to offset higher liquidity costs. Uncertainty can also lead to more difficulties in mobilizing capital globally. A smaller annual decrease in LCOE is expected in 2020, with financing costs remaining at the same level or increasing as a result of new risks.

The impact of the COVID-19 crisis on investments in renewable energy

In the current international environment, governments have an unprecedented opportunity to accelerate clean energy transitions, making investment in renewables a key part of stimulus packages to revitalize their economies in the wake of the COVID-19 crisis. Investments in renewable sources, whose costs continue to fall rapidly, can stimulate job creation and economic development, while reducing emissions and fostering further innovation (Box 1).

Box 1: Promoting investment in renewable energy – driver of economic recovery after the pandemic crisis

Energy efficiency recovery - While it is now unanimously accepted that citizens' health remains the number one priority for governments facing the COVID-19 pandemic, it is also clear that there is a need to limit the economic impact of the COVID-19 crisis. In these efforts to protect economic stability and to support the recovery of global economies, energy efficiency can play a key role in stimulating jobs, while supporting clean energy transitions around the world. Energy efficiency can stimulate an intensive increase in employment globally. Even before the pandemic crisis, in the United States and Europe alone, more than 3.3 million people were employed in the energy efficiency industry, most of them employed by small and medium-sized enterprises. Given this reality, investments in well-designed economic recovery programs can use the potential of energy efficiency to support existing jobs, create new jobs and stimulate economic activity in key labour-intensive sectors such as construction and manufacturing. In addition, energy efficiency offers a number of long-term benefits, through improved competitiveness, improved energy accessibility and lower energy bills, while reducing the dependence on energy imports and the greenhouse gas emissions.

Stimulating technological advancement - Governments often provide incentives directly to consumers (or through manufacturers or retailers) to replace old, inefficient products with new and

more efficient models through technology replacement programs for cars, refrigerators or other appliances. This may include investments in so-called "cash for clunker" programs for machines, refrigerators or other digital devices and devices. Applied to the manufacturing industry such governmental programs could provide substantial job creation results, while achieving significant environmental benefits. Of course, the global environmental impact of early technology replacement must be taken into account: jobs can be created in the recycling industry through specific circular economy programs. Some analyzes (Li, Linn, Spiller, 2013) show that cash replacement programs such as “cash for clunkers” can help create an effective economic stimulus and support jobs and production which is particularly important given the imperative of the post-pandemic economic recovery. Moreover, investment in technology replacement programs can support the manufacture and launch of new technologies, such as heat pumps, digital building management systems and electric vehicles. Moreover, supporting investment in fleet modernization programs focused on buses, trains, vans or taxis can also lead to economic stimulus and energy efficiency.

Contributing to economic digitalisation in the context of post-pandemic challenges - government investment in the post-pandemic period could focus on large digital infrastructure projects, including those related to renewable energy that generate economic efficiency and new jobs. Such projects include investments in energy-efficient infrastructure, such as smart grids and charging stations, as well as next-generation digital connectivity for a more efficient and resilient future energy system. To further support jobs even in the face of increased digitalisation, infrastructure projects could also include investment in public transport infrastructure, the creation of bicycle lanes and pedestrian areas and the widespread implementation of smart upgrades. Smart street lighting upgrades can provide, for example, more infrastructure services, as street light poles can also serve as charging stations for electric vehicles and can include 5G telecommunications infrastructure.

Case studies: US and China

USA

In January 2020, the US Government's Energy Information Administration (EIA) predicted a record year for wind and solar power in the US, with 18.5 GW of wind power and 13.5 GW of solar power for consumption, which will begin commercial operations. However the outburst of COVID-19 crisis had inevitably complicate or even postpone some of these projects. Presently, the pandemic is likely to cause a temporary, albeit significant, disruption to the growth of renewable energy on the US energy markets, while renewable energy ownership and investment landscape will be transformed.

In terms of the investment level in energy produced from renewable sources (Chart 3), we can see that the trend was increasing in the period 2013-2019, with the exception of 2018. Due to the Coronavirus pandemic, experts forecast a further slowdown in renewable energy investment for 2020, which may be even more pronounced than the one registered in 2018.

Chart 3: Investments in renewable energy in the US (USD billion)

Source: Authors based on GTR 2020 Report

According to the American Wind Energy Association, the year 2019 was the third best year in terms of new wind power capacities to the United States (9.1 gigawatts), bringing the total to 105.6 gigawatts. At the same time, the Solar Energy Industry Association registered the entry into service of 13.3 gigawatts of solar energy, bringing the total solar power capacity to 77.7 gigawatts. Together, the two sources accounted for 2/3 of the new United States energy generation capacity in 2019.

The projected increase in facilities in 2020, especially wind power, is largely the result of projects that began construction in 2016 and must be operational before the end of the year to qualify for the entire Production Tax Credit. This federal tax incentive represents about USD 24 / MWh for 10 years.

In the case of solar energy, the tax credit for investment has begun to emerge for projects that will begin construction this year. A similar increase in solar installations is likely to occur in 2023, the last year in which projects must be put into operation to claim their full value (representing 30% of the eligible costs of the project).

The imposed lockdown had severe economic consequences in US, but may not have a significant impact on the long-term prospects for renewable energy, although the imposed measures in response to the health crisis have certainly caused short-term disruption. In April, EIA revised by 5% and 10% the 2020 forecasts for the addition of solar and wind capacities.

Many wind projects working on a strict schedule in order to qualify for Production Tax Credit (PTC). The inconveniences caused by COVID-19, such as supplying, moving of equipment through the supply chain and personnel issues, could halt projects and affect their capacity to be authorised for PTC or tax credit for investment (ITC) credits. The risks posed by a delayed installation, which put a project outside the regulations, have pushed the investors to seek guidance from the Government on the situation in which the pandemic delays could be an exception to the regulations.

Looking into the future, some entities from the industry are concerned that an economic slowdown caused by the coronavirus will reduce the investors' appetite for tax capital for tax credits. These traders, usually investment banks, are likely to have lower tax revenues in the short term to offset these loans. However, the signals from investors are positive about their permanence in the market.

While the coronavirus is a short-term impediment to renewables, the long-term outlook remains favourable. One of the powerful engines of this sector is the clean or renewable energy goals set by a growing number of countries.

Thirteen states, including New York and California, have set 100% targets to be reached in the period 2040-2050. Additionally, the improved performance and low costs of renewables, along with growing concern for corporate sustainability, have encouraged utility distribution workers to consider renewable energy sources when building new facilities.

Persistent low natural gas prices as a result of the economic slowdown have the potential to shift investment decisions in favour of energy production through natural gas-fired facilities, although the likely scale is currently unclear. The EIA still forecast that the renewable energy will rise to 38% of electricity by 2050, from the current 19%, with natural gas falling slightly, to 36% from the current 37%, and coal from 24% to 13%.

The industry is pushing for the support of the United States Congress as part of broader stimulus funding. In this case, concern about job losses caused by the coronavirus will be critical to gain support; the Solar Energy Industry Association warned that 50 percent of the 250,000 jobs in the solar sector could be affected, while the American Wind Energy Association estimates that 35,000 wind jobs are at risk.

According to Eroglu, H. (2020), the number of employees laid off in the US renewable energy sector was significant: around 70,000 people. To overcome this hurdle, some suggestions proposed by specialists in the field are related to allowing companies in the solar energy sector to use the Investment Tax Credit (ITC) or to double the "Green Incentive" stimulus.

In this context, although at a lower than expected level, government actions following COVID-19 crisis have specifically targeted at the renewable energy being linked to the fact that the Treasury and the IRS have provided tax incentives for renewable energy projects by further extending the deadlines for financially supporting tax credits.

A domain with an unique demand for support is the offshore wind power. Because the technology is less mature than the onshore one, and because it can offer new capacities and jobs, there is momentum in Congress to offer a special treatment for the offshore sector. The American Wind Energy Association forecasts that the market will grow from almost zero today to 20-30 GW by 2030.

Energy storage is also poised for strong growth. The sector registered a record development in the last quarter of 2019, with a new added capacity of 186MW / 364MWh, according to indications of the Energy Storage Association. This Association and Wood Mackenzie forecast the market to grow to 7.3 GW in 2025 after the annual rollout of 523MW in 2019, with growth largely driven by public procurement.

While the pandemic undoubtedly caused short-term challenges and disruptions, cost cutting, technological advancements, and financial innovation will remains powerful drivers for the renewable sector development in the US especially because the strong user demand and the clear environmental imperative.

China

In 2020 China lost its spot on the Renewable Energy Country Attractive Index (RECAI) for the first time since October 2016, ranking second behind the United States in its quest to cut costs from its renewable energy subsidy regime.

As shown in Chart 4 the level of investments in renewable energy in China for the period 2004-2019, expressed in billions of dollars indicate that over the past three years China has reduced the amounts allocated to investments in renewable energy. It is also forecast that the COVID-19 pandemic will further slow these investments.

Chart 4: Investments in renewable energy in China (USD billions)

Source: Authors based on GTR 2020 Report

The government has gradually reduced subsidies paid for onshore wind and solar power projects, which currently support around 210 GW of wind capacity, while trying to reduce the USD 14 billion deficit in its Renewable Energy Development Fund. According to Wood Mackenzie (WoodMac), the Ministry of Finance has budgeted just USD 700 million to subsidize new renewable capacities in 2020, which is expected to support 8-10 gigawatts of new onshore wind capacity (Wood Mackenzie, 2020).

As a result, the Chinese government is encouraging wind energy projects that at the moment receive feed-in tariff payments to move to an unsubsidized system, through which they will be offered energy purchase agreements and privileged payments of unpaid subsidies for the long-term. WoodMac estimates that approximately 60 gigawatts of previous capacity, which had recovered its initial capital investment, can keep its current yield by making the change, removing some of the subsidies.

Despite these issues, WoodMac estimates that the annual onshore additions to 18.8 gigawatts in 2021 will increase to 23 gigawatts by the year 2028. However, WoodMac warns that a surge in the offshore wind market will be obstructed by the political unpredictability, limited share of subsidies and disruption caused by the pandemic in supply chains.

In the base scenario, total capacities will reach 14.5 gigawatts by the end of 2021, and new capacities will drop to just 2 gigawatts the next year before recovering to 5 gigawatts in 2025. At worst, China could reach to 11 gigawatts by the end of next year, followed by less than 0.5 gigawatts added each year for the rest of the decade if the sector does not have the support of local governments and low demand fails to produce local supply chains.

While the short-term outlook for new domestic capabilities looks bleak, Chinese companies continue to invest and position themselves for the low-carbon global transition. GCL system integration technology for the solar producer invests USD 2.5 million in a solar module factory in Hefei, Anhui Province, which will have the capacity to produce 60 gigawatts of modules, the world's largest production platform, capable of meet about half of current global energy demand for solar modules.

According to Norouzi et al. (2020), it is possible that in China, in terms of the fight against climate change, an advantage will be gained from the coronavirus pandemic, given the decline of greenhouse gas emission sectors. At the same time, they consider that there is the possibility of rapid development of renewable energy due to major energy security problems.

However, following the analysis of the stimulus package, it can be seen that the Chinese government is not focusing on renewable energy. Many investments are focused on fossil fuel industries, while support policies for the renewable energy industry are absent from the Beijing recovery programme.

China could have chosen to follow the example of the EU and Germany and direct COVID's incentive towards sustainable mobility, the hydrogen-using industry and renewable energy sources, which are the sectors where China is trying to be competitive. A small incentive was indeed created for electric vehicles, which benefited from tax exemptions in response to the COFID crisis, although only as part of a measure aimed at stimulating demand for vehicles. Until recently, Beijing promoted the use of hydrogen through several local pilot projects. Although it would have been the right time, China did not want to launch a national hydrogen strategy, leaving only in the project phase (Gosens, 2020).

Conclusion

Although renewable energy in several markets were already facing some funding uncertainties in early 2020, the COVID-19 crisis has brought new challenges. However, the post-pandemic situation could give governments the opportunity to make progress in the field, making investing in renewable sources a key part of stimulus packages designed to revive their economies. They can take advantage of the structural benefits that increasingly affordable renewables must offer, including job creation and economic development opportunities, while reducing emissions and fostering innovation.

Far from being a major impediment to the development of renewable energy the COVID-19 crisis could be an incentive. The dramatic decrease in production in the fossil fuel sector thanks to COVID-19, combined with the fact that renewable energy have proven their resilience, could stimulate new investment from the public sector, but also from the private sector, many financed even with aid to the financial support and economic reconstruction packages allocated by most states in the context of the COVID-19 crisis.

However, in order to be able to play a role in boosting economic recovery in the post-pandemic period, investment in renewable energy should take into account lessons in good practice from previous funding programmes, focusing on two major factors: expanding existing programmes with new incentives, but also reducing unnecessary regulatory barriers (given that excessive regulatory barriers, such as planning and development rules, can often hinder energy efficiency and renewable energy projects, hence requiring the elimination or simplification of red tape in order to facilitate the successful implementation of economic incentives).

In the United States, while at a lower-than-expected level, government actions following the coronavirus pandemic targeted specifically at renewable energy that have been adopted so far have been linked to the fact that the Treasury and the IRS have provided tax incentives for renewable energy projects. As for China, the government is not focusing on renewable energy, with many investments being targeted to fossil fuel industries, while support policies for the renewable energy industry are absent from the recovery programme.

Organisation Development Paths – Exemplification of Cultural Institution's Orientation

Grzegorz KRZOS
Wrocław Univeristy of Economics and Business, Wrocław, Poland,
grzegorz.krzos@ue.wroc.pl

Anna SCHNEIDER
Wrocław Univeristy of Economics and Business, Wrocław, Poland,
anna.schneider@ue.wroc.pl

Abstract

The aim of the article is to identify the orientation elements describing the path of the cultural organisation development, which will constitute the basis for developing the method and tools for measuring orientation of the cultural institution. The paper presents the research that was carried out on the basis of an exploratory, single case study, which answers the question whether the assumptions about these orientations made by the authors of the publication were correct. The following data analysis methods were used in the study: referring to theoretical assumptions and the participant observation, which took place in 2018/19. The empirical study confirmed that a sufficient, but not limited, set of cultural organisation's activities orientations describing the path of its' development includes categories like products/market, processes, functions, projects, innovation and technology, geographic expansion and inter-organisational networks. The question about the undertaking measurement of these orientations remains open. Filling in this gap requires further qualitative empirical research. The results obtained from this research should become a subject to quantitative research, which would also provide an answer to the question, whether it is possible to propose a universal set of orientations for the cultural institution's activity, which could be used to present and discuss its' development paths.

Keywords: Developmental Path, Cultural Institution Developmental Path, Organisational Development, Organisational Orientation

Introduction

The history of every organisation can determine and evidence through time its' own evolutionary development. The nature of this evolution is influenced by a variety of determined factors both internal and external. In theory these developments should drive the organisation closer to a desired conclusion, however in reality these advances do not always impact positively on the profile of the organisation. Therefore, a more defined examination of the history of the organisation provides a clearer based on its' direction. This allows us to comprehend better those impacts that have had the most important effects at any given point in time and how these can future shape its' desired targets. Earlier models of organisation development do not necessarily provide an accurate reflection of the organisation for a specific point in time. Therefore, developing a theoretical model of the organisation's development based on its' orientation can provide a clearer understanding and picture of the successes or issues faced in any given point of its' evolution. This model can be utilised for further organisation's research purposes and to identify the universal orientations of its' development (Krzos, Piwoni-Krzeszowska, 2018).

The article is a continuation of theoretical considerations and an extension of the exemplifications presented in the article titled "A conceptual pattern of organisational development path – the proposal and theoretical assumptions" that was published in "Przedsiębiorczość i Zarządzanie" (Krzos, Piwoni-Krzeszowska, 2018). The aim of the article is to identify the orientation elements describing the path of the cultural organisation's development, which will constitute the basis for developing the

Cite this Article as: Grzegorz KRZOS And Anna SCHNEIDER "Organisation Development Paths – Exemplification of Cultural Institution's Orientation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

method and tools for measuring orientation of the cultural institution. The article is empirical. An exploratory, single case study was conducted to determine whether the assumptions about these orientations made by G. Krzos and E. Piwoni-Krzeszowska in the context of the cultural organisation are correct (Krzos, Piwoni-Krzeszowska, 2018).

The basic theoretical background of the organisation's development path.

The development of the organisation is a multi-faceted process and as such there is no specific classification for its' description. Figuratively speaking we can describe the organisation's development as a progression of qualitative and quantitative measurements of various types at any given point whether these are positive or negative. (Krzos, Piwoni-Krzeszowska, 2018). The process may include changes in various areas of its' functioning (Adamik, Zakrzewska-Bielawska, 2014).

The substance of our deliberations are studies undertaken by N. Siggelkow (Siggelkow, 2001, 2002). However their range is constrained to displaying the issues related to the organisation's development and any endeavour to mark out specific areas of development. The aforesaid studies do not include efforts to present descriptions of the overall direction of the organisation and any orientation variances over time.

Development can be considered in the following dimensions: economic, organisational, personal, informative, technical and production (Stabryła, 1995), and also from the financial and strategic perspective (Bratnicki and Austen, 2005). From a theological point of view, development should lead to the improvement of the organisation's position in the environment. And this, in addition to the development of the organisation's infrastructure, requires the development of products and markets (Flamholtz, Hua, 2003). Given the specificity of the cultural sector, researchers emphasized that marketing draws attention to the twin-track approach and take the product and market orientation as two separate images (Burkiewicz, 2014). This has been supported by Sobocińska who says that "Contrary to production, product, or sales orientation, market orientation involves thinking about the way in which a market entity functions" (Sobocińska, 2019). Moreover, it is impossible to disregard the inter-organisational relations, which is evolving, and determines adaptation to changing resources needs (Stańczyk-Hugiet, 2013) and shape the conditions of competition and cooperation (Czakon, 2012).

From the standpoint of the organisation's development path as the progression of the course and differences in the direction of its' activities, the advancement of this gap appears to be a fundamental component of the functioning of the organisation's images, given that different companies consist of various images, which are utilised to describe their scope.

Based on the literature (e.g. Stabryła 1995, Bratnicki and Austen 2005, Flamholtz and Hua 2003, Siggelkow 2002) we can ask ourselves:

1. Should the cultural institution orientation set be limited to:
   a) Products/market
   b) processes,
   c) functions
   d) projects
   e) innovations/technology
   f) geographic expansion,
   g) networking.
2. How to undertake the measurement of each orientation?

Researching the solutions to these issues, requires an approach utilising in-depth empirical study and refined measurement tools.

Research Methodology

The research assumption presumes that data is incomplete, but sufficient to describe the activities of the cultural institution and its' set of orientations will be the baseline for relating the cultural organisation' development path. This provided the basis for the theoretical model of the cultural organisation' development path. As such, this focused on identifying a range of orientations and estimating them. Splitting this set of orientations was undertaken following various discussions and critiquing the literature. Therefore the foundation for the description of the orientations is primarily in the direction of: products / market, processes, projects, functions, innovations/ technologies, geographic expansion or networking.

In order to undertake the measurement of these orientations, regardless of which should be elected for the presentation of the description of the organisation's activities, there is at the same time, transparency in the option of structuring a combined measurement of each of these orientations. The measurement should be an indicator of the concentration of these orientations and the changes taking place throughout.

The following conventions were utilised for the undertaking of the orientation's measurement.

a) the dimensions of the product/market orientation can be: the number of products, the number of product modifications, the orientation of the organisational structure on the product,
b) the dimensions of process orientation can be: number of processes, number of process modifications, orientation of the organisational structure to the process,
c) the dimensions of function orientation can be: number of functions, number of function modifications, orientation of the organisational structure to functions,
d) the dimensions of project orientation can be: number of projects, number of project modifications, orientation of the organisational structure for projects,
e) the dimensions of the innovation/technology orientation can be: the number of innovative technological solutions used, the level of technological maturity, the number of patents, patent applications and know-how,
f) the dimensions of the geographic expansion orientation can be: the number of regional markets, the number of foreign markets,
g) the dimensions of network orientation can be: number of entities, frequency of relationships, nature of relationships, place in the network.

The incapacity to specifically define the cultural institution's development path, the inability to stipulate the research data, and the lack of provisions for the undertaking of its' description and fundamentally, the various inadequacies in theoretical clarifications determine the choice of the *case study* method. According to K.M. Eisenhardt (Eisenhardt, 1989) and R.K. Yin (Yin, 2013), case study is appropriate when it has relevance due to its' potential for generalization and when the research is unique and extreme.

Based on the previous conventions of the project, this research is exploratory and is a pilot study. It was the overview to the beginning of a multiple study. It is founded on a single case study, at the same time demonstrating whether the set of orientations made about the organisation's development do establish that the basis for the depiction of the path is accurate.

In the theoretical model of the organisation's development path, supposing that the expansion of the organisation, is in line with achieving maximum profit – in accepted functioning conditions, is an anticipated state, given consideration that in real conditions, organisations instigate a set of goals, and within the life cycles of organisations , relatively sudden and instrumental changes in the direction of the orientations can occur. This leads to the question: what evidence is apparent to determine that the intended aims have been achieved or not? The path of the organisation's development indicates, the progression of the pathway and alterations in the direction of its' activities which contain various images of the organisation which can be described succinctly using the

orientation's dimensions set out by the organisation; what determined these alterations, and finally, whether such changes are caused by exceeding the numerous barriers to development that the enterprise faces on its' path.

Key questions from the research methodology were posed:

1. What orientations of the cultural institution activity should be taken into account in order to comprehensively describe the picture of its' development path,
2. Can the set of these orientations be limited, but sufficient to describe the functioning of the cultural institution, when it is included in the orientations for: products/market, processes, functions, projects, innovations/technologies, geographic expansion, networking,
3. How to undertake the measurement of these orientations?

The following data analysis methods were used in the study: referring to theoretical assumptions and the participant observation, which took place in 2018/19.

The main weakness of the applied research method is analytical generalization. Increasing the probability of its' accuracy requires conducting iterative case studies in order to develop the concept of the cultural institution development path for further research and to generate a hypothesis about its' model.

Dimensions of the cultural institution orientations

The *cultural institution X* was established in 1960s and is one of the leading ballet companies of the United Kingdom. The Company performs not only across the UK but also abroad. Its' broad repertoire includes new versions of the classics, signature pieces by living choreographers, seminal pieces from the 20th century modern ballet canon and new commissions. Its' primary aim is to provide programmes of world-class dance performance and educational activity at all scales. The *cultural institution X* presents a wide range of dance to audiences across the country and abroad and employs 38 professional dancers, 65 staff and a part-time freelance orchestra of up to 60 musicians.

The dimensions of product orientation

Indisputably, in the cultural sector, performance is perceived as a product and audience as a recipient/customer. Among the products offered by a *cultural institution X* the products of high and mass culture are distinguished. The *cultural institution X* delivers a comprehensive programme with a range of access point for people with all ages and abilities, from children to elderly people, from classical to modern pieces of art. Therefore, there is a need to adopt twin-track approach and expand a product orientation to: product orientation and market orientation.

Table 1: Twin-track approach

	Product Orientation	**Market Orientation**
Concept	Traditional	Modern
Goal	Mission fulfillment	Profits
Culture type	High culture	Mass culture
Offer	Offering recipients what they need	Offering recipients what they want

Source. Own ellaboration

Authors have identified the following dimensions of a product orientation:

- number of high-culture orientated products,
- number of high-culture products modifications.

Authors have also identified the following dimensions of a market orientation:

- number of products adapted to recipient's expectations.

- growth of participation in cultural events.

The Dimensions of Process Orientation

The main process in a *cultural institution X* is the creation of a dance production. The fundamental elements which comprise this dance production would include: choreography creation, music adaptation, costumes design, promotion and stage preparation. The leaders of the processes are the managers of the respective departments.

Therefore, the dimensions of process orientation have been listed as:

- number of main processes,
- number of support processes,
- number of functions associated with processes.

The Dimensions of Function Orientation

The *cultural institution X* as with the majority of cultural organisations has functional organisational structure. The main departments are: the board, artistic team, dancers, orchestra and administration. The identified dimensions of function orientation are:

- number of functions (departments) in the organisational chart,
- number of modifications changing the functional character of organisational structure.

The dimensions of Project Orientation

During the research, it became clear that cultural projects are based on intuition and own experiences rather than project management methodologies. Despite the lack of formal project management techniques, authors have recognized wide range of projects run by the institution. Apart from dance productions which are strategic projects, the institution have been implementing educational, digital and interdisciplinary projects.

The following dimensions of project orientation have been recognised by authors:

- number of strategic projects,
- number of operational projects,
- number of interdisciplinary projects.

