Source: Eurostat

According to data published on Eurostat, the employment rate was 66.7 of the total population in 2002, and a value of 73.4 in 2019.

The increase with the highest value has been visible since 2008, when there was registered a value of 70.2 of the total population in Europe, then there was registered a slight decrease starting with 2009. Since 2015, the employment rate at the European level has registered new increases, registering the value of 70.1 and increasing to 73.4, a value for 2019. It is very important that this rate to reach the highest possible values, because once they have a job, the inhabitants of the European Union ensure their standard of living, and their well-being is visible.

As the well-being of citizens is a key objective of the European Union, it must ensure that the welfare economy is at the heart of policy and decision making process. At the same time, people's well-being and economic growth are interdependent and mutually supportive, and economic development at the European level pursues the rate of GDP growth.

Figure 3: GDP growth rate

Source: Eurostat

The global financial and economic crisis has been present in the EU-28 since 2008, when a considerable reduction in the GDP growth rate was seen, but in 2009 it proved to be a severe recession, when it was registered. a decrease of 4.3%. A recovery was registered in 2010, when the recovery at EU-28 level meant a GDP growth, this being 2.1%, and in 2011 a new growth of 1.8% was seen.

Subsequently, in 2012, the GDP decreased by 0.4%, before to be progressively registered higher positive rates of change in 2013 (0.3%), 2014 (1.7%), 2015 (2.4%), and starting with 2015, the growth was relatively stable.

Conclusions

The green economy, as defined by the recent United Nations Environment Program Report (launched in February 2011), results in improved social welfare and equity, while significantly reducing environmental risks and ecological deficit. The transition to a green economy means policies and investments that will separate economic growth from increasing current intensive consumption of raw materials and energy. A green economy can be thought as a low-emission economy, through the efficient and sustainable use of resources and social inclusion ensuring. In a green economy, revenue growth and employment should be driven by public and private investment which reduce carbon emissions and pollution, increases energy and resource efficiency, and prevent the loss of biodiversity and ecosystem services. The transition to the green economy involves an appropriate focus on knowledge, research and innovation that will create an enabling environment for long-term sustainable development.

As the time goes by, the green economy becomes a model that promotes growth, income and job creation, "green jobs" which automatically generate change when productivity is pursued. The green economy shows a substantial contribution to reducing social inequality between countries and eradicating world poverty. Similarly, it is necessary to address ways of overcoming the ideas of market liberalization and to promote the trade relations on equality terms at European level. At the same time, the green economy involves using natural resources, energy and new technologies along with clean production methods in order to favor the economic growth and the new jobs creation. Because the green economy can lead to a healthy environment and the correct use of ecosystem services, both for the current generation and for future generations, it is necessary to create new models of sustainable consumption and production that do not force the ecosystem.

Regional Development and Cross-border Public Services in the Field of Security

Stepan KAVAN

Faculty of Health and Social Science, University of South Bohemia in České Budějovice
Czech Republic, E-mail: stepan.kavan@email.cz

Abstract

The paper focuses on the topic of regional development and cross-border public services in the field of security. The topic is dealt in the conditions of cross-border cooperation of the German, Austrian and Czech sides of the Euregion. The aim of the paper is to characterize the basic public services in the field of security and to describe the individual areas that are contractually treated. The research process and methodology for this case study was very demanding, as a comprehensive analysis cross-border public services. In order to present a lively picture of cross-border public services, an extensive on-line research had to be realised because relevant information was scattered across a wide range of different sources and different languages. The Euregio-wide introductory analysis and especially the assessment of future development perspectives sucurity in the fields of helicopter emergency medical care shows that there are still considerable potentials for optimising existing cross-border public services and for developing new cross-border public services in the trilateral cooperation area.

Keywords: Cross-border Public Services; Disaster Management; Emergency; Regional Development, Security

Introduction

The trilateral Euregio Bayerischer Wald-Böhmerwald-Unterer Inn (hereinafter: "Euregio") was established in 1993 and consists of three sub-sections: (1) the Bavarian section "EUREGIO Bayerischer Wald-Böhmerwald-Unterer Inn e. V." with its office seat in Freyung, (2) the Austrian section "Euregio Bayerischer Wald-Böhmerwald / Regionalmanagement Mühlviertel" with its office seat in Freistadt and (3) the Czech section Euroregion Šumava-jihozápadní Čechy with its office seat in Klatovy. (Dušek, 2013; Dušek, 2015) Across borders, these three sections form a working community with the trilateral "Euregio Assembly" as the supreme cooperation organ.

On the German, Austrian and Czech sides of the Euregio, the cooperation area includes different territorial administrative units. In Germany, within the federal free state of Bavaria (hereinafter: "Bavaria"), the Euregio covers the county of Cham in the government district Upper Palatinate (Regierungsbezirk Oberpfalz) and the counties of Regen, Freyung-Grafenau, Straubing-Bogen, Deggendorf, Passau and Rottal-Inn in the government district Lower Bavaria (Regierungsbezirk Niederbayern). In Austria, within the federal state of Upper Austria, the Euregio covers the political districts of Perg, Freistadt, Rohrbach and Urfahr-Umgebung (i.e. the part called Mühlviertel is not a territorial administrative unit). In the Czech Republic, the Euregio covers the districts Domažlice and Klatovy in the Pilsen Region (Plzeňský kraj) and the districts Prachatice, Český Krumlov and Strakonice in the South Bohemian Region (Jihočeský kraj), with Strakonice not being adjacent to the state border.

These administrative units account for around 1.2 million inhabitants, of which two thirds live on the Bavarian side - 901,507 inhabitants and the remainder third on the Czech and Austrian sides - Czech part: 262,598 inhabitants; Austrian part: 187,632 inhabitants (Dokoupil, 2014; Kročová, Kavan, 2019).

Recently elaborated spatial analysis for the entire Bavarian-Czech border area clearly recommends that a maintenance and supply of reasonably accessible services of general interest to the population in the border areas should be done by cross-border municipal cooperation in order to better cope with the consequences linked to demographic change (i.e. population aging and declining population numbers). This cross-border municipal cooperation should coordinate the service offer on both sides of the border and open up the use of facilities for residents of the neighbouring country (e.g. hospitals, doctors, kindergartens, schools). This can also involve the conclusion of local-level cooperation agreements by which a shared use of sports facilities, swimming pools, theatres or libraries is agreed (Kováčová et al., 2014; Malerova, Pokorny, 2017). In both cases, the goal is to avoid duplication of structures, to reduce costs and to offer the broadest possible service supply (Bayerisches Staatsministerium der Finanzen, für Landesentwicklung und Heimat, 2015; Kazansky, Adašková, 2011).

The aim of the paper is to characterize the basic public services in the field of security and to describe the individual areas that are contractually treated.

Methodology

The research process for this case study was very demanding, as a comprehensive analysis cross-border public services (hereinafter: "CPS") in the Euregio did not yet exist for policy areas other than public local transport. In order to present a lively picture of CPSP, an extensive on-line research had to be realised because relevant information was scattered across a wide range of different sources and different languages (e.g. articles in local newspapers, press announcements, websites of stakeholder organisations etc.).

This broad information base was used for analysing the current state-of-play The analysis addresses a number of core elements that were introduced by the "conceptual framework" elaborated in the Inception Report for this study project. These are (Stumm, 2018):

- the cross-border needs / opportunities motivating a set-up of CPS,
- the legal framework conditions for CPS,
- the production base for a provision of CPS,
- the tasks and intervention approaches of CPS for addressing identified needs and lastly,
- the organisational structures and processes for delivering CPS.

The entire analysis devotes particular attention to unveil the complex interplay between border-related or country-specific contextual factors and CPS, and also takes a closer look at the different types of actors that are directly involved in delivering the CPS. Only this way it is possible to fully understand why and how the CPS were established and in what way these services are provided on a day-to-day basis.

A good understanding of the interplay between contextual factors and CPS is also relevant for "Euregio-external" readers who seek finding good practices for addressing challenges faced in their own cross-border areas. It helps them judging on whether the chosen cross-border solutions and forms of service (Lošonzi et al, 2016; Kavan, Brehovská, 2016) organisation / delivery include aspects that might fit with their own context conditions and needs.

Results - effects associated with the political dimension of the border

During the past four decades, the status of the politically defined borders within the trilateral Euregio has substantially changed (Dokoupil, 2014). From the pre-1990 status as an already open EEC-EFTA border (DE-AT) or as largely closed "Iron Curtain" borders that divided political and economic systems (DE-CZ, AT-CZ), they gradually evolved in the period 1994-2004 to "contact zone borders". This allowed in some parts of the Euregio a stronger cross-border integration due to EEA/EU and EU membership (DE-AT), while in other parts still important closure effects existed due to the presence of external EU-borders (DE-CZ, AT-CZ).

The current borders of the Euregio are all internal EU borders, either between old EU Member States (DE-AT) or between old and new Member States (DE-CZ, AT-CZ), with all three countries being members of the Schengen area. Since the lifting of last mobility restrictions for Czech citizens in 2011, the borders facilitate in principle all sorts of cross-border exchange relations. However, a "currency border" still separates Eurozone Members (DE, AT) from a non-Eurozone Member (CZ).

Nevertheless, the political borders between the three countries continue to be "meeting points" of different national governance systems and of diverging legal provisions or administrative proceedings. These differences may lead to obstacles that adversely affect all kinds of cross-border interactions. Due to the complex trilateral border context within the Euregio, adequate legal framework conditions for cross-border cooperation have to be in place so that an ongoing provision of existing CPS or the development of new CPS is facilitated.

However, the three countries concerned by the Euregio have not concluded bilateral interstate agreements on general decentralised cross-border cooperation that apply the Council of Europe's Madrid Outline Convention of 1980. This meant for a long time that the scope of themes and practices by which local or regional authorities are allowed to act across borders as well as the legal tools they may use for formalising cooperation have mostly derived from different country-specific constitutional provisions and other domestic secondary laws on territorial authorities.

In 2006, however, Regulation (EC) 1082/2006 introduced the "European Grouping of Territorial Cooperation (EGTC) as a new EU-wide legal instrument that also regional and local authorities from the Euregio can use to formalise their cooperation. For the period 2014-2020, the amended Regulation (EU) 1302/2013 was adopted. New domestic legal implementing provisions were adopted already in 2015 by the Czech Republic, but only in 2017 also by Upper Austria and Bavaria (CoR, 2018).

CPS may also be initiated and further developed on ground of theme-specific interstate agreements or that provide for cross-border cooperation in particular policy areas. The area of the trilateral Euregio is covered by a number of theme-specifc agreements concluded between the national governments or between neighbouring regions, which often also allow CPS to be developed or further deepened. Some agreements exist already since a while (i.e. police cooperation; mutual assistance in the event of disasters or serious accidents), while others were concluded more recently with a view to put already existing but largely informal cooperation on a more solid legal ground (i.e. rescue services; fire-fighting services).

(1) The German-Czech interstate agreement on cooperation between police and border authorities was signed already in 2000 (Regierung der Bundesrepublik Deutschland, 2002), on ground of which cooperation between police and border control authorities of both countries is taking place since 2002. Just before the Czech Republic's joining to the Schengen Area, a "Joint Centre of German-Czech Police and Customs Cooperation" in Petrovice (CZ) / Schwandorf (DE) was established in 2007; i.e. located outside the Euregio area. This Joint Centre also coordinates police cooperation in the German-Czech border zone covered by the Euregio.

(2) The Austrian-German treaty on cross-border police security and criminal law cooperation was signed in 2003 and entered into force on 1 December 2005 (Republik Österreich, Bundesministerium für Inneres, 2018b). In the event of cross-border operations, for example, this agreement makes it possible that Bavarian police officers are subordinated to Austrian security authorities for the performance of police enforcement tasks, including sovereign powers, which in practice puts them legally on an equal footing with their Austrian colleagues (Bayerisches Staatsministerium des Innern und für Integration, 2018).

Bilateral police cooperation has developed further between 2015 and 2017, first in form of a common reaction to growing flows of migrants from countries of the Middle-East that had as their destination Austria and Germany. In November 2015, the ministries of the interior of Germany, Bavaria and Austria had set up a provisional Joint Centre for border police cooperation in Passau. The center had worked well and made an important contribution to police cooperation, even beyond the then special

situation. Therefore, in March 2017, the Ministers of the Interior of Germany and Austria signed an agreement on the permanent establishment of the Joint Centre in Passau. Officials of the German Federal Police, the Bavarian State Police and the Austrian police will work closely together to support police cooperation in the border area (Bundesministerium des Innern, für Bau und Heimat, 2017), Wochenblatt, 2017).

(3) Interstate agreements on mutual assistance in the event of disasters or serious accidents were concluded between Germany and Austria - in force since 1992 (Bundesamt für Bevölkerungsschutz und Katastrophenhilfe, 2018a), between Austria and the Czech Republic - in force since 2000 (Republik Österreich, Bundesministerium für Inneres, 2018a) and also between Germany and the Czech Republic - in force since 2003 (Bundesamt für Bevölkerungsschutz und Katastrophenhilfe, 2018b). These agreements cover also the area of the Euregio and usually regulate various technical/procedural and financial matters linked to voluntary assistance missions in the neighbouring countries, e.g. cooperation procedures for preventing and combating disasters, the setting up of contact points, rules for facilitating border crossings of disaster relief teams and the import / export of relief goods or equipment; questions of operational management, reimbursement of costs, claims for damages or the performance of joint exercises etc. However, these agreements do not explicitly provide for cross-border cooperation between regional- or local-level authorities in this matter.

(4) A framework agreement on cross-border cooperation between rescue services was signed in 2013 between the Federal Republic of Germany and the Czech Republic, which entered into force in July 2014 (Regierung der Bundesrepublik Deutschland, 2015; Bundesministerium für Gesundheit, 2013). This agreement sets a legal framework for expanding the already existing informal cross-border cooperation along the borders of the German federal states of Saxony and Bavaria with the Czech Republic. It enables the deployment of German and Czech rescue teams in the border area of the other country and significantly improves the provision of emergency medical care on both sides of the border. The rescue service closest to the place of accident can now provide help across the respective border. Injured people are thus helped more quickly and reliably, because ambulance services can bring patients to the nearest and most appropriate health care facility.

This framework agreement needs to be implemented by additional “cooperation agreements” (Article 4) that are concluded between the competent administrations or the concerned territorial authorities in Saxony, Bavaria and the Czech Republic. The framework agreement therefore specifies what should be regulated in such cooperation agreements (i.e. organisation of the ambulance service, requirements for carrying out an assignment, definition of quality and safety criteria, details of liability insurance or communication methods etc.).

For implementing this framework agreement, a regional agreement on cross-border cooperation of rescue services was signed between Bavaria and representatives of the Czech regions of Karlovy Vary, Pilsen and South Bohemia in October 2016. The agreement sets out guidelines for the coordination of cross-border rescue service operations, for instance on the alerting of emergency services or the carrying out of operations and on the admission to a suitable medical care facility. Responsibilities for its practical implementation are on the Bavarian side with the public “local purpose associations for rescue service and fire alarm” operating the integrated dispatch centres Hochfranken (Hof), North Upper Palatinate (Weiden), Amberg, Regensburg, Straubing and Passau (Bayerisches Staatsministerium des Innern und für Integration, 2016).

This regional agreement will help to further develop the already long-standing and good dayto-day cross-border cooperation between ground-based rescue services from Bavaria and the Czech Republic (BASt, 2006). Some practical implementation question still need to be resolved. Options for this are, among other aspects, currently explored by the cross-border project “Competence and coordination concept cross-border rescue service” that is supported under the programme Interreg V-A Bavaria-Czech Republic and was terminated in 2019 (Bayerwald Echo, 2017; Da Hog’n, 2017).

(5) In January 2016, the Austrian-Czech framework agreement on cross-border cooperation between rescue services was signed (Republik Österreich, Parlament, 2016). This agreement stipulates that in

the neighbouring regions of Lower Austria and Upper Austria as well as in the border regions of the Czech Republic, it will now be possible to provide quick and un-bureaucratic mutual medical assistance in case of emergencies. The emergency service closest to the casualty is coordinated by the dispatch centres of the involved regions implementing the mission.

On ground of the framework agreement, detailed provisions on cross-border cooperation are laid down in regional implementing agreements that were concluded in autumn of 2016 between the Austrian Länder Lower Austria and Upper Austria with their neighbouring regions in the Czech Republic (Guten Tag Österreich, 2016). The Land Upper Austria and the Region South Bohemia signed a rescue agreement in České Budějovice and thereby paved the way for closer cooperation in field of emergency rescue (meinbezirk.at, 2016). Lower Austria concluded a cross-border rescue agreement with the regions South Bohemia and South Moravia (Jihomoravský kraj), which was also extended to the Highlands Region (Vysočina kraj) that has no direct border with Lower Austria (Amt der Niederösterreichischen Landesregierung, 2018).

(6) In May 2017, a cross-border agreement on assistance and cooperation in fire protection was signed between the Bavarian country of Cham and the Czech region of Pilsen. Cross-border contacts and cooperation between fire brigades of the Bavarian and Czech border towns / municipalities are already very good, but they have initiated the conclusion of this agreement to put their cooperation on a legally secure basis. The agreement provides for a clear definition of assistance demand procedures, contact persons and operational sequence, but also includes requirements for the coordination of cross-border firefighting missions (e.g. alerting of emergency services; implementation of assistance missions) as well as for regular joint training and exercises to overcome existing language barriers (Chamer Zeitung, 2017).