The Dimensions of the Innovation and Technology Orientation

The digital infrastructure and skills have indisputably been the strength of the institution. The openness of the entire organisation to new technologies and non-traditional ways of creating work acquired new online content and developed relationships with digital partners. With the spreading of the Covid'19 pandemic the cultural sector has noted lots of cancelations and postponements. "Out of the box thinking" has always been a strong feature of the *cultural institution X*. Recognising the damage the *cultural institution X* could face, existing digital event formats have been further improved and implemented.

Authors have identified following dimensions of innovation and technology orientation:

- number of implemented innovations,
- the level of technological maturity.

The Dimensions of the Geographic Expansion Orientation

The *cultural institution X* long history includes touring across the country and invitations to international arts events. As part of these cultural exchange international guests are invited to perform with the *cultural institution X*.

Therefore, the following dimensions have been identified:

- number of national performances,
- number of international performances,
- number of artists/institutions visiting and performing with the cultural organisation.

The dimension of networking orientation

The *cultural institution X* plays an integral role in the cultural networks. High level cooperation between the *cultural institution X* with other cultural institutions and art universities worldwide has produced the range of innovative artistic projects followed by long-term relationships. Thanks to this, joint degree programmes have been established between *cultural institution X* and educational sector. Moreover, strong focus is laid on collaboration with sponsors and donors.

Therefore, the following dimensions have been identified:

- number of strategic partners,
- number of long-term relationships with stakeholders.

Fig. 1: Development path of the cultural organisation.

Discussion on the Results

The empirical study confirms that the established set of orientation of the organisation's activity describing the path of its' development can be applied to the cultural institution. (Krzos, Piwoni-Krzeszowska, 2018). The study showed that the development of *cultural institution X* covers complementary changes in various spheres and areas of its' functioning, which is in line with the view of A. Adamik and A. Zakrzewska-Bielawska (2014).

However, it should be emphasized that this study is a pilot study, so it can be concluded that the orientations of the cultural institutions activity that should be taken into account to describe the picture of its' development path is:

- product orientation that has been highlighted by A. Stabryła (1995) and E. Flamholtz and W. Hua (2003); market orientation, which has been emphasized by Burkiewicz and Sobocińska,
- focus on processes, functions and projects in the context of the organisation's development indirectly mentioned A. Stabryła (1995) and E. Flamholtz and W. Hua (2003),
- innovation/technology orientation and the relevance of the technological dimension of development, which has also been emphasized A. Stabryła (1995),
- orientation towards geographical expansion, which has been reflected in the opinion of E. Flamholtz and W. Hua (2003),
- network orientation, which is in line with the view of E. Stańczyk-Hugiet (2013) that one cannot detract from inter-organisational relations, which are evolving, and determine adaptation to the changing resources needs.

Nevertheless, the question of how to describe the orientations of the cultural institution activity reflecting the path of its' development remains open. At this stage of research, one can only assume that the set of these orientations is sufficient, but it is not limited. The research results also show that the dimensions of cultural institution orientation are not the same as the assumptions made. This indicates the need for further, in-depth research in this field and prompts to consider, whether there is a common set of dimensions describing individual orientations, whether it is perhaps determined by the specificity of the cultural institution activity, e.g. size or type of the institution. Therefore, the analytical generalization of this conclusion requires further research in the form of multiple case studies, which should be conducted within cultural institution of different size and type.

The open question about the implementation of the orientation of the cultural institution's activity, reflecting the path of its' development inspires to set the question, whether it is possible to build an aggregate measure of each of these orientations, which would indicate their relevance and the changes taking place in them.

Conclusions

Literature reviews have shown that there is a research gap in the field of cultural organisation's development path. A single-case study confirmed that sufficient but not limited set of orientations describing the path of cultural institution development includes product/market, process, function, project, innovation/technology, geographic expansion and networking orientations. The question about the undertaking measurement of these orientations remains open. Filling in this gap requires further qualitative empirical research. The results obtained from this research should become a subject to further quantitative research, which would also provide an answer to the question, whether it is possible to propose a universal set of orientations for the cultural institution's activity, which could be used to present and discuss its' development paths. Further longitudinal research would enable the presentation of development paths of cultural institution and identification of possible accuracy in their course within the studied population. The empirical research discussed in this article indicates the directions of future research on the paths of the cultural organisation development in the methodological and empirical layer.

Activities of Marine Industries in the Russian Sector of the Caspian Sea in the Context of Modern Transformations in Eurasia

Nikolay W. GONTAR

Southern Federal University, Rostov-on-Don, Russian Federation
passat01@mail.ru

Abstract

Modern Eurasia is developing under the influence of a number of unifying projects of the countries of Eurasia itself and external actors to it. In 2015, Russia put forward a project of the Eurasian Economic Union (EAEU). At the same time, the idea of a "shift to the east" was put forward in Russia (the orientation of politics towards closer relations with the countries of the East of Eurasia). In addition, Russia proposed the integration of the EAEU and the Chinese project "One Belt-One Road", including through the North-South corridor through the Caspian Sea. The article explores Russia's strategy in the Caspian Sea, strengthening its ties on the continent and the development of the Caspian regions of Russia. The development of key sectors of the regions of the Caspian Sea (oil and gas production, shipbuilding, fishing) involves an expansion of the industry structure and an increase in its efficiency. It is also planned to improve the institutional conditions for the movement of goods along the North-South corridor, the creation of a fleet, navigation conditions and a single tariff policy for the effective operation of the sea route within the corridor. The SWOT analysis of Russia's implementation of its Eurasian priorities in the Caspian Sea reveals the strengths of the process (geographical location, developed marine complex, proximity to the countries of the region), as well as its weaknesses (inefficiency of specialization industries, limited markets, logistics problems), as the basis for the formation of Russian strategies in the Caspian Sea.

Keywords: Eurasia, Caspian Sea, Russia, Marine Industries

Introduction

The emergence of new vectors of Russian policy in Eurasia is directly related to the changing conditions of development on the continent. Thus, Russia found itself in a situation of deteriorating relations with Western countries, which gave rise to the project of a "shift to the east" and the creation of the EAEU. On the other hand, in 2015, the creation of the EAEU was dictated by the development of the PRC project “One belt one road”. As part of a strategy to maintain influence in the post-Soviet space, Russia proposed a project for the integration of the EAEU and an integration project for China (EAEU). One of the regions where such an interface is possible is the Caspian region. The basis for Russia's influence in this region is the project of the North-South transport corridor from India through Iran and Russia to Europe. Full implementation of the corridor project is only possible with the acceleration of its sea route along the Caspian Sea and the Volga. This requires the development of ports and the maritime complex of the Russian Caspian region as a whole. The relevant sectors can be seen as supporting the implementation of the North-South corridor project, as well as a tool for integrating this corridor and the OBOR in the Caspian section. The development of the maritime economy and other sectors of the Caspian regions can form a new quality of the economy of the Russian regions. This will serve to strengthen the North-South corridor, and strengthen the integration influence of Russia in Eurasia.

GONTAR“ Activities of Marine Industries in The Russian Sector of The Caspian Sea in The Context of Modern Transformations in Eurasia” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Methodological Framework

Modern approaches to the analysis of Eurasian processes take into account the diversity of forces that shape the development trajectory of the continent's countries. In this regard, the author has carried out a comparative analysis of modern projects of Russia and China on the integration of the Eurasian space. Thus, T. Summers (2016) pays attention, for example, to the role of the One belt one road project in the transformation of the subnational level. Also the formation of trans-Eurasian projects is seen as a challenge and an opportunity for China itself as Clarke (2016) says about it, and also as a challenge for other countries of the continent, according to Druzhinin et al (2018).

The issue of integration of Eurasian associations, including the Russian project of the EAEU and OBOR, is discussed in detail in the monograph by Druzhinin (2020). Also noteworthy are the works of Vardomsky (2019) and Bezrukov (2016) on the prospects for a "shift to the east" in Russian politics. Also in the Russian literature, the topic of the North-South corridor is being developed as a variant of Russia's integration aspirations in Eurasia (for example, in the work of Gontar (2019).

As a toolkit for studying the role of the maritime complex in the formation of Russia's position in the Caspian region, we used a structural analysis of the economics of marine industries. To formulate recommendations regarding the positioning of Russia in the Caspian region, a SWOT analysis was used taking into account the potential of the North-South corridor.

The Impact of Modern Transformations of The Eurasian Space on The Position and Economy of Russia

Modern geo-economic processes in Eurasia are formed under the influence of a significant complication of the trade, economic and cultural interaction of actors. Such actors are represented both by countries and associations of countries within Eurasia itself, and by external forces. The modern trend of their interaction is the formation of competing integration projects that significantly complement the previously established alliances (EU, ASEAN, APEC). Such relatively new integration ideas and projects were formed by China (OBOR), Russia (EAEU). India proposed unification within the framework of the North-South vector, the USA proposed the project "Freedom and Security of the Indo-Pacific Region". The Republic of Korea and Japan have also put forward projects to unite the countries of the continent. Another form of interaction between the countries of the continent is bilateral ties, relations between countries and associations of countries, as well as between the associations themselves (for example, in the process of uniting the EAEU and OBOR). Free trade zones are also being formed between individual countries and economic unions (for example, between the EAEU, Vietnam and Iran).

Within the framework of the trend towards the formation of new associations in Eurasia, the formation of economic unions dominates, while defense unions are significantly less. In addition, even, for example, the Shanghai Cooperation Organization, China is trying to give an economic direction. At the same time, a number of financial institutions have been formed in Eurasia that ensure the functioning of unification projects (Silk Road Fund, BRICS New Development Bank, SCO Development Bank).

The PRC project "One belt one road" is designed to cover such areas as infrastructure, trade, finance, policy coordination, people-to-people contacts. At the same time, the continental projects within the framework of "One belt one road" still account for a small part of China's investments. The research "Connectivity Wars" (2016) notes that this project creates a partnership structure in which countries become dependent on China, and this structure fully reflects the center-periphery model. Thus, the countries of Central Asia have already formed a deficit in trade with the PRC, and with the development of the transport network and an increase in trade, it will continue to grow, as will the volumes of export of natural resources to China, according to China’s ... (2017). China offers cheap loans, but these involve Chinese contractors who often overcharge for their services and demand preferences in labor, procurement and environmental regulations, as noted by Kratz (2015).

Since 2003, a "school of sea power" has been developing in China, and today China's attention to sea routes is extremely great. Thus, the PRC directs up to 90% of its exports (including the export of electronics to Russia) by sea. However, today China is developing a Eurasian path to hedge risks in its relationship with the United States. Transit across Eurasia is not great yet. The project faces the task in

the future to bring the transit of Chinese goods along continental routes to 15-20%. Also, the use of the Northern Sea Route can help reduce China's global risks.

Russia is also an active participant in the formation of modern trends in Eurasia, in particular, developing the project of the Eurasian Economic Union. This project started in 2015 and brought together Russia, Armenia, Kazakhstan, Belarus and Kyrgyzstan. Today the EAEU is focused on ensuring the customs union, but the powers of the EAEU executive body - the Eurasian Economic Commission, do not include issues of transport, investment, trade. This hinders integration into the EAEU. As a result, as well as the conservative policy of the EAEU countries regarding the opening of external borders, the trend for the growth of economic ties within the community in 2009-2018. was absent. The percentage of mutual trade in the EAEU, according to the calculations of V.L. Vardomsky (2019), was only 9%. The volume of mutual trade per person in the EAEU was $ 300, and in the EU it reached $ 7,400. The reasons for the low connectivity of the economies were their small size, the peculiarities of their structure (dominance of raw materials industries, including fuel and agricultural) and the lack of mutual investments of companies (80% of investments were represented by investments of Russian companies). In the absence of horizontal ties between companies, at the same time, social ties were well developed (as a result of the general development of the EAEU member states within the USSR). The restraint of ties between the EAEU countries was also facilitated by the orientation of the Union countries towards import substitution.

In response to the deterioration of relations with Western countries since 2014, Russia has formed the idea of a “pivot to the east” (increased interaction with countries in the east of Eurasia). However, this idea ran into problems. For example, Russia has more significant trade ties with the western rather than eastern countries of Eurasia (trade between Russia and the EU is twice as large as trade between Russia and China, Japan and South Korea taken together). The most significant infrastructure projects in Russia (ports, pipelines) are also oriented towards the West. In addition, the trading partners of the Russian Federation in the east - Japan and China, are not focused on the Russian Federation as a significant trading partner, despite the fact that China has taken the 1st place in the foreign trade turnover of the Russian Federation since 2019.

Russian export to the east is only approx. 16% of its exports. Poor transport accessibility greatly increases the cost of delivering resources from Siberia to the countries of East Asia. Thus, according to the calculations of L. Bezrukov (2016), supplies by rail increase the prices of Russian resources for the countries of East Asia by 50-70%, which makes Russian resources uncompetitive. It is cheaper to ship coal, gas, oil, metals to China and Japan by sea from other countries. As a result, Russian supplies today cover only a few percent of China's resource needs, and the capacity of the cargo ports of the Russian Far East is ten times less than the total capacity of the ports of the APR.

Finally, according to A. Druzhinin (2020), Russia actually did not make sufficient efforts to develop its regions in the Far East, despite the creation of free economic zones and the development of a number of projects in shipbuilding (Bolshoy Kamen') and transportation of hydrocarbons («Power of Siberia»).

In these conditions, Russia's unification projects are reoriented towards strengthening contacts with China, India and Iran. In 2015, the idea of pairing the One Belt One Road projects with the EAEU was put forward. In 2018, a trade and economic agreement between the PRC and the EAEU was concluded. Also, to activate Russia's position in Eurasia in 2015, the idea of creating a "Greater Eurasia" was put forward, including through the development of the "North-South" corridor.

An agreement on the creation of a North-South corridor was signed by Russia, India and Iran in 2000. Today, Azerbaijan, Armenia, Belarus, Kazakhstan, Syria and Oman joined the project. The main idea of the project is the formation of transport links between the countries of South Asia and the Middle East with Europe through the Caspian region. The advantages of the project are more than half the distance for the supply of goods to Europe as compared to the route through the Suez Canal, and a decrease in the cost of transit. Within the framework of the project, the railways of Russia, Azerbaijan and Iran, the countries of the eastern coast of the Caspian Sea were united, the routes of transporting goods through Russian ports on the Caspian Sea were tested.

Taking into account the economic advantages of sea routes, the maritime economy sectors are acquiring key importance in the implementation of Russia's Eurasian priorities in the Caspian, the development

of which is an instrument of Russia's response to the processes in Eurasia, and a proactive strategy of Russia in the Caspian region.

Marine Activities in The Caspian Regions of Russia

The analysis of the development trajectory of the sea-economic complex of the Russian Caspian regions is based on the recognition of the relevance of its two elements:

- development of the maritime complex as a reaction to the strategies of Eurasian actors on the continent,
- development as a proactive strategy to enhance the role of the Caspian region as an economic pole within the framework of Eurasian projects.

Today the Russian sector of Caspian region is represented by three regions (Astrakhan region, Dagestan and Kalmykia) where approx. 4.4 million. In the economy of Kalmykia and Dagestan, agriculture occupies approx. 25%. The industrial sector is developed in the Astrakhan region (hydrocarbon production, shipbuilding, production of equipment for oil production). In Astrakhan there are consulates of the states of the basin, their trade missions, a representative office of the Russian Foreign Ministry.

The current position of the Caspian region is characterized by peripheral position in relation to the key trans-Eurasian corridors. Thus, two key "branches" of the "One belt one road" project run north and south of the Russian Caspian region. The sea route of the Chinese project will involve the Kazakh port of Aktau, as well as the ports of the Caspian Sea (Makhachkala, Baku). At the same time, the North-South corridor is a strategically important area in which the Russian Caspian region can be involved. According to estimates, the cargo traffic through the Caspian Sea on the line "India - Iran - Russia - Europe" can reach 40-50 million tons per year. Also, in the Russian Caspian region, it is possible to integrate the latitudinal vector of the OBOR and the North-South corridor. However, today Russia accounts for less than 1% of transit within the Euro-Asian transport corridors. In the Caspian region, 80% of cargo traffic also passes by the Russian Federation.

The role of the maritime economic complex of the Russian regions in achieving the strategic goals of the Russian Federation is of paramount importance, the most cost-effective for exchange in the North-South corridor is sea traffic, including transport of the "river-sea" type. In contrast, the inclusion of railways in a corridor results in a loss of cost advantage. It is the sea traffic that can provide the advantages of the North-South corridor. The key Russian ports of the corridor, Astrakhan and Olya, have a total capacity of 11.2 million tons. The cargo turnover of the Caspian seaports of Russia amounted to 7.4 million tons.

Today, up to ½ of the structure of exports through Astrakhan (and to a large extent through the port of Olya) is grain. In the port of Olya, it is planned to develop a container terminal, while the port of Makhachkala is specialized in oil transshipment. The main export destination from the ports of Olya and Astrakhan is Iran, while Makhachkala ensures the receipt of oil from the countries of the basin and its pumping through the Makhachkala-Novorossiysk pipeline in the latitudinal direction.

The maritime complex serves as the basis for the development of the North-South corridor. Within the framework of its development, important tasks are: development of railway approaches to ports, fleet renewal, dredging in the Volga delta, construction of ferries and development of ferry crossings, development of the Olya port and construction of a new port in Dagestan. These measures should be accompanied by the formation of contracts that would ensure the sustainability of supplies to the countries of the region, the formation of a single tariff for the entire corridor, and a reduction in the procedures for its passage. To increase the competitiveness of ports, measures have been taken to reduce the number of pilotage services, which reduces the cost of pilotage

Shipbuilding of the Russian regions in the Caspian is key for the development of the North-South corridor. An impetus to the industry is given by orders from oil companies (LUKoil) for the supply of drilling platforms and vessels for oil and gas production on the Caspian shelf. Also, Russian shipyards fulfill orders from companies in Iran, Turkmenistan, Kazakhstan, and European countries.

In the segment of river vessels and vessels of mixed navigation area, an increase in orders is expected due to the aging of the fleet (more than 78% of vessels are more than 20 years old) and an increase in cargo transportation by inland river transport as Dubinina (2016) notes.

However, for the development of the industry, the problems of the low share of Russian components and low labor productivity must be solved. Thus, most of the bulk carriers, container ships and tankers are delivered to Russia from abroad. In the beginning. 2010s orders for 1.1 million tonnes of displacement for Russia were placed abroad. In Russia, a comparable order could be completed in 2–2.5 years, abroad, in 8 months, as A. Bezborodov (2010) says. To improve the efficiency of shipbuilding in the Caspian region, a free economic zone "Lotos" has been created.

Offshore oil and gas production has developed significantly in the region. According to the estimates of the Russian Government, the proven oil reserves in the Caspian are about 3 billion tons, and over 3.1 trillion cubic meters gas. The deposits of Russia can ensure the production of up to 40 million tons of oil per year. The expansion of production will require the construction of up to 10 drilling rigs for exploration, oil platforms, auxiliary vessels and tankers. LUKoil envisages the construction of about 30 large oil production infrastructure facilities. Investments in the development of the Filanovsky field and other projects in the Caspian were estimated at $ 20 billion according to Kasimova (2013). Today, the production of Russian oil on the Caspian shelf exceeds 7 million tons. It is planned to build petrochemical plants in the regions of the Russian Federation on the Caspian Sea.

A significant role in the development of the North-South corridor belongs to the Volga-Caspian Canal - a shipping route from the Caspian Sea to the Volga. Today, programs are being adopted to deepen and maintain the canal, which will make it possible to make communication along it stable for ships with a large draft.

The prospects for increasing Russian exports along the North-South corridor are associated with grain exports to Iran, Iraq, Afghanistan, where the population is growing significantly, and the consumption of grain significantly exceeds the global indicator with insignificant domestic production.

In the future, oil exports from Makhachkala may be established along the North-South corridor to Iran, which is interested in swap deals with the supply of products to the north of the country, while providing similar volumes in its southern ports.

However, container transportation has the greatest prospects for the development of the North-South corridor, especially when connecting supplies from India.

The development of the Caspian sea economic complex includes plans to increase the turnover of dry cargo by small-tonnage vessels through Astrakhan and Olya, as well as by river-sea communication, to increase transportation by large-tonnage large vessels, for which it is planned to build a new deep-water port with a container terminal by 2030. Vessels built at Russian shipyards should participate in the construction of the port. The port will allow the creation of terminals for transshipment of grain and edible oils. Container cargo turnover may increase to 300 thousand TEU by 2030.

At the same time, the potential of the port of Makhachkala is associated with the integration of the North-South and West-East corridors (OBOR) by organizing a ferry connection with Turkmenistan. The construction of ferries to saturate the route is planned at Russian shipyards.

The offshore option of the North-South corridor is promising due to Iran's 12 modern ports in the Caspian.

The task of Russia in the Caspian is the development of logistics. In general, according to Connecting to Compete ... (2018), Russia ranks 105th in terms of international supplies, and 131st in terms of customs procedures. LPI ranks 85th among 155 countries in terms of the integrated logistics indicator. In the conditions of the Caspian region, the solution to the problem can be the creation of multimodal transport and logistics centers.

The precondition for realizing the potential of the corridor may be preferential rates of railway tariffs for goods traveling along the corridor, a reduction in customs payments, and simplification of customs clearance in Russian ports on the Caspian Sea (Green Customs Corridor).

Development of Economies of The Caspian Region in The Context of Increasing the Role of The Region in The Implementation of The Eurasian Priorities of The Russian Federation

Ensuring Russia's participation in Eurasian projects and increasing the importance of the Russian Caspian Sea complement each other. Thus, the activity of shipbuilding in the Astrakhan region solves the issues of providing ships with the North-South sea corridor, and also contributes to the development of a number of economic sectors. The development of the agricultural sector makes it possible to increase the economic weight of the regions of the Russian Caspian Sea region, as well as to increase the role of the region in foreign trade.

Speaking about the development of industries that can shape the exchange of goods within the Caspian basin, we note that this is, first of all, agriculture. However, today the Astrakhan region and Dagestan cannot meet their own demand for vegetables, meat and milk. Among the reasons for this are the inefficiency of production, poorly developed infrastructure, lack of logistics, capacity for processing agricultural products, a shortage of personnel, outdated agricultural equipment, and insignificant foreign investment. Thus, labor productivity in agriculture and the food industry in Dagestan is 2.7 times less than in Russia as a whole, according to the calculations of Magomedov (2013).

Modern tools for solving problems are: the allocation of benefits by the state, for example, for updating equipment, joint projects with foreign investors (an example of which is a poultry farm with the participation of Israel in Dagestan), improving the logistics of agricultural products (for example, a trading house was created to supply products from Dagestan to Moscow).

The industrial complex of the Caspian regions (with the exception of the supply of hydrocarbons and shipbuilding products) has a limited potential for external exchanges due to insufficient production volume and an orientation towards import substitution. Thus, the Dagdizel plant in Dagestan, within the framework of such a strategy, increased the fulfillment of orders for LUKoil several times.

The fishing industry in the Caspian also does not fully use its potential. Thus, there is a shortage of courts; the existing vessels are in poor technical condition; aquaculture is not fully developed. The degree of processing of catches is low, the coastal infrastructure is not developed. Port infrastructure facilities for fish transshipment are located in Makhachkala and Astrakhan and require modernization and reconstruction. The level of development of Russia's aquatic biological resources in the Caspian reaches only 20% of the possible, which does not allow providing for the population and forming the export of products.

Development measures in these areas are provided for by state strategies and programs for the development of the fishing industry. Thus, the development of a fish terminal in Makhachkala, including fish processing capacities, is envisaged. At the same time, such capacities can be oriented towards processing fish from Iran in the amount of up to 100 thousand tons per year.

The development of the economic structure of the regions of Russia in the Caspian is possible with the creation of industrial and agro-industrial clusters focused on the demand of Iran, India, the countries of the Persian Gulf and East Africa. For example, supplies of pedigree and commercial livestock, as well as mutton from Kalmykia and Dagestan, and the organization of meat production for export were in high demand among Russia's neighbors. Prospects for cooperation with Iran are associated with the creation of a joint company for the transportation of oil from Russia by large-tonnage fleet. For this, a dock for the construction of tankers has been built in the Iranian port of Neka.

The positions and problems of the Russian Federation in the basin, taking into account its maritime potential, are reflected by the SWOT analysis presented in the table.