Discussion and Results

Nearly all identified services in the Euregio are bilateral CPS, as there is only one CPS involving partners from all three sides (i.e. trilateral forest fire-fighting). For the 16 bilateral CPS within the Euregio, it can be observed that most CPS are established between Bavarian and Czech partners (12 CPS) and that CPS between Bavarian and Upper Austrian partners are fewer in number (4 CPS). Consequently, there exists not yet a bilateral CPS involving Czech and Upper Austrian partners. Two bilateral CPS are examined in more detail under the stock-taking analysis; these are the integrated seasonal cross-border rail / bus tourism service developed around the Ilztalbahn and the first truly cross-border helicopter emergency medical service “Christophorus Europa 3”.

The Euregio-wide introductory analysis and especially the assessment of future development perspectives sucurity in the fields of helicopter emergency medical care shows that there are still considerable potentials for optimising existing CPS and for developing new CPS in the trilateral cooperation area. Nevertheless, especially the joint preparatory work processes for developing new CPS will most likely last for several years and must therefore be thoroughly prepared and continuously supported by relevant stakeholders in the Euregio.

Within the Euregio, a larger number of bilateral theme-specific interstate agreements were concluded between the involved countries. Some exist already since a while, e.g. police cooperation; mutual assistance in the event of disasters or serious accidents, while others were concluded more recently with a view to put already existing but largely informal cooperation on a more solid legal ground, i.e. rescue services; fire-fighting services.

Within the Euregio, shared needs or joint development potentials emerging from the physicalgeographical dimension of the border were and still are the most important reasons for establishing CPS. Related needs and potentials are addressed by more than half of the existing CPS: they concern policy fields such as public local transport, nature protection, emergency medical care, e.g. cross-border helicopter service or civil protection and disaster management, i.e. joint forest fire fighting and flood prevention.

Abstract

The article deals with the problems of building a digital geological model of fourth-generation mineral systems. The places and causes of errors in the digital model of the deposit, and methods of their minimization are considered. The problems of transformation of information on the deposit into structured data models are revealed. The data structure based on the presentation of semi-structured data is developed. The structure is adapted for a relational DBMS and oriented for use in a Web application.

Keywords: Digital Models, Quarry, Database, Semi-Structured Data, Information Systems, Deposit.

Introduction

The beginning of the 21st century was marked by explosive development of information technologies and active digitalization of all aspects of human activity. Mining is no exception. The level and complexity of digital control systems for mining over the past decade has changed dramatically. The introduction of digital solutions has led to a change in the activities of mining companies, and to a natural increase in their productivity. Modern programs for open-pit mining belong to the third generation and are characterized by the developed tools of 3D geometric modeling and visualization, the programs combine the functions of optimizing the main processes.

However, at present, productivity growth in the mining industry has slowed significantly, as mining companies use information technology to improve individual processes, and not the whole production. Enterprises continue to spend efforts to automate old methods instead of upgrading and improving them. A new, fourth generation of information technologies, which is now being formed, should provide a dynamic improvement in productivity.

IVANOVA "3D-Quarry: Digitization of The Geological Model of Deposit Based on A Semi-Structured Data Model" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

But for the total optimization of processes it is necessary to have comprehensive and reliable information, both about the processes themselves, and about the developed field, its structure. The understanding of such processes is based on the concept of "geological model". It should be noted that the concept of the geological model has not yet been formalized.

In the most commonly used understanding, a geological model is a volume imitation of a field stored in a computer memory as a multidimensional object, allowing to investigate and predict the processes occurring during the development in the volume of the field, continuously refined based on new data throughout its operation.

The founders of the theory of geological models in the subsoil were: D. Krige, H. Davis, J. Serra, M. David [1], I. Clark [2], G. S. Koch, Jr., Richard F. Link [3], P. Goovaerts [4], I. B. Tabakman.

In the Russian-language scientific environment the most famous works of Yu. E. Kaputin, M.V. Lesonen, M. S. Sen [5]. The principles of optimization are given in the works of O. V. Stagurova [6]. In the works of A. A. Tverdova, A. V. Zhur [7] carried out an analysis to identify the advantages of the career optimization method based on block models relative to traditional methods used in the Russian Federation.

In Kazakhstan, the issues of digital modeling of deposits were consecrated in the scientific works of K. Kh. Rakishev, A.I. Ivlev, A.F. Tsekhov, D.G. Bukeikhanov and many others.

However, recent studies have established a rapidly growing discrepancy between the true heightened level of complexity of the geological structure of the fields being developed and the simplified concepts of traditional geological exploration, oriented to large deposits with simple averaged parameters.

Methods

In work classical theoretical, mathematical and experimental methods of scientific research has been used. From classical methods used: analysis of the state of design methods for mining, analysis of modern digital systems and algorithms used, analysis of control systems based on artificial neural-like networks and analysis of semi-structured data.

In the development of digital models of deposits, the mathematical and logical apparatus of the theory of artificial neural networks, probability theory-the semi-structured data, methods of discrete mathematics and integer programming used. It also assumes the use of modern programming environments using web- languages.

At the stage of assessing the adequacy of the developed models and systems, the use of methods for planning and setting up experiments, as well as statistical processing of the experimental data, is assumed.

To determine the error of the input data at the inputs and outputs of models, the correlation regression analysis method applied.

Results and Discussion

These discrepancies began to accumulate due to the depletion of rich surface deposits and the need to develop deep deposits with a complex spatial morphology of the boundaries of mineral deposits.

The degree of "adequacy" of geological models is determined primarily by the volume and accuracy of empirical data, the completeness of the use of a priori information, as well as algorithms and methods used in the construction of models.

The causes of inaccuracies in modern geological models can be:

– mismatch of initial data volumes with the size of the Deposit and the complexity of its geological structure;
– low accuracy of initial data;
– inconsistency of modeling algorithms with the volume and accuracy of empirical data;
– a false conceptual model.

At the same time, we should not forget about the use of different units at different stages of field research. When evaluating the field, we use tens, and often even hundreds of meters: when evaluating the location of wells – meters, when evaluating cores – centimeters, microsection – millimeters. Naturally, it also generates systematic errors and loss of accuracy. Although modern automatic measuring systems and positioning systems "try" to reduce these errors to a minimum.

To improve the accuracy in the area of occurrence of mineral resources, firstly, use the methods of hole mesh compaction.

Secondly, in the majority of modern information systems a method of spatial modeling is implemented according to the testing of exploratory boreholes with the possibility of specifying the parameters of ore body placement according to geophysical studies or vice versa [8].

In modern conditions of the state of computing systems, it is possible to refine models based on the results of deposit development, for example, on mining of sides. Although this requires either recalculation of the entire previously created model or the use of “flexible” modeling mechanisms. So now, for example, in most oil and gas companies they are already actively applying the principles of support and updating geological models at all stages of field development. There is a legitimate question why this is not applicable for other types of deposits.

Fig. 1: Units of measure for the elements of the formation of the model of the deposit

The fourth way to improve the adequacy and accuracy of the field model are the methods of paleogeographic reconstruction of the deposit. However, the methodology of paleogeography as a geographical science is under development. There are no monographic studies in this scientific field. Separate articles in Russian-language literature devoted to theoretical and methodological issues in different years were published by M.F. Beklich, A.A. Velichko, K.K. Markov, A.A.Svitoch, Yu.G. Simonov, N.G. Sudakova and etc.

However, neither EurAsEC nor abroad found published generalizing theoretical works that would consider the methodology of paleogeography from a geographical position [9].

Currently, in digital systems to solve the problems of paleographic reconstruction using, as a rule, neural network methods or "closed" algorithms built on the basis of sequestration-stratigraphy and tectonic models

Naturally, the interpolation of exploration data, taking into account geophysical methods, reconstruction and refinement in the process of mining, can significantly improve the accuracy and adequacy of the model.

However, the construction of such a model of the field is associated with a number of problems of new problems. So the explosive development of information technologies forces the enterprises to constantly introduce more and more new methods and approaches to optimize production and enrichment. At the same time, given the diversity and heterogeneity of the tasks being solved by a modern industrial facility, the formation of optimization indicators has to be approached on the basis of a multi-criteria analysis with maximum consideration for the specifics of the production in question.

A characteristic feature of recent decades in the development of digital systems of mineral of the 21st century has been the emergence of new methods and data processing algorithms.

This gives rise to the constant emergence of new, previously unforeseen by the developers of the software data, parameters and values of the simulation objects. Naturally, this also generates a permanent change in the structures of the software databases.

The problems of constant modification of data structures can be reduced to the problems of presenting semi-structured data. Currently, data that is poorly structured is for which the exact structure is not known in advance or may change during use. Naturally, their analysis requires the use of both their own presentation models and processing algorithms, which is in bad agreement with the most common relational DBMS.

According to [10], there are four most significant systems of initial data representation: a tabular method, a method of representing data by multisets, a phase trajectory method, and a procedural representation.

Due to the fact that the implementation of the system still has to rely on the available DBMS, it was decided to partially structure the data and implement the data warehouse based on the tabular method.

For the formation of an adequate geological model, as a minimum, geodata is required, which were preliminarily recorded in essence:

- deposit;
- hole;
- core.

Thus, the structure of the data model for the exploration geological data for the field can be represented by the structure as in Figure 2.

Fig.2: Fragment of the datalogical model based on the geological data of the deposit

For ease of presentation, the field model does not display domains by date/time of data modification/entry, data owner, and who entered them.

To be able to refine the model based on geophysical research methods or to substantiate the well grid, a structure for storing and analyzing the results of these studies is necessary. Research results are usually presented in the form of 2D or 3D maps (sections).

The problem is that currently using various methods of geophysical research: magnetic, gravitational, electrical, seismic, radioactive and geophysical research methods in holes. And each of these methods gives a different accuracy of the study. For example, seismic research methods and magnetic exploration work with clusters of a minimum size of ±5 meters [11], and radiometric can be produced in increments of up to 10-20 centimeters [12].

All geophysical methods of exploration are based on the fact that ore bodies and the surrounding rocks, having different physical properties, either create around themselves in space physical fields that differ from the environment, or react differently to different, artificially created physical phenomena. Accordingly, the analysis can be reduced to the allocation in the space of a deposit of clusters with the same properties and putting them in accordance with various minerals.

Fig.3: Representation of geophysical research methods (seismic and magnetic) and their digitization for geological model

Since for most studies the results are obtained in the form of analog values, an important criterion for the selection of clusters is the choice of the sampling step. Since algorithms for finding an optimal step is not detected, it is decided about the manual step.

For simplicity of presentation the structure of a decision on the presentation of the results in the form of parallelepipeds with dimensions specified by Xb, Yb, Zb.

Thus, a fragment of the datalogical model for the results of geophysical studies can be represented as a 3D model (Figure 4).

Fig.4: Fragment of the datalogical data model for geophysical research of the deposit

In the presented fragment of the datalogical model, for ease of presentation, the structure for storing research documents is not presented.

To implement the mechanisms of paleogeographic reconstruction, a data structure based on data from sequestrant stratigraphy and a tectonic deformation model of the field is required.

Taking into account the above requirements, it is still more rational to use a geological model built on the basis of a unified block model. To present the following restrictions to it:

– use a fixed and uniform for the whole model size and shape of the blocks;
– use the effect of subunits only when necessary for individual mining sites (through the use of additional models of sites);
– to lay the possibility of expanding the number of simulated parameters (strength, fracturing, the content of several useful components, their enrichment for a specific consumer, the content of several components of harmful impurities, etc.).

In this case, the model can be represented by a number of interrelated entities:

– model (the model name, the initial coordinates of the model, the final coordinates of the model, the dimension of the blocks of the model);
– design parameters of the model (the parameter name, the value, the unit of measurement);
– data block (the initial coordinates of the block, the final coordinates of the block);
– block parameter (the parameter name, the parameter value, the parameter class).

For the convenience of describing the components of the block, it is advisable to select a table with a description of the classes of the components of the block (mineral, harmful impurity, etc.).

Due to the fact that more than 90% of the DBMS are relational, the development of datalogical and physical models is currently still more efficient to perform in this form, although you can use nonrelation DBMS. The datalohic model can then be represented by a diagram as in Figure 5.

Fig.5: Datalogical model

In the framework of the project [13], for the implementation of a data warehouse, an analysis of freely distributed web-based DBMS was carried out. It was decided to reject the use of proprietary DBMS immediately for commercial reasons. The analysis of the compliance of the capabilities of the DBMS made it possible to identify and select the relational DBMS MySQL as one of the most common for web projects.

In connection with the preparation of security documents for the developed system, the full physical structure of the database implemented in the MySQL DBMS is not disclosed in this article.

Corporate Social Responsibility in COVID-19 Times – From Work-Life Balance to Work-Life Blend

Simona CINCALOVA

College of Polytechnics Jihlava, Jihlava, Czech Republic
simona.cincalova@vspj.cz

Abstract

Corporate social responsibility is an important factor in how it is accepted by the environment. It influences customers' purchasing decisions and can be taken into account by job seekers. CSR activities have proven to be important and visible during the ongoing crisis. The COVID-19 pandemic has put the organization under the greatest pressure on the technology they have ever encountered. Most companies and their employees have adapted to the changes in the working regime they introduced during the pandemic. The goal of the article is to analyze how to move from Work-Life Balance to Work-Life Blend. It provides a few steps for the smooth progress of work-life blending in each company.

Keywords: Corporate social responsibility, COVID, employees, work-life blend

Introduction

The past decades have seen a growing pressure from various stakeholder groups on corporate firms to consider social and environmental consequences of their operations within their decision making (Engida et al., 2020). There are many of them, companies that have realized that generating nice profits and sending people a paycheck. That they want to bring something good back to the companies where they do business and create. And that they want to do more than just once in a while, fill out a check and send money to charity. There is a simple term for this in English - CSR - Corporate Social Responsibility. Profitability is a famous topic for studies of a lot of authors (e.g. Fiala et al., 2020; Hedija et al., 2017), but has not been the only goal of companies for a long time

A company that subscribes to this concept behaves responsibly not only within its stores but also in the field of environment (Norberg, 2020; Scholz et al., 2020), community (Mahmut et al., 2020; Glonti et al., 2020), education (Haski-Leventhal, 2020); considers the social impacts of the operation of the company.

It's actually a simple idea: If I do business decently and take an interest in the people and the environment around me, I will also gain a competitive advantage. Because what companies build with this approach is a good reputation. And customer confidence. A customer or client who trusts a given brand is a loyal client who likes to return.

Corporate Social Responsibility and COVID-19

The COVID-19 pandemic has put the organization under the greatest pressure on the technology they have ever encountered (Talbot and Ordonez-Ponce, 2020; Galetska, 2020). The outbreak of the pandemic forced organizations to be perhaps the most important social experiment in the future of work, and social distancing fundamentally changed the way we collaborate and interact. Hongwei and Lloyd (2020) argue that Covid-19 pandemic offers a great opportunity for businesses to shift towards more genuine and authentic CSR and contribute to addressing urgent global social and environmental challenges. However, it changes not only where the employees do the work, but also how and what we do.

Cite this Article as: Simona CINCALOVA "Corporate Social Responsibility in COVID-19 Times – From Work-Life Balance to Work-Life Blend" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Many employees perform tasks they could not even imagine before. Examples are textile and clothing companies, which have shifted from day to day to manufactures of protective equipment. Food companies, in turn, produce disinfectants, and IT companies, for example, are developing platforms to allow small traders to sell online while their brick-and-mortar store is closed. (Butler, 2020)

According to Aguinis et al. (2020), CSR policies in response to COVID-19 are created by organizations but are implemented by individual employees. The goal of the article is to analyze how to move from Work-Life Balance to Work-Life Blend. It provides a few steps for the smooth progress of work-life blending in each company.

The current situation is actually a great opportunity to start reorganizing jobs in the organization and let employees take on various responsibilities to better respond to the evolving needs of companies and customers. It's a great opportunity for agile transformation, about which so much has been written. How to prepare for it?

For most full-time employees who are used to commuting to the office, the transition to working from home can be challenging. People communicate more often across a variety of digital communication tools and expect immediate responses. Many of them experience cognitive overload. He gets lost in the organization.

How to Work-Life Blend

With a changing demography and social structure, the work-life balance is according to Bhattacharya et al. (2020) a major concern felt by employees of most organizations. Work-Life Balance is a term for the relationship between the type of working day and housework or family care (balance between paid and unpaid work). Alonso-Dominguez et al. (2020) came to conclusion, that their data indicate that the type of working day affects the balance between paid and unpaid work less than might be expected, since in all cases, it is women who do more unpaid work, while men’s involvement in housework changes little, whether they have a continuous or a split working day.

At present, it seems that Work-Life Balance, when it comes to finding a balance between work and private life, its structure and content, is no longer working (Bhende et al., 2020). We live in a time when it is not possible to separate all our aspects of life well enough. Or even if it were possible, for many people the traditional model with the division of time into working and free time and necessary to ensure the physiological needs of life does not work.