Table 1: table title here
SWOT analysis of Russia's implementation of its Eurasian priorities in the Caspian

	Opportunities	Threats
Strengths	Direct waterway along the Caspian and Volga to Europe, Developed shipbuilding and shipping industry, Development potential of Caspian hydrocarbon processing, Significant trade turnover between South Asia and Europe	The proximity of the Russian Federation to the Caspian countries, in contrast to other actors of processes in Eurasia (USA, China), Unification of the Caspian countries and the Russian Federation within the framework of the EAEU, SEZ, "Greater Eurasia", Resources for increasing port capacities and ferry services, Removing Barriers to Mutual Access to Caspian Markets
Weaknesses	The demand for agricultural products of the countries of the North-South corridor, The need for sales markets for the Caspian states, Conjugation potential of North-South and East-West corridors in the Caspian, Resources for diversifying the economy	National disunity of the North-South corridor sections, Competition of the Caspian countries in the markets of hydrocarbons, agricultural products and logistics, Instability of demand for goods of the regions and countries of the basin, Small volumes of own product offer for filling the corridor

Based on the SWOT analysis, it can be recommended to use such resources to strengthen Russia's position in the region as: increasing the activity of foreign trade through the creation of joint ventures with the countries of the corridor, the integration of the North-South and OBOR, the integration of Iran into the Eurasian Economic union, development of the sea "branch" of the North-South corridor. Such measures could turn the Russian Caspian Sea region into a continental hub.

Conclusion

Modern integration associations in Eurasia are numerous and are in complex interaction. An example of this kind is the Russian EAEU project and China's “One belt one road” project. Russia's initiative to integrate these projects can be successfully implemented in the Caspian region. This region is peripheral in terms of the Russian economy, and in relation to the continental projects of transport corridors. However, the maritime economic complex and ports of the Russian regions in the Caspian are the key infrastructure that ensures Russia's response to the continental projects of other countries, and also allows it to pursue an initiative policy in the Caspian region. The basis for the formation of the strategic policy of Russia in the Caspian region can be a SWOT analysis, which will allow to connect sectoral and regional priorities and form a new quality of development strategies for the Russian Caspian region.

Abstract

Brexit poses a great challenge to the EU, whose R&D potential will be significantly weakened. In general terms, this would mean a downturn in EU research and development, considering the necessity of gaining some distance on the USA and East Asia. In the paper, the authors attempt to identify opportunities and threats to the development of R&D in the EU after Brexit. The study also aims to establish the impact of the UK on the EU in the area of R&D and the importance of the EU in the global economy as well as determining opportunities for the development of R&D potential after Brexit and possible threats arising from this process. It seems necessary to specify postulates regarding actions to avoid negative effects on the R&D potential of the EU. Therefore, directions and areas of desirable actions will be developed for strengthening EU R&D, especially in the aspect of shaping the EU's innovation policy.

Keywords: Research and development, EU industrial R&D, EU innovation policy, EU funds, Brexit, global system of R&D.

Introduction

The United Kingdom's withdrawal from the European Union involves various social and economic changes for both parties. However, no agreement has been reached with regard to specific arrangements (other than the Political Declaration) concerning bilateral EU–UK relations after 2020[1]. As early as 2017, there were first clear conditions for the necessity to design critical changes in the EU to respond to the effects of the looming Brexit for the future of a disintegrated Community. The initial step was the White Paper prepared by the European Commission (2017a) as an introduction to an in-depth discussion, the development of scenarios for the future EU-27 and the nature of the EU–UK relations. The consequences of Brexit have been widely studied and analysed from the perspective of the EU economy (Sapir et al., 2017; Huhe et al., 2017; Hix, 2018; Etiubon and Ibietan, 2018; Vandenbussche et al., 2019). Various scenarios and forecasts of the future relations between the EU and the UK have also been described by HM Government (2016), Darvas et al. (2017), Hook and Szomszor (2016), Núñez Ferrer and Rinaldi (2016), Duff (2020).

It must be pointed out, however, that relatively little attention has been given in the literature to sector-specific relations between the UK and the EU in the future; in particular, such a neglected sphere is R&D, the present-day basis for building competitiveness and innovation. Therefore, R&D is a key area in which the UK and the EU should design a favourable partnership framework to achieve permanent growth of their respective economies (Leigh et al., 2020), also bearing in mind global competition in

this field from the USA and East Asia. Taking into account the impact of Brexit on EU R&D and the considerable importance of the R&D area to modern economies, this article attempts to outline possible benefits and threats in the field of R&D.

This study aims to determine the influence of Brexit on the European Union's R&D potential in the global economy from the point of view of its development opportunities and the threats involved as well as to identify measures to be taken to mitigate negative effects of Brexit s. The following research hypothesis was adopted: despite the EU's weakened position in R&D, Brexit may be an impulse to introduce changes aimed at reinforcing the EU's R&D potential.

The study is composed of two parts. Part one attempts to analyse the EU's post-Brexit position in the global R&D system. Part two discusses the issue of future relations between the EU and the UK, including the financing of R&D. The examination was conducted using the critical analysis of the existing literature and available statistical data as well as the observational and experimental methods. The statistical material was retrieved from the databases of Eurostat, the OECD and the rankings of the top business investors in R&D.

Brexit and the EU's position in the global R&D system

From the 1990s, the world's R&D system experienced major changes due to the decentralisation process; as a result, in addition to the traditional triad, developing countries gradually gained in importance as well (UNCTAD, 2005a; 2005b). After the mid-1990s, the world's top performers (the USA, Japan, Germany, France and the UK) were joined by South Korea, soon followed by China (Huang and Sharif, 2015). Therefore, the global R&D system underwent substantial changes, with a steadily growing role of East Asia (Japan, China, Korea and Taiwan), whose total expenditure on R&D exceeded that of the EU in 2004 and that of the USA in 2010. Thus, the global R&D system is based on three centres: East Asia, the USA and the EU. But other characteristic features of the system include the incessantly dynamic growth in East Asian R&D, mostly due to remarkable activities of China and Korea, and a relatively steady but minor increase in R&D spending in the USA and the EU (Figure 1).

Figure 1: Three centres of global R&D – Gross Domestic Expenditure on R&D (USD billion)
Source: calculated by the authors based on OECD (2020).

In 2018, the overall R&D expenditure of the Asian centre was USD 781.1 billion, whereas the USA and the EU spent on R&D USD 581.6 billion and USD 464.9 billion respectively. It must be emphasised that the Asian centre has been clearly strengthening its position as the leader, particularly since 2016, leaving the USA and the EU increasingly farther behind. The Asian centre account for ca. 38.6% of global R&D expenditure , whereas the USA and the EU represent ca. 26.3% and ca. 20.7%

respectively. In this context, the impact of Brexit seems very alarming as the UK played a major role in building the EU's position in the global system. Figure 1 also illustrates R&D expenditure in the EU without the UK (the EU-27), which shows a marked weakening of that centre of global R&D as in 2018 the UK's spending on R&D was USD 54 billion; as a consequence, it pushed down the EU-27's share in global expenditure on R&D to ca. 18.3%.

Another significant post-Brexit threat to the EU is a distinct fall in human potential in R&D, due to the impressive resources of the UK: the R&D personnel of 463,500, including 305,800 researchers. In 2018, the EU-28 had R&D personnel of 3.3 million, including 2.1 million researchers (OECD, 2020); therefore, Brexit will involve an abrupt fall in the EU-27's human potential by ca. 14%. A decrease in human potential will undermine capabilities to create new knowledge, especially due to the EU's low efficiency: the number of researchers in the EU is higher than that in the USA (1.4 million in 2017), but the EU performs worse in the magnitude or intensity of R&D activities. In this context, the fact that after Brexit the EU-27 will still have more researchers than the USA seems to be of secondary importance. At the same time, the human potential of East Asia is impressive: R&D personnel of 6.0 million, including 3.1 million researchers in 2018 (OECD, 2020).

Therefore, Brexit gives rise to considering the issue of maintaining the EU's position as an attractive global R&D centre, or a cooperation partner for the other two centres, which will certainly pose a major challenge to the EU. It seems necessary to intensify endeavours to dynamise and speed up the EU-27's technological progress, thus to boost funding within the EU R&D policy and to improve efficiency in the area. It will be essential for individual Member States to increase efforts to boost expenditure on R&D. Although Member States have been making progress in improving innovation, it seems insufficient, as reflected in the European Innovation Scoreboard results (European Commission, 2020a). The Innovation Leaders in the EU are small economies (Sweden, Finland, Denmark, Luxembourg, the Netherlands), unable to substantially strengthen the EU's global position. Simultaneously, the largest Member States, such as Germany and France, are classified as Strong Innovators (together with Austria, Belgium, Estonia, Ireland and Portugal). Italy ranks among Moderate Innovators, the largest group of the EU Member States. Furthermore, in comparison with the other two global centres, the EU has noted the least significant progress since 2012 – 3%, against 4.9% in the USA and 17.3% in China, 15% in Korea and 8% in Japan. Therefore, Brexit has further aggravated the problem of maintaining the EU's position in the global R&D system.

The key to maintaining the EU's position seems to be stimulating cooperation in research and innovation with the UK as well as with the global R&D centres. Whereas the shape of mutual relations between the EU-27 and the UK in that area remains an open question, the EU formalised the rules of cooperation with the world's R&D leaders years ago and has gradually developed its scope and principles. The cooperation framework includes the EU–China Science and Technology Cooperation Agreement signed in 1998, again renewed and upgraded in 2018 (European Commission, 2018b); the multi-annual science and technology cooperation agreement with the USA, repeatedly updated and extended, dated 1990 (European Commission, 2018c); or the Agreement on Science and Technology Cooperation with Japan from 2011, subsequently renewed (European Commission, 2018d). Under the above-mentioned agreements, researchers from those countries participate in the EU's science and technology programmes (e.g. FP7, Horizon 2020, Euratom), whereas the established relationships favour the transfer of knowledge and the building of science and technology cooperation networks.

A particularly important role in building R&D potential is played by business, including transnational corporations (TNCs): on account of their global operations, TNCs are very active in R&D investment, gaining competitive advantages in a competitive international environment . Thus, they become drivers of global R&D, not only due to the amounts spent but also as initiators of R&D internationalisation, building cooperation networks, knowledge and technology transfers and the commercialisation of created knowledge (Karlsson, 2006; Moncada-Paterno-Castello et al., 2011; De Prato and Nepelski, 2013; Zimmermann, 2015).

The current situation of the EU is hardly favourable; although EU-based TNCs rank among firms with the highest R&D investment, the EU is outperformed by East Asia and the USA. The 2500 best-

performing TNCs in terms of R&D expenditure (Top 2500) included 551 enterprises from the EU-28, whereas the respective numbers for the Asian centre and the USA were 984 and 769. However, taking into account R&D expenditure, the US corporations unquestionably led the way with investments of EUR 312.5 billion in 2019. At the same time, TNCs established in the EU-28 spent EUR 208.4 billion, less than East Asian corporations, accounting for EUR 253.3 billion; the Asian centre is led by Japan-based TNCs (European Commission, 2020c, pp. 27–28).

Considering that the position of EU TNCs is much less favourable than those of US and Asian firms, Brexit entails a considerable deterioration in that regard; 127 TNCs from the Top 2500 are headquartered in the UK, i.e. the number of corporations from the EU-27 decreased by 23% to 424 firms and R&D expenditure fell to EUR 179.1 billion (Table 1). Although the strong core of EU-based TNCs includes German businesses (130 TNCs with R&D investment of EUR 82.9 billion) and French companies (68 firms – EUR 30.9 billion), the impact of Brexit is very significant in that field and changes the balance of power in the global R&D system towards the USA–East Asia axis.

Corporate R&D activities are strongly concentrated in specific sectors: in the Top 2500, as much as 76.6% of R&D investment is made in four industries: the automotive industry – 17.2%, health sectors (biotechnology, pharmaceuticals, medical equipment and health care services) – 20.7%, ICT producers – 23.3% and ICT services – 15.4%. In their R&D operations, the EU-based TNCs primarily specialise in the automotive industry, aerospace and defence, whereas the whole ICT industry plays a relatively limited role (with the USA leading the way – 67% in ICT services and 41% in ICT producers – and high performance of East Asia in ICT producers). The contribution of health industries is crucial as well: EU TNCs are behind US firms accounting for 49% of the sector's R&D expenditure in the Top 2500 (European Commission, 2020d, pp. 29–50).

Table 1: EU TNCs' R&D in the Top 2500 by industrial sector

Industrial sector	EU-28			EU-27		
	Number of companies	R&D investments (EUR billion)	R&D in % of the total industry in the Top 2500	Number of companies	R&D investments (EUR billion)	R&D in % of the total industry in the Top 2500
Automobiles	46	64.6	46	40	63.1	45
Health industries	110	45.4	27	78	33.8	20
ICT producers	63	26.9	14	56	25.7	13
ICT services	49	14.8	12	29	11.6	9
Industrials	82	12.1	26	70	11.5	25
Aerospace & Defence	16	9.2	46	10	7.3	37
Chemicals	21	5.2	24	18	4.8	22
Other	164	30.2	29	123	21.4	20
Total	551	208.4	25	424	179.1	22

Source: calculated by the authors based on the European Commission (2020d).

It follows from the data presented in Table 1 that Brexit will bring about the most serious changes in the EU's health industries, with the share of EU-based TNCs in the Top 2500 dropping from 27% do 20%. It results from the fact that the health sector is characterised by significant activities of UK TNCs, third in the world behind US and Swiss corporations. Although the EU's potential is also created by German, French, Irish and Danish TNCs, the EU's diminished role after Brexit is a distinct threat. However, opportunities can be seen in the strong position of the EU's automotive TNCs: the industry will be hardly hit by Brexit. In that sector, EU-based TNCs will maintain their leading position and global attractiveness. In contrast, there will be a marked post-Brexit drop in the share of R&D expenditure in aerospace and defence (from EUR 9.2 billion to EUR 7.3 billion). A mild deterioration will be noted by EU TNCs in ICT, an industry that is not the EU's domain, as already mentioned. It is

also worth adding that in the group of other industries Brexit will involve a loss of the EU's position in sectors such as banking, media and entertainment, dominated globally by TNCs from the UK.

Therefore, it seems justified to rely on the automotive industry, the source of the EU-27's R&D power, in building the potential of EU TNCs after Brexit. It is also desirable to strengthen the health sector to maintain the global attractiveness of EU TNCs. A certain opportunity in that regard is offered by the allocation of EU funds of ca. EUR 1 billion for research related to the coronavirus pandemic in 2020 (European Commission, 2020e).

The future relations between the EU and the UK in R&D policy

The UK largely contributed to the EU's position in research activities, also due to its openness to attracting foreign talents (European Commission, 2020b). As noted by Meulenaer and Veugelers (2019), there are two crucial pathways to excellence: openness to scientific talent and the capacity to engage in research partnerships. In order to maintain its status, the EU must ensure that research mobility and exchanges with the UK should be hampered as little as possible after Brexit.

Scientific cooperation and joint research can be facilitated by various international research programmes established, possibly financed from national funds; undoubtedly, however, the EU programmes create European Value Added, also attracting non-EU countries such as the UK. Further cooperation between the EU and the UK will be beneficial to both parties through shaping scientific excellence, although the very financing from the European Commission, in relation to other external sources, will not be vital to the UK.

To date, the European countries most exchanged in cooperation with the UK have been Denmark, Norway, the Netherlands, Germany, Switzerland; those countries could lose the most to Brexit in terms of research partnerships. As regards the ability to attract talent, the European Research Council (ERC) is another important body for researchers' mobility. The UK attracts talents from the EU, especially from Italy, Germany and Spain; therefore, in this aspect, the countries concerned would also suffer losses due to Brexit should no framework for continued cooperation be established (Meulenaer and Veugelers, 2019).

Although for several decades certain fields of research have been international, recent years have witnessed increasingly globalised and multi-polar networks of scientific and technological entities (European Commission, 2018a). In this context, the EU's policy priority, i.e. keeping up with key competitors in the global R&D system, requires closer cooperation with partner countries, including the UK, to ensure access to world's best talents, expertise and resources in research and innovation (European Commission, 2017b).

In May 2018, the European Commission submitted a proposal for the 2021–2027 Multiannual Financial Framework (MFF), taking into account the result of the 2016 referendum in the UK. However, despite the departure of the UK from the EU, some funds covered by the new MFF will undoubtedly be connected with EU–UK relations. Participation in the EU's future programmes will require the UK's appropriate financial contribution to the EU budget (European Scrutiny Committee, 2018). A likely solution is to apply the mechanism also used for Norway and Iceland (EFTA, 2020), with the financial contributions of those countries calculated on the basis of the GDP of the country concerned relative to the total GDP of the European Economic Area. But it must be stressed that detailed provisions of agreements with the EU vary between countries (Keep, 2019, p. 13). In such a scenario, the UK might become the second-largest payer after Germany. In terms of EU funds received for R&D in 2014–2018, the UK was also the second-largest beneficiary after Germany, but in relative terms (in relation to GDP) the country ranked outside the top ten (Figure 2).

Figure 2: Expenditure on R&D from the EU budget (2014–2018)
Source: prepared by the authors based on Eurostat (2020).

Due to the UK's high research potential, the advantage of improving the quality, scope and critical mass in science and research by combining national and EU funds may be less important than to other countries. As a third country, the UK will be able to collaborate under EU projects, but access to them may be more hindered for procedural considerations, whereas the UK will have no influence on their shape, i.e. the objectives and tasks contained in EU programmes intended to finance R&D. It must also be pointed out that EU measures are increasingly interrelated to produce a synergy effect, i.e. for the results in certain fields to be useful in other areas. In this context, the UK's selective participation in EU programmes may prevent such a synergy effect (Beun and al., 2019). In February 2020, the position of the UK government on the future relations of the UK with the EU emphasised possible participation in several EU programmes, including Horizon Europe (at present: Horizon 2020). In contrast, engagement in the student mobility programme Erasmus+ was indicated as optional and only considered on a time-limited basis (UK Parliament, 2020). As emphasised by Mazzucato (2018), the complexity and specialisation of today's science make openness and cooperation key success factors. In this case, it is difficult to predict whether the UK's being a non-EU country leads to deteriorated arrangements since both parties need one another (Mazzucato, 2018, p. 5).

Indisputable advantages of the joint creation of a European R&D area should not prevent the consideration of the drawbacks of EU funding: multiple sources, i.e. funds and programmes, red tape complications, excessive and non-transparent legislation. Creating a new MFF every few years should be an appropriate solution leading to the implementation of good practices and learning from mistakes, but many programmes and procedures become increasingly complex (cf. Leceta et al., 2017; European Commission, 2017c). Nevertheless, the procedures of the functioning of the EU and its growing focus on innovation and support for research must be appreciated as they go beyond national structures which may hinder scholars through national financing policies (unless private support can be acquired).

It is a rather widespread belief that the EU funding of scientific research brings additional benefits such as (Arnold, 2012; SFIC, 2012; European Union, 2014; European Commission, 2016; European Commission, 2017c, p. 90; Schout and Bevacqua, 2018):

- the creation of EU-wide cooperation networks,
- increasing the geographical scope of research projects,

- project coordination,
- cross-border externalities and the economies of scale,
- improving science and research quality,
- greater research mobility, combining experience and skills,
- the distribution of costs and risks,
- increased access to funding research projects – the pooling of funds,
- more efficient resolution of complex scientific problems,
- influence on national R&D policies,
- coping with global competition,
- efficient use of limited public resources allowing to avoid overlapping and the optimisation of efforts or financial benefits.

However, it is difficult to measure specific benefits due to the lack of sufficient data (European Commission, 2014, 2017c). Nevertheless, the concentration of funds and the above-mentioned advantages of cross-border cooperation in R&D confirm that the beneficiaries create more innovation, whereas the quality of their publications was assessed significantly above the world average (Craciun and Orosz, 2018).

Therefore, it seems that the EU's relationships with the UK are strong enough for representatives of the 27 Member States to recognise the necessity to continue cooperation in research and development to avoid any weakening of the EU and to prevent negative (non-constructive) rivalry between the UK and the EU. The UK is also aware of the need to maintain and develop cooperation with the EU-27 for mutual benefits; therefore, it should be a priority for both parties.

Conclusion

According to the analyses conducted, Brexit has a significant impact on the European Union's R&D potential and poses a major challenge in the context of building the EU-27's position in the global R&D system, with the fast-growing role of East Asia and a strong position of the USA. Any weakening of the EU-27's potential may lead to the creation of a strong East Asia–US axis, characterised by diminishing interest in the EU centre. An important threat is the reduction of human resources in the EU-27's R&D, which may drive down its attractiveness as a cooperation partner for the other two centres and result in weakened capabilities to create new knowledge.

In this context, it is worth pointing out that supporting the potential of EU TNCs could stimulate their participation in global R&D and becoming a transmission channel for the international knowledge transfer and commercialisation as well as for attracting talents. Certainly, an opportunity for the EU-27 is further specialisation in the automotive industry where EU-based TNCs are unquestionably strong. However, measures should be taken to reinforce the potential of the health sector to maintain the EU's role in the global system. The orientation of the EU's research programmes towards health industries might speed up the creation of their potential.

Measures to be taken by the EU-27 to mitigate the consequences of Brexit certainly include the acceleration of and growth in funding within the EU R&D policy, including a focus on improving the efficiency of R&D activities, as postulated in the new financial perspective. Nevertheless, it also seems necessary to mobilise the Member States to increase their spending on R&D and to enhance innovation. Furthermore, it seems crucial to develop R&D cooperation with the other two centres and the UK in order to create global networks and to stimulate knowledge transfer. After all, cooperation and the generation of synergy effects have long been the EU's priorities, whereas its research programmes, attracting non-EU talents as well, represent a strong point in the research policy. Cooperation with the USA and East Asia should be in the spotlight in the EU, especially in industries particularly affected by Brexit (the health sector, the aerospace and defence industry), to rebuild their potential based on global cooperation networks, but it will also be fundamental to maintain cooperation with the UK partners. It seems to be in the UK's best interest as well; however, the UK may seek non-EU-27 partners. It will be of crucial importance to design a mutually beneficial framework for further cooperation in R&D.

Certainly, Brexit is a difficult time for the EU's R&D potential, involving various risks in the above-mentioned aspects; nevertheless, it may also offer an opportunity to re-orient attention and expenditure on R&D, to mobilise the reinforcement of the R&D potential at the EU and Member State levels, to re-define EU policy priorities towards improving the innovation potential and the valorisation of R&D cooperation – today's key to success.

Acknowledgment

The research has been carried out as part of a research initiative financed by the Ministry of Science and Higher Education within "Regional Initiative of Excellence" Programme for 2019-2022. Project no.: 021/RID/2018/19. Total financing: 11 897 131,40 PLN.

Abstract

The article aims to support the better understanding and actions related to the university's Third Mission, through a holistic and process-based approach. The study includes: a theoretical background; a review of some publications that address to the system approach and management of technology transfer, knowledge transfer and entrepreneurship, three fields generally associated with the university's Third Mission; a new generic model for the management system of the university's Third Mission. The proposed model is based on the European standard CEN/ TS 16555-1- Innovation Management System, but its adaptation to higher education institutions is a novelty. The case study included in the paper illustrates some fundamental aspects of this approach. The research findings are important for academics and researchers, creating the framework for future studies on the ways for developing and optimizing innovation systems appropriate to university particularities. They can also be a useful guide for decision makers on institutional development in the context of the Third Mission, both at national and institutional level.

Keywords: university's third mission, technology transfer/ knowledge transfer, entrepreneurial university, model for innovation management system.

Introduction

The university's Third Mission refers to "activities concerned with the generation, use, application and exploitation of knowledge and other university capabilities outside academic environments" (Mollas-Gallart et al., 2012). The engagement in this activity domain is not new, but it became more important in the last decades, being defined as a distinct mission (or function) of the university, which aides to education (the first mission) and research (the second mission). As many studies show, the development of the third function ensures a better capitalization of the resources available to universities and the increase of their role in solving the problems faced by society, contributing to its development and sustainability (Howard&Sharma, 2006), (Trencher et al., 2014), (Piirainen et al., 2016).

The importance given to the Third Mission can be seen in the general context of enhancing university role in knowledge-based society. According to Snelman, "knowledge society is primarily focused on knowledge production and generation of innovation", and assumes continuous changes in order to improve knowledge production and to make it more effective (Snelman, 2015). As the author states, universities have always been producers and disseminators of knowledge and generators of innovations, but in recent decades the socio-economic changes have forced major transformations in universities to address these issues.

Cite this Article as: Maria POPESCU and Lidia MANDRU "A New Generic Model for The Management System of University's Third Mission. Case Study in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

These changes in Higher Education institutions are the subject of many publications (Etzkowitz et al., 2000), (Etzkowitz et al., 2008), (Atkinson&Blanpied, 2008), (Zomer&Bennworth, 2011), (Etzkowitz, 2013). Chronologically, the emphasis was first on academic research as a source of new knowledge on materials, nature and society. Starting from the reality that discovery of new in itself does not generate advantages, the attention has been focused on the university technology transfer, knowledge transfer and entrepreneurship, which have become distinct fields of study and action, generally associated to the university's Third Mission.