Thanks to - for some because of - technology, our careers, personal and social lives are integrated and difficult to separate. Not only do we mix our personal lives between work responsibilities, but on the contrary, even during holidays or our evening "free time", technology brings us closer and brings us back to work. Moreover, the concept of seeking balance suggests to us that one side is negative. There is nothing negative about "having a job" or "having a personal life". (Alvarez-Perez et al., 2020; Rahman et al., 2020; Chaudhuri et al., 2020)

And that's why Work-Life Blend comes in handy instead of creating individual fixed time zones. Forget the work-life balance. Instead, try to achieve a natural blend of work, social and personal life without remorse. The truth is that to achieve satisfaction with the reality connecting the world of work and private, you will need to make some effort (St-Jean and Duhamel, 2020). It will be difficult, but it will be worth it.

According to available literature and studies of different authors (Mansour and Tremblay, 2018; Peters et al., 2020; Shaw, 2014), a few steps or tips could be determined for the smooth progress of work-life blending in each company (see Figure 1).

Fig. 1: Model for work-life blending. Source: own processing

Today, the deadlines are getting tighter and an individual's job is not only to match that deadline but also to give **quality output**. Due to this work pressure, it becomes exceedingly difficult to maintain a family life. It doesn't matter what work styles and habits you have, but what really matters is the quality of the output for the client.

Trust is essential on the part of the employer. Believe that the employee can set aside time to work. He has **independence** and **responsibility** in his hands and when he needs to, he will receive support and consultation. The employee wants to feel that what one is doing is one's own choice. If I can determine for myself what, when and how I will do it, I will be more motivated than if everything is prescribed to me in detail. This applies not only to employees. Too structured program, kills motivation and destroys **creativity**.

In many companies, driven by orders and prohibitions still prevails. However, for the satisfaction of employees, a functioning mutual **communication** between them and the management is necessary. In these turbulent times, open communication is a prerequisite for transparency. **Talk to people** and find out how people want to do the work activity and try to give them space to implement their ideas. Allow them to freely organize their time and the way they will perform the activity. Teams that organize themselves through “what works and what doesn't”, “what is more or less effective”, etc. feedback loops have the best performance. The boss can design the basic structure of the work and help people with implementation, monitor progress and give constructive feedback.

For many of us, this is unthinkable, and anything to **refuse** is simply not worn now. We are afraid that we will look arrogant in the eyes of others. But then we spend most of our free time doing work that is beyond our normal content. Of course, the occasional help is fine but provided that the person in question or someone on the team repays you. If it's just one-sided, then get paid for your time, or politely decline. But be prepared for strong reasons for rejection. Or suggest that you complete the task instead of another one you were supposed to work on at the time. You will show willingness, but at the same time, you will clearly define the rules.

In a pandemic situation where even cafes and bars are closed in many cities, working from home with limited **interpersonal interaction** (no community life) can evoke feelings of loneliness in some people, which can undermine productivity and engagement. However, it can be beneficial for each employee to participate in regular business phone calls or video calls with their colleagues or to use digital tools for easier collaboration. Examples of suitable measures include virtual coffee sessions, happy hours, book clubs, online gaming and other ways of virtual socializing. While these activities may not replace common rooms, kitchens, and community events in the workplace, they at least help maintain the spirit of the community until life returns to normal.

Conclusions

Modern technologies give us enormous opportunities, but at the same time deprive us of a balance between privacy and work. It's getting harder to keep her. Widespread use of work from home. A mixture of work and personal and family and social life. The phenomenon of recent months.

The coronavirus crisis has caused profound mental changes in thinking about how to continue working and organizing the work of its people. And not only from where to work but also how to (in) flexibly approach the reconciliation of work and personal life from the employee and the employer. The well-grasped Work-Life Blend model allows companies to survive periods of change and crisis. And it can be the answer and potential for the more challenging challenges of today's volatile world.

However, all steps must be individualized and adapted for a specific company. Flexible settings may not work for everyone. Needs change over time, depending on the things we are currently experiencing and solving (childcare, help for parents, health problems, internships abroad, etc.).

Abstract

If consumption needs of a household are deterministic (except the stochastic factor of life-length) and a life-long financial plan allows for incomplete retirement, dynamics of a cumulated net cash flow (cumulated surplus) reflects a financial situation of the household in the best manner. The goal of the paper is to combine a two-person survival process with the expected discounted utility model, so that it suits Feldman, Pietrzyk and Rokita (2013) framework. This will constitute a theoretical basis for constructing an algorithm that will facilitate household financial plan optimization based on Monte Carlo method. The outcome of a financial plan is reflected by a set of term structures of cumulated surplus, corresponding to a set of scenarios. For a cumulated net cash flow model to be utilized as a tool for facilitating an optimization plan, it is required to capture and analyse the entire process, not just the expected trajectory. In a discrete version, all trajectories of the process may be generated. The article presents a proposal of their further use. This concept differs significantly from the traditional approach in which discounted utilities of consumption have been multiplied by the subsequent conditional probabilities of survival. That might function well for an individual for whom only two survival states (alive or not) are possible. In our proposal, each possible trajectory of the process is weighted with its unconditional probability. Such an approach seems to be much better tractable than any one with conditional probabilities applied to each moment on the timeline.

Keywords: household life-long financial planning, cumulated surplus, optimal financial plan, longevity risk, early-death risk

Introduction

Household life-long financial planning is already a well-established area of research, but there is still vast potential to implement improvements to the yet existing models. Having led critical discussions and presented conclusions on the state of the art, Feldman, Pietrzyk and Rokita (2013) proposed a sketch of a model that could help to overcome some deficiencies of the existing approaches. This article develops a component which lies fundaments for a model to be created by the authors. Such a model is a cumulated surplus process. The discussion is limited here to a discrete version which coincides in many respects with an operation mode of a personal finance planner. A two-person household is taken into consideration (single individuals are recognized as specific kinds of two-person households, with non-existent domestic partner). Any financial manifestation of other persons is treated as part of a financial situation in which two main

members are considered (e.g. children, parents dependent due to an old age, etc.).

Classical models (Modigliani, Brumberg (1954), Yaari (1965)), as well as the majority of newer approaches stemmed from the former (e.g., Bodie at al. (2007), Bodie at al. (2012), Huang at al. (2011)), are more appropriately suited for individuals rather than households.

The process of survival lies the foundation for a two-person household financial plan. Consumption or a cumulated surplus process may be constructed on its basis. Therefore, as a consequence of facets raised by Feldman at al. (2013), a cumulated surplus process will be discussed.

The model

The proposal is composed of two main components: the two-person household survival process and a set of cumulated surplus trajectories derived from it. The cumulated surplus depends, among others, on an income, consumption and cumulated investment, and thus it is crucial to establish whether two or one household member is alive, who is alive (a member whose income is higher or lower) and, finally, if the moment of death was before or after the expected natural death time of a given person. In the further discussion it is assumed that the survival processes of the two persons are independent.

Survival Process

Let $Ai(t)$ denote random variable with value of 1 if person i is alive in period t and 0 otherwise. The composition of a household, namely – the information who is alive, will be further on denoted as $St(t)$. Formula 1 defines values of random variable $St(t)$:

$$St(t) = \begin{cases} State1 & if & A1(t) = 1, A2(t) = 1 \\ State2 & if & A1(t) = 1, A2(t) = 0 \\ State3 & if & A1(t) = 0, A2(t) = 1 \\ State4 & if & A1(t) = 0, A2(t) = 0 \end{cases} \tag{1}$$

The unconditional probability of $State\ i$ (given that at the moment t_0, when the financial plan is prepared, both household members are alive, i.e.: $St(t_0) = State1$) will be denoted as:

$$P(State(t) = State\ i) \equiv P(State\ i; t).$$

The unconditional probabilities of states are as shown in Formula 2:

$$\begin{aligned} P(State1; t) &= S(t; x_1) \cdot S(t; x_2) \\ P(State2; t) &= S(t; x_1) \cdot [1 - S(t; x_2)] \\ P(State3; t) &= [1 - S(t; x_1)] \cdot S(t; x_2) \\ P(State4; t) &= [1 - S(t; x_1)] \cdot [1 - S(t; x_2) \end{aligned} \tag{2}$$

where:

$S(t; x_i) = P(D_i \geq t; z_i(t_0) = x_i)$ – the unconditional survival probability,
$z_i(t)$ – the age of a person i at the moment t,

x_i – the age of a person i on the day of planning.

Survival probability $S(t; x_i)$ is estimated by applying a survival model (e.g., Gompertz (1928)).

Nine types of conditional probabilities are used. Let symbol $p.(t)$ denote the conditional probability of survival by Person 1, $.p(t)$ – the same for Person 2, $q.(t)$ – the conditional probability of not surviving to period t by Person 1, under the condition that this person was alive in period $t-1$, $.q(t)$ – the analogous conditional probability for Person 2. And, just for the sake of order: $\theta.(t)$ – the conditional probability of not surviving to period t by Person 1, under the condition that such a person was already dead in period $t-1$, which naturally equals 1. And finally: $.\theta(t)$ – like $.\theta(t)$, but for Person 2. Then, for example, the symbol $pp(t)$ denotes probability that Person 1 is alive at the moment t, under the condition that this person has survived to $t-1$, and, at the same time, Person 2 is alive at t, under the condition that this person was alive in $t-1$ (i.e., $pp(t) \equiv p.(t) \cdot .p(t)$).

If evolution of the survival process was described in the form of a scenario tree, its branches would be assigned to the conditional probabilities of the following types: $pp(t)$, $pq(t)$, $qp(t)$, $qq(t)$, $p\theta(t)$, $\theta p(t)$, $q\theta(t)$, $\theta q(t)$, $\theta\theta(t)$.

The construction of the the scenario tree is subordinated to the following simple rule: $State1$ may be preceded only by $State1$; $State2$ – by $State1$ or $State2$; $State3$ – by $State1$ or $State3$; $State4$ by any other states. And inversely: each $State1$ may generate in the next step either of these states: $State1$, $State2$, $State3$ or $State4$; each $State2$ may generate in the next step either $State2$ or $State4$; each $State3$ may generate in the next step either $State3$ or $State4$; each $State4$ may generate thereafter only next $Stete4$.

The phenomenon, however, becomes to some extend more complex because each particular trajectory of the survival process generates a different trajectory of the surplus. Since the surplus process is cumulative and yet path-dependent, it is far insufficient to recognize the conditional probability in a given period and possible evolution of the process in the future. Therefore, each trajectory should be treated individually throughout the entire analysis process (usu. the period when all conditional probabilities of survival diminish below some margin).

Even a component of the survival process tree (fig. 1) indicates how fast the number of trajectories grows with the period index.

Fig. 1: Survival process tree – a developed version; shortened to the first 6 periods

It is now important to be able to construct a simple algorithm of generating all trajectories in an organized way and build trajectories of cumulated surplus on them. A good start for this is to determine the number of all trajectories, which is of course equivalent to the number of branch-ends in the tree. The rule in this respect is simple:

- each Stete1 may generate in the next step either of the states: Stete1, Stete2, Stete3 or Stete4;
- each Stete2 may generate in the next step either Stete2 or Stete4;
- each Stete3 may generate in the next step either Stete3 or Stete4;
- each Stete4 may generate in the next only next Stete4.

The conditional probabilities change periodically. The unconditional probability of a trajectory is just a product of the conditional probabilities along this trajectory.

Numbers of subsequent scenarios that may originate from a node with a given state value are provided in Table 1.

Table 1: Number of future scenarios from period t up to t_n

State in period t (parent node)	No. of new branches originating
$State1$	$(t_n - t)^2 + 2(t_n - t) + 1$
$State2$	$(t_n - t) + 1$
$State3$	$(t_n - t) + 1$
$State4$	1

The main conclusion from Table 1 is depicted as the total number of possible different scenarios. Assuming that at the moment $t_0 = 0$, both persons are alive ($St(0) = State1$), the number of all trajectories is:

$$N = (t_n - 0)^2 + 2(t_n - 0) + 1 = t_n^2 + 2t_n + 1 \tag{3}$$

Having identify the number of the survival process trajectories and the unconditional probability of each, it is possible to build the process of financial surplus.

Cumulated Surplus Trajectories

As the only stochastic element of the model so far is the survival process, being familiar with all its trajectories is sufficient to determine all trajectories of a cumulated surplus process.

A general concept of the model may be captured by examining its input and output.

1. Input:

- Age at t_0 $(x_1,\ x_2)$
- Retirement age ($zR_1 = z_1(R_1; x_1),\ zR_2 = z_2(R_2; x_2)$)
- Expected length of life at t_0 $(E(D|z_1(t_0; x_1)),\ E(D|z_2(t_0; x_2)))$
- Income from job at t_0 $(Ic_1,\ Ic_2)$
- Income growth rate ($g_{Ic_1},\ g_{Ic_2}$)
- Replacement rate ($\zeta_1,\ \zeta_1$)
- Constant common consumption at t_0 (FC)
- Individual consumption at t_0 $(VC_1,\ VC_2)$
- Consumption growth rates ($g_{FC},\ g_{VC_1},\ g_{VC_2}$)
- Proportion of investments (into private pension schemes) by Person 1 and Person 2 ($\upsilon_1,\ \upsilon_2 = 1 - \upsilon_1$),

- Return on investment (r_{Iv})
- Return on 'uninvested' surplus (r_{Spl})

2. Output:
(a) Direct:

- Trajectories of consumption process
- Trajectories of surplus process

(b) Indirect:

- Income process (stochastic, but not path-dependent)
- Consumption process (in pre-retirement period – stochastic but not path-dependent; in retirement period – stochastic and path-dependent; financed partially by private pension, thus – depending on cumulated investment – and partially by accumulated surplus)
- Cumulated investment process (stochastic and path-dependent – succession to pension capital of a spouse who dies before her/his retirement age)

Numerical Example

Household parameters: a 32 year old woman (Person 1) and 34 year old man (Person 2), with income at t_0 25 000 p.a. each. Income growth rate (real terms): 2% (both). Individual consumption of Person 1 at t_0: 10 000, individual consumption of Person 2 at t_0: 10 000, Common household consumption (not attributed to any particular person) at t_0: 20 000. Individual consumption growth rate (real): 2%. Common household consumption growth rate: 1.6%. Individual share in total investment (pension scheme contributions) in pre-retirement period: $\upsilon_1 = 60\%$ – Person 1, $\upsilon_2 = 40\%$ – Person 2. Retirement age: 67 for both. Expected further length of life at t_0: 50 years for Person 1 and 40 years for Person 2. Dispersion parameter (for Gompertz model): 10 years for both. Rate of return on investments: 4%. Rate of return on 'uninvested' surplus: 0% in real terms (i.e., makes up for inflation only).

To accelerate the calculations, the scenario generator employs 5-year periods. Analysis horizon (t_n): period no. 18 (corresponding to 90 years since t_0). The younger household member would be 122 year old then.

The surface plot in Fig. 2 shows how the shape of the cumulated surplus trajectory is influenced by realizations of a survival scenario. As it can be observed, for the set of parameters defined above, a financial stability of a household is more immune against the longevity risk than a premature death. For long-life scenarios (those with low indices) a cumulated net cash flow is increasing with relatively high slope and never falls below zero. Certainly, setting different retirement goal profile (υ_1, υ_2) would result in different set of cumulated surplus trajectories. What a financial planner is obliged to do in this respect is, however, not just to compare plots like the one depicted in Fig. 2, but rather to use an optimization model that takes all these trajectories together.

Fig. 2: Cumulated surplus built on survival scenarios

Remarks on further application

Having calculated trajectories of the cumulated surplus and the unconditional probability for each, one may calculate the expected discounted utility or, more generally, the expected discounted value function. Under the assumptions of the model, the decision variable lies in the proportion of means invested by a household in a private pension scheme, attributed to particular persons ($\upsilon_1,\ \upsilon_2 = 1 - \upsilon_1$). It provides a definition for a retirement profile (whether it is $2\times$ *full*, *full–partial* or $2\times$ *partial*, as stipulated by Feldman, Pietrzyk and Rokita (2013)).

The survival process is the same for each combination of financial parameters. Thus, it is sufficient to determine all possible survival scenarios only once and afterwards apply them in the engine to calculate consumption and cumulated surplus with different values of decision variables. This is applicable also in any extensions of the basic financial plan model, however complex, unless a financial situation is assumed to influence survival probabilities.

The value function to be used in a financial plan optimization procedure might adopt the following pattern:

$$V(\upsilon_1;\gamma,\delta,\zeta,\Xi,s) = \\ = \sum_{s=1}^{N} P(s)\cdot\sum_{t=0}^{t_n}\left[\frac{1}{(1+\rho_C)^t}\cdot V_C(C(t;\Xi,s);\gamma,\delta) + \frac{1}{(1+\rho_B)^t}\cdot V_B(B(t;\Xi,s);\zeta)\right] \\ \rightarrow \max \tag{4}$$

where:

$C(t;\Xi,s)$ – consumption (in monetary terms) at the moment t, for scenario s and set of household financial characteristics Ξ,

$B(t;\Xi,s)$ – bequest (cumulated investments and surplus of both household members) at the moment t, for scenario s and set of household financial characteristics Ξ,

γ – parameter describing longevity risk aversion,

δ – parameter describing premature death risk aversion,

ζ – bequest motive parameter,

$V_C(.)$ – value function of consumption,

$V_B(.)$ – value function of bequest,

$$V_C(C(t;\Xi,s);\gamma,\delta) = \begin{cases} u_C(C(t;\Xi,s);\gamma,\delta) & if \quad St(t;s) \neq State4 \\ 0 & if \quad St(t;s) = State4 \end{cases}$$

$$V_B(B(t;\Xi,s);\zeta) = \begin{cases} v_B(B(t;\Xi,s);\zeta) \\ \quad if\ \ (St(t;s) = State4\ \ \wedge\ \ St(t-1;s) \neq state4) \\ 0 \\ \quad if\ \ (St(t;s) \neq\ \ State4\ \ \vee St(t-1;s) = State4) \end{cases}$$

$u_C(.)$ – utility of consumption, $u_B(.)$ – utility of bequest,
$\rho_C,\ \rho_B$ – rates used for discounting consumption, and bequest,
$P(s)$ – unconditional probability of scenario s.