The collocation "Technology Transfer" (TT) refers to the formal transfer of discoveries from one entity to another for their valorisation (Popescu 2016). In universities, the TT was related to academic research, including as basic activities: licensing intellectual property rights, creating new companies, doing research projects based contracts or in partnership with industry, providing consultancy and other services for third parties (Popescu&Totu, 2014), (Van Norman&Eisenkot, 2017). These activities have an important role in research-based universities, and also in education & research universities.

The collocation "Knowledge Transfer" (KT) encompasses a broader range of activities related to the collaborations between universities and society (OECD, 2014). In addition to TT activities, the university KT includes exchange of both explicit and tacit knowledge, through: people mobility, temporary placement of students and graduates, professional training courses, and university involvement alongside community in public events in many different ways (public conferences, exhibitions, media exposure, etc.) (Liyanage et al, 2009), (Ankrah&AL-Tabbaa, 2015), (Rossi, 2014), (Rossi, 2018). These activities are important in all universities, regardless of their profile (technical, sciences, arts, etc.).

The third concept, Entrepreneurial University, represents another approach related to university's Third Mission, and it is regularly associated to Higher Education institutions that play an important role in innovation and economic growth (Etzkowitz&Leydesdorff, 2000), (Gulbrandsen&Sliperslaeter, 2007). The results of the university entrepreneurship are usually measured by new spin-off and start-up companies (number of, generated employment and turnover) carried out by university members, including students. But in a broader sense, the results of the entrepreneurial universities are closely related to academic research and entrepreneurial education, being associated to KT and other innovation processes performed in universities. As Gibb (2013) states, "entrepreneurial higher education institutions are designed to empower students and staff to demonstrate enterprise, innovation and creativity in teaching, research and engagement with business and society" (Jameson&O'Donnell, 2015).

Despite the differences in their focus, these three concepts have as common element the accent on innovation, and share the idea that universities can play a significant role in solving the society problems, ensuring its development and sustainability. In the Higher Education forecasts, focusing on innovation and entrepreneurship, and the central position within regional ecosystem and knowledge valorization are presented as determinant characteristics of the future university (Blass&Hayward, 2014). The achievement of these goals implies changes at national level in policies applied both in the innovation and Higher Education sectors, but it ultimately depends on how the third function is performed in universities. According to Blass & Hayward (2014), "universities need to embrace an approach to innovation and its management that re-establishes them as the perceived centers of innovation".

Starting from these desiderata, the present paper aims to contribute to a better understanding of the factors on which the performance of the university' Third Mission depends, through a holistic and process-based approach. The paper addresses to the system approach of the university engagement in innovation, focusing on the management system. The research objectives are: 1) to analyze the publications that address to the university participation in innovation from the perspective of management; 2) to describe a model for a holistic approach of activities presumed by the university's Third Mission, based on the European standard CEN/ TS 16555-1- Innovation Management System (2013); 3) to illustrate the application of the new model on a case study. The conclusions presented at the end of the paper highlight the advantages of introducing a generic model for the management of

university engagement in innovation, which facilitates a better understanding of the complex field of university's Third Mission activities, and enables the systematic improvement of the university performance in this domain.

It has to be highlighted that the dysfunctions observed by the authors in the Higher Education sector and the actual needs of society/labor market are the ones that led to the creation of this new management system model. Before elaborating the model, the authors had a profound study of the existing specialty literature, including the latest edition of European standard CEN/ TS 16555-1 - Innovation Management System. The main objective was to create a useful, practical tool both for the educational system and for the business environment looking toward sustainability.

Overview of Studies on Models for the Management of University's Third Mission

Review Stage

The publications on the university's Third Mission are numerous. The studies are generally focused on some aspects related to university TT, KT or entrepreneurship, without a vision on the ensemble. The analysis in this section of the paper aims to be a review of the studies that address to system approach and management of TT, KT and entrepreneurship in universities.

In their study on Entrepreneurial Universities and TT, Bercovitz & Feldmann (2005) provide the conceptual framework that guides the analysis of university–industry relationships. The authors consider as important components of the TT system, university strategies, structures, mechanisms of the TT operations, and funding. They also stress the importance of the people in innovation, which is "at the heart of TT", and as a consequence, the need to implement training programs and incentive reward systems, as well as the importance of leadership in influencing behaviours and the degree of involvement in innovation of university staff. The context of innovation policy and other external parameters with impact on effectiveness of university participation in innovation are also considered.
In their study, Arenas & Gonzales (2018) present a conceptual model of TT in the context of collaboration between university and industry, based on a review of TT models described in other papers. The authors underline that TT is a complex domain, which involves as key elements, processes, behaviours, and social factors. The complexity is determined by the external factors too, which are also critical for the TT system. The TT model presented in the article is defined considering the elements of a communication process: transmitter, receiver, medium and mechanism, and the message. The role of TT offices is also discussed, as "communication supports between the transmitter and the receiver", in the particular case of the transfer in university-industry collaboration.

A more complete analysis is carried out by Kalnins & Jarohnovich (2015), which addresses the TT processes not only from the perspective of TT channels between Research & Development (R&D) and industry, but also from the complex interactions between innovation and the other two functions of the university - education and research. In the authors' opinion, the main elements of the TT model are: "educational level, government R&D funding, number of graduates, flow of brain drain, attractiveness of science field for young practitioners, industry and environment of TT system, decision making level, and information level of public". The authors listed some of the internal and external factors that can influence the TT performances. The idea that fragmented approaches are not sufficient, "only system approach and self-consistency between the elements of the system can guarantee successful TT", is also noticeable.

The study of Geuna & Muscio (2008) refers to models of the university KT in the area of licenses, spin-off and research collaboration, but the authors admit that such an approach does not provide a complete picture of the extent of university KT. The article section addressing to KT governance presents comments based on literature related to: developing right organizational support in order to facilitate the KT from university to business and society; creating strong incentive for academics in order to improve KT activities and eliminate conflicting goals; promoting policies that encourage

innovation dissemination and commercialization; developing the culture of open science in university. Starting from the finding that there is a great diversity in the KT approach in universities, the authors believe that it is not possible to produce common formulas for the governance of KT processes and support organizations. They recommend the exchange of good practices in the management of university KT.

Analyzing the literature on KT from university point of view, Schofield (2013) identified the most frequently mentioned factors that affect the KT success. In his opinion, three main categories of factors influence the potential collaboration between universities and industry: internal, environmental, and relational and cultural. The internal factors are related to organizational, individual, process and resource contexts, and can be partly controlled. The external factors are linked to market conditions, political, economic and legal risks, and can be mitigated. Relational and cultural factors are also critical for developing viable collaborations. The author recommends continuing research focused on the holistic approach of the critical success factors for university-industry research collaboration.

Entrepreneurship in university is generally treated in literature as a distinct theme. In most of these publications, approaches on the entrepreneurial university are more complex, including the TT/ KT domains, and focus on management system. Some of these studies are mentioned below.

In their paper, Vorley & Nelles (2009) make a link between the entrepreneurial university and the changes that accompany the development of the university's third function. They define the "entrepreneurial architecture" of university considering five dimensions: structures, systems, leadership, strategies and culture. As the authors underline, "the elements of the architecture are mutually supportive" and "coordination of all five is required in order to secure successful adaptation to the Third Mission". In their opinion, the entrepreneurial architecture is a theoretical framework for a comprehensive approach of university that helps to understand, analyze and develop the university's Third Mission. This model was used by Gibson & Foss (2017) within the narrative analysis conducted in several universities, aiming to identify "what actors and forces are most important in motivating institutional change in developing a university's entrepreneurial architecture". The authors underline the need to approach the entrepreneurial university in terms of process, which allows a better control of its functioning and development, in relation to the organizational context.

Referring to the development of the entrepreneurial university, Guerrero & Urbano (2010) show that "each university community is unique and its attitudes towards entrepreneurship are defined by a combination of factors". Considering the key role of human capital (staff, academics and researchers, and students), the authors state that universities would develop strategies, structures and a culture oriented to reinforce methods of quality education and incentives. They also consider as critical factors the alliances and the resources associated with the commercialization of new technologies.

In their study, Salarnzadeh et al (2011) propose a new way of approaching the entrepreneurial university, considering the specific elements of the system: inputs, processes, outputs and outcomes (in abbreviation, IPOO model). The model supposes a comprehensive vision of the university, including education and research processes. According to the authors, the entrepreneurial university is a dynamic system that contains a series of processes, namely: "teaching, research, managerial processes, logistical processes, commercialization, selection, funding and financial processes, networking, multilateral interaction, and innovation, research and development activities". It is mentioned that this classification of processes reflects the opinion of the experts who participated in the study, but other views should be considered.

A complex analysis on the phenomenon of entrepreneurial universities is conducted by Silva et al (2018), which had a systematic literature review in order to provide information for establishing a conceptual framework on entrepreneurial universities. The study illustrates the existence of a great diversity of definitions, models, actions and methodologies used in selected papers, generating multiple perspectives on the subject.

The existence of several entrepreneurial models is also highlighted in the study conducted by Sánchez-Barrioluengoa and Benneworth (2019) on UK universities. The authors refer to entrepreneurial university, engaged university and regional engaged university. Exploratory analysis on several universities that have adopted these models reveals how internal institutional configuration affects the third mission output.

A special place in the literature on university entrepreneurship belongs to the evaluation models developed in the last years. In his paper, Hannon (2013) states that the entrepreneurial university involves a way of managing that provides the ability of responding strategically and coherently to opportunities in the environment. The author points out the model created by European Commission & OECD (EC&OECD, 2012), as a guiding framework for the entrepreneurial university, which focuses on seven key pillars: leadership and governance; organizational capacity, people and incentives; entrepreneurship development in teaching and learning; university-business/ external relationships for knowledge exchange; entrepreneurial HEI as an internationalized institution; pathways for entrepreneurs; measuring the impact. A similar vision of the entrepreneurial university system is included in the accreditation methodology proposed by the Accreditation Council for Entrepreneurial and Engaged Universities (ACEEU, 2017). The entrepreneurial dimension of the university is measured taking into account the following five elements: orientation and strategy; people and organizational capacity; drivers and enablers; education, research and Third Mission activities; innovation impact. These models and other schemes actually used to the assessment of university's Third Mission are reviewed in the study written by Popescu & Mandru (2019).

Conclusion

Previous presentations bring in discussion some widely accepted ideas:

- The universities' engagement in innovation is a complex activity field that presumes approaching as a system;
- The university performances on TT, KT, and entrepreneurship are not dependent only on the internal environment, but also on external factors;
- In terms of internal environment, the TT/ KT processes and entrepreneurship involve, as key components, processes, procedures, tools, behaviours and social factors;
- The human resource represents a core element of the university's Third Mission system, but other elements are important too, namely: university strategies and policies, structures, leadership and organization culture, etc.
- Although each university has its peculiarities, introducing specific models, principles and methods in the management of Third Mission is necessary. The exchange of good practices in the management of university KT and entrepreneurship is also recommended.

As it results from the above analysis, the description of university engagement in innovation systems, TT/ KT and entrepreneurship, differs from one author to another, as well as the language used, making it difficult to understand the phenomena. In our opinion, it is imperative to introduce a common language and to develop a generic model for the system approach of university's Third Mission, with universal applicable requirements. This does not mean introducing patterns in addressing innovation activities: the application of the model requirements in universities will be different, taking into account the context and the particularities of each university.

New Generic Model of University's Third Mission Management

Given the large number of activities associated to university's Third Mission and their complex interdependencies, implementing a system approach of the university engagement in innovation represents an important way to improve the university performance in this field. The concept of system suggests that the actions are not isolated, solving the specific issues of university participation in innovation, being done in a coherent and systematic manner (Popescu et al. 2017).

The model proposed in this paper is based on the European standard CEN/ TS 16555-1- Innovation Management System (2013), which sets out the principles and guidelines to the systematic approach of innovation in organizations. Fig. 1 illustrates schematically the Innovation Management System (IMS) model as stated by CEN/ TS 16555-1 standard (CEN, 2013).

The IMS model presents similarities with other more popular patterns for management systems described in some international standards (e.g.: ISO 9001 for Quality Management Systems, 2015 Edition; ISO 14001 for Environmental Management Systems, 2015 Edition, etc.) (ISO, 2015a), (ISO, 2015b). All these models are based on principle of process approach. Using a process-based approach means that the management system is described by the processes developed within the organization in order to achieve the established goals. It also means that managers administrate the processes' interactions as a system (ISO, 2015c).

Similar to quality management, the IMS processes can be classified, considering their purpose, in the next three categories: basic processes, management processes and support processes (Popescu et al, 2017).

The basic IMS processes are those that directly contribute to innovation. Fig. 2 shows the main basic processes related to university's Third Mission, grouped into four categories: human resource development; technology transfer; entrepreneurship; other activities for regional development. This classification corresponds to the structure of the evaluation model "Regional Innovation Impact Assessment Framework for Universities", proposed by the Joint Research Center (the European Commission's science and knowledge service), which includes specific indicators for the next four domains: Education and human resource development; Research, technological development, knowledge transfer and commercialization; Entrepreneurship and support to enterprise development; Regional orientation, strategic development and knowledge infrastructure (Jonkers et al, 2018).

Fig. 1: Inovation Management System (IMS)

Source: CEN, 2013

Fig.2: The Basic Processes of University's Third Mission and Their Conections with the Education and Research Domains

The Fig. 2 also illustrates the complex connections between the Third Mission and the other two functions of university: education and research. The relationship with education refers to the fact that university entrepreneurship includes entrepreneurial education, as a basic process, whose development became a strategic objective of HE institutions in the last decades (Wilson, 2008), (Gautam&Singh, 2015), (European Commission/EACE/Eurydice, 2016). The entrepreneurial education basically focuses on developing entrepreneurial abilities. In this regard, the formal education has a significant role to play, by inclosing entrepreneurship in the curricula of bachelor, master and doctoral study programs, and also through extra-curricular activities. Nowadays, universities are encouraged to open the extra-curricular offering up to all disciplines and all levels. This orientation is on the line of the increasing quality in education, but it is also important for the development of the university's Third Mission. The second connection, between the Third Mission and academic research, is also significant, especially in research-focused universities. Licensing intellectual property, the creation of new firms and other forms of knowledge valorization largely depend on the research findings. The performances in this area are associated with the university' Third Mission development, but they are also defined as quality criteria and objectives in academic research (Popescu et al. 2007), (Panda&Gupta, 2014), (Belcher et al., 2016). Concluding, one can say that there are synergic links between the three functions of the university: the education and research contribute to the Third Mission development, but the latter in turn influences the other two, the Third Mission having the capacity to reinforce the missions of education and research.

The second category of processes, management processes, includes activities associated to the management attributes: planning, organizing, directing, and controlling. The main management

processes of the IMS are synthesised in the box “Leadership for Innovation” (see Fig. 1), which refers to: establishing innovation strategy, policies and objectives; defining roles and responsibilities related to innovation; top management commitment and fostering a culture of innovation. The scheme shown in Fig. 1 also highlights the importance of systematically carrying out the assessment and improvement activities, segments of the management process included in the “planning-doing-assessment-improvement” cycle. This cycle is specific to any effective management approach, and defines the mechanism of continuous improvement, also known as the PDCA (abbreviation from Plan-Do-Check-Act) mechanism (ISO, 2015c).

The third category of processes, generically named “support processes”, refers to providing resources for innovation, and includes specific processes for human resource, infrastructure, information management, and financial resources.

In addition to the above description of the IMS processes, it has to be emphasized that the participation in innovation of the university, as well of any organization, is made from top to bottom, with direct and decisive involvement of the superior management. In this regard, an important place within the IMS processes has the establishment of the university's strategy related to the Third Mission. By developing a strategy addressing to this domain, usually Research & Innovation strategy, the relevance and visibility of the university research and engagement in innovation activities are increased, assuring: connection to the strategic directions of the Research & Innovation established at national and European level; consistent development of the university's intellectual capital taking into account the long-term and medium-term objectives; increasing the efficiency of the "Third Mission" related changes made in university, etc. Another key responsibility of the superior management consists in making the cultural changes necessary to effectively implement the IMS and achieve sustainable results. Related to this issue, it must be highlighted that the efficient functioning of the new structures, the activity planning and controlling systematically carried out with appropriate tools, and generally, the compliance with the new working rules, depend on the promotion of a new system of values in university, specific to a new culture of organization. Saying it simply, it is about a “culture of innovation”, a culture that supports the creation of knowledge, TT and entrepreneurship. If there is no a culture of innovation in university, the IMS has a formal character (Popescu, 2016).

The effective implementation and operation of IMS empower not only the top management, but all university departments and people, including the students. In this regard, it is worth mentioning the importance of creating specialized support structures for TT and entrepreneurship in universities (Keld&Foss, 2012). In addition to the organizational aspects, there are many other aspects of human resource management with impact on innovation performance that universities need to address. They represent a key element of the university’s IMS (Popescu, 2016), (Keld&Foss, 2012), (Piciocchi, 2018).

It should be emphasized that the application of the generic model presented above does not mean the inclusion in a template: the definition of IMS processes, the structures created and the tools used must be adapted to the particularities of each university. For example, in a technical university, the TT processes occupy an important place, but this category is less important or does not exist in arts universities. Harmonization with the university's strategy is also essential in partitioning the IMS. Therefore, the engagement in innovation approach is very different in research-focused universities, in comparison with the education-oriented universities. In this regard, the Rossi’s study (Rossi, 2018) on the drivers of KT performance shows that the university KT entails varied activities, and managers should identify the KT strategies that best fit the university's particularities and improve performance in specific KT activities. The relevant aspects regarding the implementation of such a system are illustrated in the case study presented in the next section of the paper.

A Case Study on the Application of the New Model in University

The case study is conducted at the Transilvania University of Brasov (UniTBv) - a state higher education institution from Romania, the largest university in the Center region. There are 18 faculties within the university, nine technical faculties and nine non-technical faculties. The university has about

19,000 students and is served by over 1300 employees (of which about 770 teachers and researchers) (Annual Report, 2019). Teachers and students perform, in addition to educational activities, research activities and other services for society. The evolution of these activities, both in terms of volume and requirements, has been significant since 2002 (the period preceding Romania's accession to the EU), the aim being to improve performance and align with the values and lines of action promoted in the European Higher Education Area.

The changes refer to both the services offered by the university and the management system. New management structures and tools have been created to adapt to the socio-economic environment and internationalize the university, increase quality, staff involvement, achieve continuous flows of change based on innovation and incremental improvements. These changes are presented in the evaluation reports published on the university's website: annual quality assessment reports, institutional reports for the re-accreditation of the university (at 5 years); international evaluation reports (2010-2011, 2012-2013) (www.unitbv.ro).

From the published data, it can be said that in UniTBv mechanisms and tools specific to a modern management system of the third function have been implemented. A few more important ones are mentioned below.

a) **Entrepreneurship is a major part of university strategy**. The strategy promoted since 2002 had as central objective "the integrated development of education with scientific research, with an emphasis on excellence, in the context of sustainable development" (Institutional self-evaluation report, 2013). The strategic objectives for the period 2016-2020 as well as the measures to achieve them aim to increase the quality of all processes within the institution, the final goal being to transform the University into an elite one in the Romanian academic environment (Strategic Plan 2012-2016). Three of the five strategic objectives for this period can be associated with the university third mission, namely: the development of research-innovation and technology transfer; expanding relations with the economic and socio-cultural environment (collaboration with economic agents at local, regional and national level in carrying out cultural and sports activities, human resource training, research, and with local authorities for projects of common interest); internationalization of the university.

b) **Systematic actions - planning, implementation, control and improvement - related to the university third function are developed**. The strategies were translated into multi-level action programs, each change project being coordinated at a high level. Every change project was monitored and evaluated, but there are also global evaluations of the actions associated with the university third function. So far, analyses have been fragmented, due to several structures subordinated to several vice-rectors. The centralization of these data was done through the Quality Assurance office, subordinated to the vice-rector for quality, which annually prepares reports on institutional quality. The reports present both result indicators and specifications regarding the processes and tools used.

c) **Change programs.** Some of the major changes promoted in the last decade are: introducing teaching courses in entrepreneurship in many study programs; developing new structures related to the entrepreneurial dimension of university, like the Department of Technological Transfer and Entrepreneurship, the Bureau of Relations with the Socio-economic Environment, the Student Entrepreneurial Society, etc; implementation of a new system for evaluating teachers and stimulating performance in entrepreneurship, and so on. Management processes and tools have been continuously improved.

d) **Leadership.** All the change actions were based on institutional policies that promoted entrepreneurship and continuous innovation in university, simultaneously with changing organizational culture. The communication (discussions and meetings) was the main way to attract faculty staff to align with the university vision and to be part of it. The actions were also promoted on the university's website through monthly newsletters, internal and external institutional reports and other documents.

e) **Regional relationship**. An important part of this new approach was the development of a strong network, through contacts and working alliances with entrepreneurs, companies, and other individuals

and organizations concerned about innovation. The university provides continuing education, scientific research, consulting and expertise services. These activities are coordinated and carried out through the Centre for Continuing Education, the Institute of Research and Technological Development, the Bureau of Economic Relations, and other structures, but involve staff, teachers and students from all faculties. Although brief, the above presentation reveals that UniTBv has many elements associated with modern management systems regarding the commitment to innovation. It can be noted the university enrollment in the HEInnovate exercise initiated by the OECD and the European Commission, which involves the systematic evaluation of the potential and outcomes of university KT and entrepreneurship. The program started in 2018 and is based on the Guiding Framework for Entrepreneurial Universities (EC&OECD, 2012). The use of the model for IMS proposed in the paper will allow the further improvement of entrepreneurship within the institution. The starting point is an evaluation report of the current system, highlighting the strengths and weaknesses, and establishing priority directions for action. An element to consider is the integration of the new system with the quality management system implemented in the university.

Conclusions

University's Third Mission is a domain of wide interest that is the subject of numerous publications. The approaches are diverse, many of them focusing on certain aspects and activities associated with the university TT, KT and entrepreneurship, without describing the whole system. This article analyzes publications that attempt a more complex approach of the university participation in innovation from the management point of view. Many authors state that, although each university has its peculiarities, introducing some methods and rules in the management of university engagement in innovation is necessary and possible. In this respect, several studies propose different models, but the diversity of solutions makes it difficult to understand and, above all, apply them.

The proposal presented in this study is to develop a generic model for the management system of university's Third Mission based on IMS model as stated by the CEN/ TS 16555-1 standard. In the authors' opinion, using an IMS model based on a European standard is an advantage, creating the prerequisites for its recognition and adoption at national and institutional level. In this regard there is a similarity with other recognized standards, such as ISO 9001 - Quality Management Systems, IS0 14001 - Environmental Management Systems and other generic models for management systems that have been implemented in many universities around the world. In order to facilitate the use of the European standard in universities, establishing a certain configuration of IMS processes adapted to Higher Education institutions is necessary. In this paper, a possible structure proposed by the authors is described, but the setting of a better model with the participation of a wider group of experts is recommended.

As it was already mentioned, the implementation of IMS based on a standardized model does not mean enrollment in templates, each university has to adapt the requirements of the generic model to its particularities. It is to stress that the model applies to any university, whether it is focuses on education, on research, or on education & research. Also, it is not specific to business universities, but encompasses technical, medical, art, science and humanities universities and departments. The application of the model will be different from one university to another, the superior management of university having the responsibility to set the strategic objectives and actions for the development of the entrepreneurial dimensions that best fit to the university profile and capabilities.

The implementation of IMS in university ensures a better coordination of engagement in innovation activities, by: directing activities of the university's Third Mission through strategies and policies harmonized with the national and European ones; developing IMS processes and managing them; optimizing the organizational framework and clearly defining the responsibilities for engagement in innovation; ensuring the necessary material, financial and human resources correlated with the established objectives; monitoring and evaluating the processes and results of the Third Mission; continuous improvement of the university performances and IMS. Introducing a unitary model creates

the premises for optimizing the IMS processes and tools used, such as tools for assessing the Third Mission, TT and entrepreneurship.

The implementation of such a system implies a new approach to the university's Third Mission, based on principles of the modern management: focusing on the processes on which the university performances in engaging in innovation depend; opening up to the socio-economic environment; developing leadership; emphasis on staff involvement; continuous improvement, and so on. Practically, the implementation of these principles implies complex changes in university, related to structures, processes, working methods, and organizational culture. Difficulties arise especially in terms of organizational culture: when the assumed values and employee behaviors remain constant, the new management system does not work, even if the structures and working procedures have been modified.