This concept differs significantly from the traditional approach in which discounted utilities of consumption have been multiplied by the subsequent conditional probabilities of survival. That might function well for an individual for whom only two survival states (alive or not) are possible. In our proposal, each possible trajectory of the process is weighted with its unconditional probability. As the survival process is binominal, such an approach seems to be much better tractable than any one with conditional probabilities applied to each moment on the timeline.

Summary

The proposal demonstrated in this article provides a more thorough view on how to apply the concept by Feldman, Pietrzyk and Rokita (2013). One of important questions left unanswered there was just how to combine two-person survival process with expected discounted utility of consumption and bequest. Now, it seems that this problem may be recognized as solved (at least for a discrete version).

The potential research in the future should extend the model so that it allows for any number of financial goals to be considered. It should also take into account multiple ways of financing such goals. One shall acknowledge not only investments with different levels of risk and expected returns but also post-financing with loans. The latter is certainly inapplicable for a retirement goal but still exercises great significance for housing or education goals. Including many goals and investment opportunities will impose the necessity to refer to the dynamic portfolio analysis. The literature on the portfolio management from an intertemporal-choice perspective is already well developed (ref., e.g., Samuelson (1969), Merton (1971), Bodie at al. (1992), Bodie at al. (2004)). Combining these findings with the two-person household life-cycle would be a natural generalization and a valuable contribution.

The further direction of the research study might be realized by applying more advanced survival models like the stochastic mortality force (Huang at al. (2012)), or by allowing for dependence between survival processes of individual household members to be considered. Moreover, even introducing dependence between the survival and a financial situation estimated with the pattern proposed by Scholz and Seshadri (2012) may contribute to the potential development of such research. It should be stated that the scholars treat health as an important parameter not only for the survival process underlying the model but also for its financial part.

Also attempting to develop a continuous generalization of the proposed model might be worthwhile. A continuous version of the model might be a starting point for a further research aimed at finding an analytical solution to the financial plan optimization task. In the form in which it is now, the model allows only for numerical optimization, with high utilisation of computing power.

Towards Proergonomic Project Management- Initial Assumptions for The Application of Agent- Based Model in The Context of Project Success Factors

Wiktoria CZERNECKA

Poznan University of Technology, Faculty of Engineering Management,
Poznań, Poland
wiktoria.j.czernecka@doctorate.put.poznan.pl

Abstract

Projects are becoming an increasingly popular form of business activity in modern organizations. They allow for a structured approach to problem solving and thus increase the potential and competitiveness of the organization, as well as support the fulfillment of customers requirements. It is even intuitively assumed that the implementation of the project in the enterprise should be successful. With this in mind, criteria for project evaluation and methods of their analysis are sought. The same needs also occur in the case of projects with an ergonomic link, which, due to their specificity, can be assessed in many categories in relation to project management, but also implementation practice. This article presents a preliminary study of the applicability of agent-based modeling in assessing the success of a proergonomic project in the context of success factors identified on the basis of a literature review and expert recommendations. The process of selection of critical criteria for the project success was presented and the initial assumptions for the development of agents characteristics were indicated. Further directions of the model development and limitations of the conducted research were also listed.

Keywords: project management, ergonomic project success criteria, agent- based modeling, proergonomic approach in project management

Introduction

The activities of modern production companies are customer-oriented. This requires the flexibility of production processes to meet emerging or changing needs and requirements. This imposes on enterprises the need to create the possibility of a quick change of the production profile, which along with the development of the Industry 4.0 concept (processing large amounts of data, often with the use of artificial intelligence) contributes to the search for effective methods of managing production and other processes within the organization (Weyer, Schmitt, Ohmer and Gorecky, 2015, p. 580).

In order to meet new requirements, companies more and more often develop and implement projects. Thanks to the structuring of activities and the division of tasks into individual stages, such organizations deal more easily with the problem of flexible adaptation to customer requirements through, among others, identification and definition of procedures in the event of risk occurrence, integration of knowledge and skills of various company members, the possibility of a systemic look at identified problems, obtaining innovative solutions at various stages of projects. For this reason, such organizations are perceived on the industry market as more innovative and competitive (Gemünden, Lehner and Kock, 2018, p. 147-150).

With the growing importance of projects, criteria for their evaluation began to be searched. It is indicated that the basic parameters of project evaluation are the elements of the so-called "iron triangle" - time, cost and quality. If the project was completed within the assumed time, without

exceeding the budget and the result meets the client's requirements, it can be considered a success (Atkinson, 1999, p. 338). It was quickly noticed that these are not the only factors qualifying the project as a success and other factors should also be taken into account, e.g. customer and end-user satisfaction, benefits for the organization, payback time, no violation of occupational health and safety rules. Along with the evaluation criteria, a proposal for their qualitative presentation was also introduced (Shenhar, Dvir and Levy, 1999, p. 7- 9; Jugadev, Perkins, Fortune, White and Walker, 2013, p. 544- 545; Alexandrova and Ivaniva- Stankova, 2013).

Similar criteria are also sought in the case of ergonomic projects (Pikaar, 2007, p. 8; Silva e Santos, 2012, p. 2647). This article presents the initial assumptions for the application of the agent-based model based on the success factors of a proergonomic project. It is a recognition of this issue, therefore the final part of the article presents the limitations of the research.

Project in Scientific Research

The term "project" began to be used in the 1950s and 1960s, thus defining initiatives of a unique nature. The Project Management Institute (an international non-profit organization operating since 1969, promoting good practice in project management) described it then as a temporary effort to create a product or service. Over the years, this definition has evolved and a project can now be defined as a highly complex, pre-planned activity that is unique and has a specific purpose. Its characteristic features are also: determination of the beginning and the end in relation to time, team performance of tasks, targeting a specific group of stakeholders, specific resources necessary to implement the project, going beyond the daily activities of the organization, specific organization of activities (Wysocki and McGary, 2005, p. 47).

Regardless of the type of project, it is subject to a specific life cycle, which covers the time from determining the feasibility of the project to its official completion. Due to the differences in the perception of projects in various industries, it is not possible to indicate one binding definition of the project life cycle, but the following stages are usually distinguished: conceptualization, planning, testing, implementation and closure (Labushagne and Brent, 2005, p. 161).

It is advisable to consider the project in a broader time perspective (apart from the period from start to completion), because, as Engwall (2003, p. 789) points out - "no project is an island", which means that the project is part of the implementation of the company's strategy, therefore its assumptions must at least to some extent be part of it.

Project management, on the other hand, is defined as a process of deliberate planning and control of project activities and appropriate allocation of resources using appropriate techniques and methods of project management (A Guide to Project Management Body of Knowledge, 2008, p. 5). There are the following phases of project management: planning, preparation, execution and completion.

A specific type of project is an ergonomic project, the aim of which is to improve working conditions in terms of optimizing various types of loads by proposing a new technical and organizational solution or by changing the awareness of employees working at a given workstation (Suszyński, Butlewski, Stempowska, 2019). Ergonomic project may involve part or all of the work system and is typically structured as follows: feasibility determination, problem definition, current state of work system analysis, functional system analysis, initial solution proposal, detailed design, implementation, real-life verification and project completion (Pikaar, 2007, p. 8). In this article, as a proergonomic projects, projects having the character of ergonomic analysis and projects with elements of ergonomics, supporting to some extent the improvement of ergonomics of workplaces are considered.

The interest of various organizations in focusing their activities on project management is a response to the changing customer requirements and the growing importance of teamwork in solving problems, which is signaled in scientific research in the field of management. However, it is noted

that in the case of many projects there are problems with defining the requirements for each of the implementation stages and thus classifying the project as a success or failure after its completion.

Project Success as the Main Goal of Project Management

Project success is defined as a complex, multi-dimensional, subjective evaluation of the project results. It takes into account the detailed and general assessments of the project participants. The project is considered successful if all involved stakeholders assess the quality of the solution (effectiveness) as well as meeting the time and cost targets (efficiency) as generally positive (Gemünden and Lechler, 1997). The success of project activities should be viewed from the perspective of: end user, project manager and project client (Dvir, Raz and Shenhar, 2003).

The project is a component of many aspects, and its perception has evolved over the years- initially the focus was on project evaluation by its stakeholders, then began to pay attention to the importance of risk as well as to the project management processes. Some researchers note that the success of the project is a reflection of the success of the project management process, and this is reflected in the positive perception of the project outcome (Fig. 1).