Another important underlining is that the innovation system as described above refers only to the TT, KT and entrepreneurship activities associated with the university's Third Mission. Other internal changes, related to education, research, management, etc., made by universities in order to increase market, services' quality and efficiency, were not considered (e.g.: opening of subsidiaries; introducing new teaching-learning technologies; developing infrastructure in university campus etc.). Similar to the innovation management system in business organizations, the generic model for the system approach of innovation in university can be applied considering the whole organization and all forms of innovation. But such an approach does not exclude the distinct reporting to the components associated with the university's Third Mission, given their importance.

Originality Value

The novelty of the paper is the proposal of a unitary model for the Third Mission management in universities, based on the European standard CEN/ TS 16555-1 (2013). This standard is known and applied in industry, the novelty consisting in its adaptation to universities. It comes as an alternative to the various models more or less similar proposed by other authors, and creates the framework for developing a generic model specific to the Higher Education institutions, adapted to the particularities of this domain. Developing the model also involves defining the concepts with which it operates.

It can be noticed that there are similarities between the IMS model based on the CEN/ TS 16555-1 standard with other models presented in various publications, especially with the university "entrepreneurial architecture" proposed by Vorley & Nelles (2009), and the configuration of the management system from "A Guiding Framework for Entrepreneurial Universities", produced under the aegis of the European Commission in cooperation with the OECD (2012). The existence of common elements with other models applied in universities is auspicious; it reflects the convergence of the views of specialists and increases the chances of implementing the new model.

Implications

Implementation of the proposed model enables the systematic achievement of the Third Mission activities and the improvement of the university performance in this domain. It also facilitates the understanding of the complex field of university's Third Mission and the training of specialists in management and leadership of university KT and entrepreneurship. It is widely accepted that achieving good results in the university Third Mission requires a professional approach.

The paper creates the premises for other theoretical studies on university IMS and also contributes to improving public policy and management in HE.

As a theoretical approach, the first step should be to develop a specific model for the IMS in HE institutions, based on the by CEN/ TS 16555-1 standard. The existence of such a model has many advantages. First of all, it offers a comprehensive framework to understand the dynamics of the Third Mission within the university and the influence factors. Secondly, the IMS model creates the

framework for a new approach, in an integrative manner, to areas defined as components of the university innovation system, such as: entrepreneurial education, research and innovation strategies, structures and networks, resources, evaluation, leadership and culture of innovation, etc. In all these areas, a process-based approach can lead to an increased optimization and formalization of the working rules, methods, procedures and tools used.

Regarding the public policies and the management of the HE institutions, the generic IMS model can be a useful guide for decision makers on institutional development in the context of the Third Mission, both at national and institutional level.

In this regard, the role of the state is important in all countries, regardless of the degree of governance centralization, relying on national strategies and HE programs, regulations on the evaluation of Higher Education institutions, funding systems and support structures in innovation. A suggestive example is the introduction of national tools for assessing the entrepreneurial dimension of universities, which can contribute to the emergence and development of the Third Mission in Higher Education institutions.

As regard the implications of the present study on the Third Mission management at institutional level, universities can move on to a more systematic approach of the changes for the development of the third function, setting their goals and projects of change to the overall strategy. The existence of a generic and standardized model of IMS gives more rigor and coherence to the actions focused on the development of university's Third Mission, supporting the projects of the university management that address to the IMS implementation/ evaluation and improvement. It also allows a better understanding of the IMS integration with other management systems: e.g. integrated quality-innovation management systems in universities, a subject of great importance that has not been studied so far.

Abstracts

To ensure the sustainable development of the national economy, export potential plays a big role, the formation of which occurs at enterprises that are independent participants in foreign economic activity. The implementation of export simultaneously indicates the efficient operation of the enterprise in terms of its counterparties and the external environment. Gradually, the regions move to work according to the regional export standard, which is being improved more and more every year. Regional export standard 2.0 as a set of measures is necessary for local authorities and business communities to become more actively involved in export activities and act within the framework of institutional guidelines. The phased introduction of a regional export standard will allow regions to adapt and adopt the experience of other regions in its implementation.

Keywords: Export, Regional Export Standard, Rating, Russian Export Center.

Introduction

Regional Export Standard 2.0 is one of the national projects that was developed by the Russian Export Center JSC and so that the regions could fully realize their foreign economic potential. This project has a wide variety of tools to support the foreign economic (export) activities of the constituent entities of the Russian Federation. The staged implementation of the Standard will allow you to see errors in its implementation in a timely manner. The first 10 "pilot" constituent entities of the Russian Federation in 2019 made an important step in the formation of new ways of developing the national economy. In 2020, a total of 40 more subjects will join this project, and in 2021 - 35 subjects of the Russian Federation. Russia is now going through a difficult economic period. Therefore, it is necessary to support exports with financial and non-financial instruments. In world practice, there is a large number of export promotion infrastructure. Financial measures include government loans, customs and tax incentives, compensation for transportation costs. Non-financial includes technical assistance to events abroad and providing the necessary information to experts.

The constituent entity of the Russian Federation must ensure the availability of an advisory infrastructure to support existing exporters and companies. This object can be both a legal entity and a structural unit in the municipality of the infrastructure for supporting entrepreneurship.

The functional of the object of the consulting infrastructure to support export activities can be endowed with an association of entrepreneurs an industry union or a public organization that has the necessary information and status

Review Methodology

The research information base includes materials of various types: decrees, decrees of the government of the Russian Federation, the Ministry of Economic Development of the Russian Federation, messages from leading Russian news agencies, materials from the official website of the Ministry of Industry and Trade.

As the fundamental methods, we used separate methods of statistical evaluation of the phenomenon under study, the method of theoretical analysis of the sources of the problem under study, and the illustrative-graphic method.

The export potential of this or that country has always been subject to assessment among researchers, specialists, economists. But the study of export standards at the level of regions, oblasts, districts or lands (in different states, administrative units are called differently) is a completely different area of knowledge, more specific, more applied. Chinese researchers have made significant progress in this area. BingqianYan, Yuwan Duan, Shouyang Wang showed that the export model and the regionalized model that distinguishes the export of processing at the national level [1].

Hong-Hao Zheng and Zheng-Xin Wang believe that based on traditional export difficulty indices, it is necessary to develop and use standards at the national level. The authors propose to apply such a development in the field of new energy products and new energy industries at the national and transnational level [2].

Julie Regolo examines the extent to which export diversification is associated with trade regionalization by examining the destination structure of new exported goods. The author uses a panel database on bilateral trade between 116 countries producing 1,090 goods over the period 2000–2010. Based on the results, the author concludes that export diversification is accompanied by trade regionalization, at least in the medium term [3].

Regional and sectoral indicators of export development are considered in the works of Xuemei Jiang, Yuwan Duan, Christopher Green [4], Yan Zhang, Jingbo Cui, Chenghao Lu [5], Daniela Federici, Valentino Parisi, Francesco Ferrante [6].

In domestic science, at least two approaches have developed, in which the assessment of the country's export potential appears. The first approach is associated with the assessment of the data itself of the export potential of the country as a whole, the second approach assesses exclusively the potential in the export direction of enterprises through their foreign trade activities. Both approaches associate their data and their assessment not only with quantitative indicators, but also with those factors and conditions that create a potential environment for the development of the export potential of either a country or individual enterprises. Moreover, these factors and conditions are quite diverse: from natural and climatic, to political, legal and economic, related to customs regulation or its absence.

The difference in these two approaches consisted in the specifics of the application and analysis of factors influencing the export potential.

To analyze the export potential of the country, the factors controlled and uncontrolled by the state are identified. For example, export control procedures are necessary in the implementation of foreign economic transactions related to a special group of goods and technologies. Export control as a system of state regulation of foreign economic activity is enshrined in the following legal sources:

1. Federal Law of 18.07.1999 No. 183-FZ "On Export Control";
2. Decrees of the President approving six Checklists;

3. Government decrees;
4. Orders and other orders of the FSTEC of Russia.
5. Order of the Ministry of Economic Development of Russia dated September 25, 2019 No. 594 "On approval of the requirements for the implementation of measures for the creation and development of export support centers carried out by the constituent entities of the Russian Federation."The presented review of the literature suggests that Western researchers are already in practice implementing the rules of the export standard for individual raw materials sectors of the economy, domestic - these problems have yet to be solved.

The research goal. The goal is to study the theoretical and methodological foundations for the implementation of the regional export standard 2.0.

Tasks:

1 To highlight the factors that determine the export potential of the enterprise;
2. Analyze the rating of innovative development of the constituent entities of the Russian Federation;
3. Describe the monitoring activities of the analytical conjuncture centers of the Joint Stock Company "Russian Export Center"

The Main Research Results

During the course of work there were studied the Regional export standard 2.0 and also studied the complex plan of measures and tools for the development of export activities within the regional export 2.0 standard technique of index of export activity of subjects of the Russian Federation, monitoring the activities of the center of export support.

Was developed the model form of the certificate on export of subjects of the Russian Federation, namely the Leningrad region, Nizhny Novgorod region, Novosibirsk region, Rostov region, Smolensk region, Sverdlovsk region, Perm Krai, Primorsky Krai, Stavropol Krai, Republic of Bashkortostan, the Republic of Tatarstan[7].

Having identified the evaluation criteria and factors that determine the effectiveness of the export potential implementation, we can say that the study of the criteria and evaluation of factors that determine the effectiveness of the export potential implementation leads to the conclusion that exports simultaneously act as a factor and as a result of the effective work of enterprises that are independent participants in foreign economic activity. The effectiveness of the export potential implementation is determined by factors that affect the competitiveness of the enterprise, the quality of the assortment, and the ability to produce products in the required volumes. Regarding the multi-factor assessment of the export potential of the organization, all the problems that require attention for the company to enter the international market can be formulated.

After conducting a study of the export promotion infrastructure and support system for domestic producers, it is revealed that at the moment Russia is making more and more efforts to support its exporters. The initiative is primarily aimed at supporting domestic producers, as it creates a more or less guaranteed market for Russian products. However, the experience of other countries where other measures and support institutions have shown positive results should also be taken into account. The existing tools and infrastructure to support Russian exports allow manufacturers to effectively promote their national products to the world market.

We have developed checklists for the tools of the regional export standard 2.0 that will improve the convenience and efficiency of quality audits of the regional export standard, reduce the response time to identified inconsistencies, and ultimately reduce losses and improve the quality of the regional export standard[8].
A standard form of export certificate for the subjects of the Russian Federation (Leningrad region, Nizhny Novgorod region, Novosibirsk region, Rostov region, Sverdlovsk region, Smolensk region) was developed.based on the analysis of the Smolensk region's exports, it was determined that the

priority markets for Smolensk exports were Belarus, Kazakhstan, Poland, Uzbekistan, Turkey, and Armenia. Priority sectors of Smolensk export: diamond industry, chemical industry, timber industry, agro-industrial complex, light industry, power engineering. Priority products of Smolensk export: finished food products, agricultural and agro-industrial products, children's clothing, lighting equipment, construction materials, packaging. All economic indicators are growing in the Leningrad region. The Leningrad region was among the top five regions in terms of social, economic and political indicators, and also received a Federal grant of almost one and a half billion rubles.

In the Nizhny Novgorod region during the study period, exports suffered significant decreases, this change was influenced by a decrease in the rate of import of machinery and equipment to the region, and a decrease in the volume of import of metals. The decrease in the volume of trade in metals produced in the Nizhny Novgorod region affected the export indicators[9].

There has been a significant change in the structure of foreign trade in the Novosibirsk region: if earlier imports prevailed over exports, last year it was almost balanced, with a slight advantage of exports. Exports increased due to deliveries to China (growth of 5%), Germany (growth of 38%), Kazakhstan (growth of 13%). The leaders of the rating of countries with the largest export supplies from the region included Saudi Arabia, Bulgaria, Korea and India.

Key economic indicators of the Rostov region have fallen below the level of previous years, mainly in the industrial region. However, the Rostov region has achieved a significant positive balance of foreign trade: sales of don goods in foreign markets almost tripled (2.7 times) exceeded the volume of purchases of imported goods.

After analyzing the standard form of the export certificate of the Russian Federation subjects (Perm Krai, Primorsky Krai, Stavropol Krai), it was found that foreign economic activity in the Perm territory is export-oriented: the volume and specific weight of exports significantly exceed the volume of imports. The Perm region's export structure is dominated by mineral products and chemical industry products, which characterizes the region as the largest supplier of raw materials. The largest trading partners for exports are the Netherlands, Brazil, the United States, and China[10].

According to the study of the Stavropol territory, it was revealed that it is one of the pilot regions for the introduction of a new model of export support aimed at improving and increasing the export potential of industrial and agricultural enterprises in the Stavropol territory. Exports from the Stavropol territory prevail over imports, which determines the high level of development of foreign economic activity with foreign countries. For Stavropol territory, the development of industry (20.2%), wholesale and retail trade (15.8%) and agriculture (14.7%) is becoming the most important direction of the economy and social sphere of the pilot region[11].

Regarding Primorye territory, it can be argued that the predominance of exports from Primorye in China (50.5%) and the Republic of Korea (27.5%) determines that exports from Primorye are an important destination for East Asian countries. The implementation of the national project "international cooperation and export" will increase the volume of exports of industrial products of local production. The growth of investment attractiveness is the basis for the growth of GRP – an important economic indicator of the Primorsky territory.

As for the Republic of Tatarstan, which exports raw materials, it is important to carry out the following activities: to concentrate efforts in promoting the product on competitive advantages; to clearly identify the sources of export growth in the segment (from the position of competitors and consumers); to build a clear strategy to fight competitors against whom companies have clear advantages. However, it should be noted that in the current economic conditions, which differ by complex political and economic processes, it is necessary to ensure diversification of the export potential of the Republic and the country as a whole, since the maintenance of the export structure with the raw material orientation, as well as unjustified increase in foreign trade may result in the maintenance risks from fluctuations on global commodity markets[11].

Having identified the methodology of the index of export activity of subjects of the Russian Federation, we can say that after analyzing the ranking of "Export activity" and considered the methodology of the index of export price of subject of the Russian Federation, it can be argued that Regional export rating tool created by the export centre for the comparative analysis of constituent entities of the Russian Federation key indicators of export activity and export environment. Despite the difficulty of comparing export statistics due to the variety of initial conditions for export activity, the "pilot regions" found this rating a useful tool. The rating "Export activity" was created by THE HSE in connection with the need to analyze the results of export activities of the Russian Federation's subjects. It allows you to get up-to-date information about the results of export activities of regions, as well as to assess the dynamics of development of each of them. I would like to note that the rating takes into account the results of export support in the region and the activities of the Executive authorities of the Russian Federation to implement the Regional export standard.

Conclusion

Making a general conclusion about the instruments of the Regional Export Standard 2.0, we can single out: firstly, the implementation of the standard will make it possible to adopt acts of simplification of foreign exchange control on the territory of the Russian Federation, expand access to the customs procedure for servicing exported goods.

Secondly, the “Export Activity” rating was created by the NRU HSE in connection with the need to analyze the results of export activities of the constituent entities of the Russian Federation. It allows you to receive up-to-date information on the results of the export activities of the regions, as well as assess the dynamics of development of each of them.

Thus, the Regional Export Rating is a tool created by the Russian Export Center for the comparative analysis of the constituent entities of the Russian Federation in terms of key indicators of export activity and the export environment.

An analysis of the practice of implementing the standard at the regional level will allow adopting administrative acts and adjusting the directions of development, improving export control, highlighting areas of liberalization of administrative responsibility, adjusting customs procedures for exported goods, and also finding suitable incentives to involve regions in the work under the Regional Export Standard program. 2: 0.

Abstract

The article provides a brief analysis of the reasons for lowering the Bank of Russia's key rate to 4.25% in July 2020. Based on this analysis and identification of the main factors for lowering the key rate, a forecast is made for further changes in the Bank of Russia's key rate level in the short term. The article also briefly highlights the main forms of state support to increase the availability of credit and reduce its cost.

Keywords: Bank of Russia, Key Rate, Inflation, Credit.

Introduction

The Central Bank of the Russian Federation at its regular meeting on July 27, 2020, decided to lower the key rate to 4.25%. At the moment, this level of the Bank of Russia's key rate is historically low. The real rate level, taking into account the forecast value of inflation in Russia, has also significantly decreased and is approximately 0.25%. The reduction of the Bank of Russia's key rate to the level of 4.25% has seriously strengthened the intention to implement a soft monetary policy in the short term.

Analysis

In order to analyze the reasons for the reduction of the key rate level to the above value, we will turn our attention to the main macroeconomic indicators of the Russian Federation in the conditions of quarantine restrictions in the spring of 2020. Pic.1 reflects the dynamics of changes in inflation in the first half of 2020. Based on the data shown in Pic.1 it can be seen that there was a slight increase in inflation in March and April 2020, which was caused by seasonal factors rather than other reasons.

Cite this Article as: Marina E. Lebedeva And Sergey N. Slavin“ Current key Rate Policy of the Bank of Russia” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Pic. 1: Consumer market inflation (month to the corresponding month of the previous year,%) [2;4]

However, starting from May 2020, due to lower consumer activity and quarantine measures, deflationary processes took over, and inflation begins to decline.

Also noteworthy is the decline in inflation expectations in the Russian economy. This decrease is due to a drop in demand, which is likely to be deeper than initial forecasts, which will slow the recovery of the Russian economy after the quarantine measures caused by the fight against a new coronavirus infection. However, with the return of business activity around the world, the recovery in the price of one of the main Russian export products – oil is also noticeable. This circumstance supports the Russian ruble and helps reduce the risk of financial stability. If 3 April 2020, the price of Russian oil grade Urals was at the level of 17.39 USD per barrel of oil of this brand, on 29 June 2020 price of this brand of oil recovered to the level 42,59 USD per barrel. In June 2020, there was a positive trend in the strengthening of the Russian ruble. Pic.2 reflects the dynamics of changes in the Russian national currency in relation to the US dollar. At the same time, it is necessary to understand that the strengthening of the Russian ruble is a process that contributes to deflationary processes in the Russian economy.

Pic. 2: Dynamics of changes in the value of the Russian ruble against the US dollar for the period from March 2020 to June 2020 [3; 1]

This circumstance is due to the high share of imported goods on the Russian market. Thus, the strengthening of the Russian ruble also contributes to the easing of monetary policy.

Attention is also drawn to the fact that in the conditions of the Russian economy's exit from the quarantine regime, it is necessary to support business activity by reducing the cost of borrowing. The price of credit, of course, depends not only on the price of the resource, but also, in many ways, is determined by the level of credit risk, which is certainly growing. For example, a commercial Bank, when considering a loan application of a potential borrower, will analyze its financial position and ability to service the loan. Different criteria are important: the ability to service loans based on current income and existing liabilities, the client's reputation, collateral, and the cost of resources for a commercial Bank. At the same time, short-term financing is more sensitive to changes in the Bank of Russia's key rate, as other factors become less significant in the short funding interval. Moreover, with increasing uncertainty in the crisis, commercial banks are trying to adhere to a more conservative credit policy, which contributes to an increase in short-term lending. Short-term lending, in this case, is less risky, since it is easier to predict the repayment of a loan for a short period. With such a credit policy of commercial banks, the key rate becomes more significant. Credit risk analysis is also important. When risks increase in the national economy, commercial banks are more attentive to the analysis of this risk and increase credit rates. At the same time, the role of the key rate in credit pricing is slightly reduced. Another situation is typical for an economic situation in which the Central Bank significantly increases the key rate. This situation was typical for December 2014 in Russia. The Bank of Russia tried to hold the exchange rate of the national currency in order to keep inflation in the planned corridor. The task was to set virtually barring conditions for issuing loans, which led to a certain deficit of the ruble in the short term. Also, the currency position on REPO transactions was increased. In this case, the instrument of changing the key rate, together with other factors, had a significant impact on the market. The fourth quarter of 2014 was characterized by a rapid fall in oil prices, which caused pressure on the ruble. If in September 2014 oil prices were at the level of 94 us dollars per barrel, by December 2014 the price had already fallen to 57 us dollars per barrel. Back in May 2014, the market could not have predicted such a sharp collapse in the price, despite the existing downward trend in the price of black gold. This circumstance could not but affect the Russian economy and, taking into account the significant import component of the national economy, it promised a surge in inflation. The measures of the Central Bank of the Russian Federation were really revolutionary for the money market of that time. On 16.12.2014, it was decided to raise the key rate of the Central Bank of the Russian Federation from 10.5% to 17%. The banking market reacted by significantly reducing the supply of money to the economy. Commercial banks have actually suspended lending even under previously approved loans and existing credit agreements. With these measures, the Central Bank of the Russian Federation actually artificially, using existing tools, contributed to the creation of a" deficit " of the ruble. The goal of this policy was to keep inflation within the specified forecast limits. Many experts blamed the Central Bank of the Russian Federation for the belated measures, many were surprised by such a sharp increase in the key rate, which actually indicated that this level of the price of money in the market is a barrier to lending operations. The fears of the Central Bank of the Russian Federation were not groundless because monthly inflation in the Russian economy has been growing rapidly since August 2014. In our view, this growth was primarily due to the decline in oil prices, combined with the expectation of a planned devaluation of the ruble (at that time, the Central Bank of the Russian Federation had already switched to a policy of free pricing of the ruble). The population showed an increased demand, the purpose of which was to transfer money savings to property, which is confirmed by the expectation of accelerated inflation. The decision was made not in favor of the development of the economy and the consumer market. The increase in the key rate of the Central Bank of the Russian Federation to 17% led to the actual suspension of lending by commercial banks, which in turn significantly reduced the supply of money. Moreover, many commercial banks, including system-forming ones, have started to change the terms of existing loan agreements in terms of increasing the interest rate. The Bank of Russia has been subject to global criticism from both the banking community and real business.

Therefore, the reduction of the key rate of the Bank of Russia, with a time lag, has some impact on the final price of credit in the economy. Simultaneously with the easing of the Bank of Russia's monetary policy, the Government of the Russian Federation, under quarantine restrictions, is implementing a number of programs to reduce the cost of credit (interest rate subsidies under government Resolution No. 422, a loan to resume operations under government Resolution 696, and preferential mortgages

under Government Resolution No. 566). At the same time, for example, within the framework of a loan to pay salaries to employees, commercial banks participating in this program receive a subsidy if they meet the established criteria [1,1-3]. Thus, this loan, issued for a year, for the first 6 months is free for the borrower, and then it is serviced at a preferential rate of 3.5% per annum.

Taking into account the above, we will highlight the main factors for reducing the key rate of the Bank of Russia on July 27, 2020 by 0.25% to the level of 4.25%:

 Reduction of short-term inflation expectations in the Russian economy;

 Slowdown in inflation growth in may-early July 2020;

 Recovery in the price of one of Russia's main export products (oil prices), which helps reduce the risk of financial stability;

 The decline in consumer activity due to quarantine measures, as well as the propensity of the population to save due to increased economic instability – is one of the factors of the deflationary process;

 The need to reduce the cost of credit in order to increase business activity and the need to restore the Russian economy after the quarantine regime;

 Some strengthening of the Russian ruble is one of the factors reducing the risk of financial stability.

Conclusions

It should also be noted that the reduction of the Bank of Russia's key rate by 0.25% to the level of 4.25% is an exception to the rules, rather than a reason for further rapid reduction. The target for inflation in 2020 is in the range of 3.8% - 4.8%. At the same time, the desired target is not higher than 4%. The Bank of Russia will closely monitor further changes in the macroeconomic indicators of the Russian economy for the purposes of further implementation of monetary policy. At the moment, there are no significant grounds for further rapid reduction of the key rate of the Central Bank of the Russian Federation. The probability of a negative real key rate simultaneously with the low level of investment attractiveness of the Russian economy will lead to a rapid increase in inflation in the country. Therefore, a further sharp reduction in the key rate in the short term is unlikely.

Abstract

Development of the social security system is viewed at present in close relation to the level of economic development. The present study is aimed at the development of methodological approaches to the evaluation of the functioning of the social protection system with the account of the reciprocal influence of social and economic determinants. Theoretical part of the research deals with the review of the research papers written by different authors about the reciprocal influence of the social protection level and the country's economy and methodological approaches to their evaluation. Methodology describes the authors' approach to the evaluation of the functioning of social protection systems using two synthetical integral indexes: integral index of economic development (IIED) and integral index of social development (IISD) that are aggregated into the final integral index – integral index of social protection system functioning efficiency (IISPSFE). Specific features of this methodology are: 1) author's suggestion of the gradation of the value of each integral index; 2) suggested by the author graphic interpretation of the interaction of two integral indexes using modified Gartner quadrant (Gartner magic quadrant) that makes it possible to make the gradation of the countries according to the development level and functioning of their social protection systems (Magic Quadrant for Evaluating the Functioning and Development of Social Protection, term suggested by the author.). In the empirical part the author evaluates the interaction of social and economic development of the OECP countries over the period from 1995 to 2015 based on the suggested methodology.

Keywords: social protection, economic development, integral index, Magic Quadrant, OECP.

Introduction

Social protection of the population has always been in the close interrelation with the economy and its main determinants (labor market, wage rate (income level), labor productivity, investment level, economic growth, etc.). Therefore scholars consider the social protection system not only from the social point of view, but as a mechanism of stimulating economic development of a country. This

approach requires an in-depth analysis of the interrelation of social-economic factors and social protection of the population. As studies show this relation has a reciprocal character.

Thus, it means that not only social and economic factors influence social protection, but its tools as well (various social services and benefits) exercise the influence on the dynamics of some or other factors. Economic and social components of the state are closely interrelated and influence each other. At the same time, science and practice prove that social expenses (total expenses on the funding of all social payments and programs in the state within the system of social protection of the population financed by the state and private funds) should be in harmonious connection with economic indexes of the country that directly influence the formation of the main funding sources of social protection of the population. Thus, economic resources should create a fundamental basis and be the form of the economic content of social protection. Difficult demographic situation and permanent economic and financial crises generated serious problems in the financial provision of the social protection of the population, which negatively affects not only the welfare level of the population but also the economy in general.

This makes the governments of the OECP countries search actively the ways to reform their social protection systems, leading to the establishment of new social policy models aimed at the elimination of the contradiction among the laws of the market and social goals. One of the main conditions of further stable functioning of the social protection system is to ensure the balance between economic and social goals that, on the one hand, provided maximum possible social protection of the population and, on the other hand, didn't have considerable negative pressure on the economic development of the state. It can be achieved provided that effective tools are created that would give the possibility to evaluate the level of economic and social development in their interaction.

Analysis of the latest studies and publications

Social protection and economic development have always been in close interaction. On the one hand, economic indexes influence directly the formation of financial resources to provide various social payments and programs, and, on the other hand, social protection can be the driver of economic growth as well as the reason for recession. Fig.1.

Fig 1: Main interrelations of social protection and economic factors
[Source: proposed by the authors].

Reciprocal influence of economic development and social protection depends to a great extent on the economic policy implemented in the country. Therefore, direct influence on the amount of social payments cannot be accurately defined, since it is formed under the influence of different market and non-market factors. For example, unemployment and early retirement directly influence on the growth of social expenses, but have a negative influence on the economic growth because of the reduction of employees and insurance contribution payers or tax payers. At the same time, financing of medicine increases labor productivity, reduces economic losses as a result of the reduction of the diseased and duration of sick leaves.

It is necessary to remember that social protection is in the first place a compensation mechanism that regulates relations which present no interest from the point of the market economy like helping the poor, compensation of the lost income because of various social risks, etc.

However, social protection influences the economic development of the country without producing any products. That is why, as far back as the XX century the governments understood that social protection could be an effective tool to stimulate the economy and the growth of the national income. In particular, J.M. Keynes substantiated that public expenditures directed to social goals are simultaneously incomes, because they stimulate consumer demand that increases the amount of paid taxes as a result of expanding production [Keynes, J. M. (1937)]. American economist B. Eichengreen (1994) notes that it was the state social expenses that gave the impulse of economic growth in the developed countries after the WW II. There is a great amount of studies of many scholars dealing with a reciprocal influence of social protection and economic growth: Alderman, H. and R. Yemtsov, R., (2012); Arjona, R. et all., (2003); Barrientos, A., (2012); Cichon, M., et all., (2004); Feld, L.P. and Schneider, F, (2010); Dafermos, Y. and Papatheodorou, C., (2010); Furceri, D. and Zdzienicka, A., (2011); Piachaud, D., (2011); Damerau, T.M., (2011); Gebregziabher, F., (2014); Egger, P. et all., (2016); Murshed S. Mansoob, (2017); Tridico, P. and Meloni, W., (2018). These studies and findings outline the main tools with the help of which the social protection system can potentially influence the factors determining the economic growth in a country.

It is worth mentioning that quite often some social-economic factors being the catalyst of a positive influence on the economic development of a country can have a negative impact on other social-economic determinants, which sometimes cancels out their positive influence.

Therefore, in many studies, the influence of social protection on economic growth turns out to be quite ambiguous. For instance, one group of scientists Furceri, D. and Zdzienicka, A., (2011); Furceri, D., (2010); Alderman, H. and Yemtsov, R., (2012); Alderman, H. and Hoddinott, J, (2010); Barrientos A. and Scott D., (2008); Li, Y., Wang, X., Westlund, H., (2015) in general note a positive influence of social expenses (or payments from a state budget on social goals) on economic growth. However, some of them interpret the results of their studies with caution. Arjona, R. et all. (2003) indicate in their research that the countries worldwide with a high level of economic development have a developed system of social protection of the population, which receives considerable funding, though it remains unproved whether this growth of social payment causes faster economic growth. Other authors Hansson, P. and Henrekson, M., (1994); Commander, S. J., Davoodi, H. R. & Lee, U. J., (1997); Gwartney, J. D., Lawson, R., Holcombe, R. G., (1998);, Levy, S., (2007); Sahn, D. and Alderman, H., (1996) prove that the increase of expenditures on social protection, in general, has a negative influence on the economic growth.

According to the point of view of some authors, such differences in the obtained results can be explained by specific features of social policy models and chosen methods of the financing principles. The part of scientific research focuses on investigating the influence of different economic factors on social protection (as a whole as well as in the context of some social programs) in short-, medium- and long term perspectives. Thus, for example:

- implementation of micro-financial programs makes it possible to reduce unemployment and to increase the level of income of the population, which positively influences the reduction of the burden on the system of social insurance for fighting unemployment and poverty rate [Lustig, N. C.

(2010); Lelkes, O. (2007); Zhen, Z. (2019)];
state support of the agrarian production development reduces the social vulnerability of the households (Tirivayi, N., Knowles, M., & Davis, B. (2016); Devereux, S. (2001)];
-state financing of active labor market programs that (ALMPs) is used to reduce the risk of unemployment and to increase the earnings capacity of workers [Betcherman, G., Dar, A., & Olivas, K. (2004)];
-activation of the non-state social insurance systems (including state financial support in the form of tax benefits, partical financing, etc.) in the future reduces financial burden on the state system of social protection and has a positive influence on the poverty rate among elderly people [Piljan, T., & Brzaković, T. (2017); De Freitas, N., Clark, G., & Legendre, B. (2009); Doerr, U., & Schulte, K. (2012)] etc.

Thus, there is a close interrelation between social and economic development that should be taken into account when making decisions as to the changes in the social protection system as well as in the economic policy of the state.

At present, a considerable number of various indexes and indicators characterising the state and development of social protection systems is being used in the world practices. A comprehensive analysis of scientific studies showed different approaches to the evaluation of the state of the social protection and well-being of the population. Some approaches are based on the evaluation of the general level of the social protection using already existing indexes and indicators that are calculated in statistics (for example, the size of the subsistence minimum, poverty level, income level of some population strata, etc.) and used by international organizations (indexes that are the part of Human Development Index are used most frequently) [Netoiu, L., & Cârstina, S. (2014); Atkinson, T., Cantillon, B., Marlier, E., & Nolan, B. (2002); Paetzold, J. (2013); Arredondo-López, A., & Orozco-Núñez, E. (2014)].

In this case, integral index of social protection efficiency is expressed by such categories as quality of life, standard of living or well-being. Other approaches are based on the calculations and the use of synthetic indexes of well-being. Somarriba, N., & Pena, B. (2009) consider three possible methodologies for obtaining synthetic indicators for the area of welfare and quality of life. Furthermore, in their paper they analyze the quality of life in the European Union (EU) as a methodological exercise to demonstrate the principles of calculation, implications and differences among three indicator-construction approaches.). Espina, P. Z., & Arechavala, N. S. (2013) suggest using the synthetic indicator of welfare that comprises information on different social indicators from various life domains and enables classification of Spanish provinces, as well as a study of the impact of each individual indicator in order to determine provincial disparities in social welfare levels.

Some researchers propose to calculate and use special integral indexes characterizing the state of social protection systems functioning in different countries throughout the world. Thus, for example, Baulch, B., Wood, J., & Weber, A. (2006) recommend using social protection index that systematically and consistently quantifies activities at the national level. It consists of four summary indicators representing the cost, coverage, poverty targeting and impact are scaled and weighted to produce an additive index of the overall level of social protection provision. The index is calculated for six very different Asian countries: Bangladesh, Indonesia, Mongolia, Nepal, Pakistan and Vietnam. Considerable contrasts are revealed between their levels of social protection provision.

Despite a considerable number of existing scientific approaches to the evaluation of the state and efficiency of social protection, it is necessary to mention that they are focused on the evaluation of separate aspects of the research object without taking into account the reciprocal influence of social and economic development indexes of a country.

The purpose of the article

The aim of the article is to develop methodological approaches to the evaluation of the social protection system functioning with the account of the reciprocal influence of social and economic

determinants.

Materials and Methods

To evaluate the functioning of social protection system with the account of the influence of economic as well as social elements the author suggests using two synthetic indexes: integral index of economic development IIED and integral index of social development IISD that will be combined in one integral index of social protection functioning efficiency IISPSFE.

When developing the data of integral indexes it was taken into account that they should be simple at calculations, and some of their components are available in statistical databases and understandable for interpretation. The methodology of evaluation of social protection system functioning suggested by the author is based on the calculation and comparison of the interrelation of two integral indexes that depict the level of economic and social development of every single country.

Specific features of the present methodology are: 1) suggested by the author gradation of the values of each integral index; 2) suggested by the author graphic presentation of the interrelation of two integral indexes using Gartner magical quadrant that enables the scaling of the countries according to the level of the development and functioning of their social protection systems (author's term - Magic Quadrant for Evaluating the Functioning and Development of Social Protection). Succession of the steps undertaken to evaluate the functioning of social protection systems is presented in fig.2.

Fig. 2: Succession of the steps undertaken to evaluate the functioning of social protection systems

[Source: proposed by the authors].

Data

Economic and statistic research covered 36 OECP countries over the period from 1995 to 2005. Two factors were considered to choose the given period: 1) availability and completeness of the data that were necessary for calculating integral index of economic development and integral index of social development; 2) this period is characterized by a gradual deviation of OECP countries from the concept of the state as a welfare state. All quantity indexes used to construct integral indexes were taken from the open statistic database of OECP (OECD Data https://data.oecd.org/).

To form the integral index of social development the author suggested using 9 separate indexes that characterize the achievements of different goals of social protection (the number of index values can be changed by other researchers): 1) Gini index (GI); 2) Poverty rate (PR); 3) Net pension replacement rates (PRR); 4) Total fertility rate (per woman) (TFR); 5) Life expectancy (LE); 6) Infant mortality rate (IMR); 7) Elderly poverty rate (EPR); 8) Replacement rate (RR); 9) Unemployment rate (UR).

To construct integral index of economic development the author used 11 separate indexes that

indicate the level of economic development of the country: 1) GDP per hour worked (GDPHW); 2) Gross domestic product per capita (GDPPC); 3) Real GDP (RGDP); 4) Gross fixed capital formation (GFCF); 5) Household savings (HS); 6) Pension funds' assets (PFA); 7) Saving rate (SR); 8) Inflation (CPI); 9) Social security contributions (SSC); 10) Tax revenue (TR); 11) Average annual wages (AAW)

Scaling

On having chosen the parts of integral indexes and having defined their values it is necessary to conduct their scaling (standardization) at the second stage since their values are presented in different absolute and relative indexes.

The following method is suggested. It is the range scaling method used by the Human Development Index [Bob Baulch, Joe Wood and Axel Weber (2006)]:

$$ScaledValue = \frac{V_i - V_{\min}}{V_{\max} - V_{\min}}$$

where Vi is the value of the selected indicator for country i and Vmax is the maximum value for this indicator across all countries in the data set, Vmin is the minimum value for this indicator across all countries in the data set.

This scaling method results in a scaled value which varies between zero and one. Thise scaling method provides summary indicators that are simple to understand, as they always vary between zero and one, and provide a direct comparison with the maximum achieved by any country in the data set.

Aggregating (calculation)

Aggregating (calculation) of integral index of economic development and integral index of social development based on separate parts whose values should vary from 0 to 1 in the process of scaling can be conducted in following ways:

1. Summing up the values of all obtained variables.
2. Summing up the values of all obtained variables with the account of weighting factors
3. Calculation of mean arithmetic value of all obtained variables with equal weighting coefficients of all components of the integral index.

Calculation of mean arithmetic value of all obtained variables with different weighting coefficients of all components of integral index. Since in our case it is quite difficult to detect weighting coefficients of some components in the context of different the countries, the method for aggregating was suggested that is based on the calcucation of the mean arithmetic value of all obtained variables with different weighting coefficients of all components of the integral index:

$$S = \frac{1}{n}\sum_{i=1}^{n}(\pm 1) * x_i^{(Un)}$$

The same method of aggregating is also used to calculate the summary integral index – integral index of social protection system functioning efficiency (IISPSFE).

Gradation of the obtained values of the integral indexes

The gradation of the values of the summary integral index (integral index of social protection system functioning efficiency IISPSFE) is performed at the fourth stage. The author's gradation of the values

of integral indexes presented in table 1 includes the division of the obtained values into 5 levels and establishing their range which allows us to perform objective comparative characteristics of the development level of social protection systems in different OECP countries as well as to detect problematic zones (table. 1).

Table 1: Gradation of the values of the integral index of social protection system functioning efficiency IISPSFE

The name of the level	high	sifficient	average	unfavorable	low
values range	[0,8 … 1,0]	[0,6 … 0,8]	[0,4 … 0,6]	[0,2 … 0,4]	[0,0 … 0,2]
brief description	High level of the balance between economic and social indexes, accompanied by by their stable growth. Income level of the population is high. The population is satidfied living standards.	There is a shift of the balance level towards one of the sides. Despite the growth of economic and social indexes their slowing down is observed. Income level of the population is quite high. In general, the population is satisfied with a living standard, however there are some catagries that need additional help.	There is a considerable disbalance towards one of sides. There is slowing down of all indexes and even their reduction. The income level of the population is decreasing. The population is at the marginal level. The number of poor population is increasing.	The indexes of economic and social development tend to decrease. The income level of the population is low. Significant number of the population needs social help. Poverty level is quite high.	The country is in a deep and long-term economic and social crisis. Most population doesn't have means of living and needs help. The country isn't able to provide social support of people at the minimal level at the cost of own resources. The most population is on the verge of poverty or beyond the poverty line.

[Source: proposed by the authors]

Graphic interpretation of the obtained results

To give the graphic interpretation of the obtained results and to grade the countries according to their development level it is suggested to use modified Gartner magic quadrant (Magic Quadrant for Evaluating the Functioning and Development of Social Protection). In the Magic Quadrant for Evaluating the Functioning and Development of Social Protection the values of the calculated integral index of social development are arranged on the Y-axis and the values of the integral index of economic development are arranged on the X-axis. Magic Quadrant for Evaluating the Functioning and Development of Social Protection is divided into 4 sectors (the value 0.5 is the division center on both X and Y axes). Every OECP country is located in the square on the ground of the interaction of two calculated integral indexes – integral index of economic development (IIED) and integral index of social development (IISD).

Each of the four squares is given a title and attributed a corresponding description (fig. 3), that enables us to define the present state of the development of the social protection in each OECP country (with the account of the interaction of achieved economic and social indexes). On that

ground, it is also possible to develop recommendations as to the desirable development of the country's social and economic indexes.

Leaders are the countries that managed to provide the relative balance between economic and social goals. Provided that quite a high level of economic development is maintained, the system of social protection is quite developed and covers the most population of the country and the level of social payments is high. Due to this fact, there is a low level of poverty, reduction of disparity in the income of some social categories, reduction of unemployment rate and increase of life expectancy as well as health care of the population. The main aim of such countries is to support this balance and to develop gradually both economic and social indexes. The main threat is the desire of the politicians to increase their popularity among the population through ungrounded increase of social payments, which can lead in the future to the transition of such countries into the socialist countries with gradual movement to quadrant Unhappy.

Fig. 3: Magic Quadrant for Evaluating the Functioning and Development of Social Protection
[Source: proposed by the authors on the basis of Gartner Magic Quadrant https://www.gartner.com/en/research/methodologies/magic-quadrants-research]

2. Socialists are the countries that have highly developed systems of social protection with a maximum level of state paternalism. To provide high levels of social payments these countries have a considerable burden on the payroll budget and significant expenses from the budget on the social goals. In this group of the countries there is a transition of the focus to social goals, which has a negative influence on economic development. Conducting this policy in the long run can lead to the deterioration of the social situation as a result of the increase of financial resources deficit for the support a considerable part of social programs. On the other hand, there is a low level of poverty in these countries, income disparity is not high, and high expectancy life. The goal of these countries is to build up economic potential to to join Leaders-countries. In this period it is necessary either to keep social payments at a stable level or, if necessary, to reduce them. Revision and reformation of social programs and payments is necessary because the increase of financial resources deficit to

provide social goals can lead to the enhancement of negative trends in the economic development and transition of such country to the quadrant Unhappy.

3. Liberals are the countries with a focus on the achievement of economic goals. Despite a developed system of social protection, it functions according to an excessive principle. A state supports only low-income social groups. Despite high indexes of economic development, a large part of the population has a limited access both to social services and to health care system. Indexes characterizing the level of social protection (poverty level, income disparity, life expectancy, etc.) are lower if compared to the Leaders- and Socialist Countries. At the same time, there is sufficient economic potential in these countries to improve indexes over certain period of time to the level of Leaders-countries. Measures on the expansion of social protection system to increase the level of social payments should correlate with economic indexes since there is a threat of transition of such countries into the quadrant Unhappy.

4. Unhappy are the countries with low indexes of economic development and relatively low level of social protection. The main way of development for such countries is to build up economic potential in order to transfer to the Leader-countries, since the transition to Socialist-countries is impossible because of the scarcity of resources for the financing of the social protection system. To achieve this it is necessary to conduct serious structural reforms in economic and social systems. Over a certain period of time it is necessary to conduct unpopular reforms that will be accompanied by freezing and even by reduction of social programs and social payments.

Results

Based on the suggested method, the authors calculated two synthetic integral indexes: integral index of economic development (IIED) and integral index of social development (IISD) for 36 OECP countries over the period from 1995 to 2005. They were combined into the summary integral index – integral index of social protection system functioning efficiency (IISPSFE). Calculation of IISPSFE was performed for separate years (to evaluate the dynamics of the index change) and on average over the period from 1995 to 2015 (to minimize the influence of the appearance of sudden maximum and minimum values of some indexes that are involved into calculated integral indexes).

The table 2 presents the gradation of OECP countries according to the value of the obtained IISPSFE. None of the OCEP countries according to IISPSFE corresponds to the indexes of high level and only IISPSFE of 9 OECP countries equals to sufficient level. At the same time, the obtained results show that over the period from 1995 to 2015 the most OECP countries worsened their indexes. Only IISPSFE of Ireland increased form 0.650 to 0.710. According to the obtained results, it appears probable that social and economic changes in some OECP countries over the analyzed period didn't lead to noticeable changes in the resultative indexes, they worsened the economic and social situation as well.

Table 2: Gradation of values of the integral index of social protection system functioning efficiency

[Source: the data of the OECD https://data.oecd.org/ (calculated and proposed by the authors)]

Special attention should be payed to the countries that over the period from 1995 to 2015 shifted in

the value range from the top group to the low one (Australia, Austria, Estonia, Finnland, Greece, Corea, Turkey, Great Britain).

The authors used Gartner quadrant (Magic Quadrant for Evaluating the Functioning and Development of Social Protection) for the graphic interpretation of the obtained results and the gradation of the countries according to their development. To construct a modified Gartner quadrant (Magic Quadrant for Evaluating the Functioning and Development of Social Protection) the mean values of the calculated integral indexes were used over the priod from 1995 to 2015 (fig.4.).

Fig. 4: Magic Quadrant for Evaluating the Functioning and Development of Social Protection (країни OECPcountries, indexes from 1995 to 2015 – mean value)

[Source: the data of the OECD https://data.oecd.org/ (calculated and proposed by the authors)]

Fig. 4 shows that 2 OECP countries get into the quadrant Socialists and quadrant Leaders according to the mean values of integral indexes over the period from 1995 to 2015. However, it is necessary to mention, that the number of the countries in the quadrant Leader is the lowest and some of them are close to the quadrant Socialists. Such results show that in most OECP countries there is a shift of the main focus of the state policy towards social goals. On the one hand, it is a positive trend, since it provides high living standards of the population due to a great number of social programs and high level of social payments, and, on the other hand, highly populist state policy will have a negative impact on the economic development in the future. A great number of the countries are in the critical zone of getting into the quadrant Unhappy.

Using suggested methods it is possible to make calculations for some OECP countries and to trace the dynamics of their movement in Magic Quadrant for Evaluating the Functioning and Development

of Social Protection. It enables us to evaluate in what way social or economic changes influence the resultative indexes. For example, fig. 5 presents the evaluation for the USA.

Fig 5: Magic Quadrant for Evaluating the Functioning and Development of Social Protection (USA, indexes from 1995 to 2015)

[Source: the data of the OECD https://data.oecd.org/ (calculated and proposed by the authors)]

The USA was in the quadrant Liberals form 1995 to 2005. However, the level of both IISD and IIED went down in that period. Such lowering can be the result of: 1) reduction of absolute values of some social and economic indexes; 2) low growth rates of some social and economic indexes compared to the OECP countries-leaders over this period.

Conclusions

Social protection is considered by scholars not only from a social point of view but also as a mechanism to stimulate the economic development of a country. At present, the approaches to evaluate the development of the social protection system with the account of the reciprocal influence of social and economic determinants are insufficiently worked out.

We consider that the present research will complement the existing approaches as to the evaluation of social protection and create effective tools for consideration of the reciprocal influence of social and economic development indexes.

The methods suggested by the authors:

- imply a clear succession of the steps to evaluate the functioning of social protection systems;
- suggest using different indexes to calculate integral indexes, that show very different aspects of the social and economic development of a country. In this case, a set of data of the indexes can be easily changed (increased or decreased) proceeding from the set goals of the research and availability of statistic data;
- are based on simple calculations;

- enables to conduct a comparative analysis of the countries according to summary integral index;
- imply a graphic interpretation of the obtained results using a modified Gartner quadrant (Magic Quadrant for Evaluating the Functioning and Development of Social Protection), which makes it possible to understand and interpret obtained results to substantiate further ways of development of the social protection system for each country.

Application of the suggested methods will allow the governments of different countries to perform effective control and to model scenarios of the development of the national social protection systems with account of changeable social and economic indexes compared to the indexes of other countries.

Models for Scheduling Batch Production of Items with Lot Streaming in Hybrid Flow Shops

Madalin-Gabriel CATANA

University POLITEHNICA of Bucharest, Manufacturing Engineering Department, Bucharest, Romania, mg_catana@yahoo.com

Abstract

Being a common concern faced by nowadays production managers, the problem of minimizing the makespan of batch production schedules of items by using the lot streaming strategy in hybrid flow shops is insufficiently studied by operations researchers. To address to the limitations found in the literature on this subject, this paper formulates two comprehensive mathematical models to solve the problem, a linear programming model and an enumeration model. The following general production conditions are supposed to exist by the models: a processing cycle time limit prescribed for the batch production of item; no-idling of batch operations; not-negligible times for transportation of streamed lots between processing stages; a multi-machine or a single-machine processing of lots at the parallel machine group in each stage; not-negligible times for set-up the stage operations; an anticipative or a reactive scheduling of the setup work; a fixed number of equal-size lots used for streaming the batch production. Under these conditions, the models minimize the length of batch production schedule by minimizing the start time lag between pairs of successive process operations. OpenSolver add-in for Microsoft Office Excel was used for implementing the linear programming model, and a Visual Basic for Applications procedure was coded in Excel for the enumeration model. A numerical example for the utilization of the models was used to discuss the quality of scheduling solutions under different models' settings, and also to compare in terms of quality and feasibility the solutions implying equal-size lots with other possible scheduling solutions, assuming optimally-sized, different-in-size lots.

Keywords: operations research, lot streaming, hybrid flow shop, scheduling, linear programming, spreadsheet optimization.

Introduction

A review of scientific literature concerning managerial solutions possible to be applied for reducing the makespan of batch production schedules of items is presented in the followings. Conclusions of the review are used to define after that motivation and scope of the study presented in this paper.

Literature Review

In the book by Catana (2019) is mentioned that batch production is the most prevalent manufacturing strategy that is employed in industry for an efficient fabrication of items. A batch for an item to be produced represents the quantity or the number of units of item that will be processed continuously in the shop after the setup of machines allocated for processing operations. Catana (2019) also observed that the size of a batch of item may be optimally determined by using production cost minimization mathematical models or may be imposed by production managers based on important manufacturing restrictions, such as the size and the frequency of distribution orders for the produced item.

To reduce the duration or makespan of batch production schedule for an item with multi-operational or multi-stage processing at different machines, the strategy of lot streaming is frequently used in industrial practice and, therefore, studied by operations researchers. As defined by Defersha (2011), lot streaming is the technique of splitting the production batch of an item in smaller-sized lots with

individual transportation among the processing machines of a multi-stage manufacturing system, denoted flow shop, so that different processing operations of the batch can be overlapped in time, in order to shorten the makespan of batch production schedule. A comprehensive review of traditional settings and terminology of a lot streaming operations research problem is presented by Chang and Chiu (2005), who evoked the following main concerns of a problem of this nature: single-item or multiple-item batch production; equal, consistent or variable size for lots of item to be transported among the processing stages; integer or non-integer sizes of streamed (transported) lots; no-idling or intermittent idling of batch processing operations of item; an anticipative or a reactive operation and machine setup for processing the item batch; transportation time dependent or not-dependent on the streamed lot size; cost-based or time-based performance measures to be minimized. Typical decision variables for a lot streaming problem are considered to be the number and size of streamed lots in each item batch and the processing sequence or schedule for these lots at the machines in flow shop. As observed by Defersha (2011), most researches of lot streaming problem assumes the production environment of a pure flow shop, having only one processing machine available in each operational stage. Significant research contributions on traditional lot streaming problem in pure flow shops are presented within the books of Baker and Trietsch (2019) and of Sarin and Jaiprakash (2007), where numerous mathematical models and algorithms for making lot streaming decisions in both single-item and multiple-item batch production situations are shown. Other contributions relating specific solution procedures for different settings of lot streaming problem in pure flow shops are presented also by Chen and Steiner (1998), by Huang (2010), by Kalir and Sarin (2001) and by Low, Hsu and Huang (2004). Finally, the work of Catana, Neagu and Tonoiu (2009) uses the restrictions of a lot streaming strategy with known, equal-size streamed lots and no-idling of batch operations within a resource-constrained scheduling model for multiple-item batch production projects. The model was implemented in a Microsoft Office Excel workbook, with specially designed cell ranges for initial data input, and cell formulas and Visual Basic for Applications (VBA) code modules for solution output.

An other possible strategy to reduce the makespan of production schedule in the case of single-item or multiple-item batch manufacturing is to allocate the multi-operational processes to a hybrid flow shop (HFS), which comprises more than one machine available for utilization in several bottleneck processing stages and, therefore, permits different processing operations of items to be overlapped or even shortened in time. However, as observed by Defersha (2011), the majority of researches about the problem of production scheduling in hybrid flow shops with makespan minimization objective does not take into account the application of lot streaming strategy. Important contributions relating specific solution procedures for different formulations of multiple-item hybrid flow shop scheduling problem, with makespan minimization objective and in the absence of the lot streaming strategy, are presented in the books of Emmons and Vairaktarakis (2013), of Lopez and Roubellat (2008) and of Pinedo (2016). Besides, all the above studies and also the works of Burtseva et al (2012), of Defersha (2011), of Liu (2008) and of Zhang, Liu and Linn (2003), which investigate the use of lot streaming strategy in hybrid flow shops, consider the number of parallel machines available for the production of items in each processing stage of hybrid flow shop to be known beforehand, as an initial data for the scheduling problem. In the book by Catana (2019), it is commented that if there exists an average cycle time limit C to be met by a batch production process of an item with m operations performed in a hybrid flow shop with m processing stages, then the number of parallel machines M_k that should be allocated in stage k ($k = 1,\ldots, m$) for the execution of operation with unit processing time P_k must be sized with the following equation:

$$M_k = \left\lceil \frac{P_k}{C} \right\rceil \qquad (1)$$

Mathematical symbol $\lceil\ \rceil$ used in equation (1) denotes the round-up to the smallest integer function.

An even higher degree of batch production makespan reduction can be obtained when employing the strategy of lot streaming for multi-operational processes run in hybrid flow shops, as demonstrated by the researches of Burtseva et al (2012), of Defersha (2011), of Liu (2008) and of Zhang, Liu and Linn (2003). All these researches propose mixed integer linear programming (MILP) formulations for the specific hybrid flow shop lot streaming problem taken into account. All the models are constructed

with the constraint that a streamed lot is to be allocated for processing on exactly one machine from those, several, available for utilization in a manufacturing stage of hybrid flow shop. This constraint corresponds to the application of a single-machine processing scheme (SP) for streamed lots at the manufacturing stages of hybrid flow shop. It will be demonstrated in this research that for streamed lots of large size, SP scheme becomes less effective in ensuring a high utilization level for the group of M_k parallel machines throughout the processing time of operation k, in order to meet the required process cycle time C. A different processing scheme for lots that will be investigated in this research is expected to improve the utilization level for the group of M_k parallel machines. This is the multi-machine processing scheme (MP) for streamed lots at the manufacturing stages of hybrid flow shop, implying the split of each lot in balanced shares to be processed in parallel by all the machines in the group. This scheme may easily be implemented in production by maintaining unique work-in-process input buffers in front of the groups of parallel machines available in processing stages of hybrid flow shop. Another constraint that is used in the MILP models of Liu (2008) and of Zhang, Liu and Linn (2003) concerns a so called "rotation" method to be applied for deciding the allocation of streamed lots to individual machines in a stage while using SP scheme. This method proved to be supportive for makespan minimization of single-item batch production schedules by allocating evenly the lots to machines in a group, as follows: lot 1 to machine 1; lot 2 to machine 2; …; lot M_k to machine M_k; lot M_k +1 to machine 1 and so on. An adapted allocation method that will be used in this research for the case of MP scheme implies a unit-based allocation of item to machines, as follows: unit 1 in the batch to machine 1; unit 2 to machine 2; …; unit M_k to machine M_k; unit M_k +1 to machine 1 and so on. As all the four researches mentioned before do consider a negligible transportation time of streamed lots between processing stages, this research will examine also the influence of the lot transportation time on the makespan of batch production schedule. Moreover, there will be studied the influence exerted on schedule makespan by each stage setup time required before processing the item batch, by taking into consideration two alternative setup schemes possible to be applied according to item's process plan: the anticipative setup (AS), which can be started at the machines in a stage before the arrival of any streamed lot from the previous processing stage; reactive setup (RS), which can be started at the machines in a stage only after the arrival of required number of streamed lots coming from the earlier processing stage. The schedule for setup work in a stage will depend on both the adopted streamed lot processing scheme (SP or MP) and operation setup scheme (AS or RS), and on general requirements to achieve the continuity of entire batch operation (no-idling requirement) and to ensure the highest possible utilization level for machine group in the stage during the batch operation execution time. A direct consequence of the latter requirement is that all the parallel machines in a processing stage will have a common setup schedule, in order to be set-up for the stage operation in the same time interval.

Motivation and scope of present research

Literature review from above clearly indicates that the use of lot streaming strategy in a hybrid flow shop is the most effective option for reducing schedules makespan for single-item multi-operational batch production processes with cycle time limits that must be met. However, the review concludes also that the research contributions on lot streaming batch production in hybrid flow shops should be much more numerous, diverse or complete, in order to effectively be applied in managerial practice.

Present research is primarily focused on the sequencing and scheduling components of lot streaming problem, in the case of a single-item multi-operational batch production process run in a multi-stage hybrid flow shop. The number of machines in each processing stage of hybrid flow shop is sized in accordance with the cycle time limit prescribed for entire process. Research objective is to find the batch production schedule of shortest length, given by the combinations of SP and MP lot processing schemes with AS and RS operation setup schemes, under the restrictions of no-idling the operations and of best-using the operational time of parallel machines in hybrid flow shop. A "rotation" method adapted for streamed lot processing schemes SP and MP is used for allocating the lots to individual machines in a group. Transportation time of streamed lots between processing stages and setup time of stage operations are taken into account in scheduling. The number of streamed lots in the batch is considered to be known in advance, as it could come from limited number of available transporters as mentioned by Kalir and Sarin (2001) or from the solution of a transportation cost minimization model as indicated by Catana (2019). The streamed lots are considered to be integers of equal size for easy

management, but solutions of the problem with different, optimized integer sizes of lots will be also provided and compared in terms of quality and feasibility with equal-size lot scheduling solutions.

To address to the issues mentioned above, two models for scheduling batch production of items with lot streaming in hybrid flow shops, a linear programming (LP) model and an enumeration model, are proposed in section 2 of this paper. Implementation of the proposed models in Microsoft Office Excel spreadsheet formats, by means of OpenSolver optimization add-in by Mason (2012) and VBA code, is then presented in section 3. A numerical example for the utilization of the models is provided after that in section 4, and comparisons are made on the quality and feasibility of solutions under different models' settings. Research conclusions are displayed in section 5 of the paper.

Models for scheduling of batch production with lot streaming in HFS

For describing the two mathematical models proposed for scheduling the batch production with lot streaming in HFS, it is necessary to previously define the underlying problem parameters as shown below. These parameters will be subsequently used in the formulation of the models.

Definition of Problem Parameters

Let be:

m Number of processing stages in HFS where stages are indexed by k with $k = 1,\ldots, m$;

P_k Processing time for one unit of item in the operation performed in stage k;

C Average processing cycle time limit to be met in each batch production operation of item;

U_k Setup time for operation on each machine available for batch processing in stage k;

T_k Transportation time for each lot streamed from processing stage k to the following stage;

M_k Number of parallel machines required to be set-up and used for item batch processing in stage k of HFS, which comes from equation (1);

B Size of processing batch of the item in each operation performed in HFS;

n Number of streamed lots in the batch where lots are indexed by i with $i = 1,\ldots, n$;

L Size of each streamed lot throughout the process run in HFS, which is given by equation:

$$L = \frac{B}{n} \quad \text{.....(2)}$$

b_{SP} Binary data equal to 1 if SP scheme will be used for scheduling the processing of streamed lots at parallel machines allocated to operations, and equal to 0 otherwise;

b_{MP} Binary data equal to 1 if MP scheme will be used for scheduling the processing of streamed lots at parallel machines allocated to operations, and equal to 0 otherwise;

b_{AS} Binary data equal to 1 if AS scheme will be used for scheduling the setup time of parallel machines allocated to operations, and equal to 0 otherwise;

b_{RS} Binary data equal to 1 if RS scheme will be used for scheduling the setup time of parallel machines allocated to operations, and equal to 0 otherwise;

$S_{k,i}$ Start time of the part of operation in stage k related to the process of streamed lot i, which is expressed relative to the beginning of operation setup with general equation:

$$S_{k,i} = b_{MP} \cdot \left(P_k \cdot \lfloor L \cdot (i-1)/M_k \rfloor + X_{k,i}\right) + b_{SP} \cdot \left(P_k \cdot L \cdot \lfloor (i-1)/M_k \rfloor + Y_{k,i}\right) \quad \text{.....(3)}$$

In equation (3), mathematical symbol $\lfloor\ \rfloor$ stands for the round-down to the largest integer function and terms $X_{k,i}$ and $Y_{k,i}$ control the inclusion of setup time in value $S_{k,i}$ as follows:

$$X_{k,i} = \begin{cases} 0, & \text{if } \lfloor L \cdot (i-1)/M_k \rfloor = 0 \\ U_k, & \text{if } \lfloor L \cdot (i-1)/M_k \rfloor > 0 \end{cases} \quad \text{.....(4)}$$

$$Y_{k,i} = \begin{cases} 0, & \text{if } \lfloor (i-1)/M_k \rfloor = 0 \\ U_k, & \text{if } \lfloor (i-1)/M_k \rfloor > 0 \end{cases} \quad \text{.....(5)}$$

$F_{k,i}$ Finish time of the part of operation in stage k related to the process of streamed lot i, which is expressed relative to the beginning of operation setup with general equation:

$$F_{k,i} = b_{MP} \cdot \left(P_k \cdot \lceil L \cdot i / M_k \rceil + U_k\right) + b_{SP} \cdot \left(P_k \cdot L \cdot \lceil i / M_k \rceil + U_k\right) \quad (6)$$

S_{k+1_k} Start time lag of successive operations k and $k+1$ with respect to the item batch, which is the minimum positive distance in time that may exist between the starts of operations k and $k+1$ under all the constraints of scheduling models (this parameter will be optimized by models);

$T_{k+1_k,i}$ Transfer time lag of successive operations k and $k+1$ with respect to the streamed lot i in the batch is deduced with the following equation and should suit the required transportation time of lot i between operational stages:

$$T_{k+1_k,i} = S_{k+1_k} + S_{k+1,i} - F_{k,i} \quad (7)$$

D_k Duration of batch operation in stage k is dependent on the processing scheme of streamed lots and may be obtained with the following general equation in case of equal-size lots:

$$D_k = b_{MP} \cdot \left(P_k \cdot \lceil B / M_k \rceil + U_k\right) + b_{SP} \cdot \left(P_k \cdot L \cdot \lceil n / M_k \rceil + U_k\right) \quad (8)$$

In general, D_k is the distance in time between the start and the finish of operation in stage k;

D Duration (makespan) of the schedule of batch production process is given by the equation:

$$D = \sum_{k=1}^{m-1} S_{k+1_k} + D_m \quad (9)$$

In general, D is the distance in time between the start of first batch operation (in stage 1) and the finish of the last batch operation (in stage m).

It is worthy to be pointed out that all terms in equations (3) and (6) besides $X_{k,i}$, $Y_{k,i}$ and U_k define the limits of scheduling interval for processing the lot i in operation k, under the conditions of no-idling the batch operation and of the specific "rotation" method used for scheduling the processing time of equal-sized lots within MP and SP schemes.

Definition of Linear Programming Model

By using the parameters introduced above, the linear program for scheduling the batch production of an item with lot streaming in HFS is described below. The objective function and the constraints of LP model concern the part of production schedule relating to a pair of generic, successive operations k and $k+1$.

Minimize S_{k+1_k} .....(10)

Subject to:

$$S_{k+1_k} \geq 0 \quad (11)$$

$$T_{k+1_k,i} \geq b_{MP} \cdot \left(b_{AS} \cdot (T_k - U_{k+1} + X_{k+1,i}) + b_{RS} \cdot T_k\right) + b_{SP} \cdot \left(b_{AS} \cdot (T_k - U_{k+1} + Y_{k+1,i}) + b_{RS} \cdot T_k\right) \quad (12)$$

$$\forall (i = 1, \ldots, n).$$

The objective function in equation (10) is to minimize the start time lag of successive operations k and $k+1$, which is equivalent to minimizing the schedule makespan for batch production process, in the conditions of equations (8) and (9). The constraint in equation (11) ensures the condition of non-negativity for the model variable and objective function S_{k+1_k}. The group of constraints in equation (12) provides that the transfer time lag of successive operations k and $k+1$ for each streamed lot i is larger than or equal with a minimum value required to accommodate the transportation time of lot under different combinations of schemes applied for lot processing and operation setup. It is evident that despite the comprehensiveness of this model accompanied by the data given by equations (1) to (7), to solve the model one should use proper binary values for the parameters b_{SP}, b_{MP}, b_{AS} and b_{RS} according to the schemes chosen for lot processing and operation setup.

Definition of Enumeration Model

The enumeration model designed for scheduling the batch production of an item with lot streaming in HFS is based on the algorithm shown in pseudocode below. The approach of the model is to calculate repetitively, for each operation k with $k = 1,\ldots, m-1$ and each lot i with $i = 1,\ldots, n$, the minimum start time lag $S_{k+1_k,i}$ required to exist among operations k and $k+1$ under the constraints of needed transfer

of lot i between operational stages and of applied schemes for operation setup and lot processing. The largest value of $S_{k+1_k,i}$ for all lots streamed from operation k is retained as the start time lag S_{k+1_k} and it is used afterwards to compute start and finish times S_k and F_k for each operation k with $k = 1,\ldots, m$. Specific equations that are used in the model for the calculation of parameter $S_{k+1_k,i}$ are as follows:

$S_{k+1_k,i}$ For the combination of MP and AS schemes:

$$S_{k+1_k,i} = U_k + P_k \cdot \lceil L \cdot i / M_k \rceil + T_k - U_{k+1} - P_{k+1} \cdot \lfloor L \cdot (i-1) / M_{k+1} \rfloor \quad (13)$$

For the combination of MP and RS schemes:

$$S_{k+1_k,i} = U_k + P_k \cdot \lceil L \cdot i / M_k \rceil + T_k - X_{k+1,i} - P_{k+1} \cdot \lfloor L \cdot (i-1) / M_{k+1} \rfloor \quad (14)$$

with term $X_{k+1,i}$ obtained with equation (4);

For the combination of SP and AS schemes:

$$S_{k+1_k,i} = U_k + P_k \cdot L \cdot \lceil i / M_k \rceil + T_k - U_{k+1} - P_{k+1} \cdot L \cdot \lfloor (i-1) / M_{k+1} \rfloor \quad (15)$$

For the combination of SP and RS schemes:

$$S_{k+1_k,i} = U_k + P_k \cdot L \cdot \lceil i / M_k \rceil + T_k - Y_{k+1,i} - P_{k+1} \cdot L \cdot \lfloor (i-1) / M_{k+1} \rfloor \quad (16)$$

with term $Y_{k+1,i}$ obtained with equation (5).

The algorithm for enumeration model is as follows.

```
Read initial data: m, C, B, n, L; P_k, U_k, T_k, M_k for each k; D_k for each k and scheme MP and SP
For k = 1 To m - 1
  Let S_{k+1_k} = 0 for each of AS and RS schemes
    For i = 1 To n
      Calculate S_{k+1_k,i} with equation (13) for the combination of MP and AS schemes
      Calculate S_{k+1_k,i} with equation (14) for the combination of MP and RS schemes
      Let S_{k+1_k} = max (S_{k+1_k} , S_{k+1_k,i}) for each of AS and RS schemes
    Next i
Next k
For k = 1 To m - 1
  Let S_{k+1_k} = 0 for each of AS and RS schemes
    For i = 1 To n
      Calculate S_{k+1_k,i} with equation (15) for the combination of SP and AS schemes
      Calculate S_{k+1_k,i} with equation (16) for the combination of SP and RS schemes
      Let S_{k+1_k} = max (S_{k+1_k} , S_{k+1_k,i}) for each of AS and RS schemes
    Next i
Next k
Let S_1 = 0, F_1 = D_1 for the first operation in each of the four schedules given by combined schemes
For k = 2 To m
  Let S_k = S_{k-1} + S_{k_k-1} for each of the four schedules given by combined schemes
  Let F_k = S_k + D_k for each of the four schedules given by combined schemes
Next k
Write solution data S_k and F_k for each operation k in the four schedules given by combined schemes
```

Spreadsheet implementation of Scheduling Models

For an easier testing and utilization of the proposed models by scheduling scholars and practitioners, both models were implemented in Microsoft Office Excel worksheets, with required solution tools embedded inside the sheets as shown below.

Implementation of Linear Programming Model

Linear programming model and initial data required to be used by the model were arranged inside an Microsoft Office Excel worksheet as displayed in figure 1. The range of cells with green background in figure 1 contains manually-entered or formula-based calculated initial data. Data within this region

is used by the formulas provided in the range of cells with yellow background, where the LP model is located. Only the binary data indicating the alternative use of AS or RS and MP or SP schemes in the model is required to be manually-entered in the yellow part of the sheet. As OpenSolver optimization add-in for Microsoft Office Excel was used to declare the structure of the model (objective function, variables and constraints), this structure is indicated by highlighting and labeling the included cells as shown in figure 1. This feature and many other advantages of OpenSolver over Excel built-in Solver that were shown by Mason (2012) made that this add-in to be preferred for the implementation of LP model. As seen in figure 1, the implemented LP model locates in cell L7 the objective function and single decision variable described in equation (10), in range L7:M7 resides the constraint in equation (11) and in range J7:K11 are placed the constraints in equation (12). Optimal solution to the model is given by OpenSolver with the incorporated Coin-OR CBC linear optimization engine.

Fig. 1: Excel worksheet with data of LP model

Implementation of Enumeration Model

A similar arrangement of model's data in a Microsoft Office Excel worksheet was preferred also in the case of enumeration model, as observed in figure 2. The green range of cells in figure 2 contains manually-entered or formula-based calculated initial data, while the yellow range of cells holds the solution given by the VBA procedure attached to the brown command button with label "Schedule". After initial data is entered and button "Schedule" is clicked, model solution will be written within the dedicated cells. The algorithm for enumeration model shown in previous section was translated into VBA code, as can be remarked in the portion of the code window displayed in figure 3. Slight difference may be observed between the names of some parameters in VBA code and in description of the model from previous section.

Fig. 3: Portion of Excel VBA code window implementing the algorithm of enumeration model

Numerical Example

A numerical example for the utilization of proposed models is presented in the following, by using the initial data already displayed in figures 1 and 2 from previous section. It can be noticed that the example concerns a batch production process with two operations, performed in a hybrid flow shop with the number of machines in the two stages sized in accordance with an imposed limit for process cycle time C of 2 minutes/unit. All the other times taken as initial data are also expressed in minutes. To compare the quality of scheduling solutions with respect to the level of utilization ensured for the group of parallel machines allocated for each stage, the average processing cycle time of operations will be used. A small average processing cycle time of an operation corresponds to a high utilization level of allocated machines. Average processing cycle time C_k concerning the operation with index k will be calculated with the following equation:

$$C_k = \frac{D_k - U_k}{B} \quad \text{.....(17)}$$

The four schedules given by the models with the provided initial data are depicted in figures 4, 5, 6 and 7. It can be checked that in the case of schedules from figures 4 and 5 based on MP scheme, C_1 is 1.56 and C_2 is 1.8, while for the schedules in figures 6 and 7 based on SP scheme, C_1 is 1.8 and C_2 is 2. Despite that all values meet the process cycle limit of 2 minutes/unit, the solutions obtained with MP scheme prove generally to be of a higher quality than those given by SP scheme. The makespan of batch production schedule is shortened by the usage of MP scheme instead of SP scheme for lots processing and also by the application of AS scheme instead of RS scheme for setup of operations.

Fig. 4: Allocation and schedule of equal-size streamed lots at machines under MP and AS schemes

Fig. 5: Allocation and schedule of equal-size streamed lots at machines under MP and RS schemes

Fig. 6: Allocation and schedule of equal-size streamed lots at machines under SP and AS schemes

Fig. 7: Allocation and schedule of equal-size streamed lots at machines under SP and RS schemes

In order to know if and how much the makespan of batch production schedule can be shortened more by the relaxation of the restriction to use equal-size streamed lots, the LP model discussed within this paper was radically adapted and transformed into a MILP model with the following main features: for a known number of not-nil streamed lots in the batch, the integer sizes of lots are optimized in order to give the shortest possible makespan of production schedule and the highest quality of the schedule (measured by C_k values) under different combinations of MP or SP and AS or RS schemes. Solution shown in figure 8 relates the combination of MP and AS schemes, while that in figure 9 refers to the combination of SP and RS schemes. It can be remarked that the schedule makespan is shortened by the solution in figure 8 only with one minute as compared to the solution in figure 4 (with equal-size streamed lots). However, schedule in figure 9 is eleven minutes shorter than the equivalent schedule in figure 7 (with equal-size streamed lots). The roughly 2 percent reduction of production makespan in the first case may not worth the difficulties of monitoring the streaming of variable size lots, while the nearly 8 percent reduction in the second case may probably be worthy.

Fig. 8: Allocation and schedule of optimally-sized streamed lots at machines for MP and AS schemes

Fig. 9: Allocation and schedule of optimally-sized streamed lots at machines for SP and RS schemes

Conclusions

Present study was motivated by the observed limitations of the published researches in addressing to the scheduling issues related to the problem of streaming the batch production of items in multi-stage hybrid flow shops. There is made no connection in the relevant researches between the sizing of the processing stages of hybrid flow shops and the cycle time limits commonly prescribed for the batch production processes of items. Furthermore, existing researches on the optimization of lot streaming production in hybrid flow shops don't mention the multi-machine processing as a possible scheme to allocate the streamed lots to parallel machines in a processing stage, and also they do not investigate the combined influence exerted on the production schedule makespan by the transportation times and processing schemes adopted for streamed lots and by setup times and setup schemes that are used for operations. Under these circumstances, this paper proposes two comprehensive mathematical models, a linear programming model and an enumeration model, that can be used for optimal scheduling the batch production of an item in the case of lot streaming in a hybrid flow shop, under the most general production conditions. A fixed number of streamed lots and an equal size of lots are considered in the models. Proposed models were implemented in Microsoft Office Excel worksheets and were solved to optimality with OpenSolver optimization add-in, in the case of first model, and with a VBA coded procedure, in the case of second model. A numerical example for the utilization of scheduling models was also presented, and obtained solutions were compared with respect to their quality. Two solutions of the lot streaming problem having optimally-sized, different-in-size lots were finally revealed and compared with equal-size lot solutions in terms of makespan length and of feasibility for application in practice. The models presented in this paper are flexible enough to be applied without modification for optimizing batch production schedules of items produced with lot streaming in pure flow shops or even without lot streaming in pure or hybrid shops.

Abstract

The purpose of the article is to assess the impact of individual countries' scientific activity on their economic security. Research methods are as following: index method, ranking, cluster analysis and regression models development. The research of the dependence of a country's economic security on the science development level includes the following stages: calculating the science development index; determining groups of countries depending on the science development level; modeling economic security depending on the level of a country's science development. In the work based on the development of regression models the hypothesis about the influence of scientific developments on the economic security indices is confirmed. The calculation of the world countries' scientific development index was carried out which is a complex index and includes scientific potential evaluation, scientific activity results and evaluation of scientific activity and potential growth rates for 72 countries in the world. This allowed ranking countries by the level of their scientific development and grouping them by scientific results and scientific potential. Three groups of countries were identified: catching-up countries by the science development level, potential leaders in science development and leaders by the science development level. Economic security indicators were modeled according to the scientific development level in the groups of countries. The models developed allow forecasting the values of economic security indicators depending on the scientific developments management in the country.

Keywords: scientific development, scientific development index, modelling, economic security.

Introduction

Providing economic security is one of the main national priorities since it not only guarantees economic independence of a country, stability, efficiency of the society's activity and economic development sustainability, but also facilitates human capital development and stability of a country's national production facilities and institutions. Emergence of economic threats, which have a negative impact on a country economy, infringing upon its economic interests, requires studying factors and indicators of economic security assessment. The problem of economic security identification in the context of a society's scientific and technological development requires studying dependence of the economic development results on the main factors, which determine it.

The urgency of ensuring a country's economic security determines numerous studies among the scientists from all over the world. The studies cover the following problems: identifying economic security as it is (Grigoreva and Garifova, 2015; ILO, 2004), characterizing its main components (Petrova, 2018), determining factors of impact on its provision (EU, 2018; Denezhkina and Suzdaleva,

2014; Karanina, and Loginov, 2017; Astakhova, Reshetnyak, and Ilchenko, 2019; Kyzym, Reshetniak, and Lelyuk, 2019; Kyzym, Khaustova, Reshetnyak and Danko 2020) and identifying its assessment indicators (Shvaiba, 2019; Muzichenko, 2015). Having profiundly studied research on this topic, we have come to conclusion that a country's economic security level is most often assessed by the following (1) single macroeconomic indicators: GDP per capita (current USD), manufacturing and value added (% of GDP) and (2) complex indicators: Human Capital Index (HCI) and the Global Competitiveness Index.

Economic threats are divided into two types: internal and external (EU, 2018; Karanina and Loginov, 2017). Internal threats are a country's inability to provide self-preservation and self-development, weakness of the innovative, scientific and technological development, inefficiency of the state economic regulation system and so on. External threats emerge against the background of changes in the world situation, scientific and technological progress, global problems, excessive import dependence, domination of primary products exports over science-intensive ones, etc.

The country's economic security depends to a significant extent on creating new innovative technologies and production facilities based on the advanced scientific achievements. Scientific activity development is one of the main priorities for government policy in many world countries, because only an ongoing process of the own scientific developments with their further use in the innovative activities at enterprises can ensure the state's global competitiveness. The leading world countries, providing sustainable growth of GDP per capita, use an innovative development model, which means applying and commercializing the results of scientific and scientific-technological activities to ensure the release of new competitive goods and services to the market.

The research of the world countries' scientific-technological development level is carried out by many foreign scholars, e. g., A. Ghani (2009), A. Muzichenko (2015), M. Desai (2002), M. Shahab (2016), D. Shvaiba (2019) and others.

Measuring scientific-technological activity at the national level began in the 1930s. Later. In 1963, «The Measurement of Scientific and Technical Activities: Proposed Standard Practice for Surveys of Research and Development» (known as Frascati Manual (OECD, 2015)) was published, providing a unified approach to measuring the industrial research and technological development was formed.

Now, the most important and reliable information banks that provide information to match the individual world countries' development level, including in terms of science and technology, are the World Bank, the OECD and UNESCO.

The World Development Indicators, a compilation by the World Bank (2020), including the indicators reflecting scientific and technical development for 217 economies and more than 40 groups of countries, is published annually, among others containing the data for several indicators, accumulated for the period of above 50 years. The main indicators that characterize the scientific activity development level include inter alia: internal research and development costs (% of GDP); number of researchers (per 1 million people); share of ICT goods in exports (% of all goods); share of ICT goods in imports (% of all goods); number of scientific articles in the journals that are reviewed; number of technical staff, engaged in scientific research and developments (per 1 million people), share of high-tech goods in exports (% of all goods); number of patent applications, etc.

Taking into account the world economy globalization, implementation of the sustainable development strategy by the leading economies, the idea of the role science plays in a particular country compared to other countries can contribute to its dynamic development and more grounded decision-making as for strategic management in the scientific sphere, justifying its financing support. To evaluate the state of scientific activity in the selected world countries relative to other countries it is necessary to generalize all the individual indicators. A comprehensive assessment of world countries according to different characteristics and determination of their positions relative to other world countries traditionally takes place on the basis of the international rankings and by computating various indices. But, as shown in the analysis (Reshetnyak, 2020), there is no index that would

evaluate scientific development to the fullest. There are indices that include the scientific development assessment as a constituent of the general indices that characterize a country's scientific-technological development, its competitiveness, economic development level, human resources, etc. Therefore, it is necessary to develop an index that would fully reflect the state and trends of scientific development in the country, taking into account the scientific potential, scientific activity results and ongoing changes in the scientific policy, and exploring its impact on the provision of the country's economic security.

Thus, a hypothesis could be suggested that a country's economic security depends on the national scientific development level and a possibility to ensure the scientific potential formation. This paper tries to check this hypothesis.

The purpose of the article is to evaluate the impact of individual world countries' scientific activity on the provision of their economic security.

Materials and Methods

Methods of studying the dependence of a country's economic security on the national scientific development level include the following steps (Figure 1):

(1) calculating the Index of Scientific Development (ISD);
(2) identifying country groups depending on the scientific development level ; and
(3) modelling economic security depending on a country's scientific development level.

In order to assess the impact of scientific development indicators on a country's economic security level it is necessary to calculate an integral indicator, which would take into account indicators of the scientific potential formation, scientific activity results and scientific activity growth rates. Methods of calculating the Index of Scientific Development, which are offered in this paper, are based on the identification of its main three components, or sub-indices: that of the scientific development potential, scientific development results and scientific growth. Sub-index of the scientific development potential characterizes potential possibilities to form scientific resources through two components: education (capabilities in creating specialists of the highest qualification) and science (capabilities in developing the scientific potential through using high-level professionals and financing scientific research). Sub-index of the scientific activity results characterizes scientific activity results through registered scientific products (patents and articles in scientific journals), using intellectual property and income from the high-tech exports. Sub-index of the scientific growth characterizes dynamics of scientific potential growth and scientific activity results .

The Science Development Potential Index includes 10 indicators available from the World Bank database (Reshetnyak, 2020). Indicators F1.1 - F1.9 are direct indicators presented in the World Bank database. Indicator F1.10 (Research and Development expenditure per researcher, USD / person) is calculated on the basis of World Bank data as:

$$F1.10 = \frac{x_1 \cdot x_2}{x_3 \cdot x_4}, \quad (1)$$

where x_1 is the Research and development expenditure (% of GDP), x_2 is the GDP (current USD), x_3 is the Researchers in R&D (per million people), x_4 is 1 million people.

Fig. 1: Model of calculating the index of scientific development (ISD)

Source: own modelling

The sub-index of the scientific activity results includes 10 indicators, the calculations are given in table 1.

Table 1 : Calculating indicators of the scientific activity results index

Indicator	Calculations*
$F_{2.1}$. GDP per researcher, USD / person	$F_{2.1} = \frac{x_2}{x_3 \cdot x_4}$
$F_{2.2}$. High-technology exports (current USD), %	$F_{2.2} = x_5$
$F_{2.3}$. High-tech exports per technician, USD / person	$F_{2.3} = \frac{x_5}{x_3 \cdot x_4}$
$F_{2.4}$. Fees for Intellectual Property Use, Researcher Revenue, USD / person	$F_{2.4} = \frac{x_6}{x_3 \cdot x_4}$
$F_{2.5}$. Intellectual Property Use Fees, Payments per Researcher, USD / person	$F_{2.5} = \frac{x_7}{x_3 \cdot x_4}$
$F_{2.6}$. Ratio of Intellectual Property Use to Payments, unit	$F_{2.6} = \frac{x_6}{x_7}$
$F_{2.7}$. Patent applications from residents for one researcher, unit / person	$F_{2.7} = \frac{x_8}{x_3 \cdot x_4}$
$F_{2.8}$. Non-resident patent applications for one researcher, per person	$F_{2.8} = \frac{x_9}{x_3 \cdot x_4}$
$F_{2.9}$. Scientific and technical journal articles per researcher, unit / person	$F_{2.9} = \frac{x_{10}}{x_3 \cdot x_4}$
$F_{2.10}$. Trademark applications for one researcher, unit / person	$F_{2.10} = \frac{x_{11}}{x_3 \cdot x_4}$

*where x_5 is the High-technology exports (current USD), x_6 is the Charges for the use of intellectual property, receipts (BoP, current USD), x_7 is the Charges for the use of intellectual property, payments (BoP, current USD), x_8 is the Patent applications, residents), x_9 is the Patent applications, non-residents, x_{10} is the Scientific and technical journal articles, x_{11} is the Trademark applications, total

Source: own compilation

Indicators of the Scientific growth sub-index are calculated on the basis of the World Bank data for 5 years as a geometric mean of their growth rates.

All variables are normalized in the [0, 1] range for adjusting for differences in terms of the index indicators and variation ranges. Data scaling is carried out taking into account the minimum and maximum values of each variable in the index indicators using the formula:

$$I_{indic} = \frac{x_f - x_{\min}}{x_{\max} - x_{\min}} , \quad (2)$$

where I_{indic} is the index, which is calculated for individual indicators, x_f is the actual value of an individual indicator, $x_{\min}$ is the minimum indicator value, which is observed in the studied countries, $x_{\max}$ is the maximum indicator value, which is observed in the studied countries.

Sub-indices of the scientific development potential (SDP), scientific activity results (SAR) and scientific growth (SG) are calculated as an arithmetic mean of the obtained values of individual indicators, which characterize them. Index of scientific development (ISD) is a geometric mean of these three sub-indices: $ISD = \sqrt[3]{SDP \times SAR \times SG}$.

Further, we analyze the obtained results and divide the countries into groups taking into account data by three sub-indices and resulting index with the use of the cluster analysis. In order to identify a number of clusters and proximity of countries with respect to scientific development, we apply the hierarchy classification applying the rule of unification by the complete-linkage clustering with the Euclidian distance used as a proximity measure.

Dependence models of indicators, which characterize a country's economic security , on the scientific development level by specified clusters are developed at the final stage. The paper uses the linear regression model $f(x, \beta_0, \ldots, \beta_k) = \beta_0 \phi_0(x) + \ldots + \beta_{k-1} \varphi_{k-1}(x)$, where $\varphi_0(x), \ldots, \varphi_{k-1}(x)$ is a system of functions. The obtained models are assessed using the criterion of R^2, which is calculated as:

$$R^2 = 1 - \frac{\sum_{i=1}^{k} (y_i + \tilde{y}_i)}{\sum_{i=1}^{k} (y_i - \bar{y}_i)} \tag{3}$$

where k is the number of observations, y_i is the value of the economic security indicator, $\bar{y} = \sum_{i=1}^{k} y_i \Big/ k$ is an average value of the economic security indicator and $\tilde{y}_i$ is a model value, obtained by the assessed parameters.

Results and Discussion

In accordance with the offered methods (Figure 1), the paper contains calculations of sub-indices of the scientific development potential, scientific activity results and scientific growth, as well as the index of scientific development for 72 countries in the world [13]. The paper also contains ranging of the world countries in accordance with the calculated index of scientific development. Thus, the United States took the 1st place in the rating (ISD – 0.463), Singapore – 2nd place (ISD – 0.425), Switzerland – 3rd place (ISD – 0.419), Japan – 9th (ISD – 0.327), China – 12th place (ISD – 0.317), Greece – 46th place (ISD – 0.191), Ukraine – 59th place (ISD – 0.153) and Pakistan – 72nd place (ISD – 0.081). However, the country rating was different by individual indices: (1) sub-index of scientific development potential – 1st place in the rating is taken by Switzerland (SDP – 0.742), 2nd place – by the US (SDP – 0.637), 3rd place – by Denmark (SDP – 0.615), 47th place – by Ukraine (SDP – 0.238); (2) sub-index of the scientific activity results – 1st place in the rating is taken by the US (SAR – 0.286), 2nd place – by Singapore (SAR – 0.278), 3rd place – by Luxemburg (SAR – 0.257), 64th place - by Ukraine (SAR – 0.035); and (3) sub-index of scientific growth – 1st place in the rating is taken by China (SG – 0.604), 2nd place - by the US (SG – 0.545), 3rd place – by Slovak Republic (SG – 0.542) and 47th place – by Ukraine (SG – 0.424).

Further, we conducted the cluster analysis of the obtained results in order to divide the world countries into groups taking into account the data by the three sub-indices and index of scientific

development using the Statistica 10 package. Hierarchy classification was applied, which allowed allocating 3 clusters. The cluster nature was checked using the K-average method based on the variance analysis to identify the significance of difference between the obtained clusters (Table 2).

Table 2: Variance analysis to identify the significance of difference between the obtained clusters

Indicator	Between SS	cc	F	Level of significance *p*
Index of scientific development (ISD)	0.247	69	243.423	0.000
Sub-index of scientific potential	0.201	69	12.581	0.000
Sub-index of scientific activity results	0.156	69	9.168	0.000
Sub-index of scientific growth	0.247	69	243.423	0.000

Source: calculated by the data (WB, 2020)
So, $p < 0.05$, which shows a significant gap between the clusters.

Thus, we obtained the following country groups by the level of their scientific development:
Cluster 1 represents catching-up countries in the scientific development. These are countries, which insufficiently invest in the scientific potential development, demonstrate insignificant results of scientific activity with low rates of increase in the scientific potential and scientific and technological activity results. This cluster includes the following countries: Columbia, Malaysia, Mexico, Chile, Philippines, Croatia, Tunisia, Romania, India, Salvador, Bulgaria, Venezuela, Ecuador, Montenegro, Ukraine, Argentina, Kazakhstan, Moldova, Serbia, Madagascar, Guatemala, Bosnia and Herzegovina, South Africa, Morocco and Egypt.

Cluster 2 represents potential leaders in scientific development. These are countries, which invest in the scientific potential development, use new technologies, ensure achievement of significant scientific results; however, the rates of their growth are lower than those of the leaders. This cluster includes the following countries: China, Malta, Panama, New Zealand, Italy, Cyprus, Czech Republic, Hong Kong, Spain, Hungary, Costa Rica, Lithuania, Slovak Republic, Poland, Latvia, Estonia, Brazil, Greece, Portugal, Uruguay, Turkey, Russian Federation and Georgia.

Cluster 3 represents leaders in scientific development. These are countries, which are on the frontline of independent scientific research and implementation of scientific results, which demonstrate high achievements in formation and development of the scientific potential, have significant scientific and technological achievements and ensure high rates of growth of the scientific potential and results. This cluster includes the following countries: the United States, Singapore, Switzerland, Luxemburg, Finland, Ireland, South Korea, the Netherlands, Japan, Denmark, Sweden, the United Kingdom, Germany, Norway, France, Belgium, Israel, Australia, Austria, Canada, Slovenia and the United Arab Emirates.

The next step of the study is to identify the dependence of economic security indicators on the country's scientific development level. Thus, the impact of the index of scientific development on GDP per capita is assessed as significant, as the correlation ratio is 0.8401. The obtained results are confirmed both by the regression model and graphically (Figure 2). It is possible to separate the country groups, obtained in the result of the cluster analysis.

Fig. 2: Dependence of GDP per capita in the countries on the Index of Scientific Development (ISD)

Source: built using our own calculations and data (WB, 2020)

Models of the dependence of other economic security indicators on the countries' scientific development level and by the country groups are presented in Table 3.

Table 3: Models of the dependence of other economic security indicators on the economic development level by the country groups

Indicators of economic security	Cluster 1	Cluster 2	Cluster 3
GDP per capita (current USD)	y = 227371x – 26411; R² = 0.8401		
	y = 13242x² + 24830x - 101.91 R² = 0.5778	y = -615520x² + 352496x - 29056 R² = 0.6307	y = 117754x + 15764 R² = 0.7387
Manufacturing, value added (% of GDP)	y = 60.587x + 1.2022; R² = 0.7765		
	y = 51.974x + 4.6102 R² = 0.4542	y = 126.6x – 15.486 R² = 0.6069	y = 106.3x – 15.3 R² = 0.5431
Human capital index (HCI)	y = 0.7271x + 0.5123; R² = 0.628		
	y = 0.775x + 0.6581 R² = 0.3154	y = 0.1576x + 0.725 R² = 0.3048	y = 0.2518x + 0.8704 R² = 0.5235
The Global Competitiveness index	y = 5.9395x + 3.2581; R² = 0.7182		
	y = 6.0366x + 3.2331 R² = 0.498	y = 5.767x + 3.2518 R² = 0.5758	y = 3.5374x + 4.1342 R² = 0.6006

Source: calculated on the basis of the data [(WB, 2020; WEF, 2018; WB, 2018)]

Thus, it is possible to confirm the hypothesis of the dependence of the economic security indicators on the country's scientific development level using the analysis of the obtained regression models and indicators of their adequacy R^2. Impact of the scientific development on individual economic security indicators is different: the biggest impact is on GDP per capita ($R^2=0.8401$), while the smallest one is on the Human capital index ($R^2=0.628$). Impact of the scientific development level on individual economic security indicators in different country groups is also different: it is less than in

the analysis of the general impact (which is justified by the proximity in economic and scientific development of countries, which belong to a respective cluster). However, despite the different levels of impact of the scientific development level on economic security indicators, we can be sure that scientific activity development in a country is a positive phenomenon, which strengthens a country's economic security.

Conclusion

Ensuring economic security is among the main tasks of any country government. Namely, that is why it is very important to identify the main threats and drivers of strengthening economic security within the globalization process. In accordance with the paper goals, it confirms the hypothesis that scientific development influences economic security indicators. To achieve this goal, we calculated the index of scientific development in various countries, which is a complex indicator and includes assessment of the scientific potential, scientific activity results and the growth rates of scientific activity and potential for 72 countries in the world. This allowed ranging the countries by the level of their scientific development and grouping them in accordance with their scientific results and scientific potential. We allocated 3 country groups: catching-up countries in scientific development, potential leaders in scientific development and leaders by the scientific development level. Modelling the indicators of economic security was conducted depending on the level of scientific development in the country groups. The models built give a possibility to forecast values of the economic security indicators depending on the management of a country's scientific development.

Abstract

Through this study we want to generate an overview of the concept of "Green Economy", considered by some specialists a solution to the problems facing all mankind. In the latest research conducted over the last 30 years, it has been found that new concepts have emerged in the global economy, concepts that start from the same premise, namely, how society will manage to create a balance between available resources, which are limited, and the needs or wishes of its members, which are potentially unlimited. Thus, currently it is pursued which of these concepts is more comprehensive, more appropriate, what similarities and differences are between them, and which will answer the best to the present and future needs of society.

Keywords: Green Economy, Development, Policies, European Union.

Classification JEL: F63, O10, O17, P26.

Introduction

As a concept, *the green economy* precedes the bio-economy and the circular economy. It made its debut in 1989 in the Blueprint for a Green Economy report (Pearce et al., 1989), a report requested by the British government in order to see if there is a consensus on the term sustainable development and its implications for measuring the economic progress. A most commonly used definition is the one proposed by the United Nations Environment Program (UNEP) in 2011 which states that the green economy is "the one that results in improved human well-being and social equity, significantly reducing the risks to the environment and the ecological deficit, generate low carbon emissions, is resource efficient and socially inclusive. "

As the concept of the "Green Economy" is hotly debated, it has recently been concluded that it is essential for the proper development of the world economy. Thus, it is followed to find concrete solutions with applicability in the international issue of environmental development as a result of the massive problems generated by the multiple crises that can no longer be solved. At the same time, the international community aims to find long-term alternatives in order to improve the quality of life and eradicate the population poverty as much as possible.

Sustainable economic development requires transformation, but this requires a transition with multiple implications both at the level of governments, as well as at the level of the private sector.

Cite this Article as: Mihaela MUŞAT, Elvira NICA Maria Gabriela HORGA "Green Economy and European Politics" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Thus, a joint effort is needed between the public and private sector, an effort that aims to separate the economic growth from excessive use of resources, and the main objective remains to pursue an increase in quality of life along with reducing environmental risks and social deficit. In order to implement the green economy, it is necessary to ensure a transition and to pursue an economy based on policies and investments that link economic development, biodiversity, ecosystem, climate change, health and well-being of the population in the medium and long term. The transition to the "Green Economy" implies an appropriate focus on knowledge, research and innovation that will create a favourable framework, meant to favor long-term sustainable development.

The new economy, the ecological economy, promotes the economic growth in conditions of increased environmental protection, accelerating the reduction of physical consumption, in favor of capitalizing on information and knowledge, shifting the center of gravity from investment in fixed assets to investment in human capital.

The European Union and the transition to the green economy

The European Union plays a key role in the transition to the green economy, being actively involved in order to relaunch the sustainable development among the European population, as well as among institutions around the world.

The transition to a green economy is mainly driven by a long-term global trend of diminishing resources and rising energy and raw materials prices, a trend exacerbated by Europe's growing dependence on resource imports. To face these challenges, the EU has implemented a number of policies and strategies aimed at supporting the transition to a low-carbon and resource-efficient economy, while strengthening the E.U.'s competitiveness.

The EU is, therefore, trying to create a coexistence of a public-private sectors partnership in order to actively support the special importance of sustainable development both for society and especially for the global economy.

In the European Union development, the phenomenon of globalization is considered as a paradigm, being a double-edged sword, as it supports economies in developing, but at the same time the threat of "falling" does not disappear. In order to follow the European Union development, we must analyze both the economy and the population, which in case of shortages suffers the most.

One of the main actions pursued by the green economy, in the context of the European Union development, is the eradication of poverty, so as to guarantee a better quality of life without affecting the natural resources. For this reason, spreading the green economy concept without taking into account the needs of vulnerable groups and natural deterioration is a mistake, given that a recovery of environmental and social dynamics can be achieved in the short, medium and long term. In 2015, Biswas & Roy proposed the following to achieve these objectives.

Figure 1: Strategies for achieving the objectives of the green economy

Source: Biswas, A. & Roy, M. (2015). Green products: an exploratory study on the consumer behaviour in emerging economies of the East

The green economy development in the European Union

In order to support the green economy implementation in each state, there is a need for the consumers and the business environment deep involvement, along with the implementation of the main framework of measures proposed and adopted at the level of national and international governing bodies. Thus, the objectives of the state on the one hand, and the policies that could be used in the ecological economy on the other hand, must be taken into account.

Table 1: The objectives of the EU member states and political instruments for the green economy development

The long-term goals of states	The political tools that could be used within the green economy
The population well-being and health on long-term	Public investment in sustainable infrastructure
The economic development	Correct pricing
Poverty eradication	Public support for research and development in the field of green technologies
Food security	Social policies for reconciling social objectives with economic policies

Over the time, the European Union's economy has been severely affected by economic crises, with a slowdown in sustainable economic growth, and Europe's population has become more cautious, avoiding to make investments and seeking to reduce its own expenditure, all these actions being fueled by the strict conditions in the field of bank lending, as well as by the alarming figures of the unemployment rate.

At European level, for the population aged between 20 and 64, the unemployment rate has increased from year to year, according to Figure 2. presented below.

Figure 2: Employment rate at European level