Fig. 1 : The three levels of project success

Source: Caccamese and Bragantini, 2013, p. 2.

Based on the analysis of the literature referring to the project success factors, it is possible to divide the project success factors into endogenous and exogenous. Examples of such factors are shown below (Fig. 2).

Fig. 2: Project success factors

Source: own preparation based on: Joslin and Müller, 2015, p. 1388; Gemünden, Sören and Krieger, 2014, p. 368- 370; Pace, 2019, p. 62; Hyväri, 2006, p. 36; Gabryelewicz, Krupa and Sadłowska–Wrzesińska, 2017, p. ; Williams, Ashill, Naumann and Jackson, 2015, p. 1845; Caccamese and Bragantini, 2013, p. 7; Gunduz and Ali Yahya, 2018, p. 69.

The endogenous factors of success include: factors related to the project itself, factors related to project management, factors related to project stakeholders and factors related to the internal structures of the organization. The exogenous factors of the project success include those related to the micro- and macro environment of the organization running the project.

Agent- Based Modeling Assumptions

The agent- based model is defined as a tool that allows for the analysis of the behavior of groups represented by so-called "agents" who are autonomous units, e.g. people, buildings, cars, landscape elements, features of a given thing, etc. (Bonabeau, 2002, p. 7281). There is a problem in the literature in presenting an unambiguous definition of agents, but most often it is indicated that they show the following features: autonomy, heterogeneity, goal and reactive orientation, interactivity and communicativeness, mobility, adaptability and learning (Crooks and Heppenstall, 2012, p. 87- 88). Agents are usually represented by computer program units and on the basis of data entered into the system, they can propose a decision aimed at achieving the assumed goal. Principles of agent-based modeling are presented below (Fig. 3).

Fig. 3 : Agent- based modeling steps

Source: own preparation based on: Helbing and Belietti, 2011, p. 11- 12.

Agent-based modeling is supported by IT tools that provide the defined agents with appropriate descriptions and create the possibility of adaptive decision- making support. For this purpose, it is possible to use:

- Spreadsheets: e.g. Excel,
- Dedicated agent- based environments: e.g. Repast Simphony, StarLogo, NetLogo,
- General Mathematics Systems: e.g. MATLAB,
- Repast Large-Scale Agent Development Environments e.g. Swarm,
- General Programming Languages: C++, Java, Python (Macal and North, 2009, p. 94- 95).

Materials and Methods

The development of the initial assumptions for the use of the agent- based model in supporting the management of proergonomic projects (in order to complete them successfully) was carried out in the following stages:

1. Initial identification of the need to support project management on the basis of the identified success factors.
2. Identification of the project's success factors (endogenous and exogenous) on the basis of the analysis of the literature, experience in conducting ergonomic projects of the author of this article and factors indicated by 6 experts participating in the study (the experts were deliberately selected from the group of project managers or specialists dealing with ergonomics in production enterprises).
3. Assessment of the importance of the project success factors by 6 experts (Sossa, Halal and Zarta, 2019, p. 526- 530). Experts were selected based on the position held in the company (OHS Specialist, Ergonomics Specialist or Project Manager). Experts work in large production companies (over 700 employees) in the Greater Poland Voivodeship in Poland.
4. Selection of project success factors for building an agent- based model and indication of the required degree of their definition by experts on a scale from 1 to 5 (5- very high level of definition necessary, 4- high level of definition necessary, 3- medium level of definition, 2- basic definition, 1- no need to define).
5. Presentation of assumptions for building an agent- based model.
6. Identifying the limitations of research and further development directions.

Research results and assumptions of the agent- based model

The results of experts' assessments in both rounds of the expert study (taking into account the choice of factors for building the model and identification of the required degree of their definition) are presented below.

Table 1 : Identified success factors of the project and the results of the expert study (own preparation)

Success factor category		Project success factor	Indication by experts (%)	The required level of definition (d)
1	The Project Team	Ergonomic knowledge of the project manager	87	4,8
2		Project team qualifications	56	3,8
3		Involvement of the project team and their motivation	71	3,8
4		Project manager team management skills	77	4,4
5		Correct definition of customer requirements	74	4,8
6		Correctly identifing end user requirements	62	4,8
7		Commitment of top management	38	
8	Organization of the project	Reliable identification of the project goal and its measurability and reality	66	4,4
9		A realistic project implementation plan	71	4,2
10		Determining the exact project schedule	56	3,8
11		Establishing the project budget	37	

Success factor category		Project success factor	Indication by experts (%)	The required level of definition (d)
12		Identifying the characteristics of the project: type, size, complexity	56	3,8
13		Defining the milestones of the project and specifying how to monitor their achievement	70	4,2
14		Defining communication methods in the project	61	3,8
15		Ensuring the autonomy of the project in relation to the activities of the organization	48	
16	Project Management	Risk identification and response plan development	60	4,4
17		Monitoring the performance of tasks and assessing the degree of their implementation	53	4,2
18		Determining the future performance potential for the organization	44	
19		Appropriate selection of project management methodology	42	
20		Application of techniques and tools supporting project management	43	
21		Adaptive change management in the project	45	
22		Defining the satisfactory quality of the final project result	43	
23	Internal conditions of the organization	Implementation of the project based on sustainable development	27	
24		Ensuring safe conditions for the implementation of the project	37	
25		Providing ergonomic conditions for project implementation	35	
26		Organizational culture of the company leading the project	30	
27		The openness of the enterprise	53	4,2
28		The atmosphere in the company	40	
29	Factors outside the organization	Exchange of experiences with organizations that run a similar project or operate in a similar industry	43	
30		Application of modern trends in project management	18	
31		Correct identification of the legal conditions of the project	46	
32		The project will have a positive impact on the company's competitiveness	38	
33		The organization's financial capacity to carry out the project compared to other companies	40	

Success factor category		Project success factor	Indication by experts (%)	The required level of definition (d)
34		Technological advancement of the organization compared to other companies	37	

Project success factors, the importance of which were indicated by experts in 50 percent or more, were selected for the construction of the proposition of an agent-based system to support project management in the proeconomic context. It allowed to take into account 15 factors. It can be noticed that the factors that were rated highest by the experts belonged to the group of factors related to the project team and project organization, as well as project management. One factor (company openness) is a factor related to the internal conditions of the organization.

Based on the above results, the following elements (agents) of the agent-based model can be proposed:

1. Database Agent (DA) - an agent containing a database of project success factors. Each of them is described in detail and the ergonomic context that needs to be taken into account is indicated. The data that the agent has at its disposal comes from the analysis of the literature and the experience of specialists in the practical implementation of projects in enterprises. The agent is not interactive, but requires detailed preparation and description of each factor.
2. Project Data Agent (PDA) - an agent communicating with the user (project manager). It contains user data (login data, verification, basic information) and also allows the user to enter information about the current degree of definition of the project data for each success factor identified in the Database Agent section.
3. Processing Agent (PA) - an interactive agent that processes data entered by the user of the system and saves it in an appropriate format for later reporting to the Definition Gap Agent.
4. Definition Gap Agent (DGA) - an agent determining the differences between the current state of the analyzed project (p) indicated by the project manager and the data held by the Database Agent (d).
5. Possible Action Agent (PAA) - an interactive agent proposing, on the basis of the identified definition gap, possible actions that can be taken by project team members in order to better pre-identify individual project elements and thus increase the chances of success of the final project result.

The structure of the proposed model is shown below (Fig. 4).

Fig. 4: Agent- based model in proergonomic project management
Source: own preparation.

The diagram above presents the basic assumptions of the agent- based model supporting pro-ergonomic project management. It should be noted that the assumptions of the model should be supported by an IT tool that enables data linking and obtaining appropriate outputs from the agents' activities. Correct preparation of data in the model requires the cooperation and involvement of the project manager and the model owner, whose task will be to supply the model (Database Agent) with input data.

Limitations

The above research was aimed at preliminary determination of the possibility of using agent-based modeling in supporting proergonomic project management. Therefore, the following limitations of this approach can be identified:

1. Failure to indicate an IT tool organizing the presented issue. This will be taken into account in the further development of the model.
2. Assessment of project success factors by only 6 experts- increasing the number of experts would provide more representative results.
3. Failure to define the input data of the Database Agent- the development of a set of precisely characterized project success factors will take place in the phase of building the final version of the model.
4. Failure to take into account the factors of project success related to the external environment of the organization in the model. The results of the experts' assessment did not allow for taking into account these factors, however, they may have a significant impact on the project, therefore they should be taken into account in the improved version of the model.

5. Due to the characteristic type of the considered projects, difficulties arise in comparing the results and the proposed model with the models presented by various researchers who take up the subject of agent-based modeling.

Conclusions

The conducted preliminary research indicates that it is possible to use agent- based modeling in supporting proergonomic project management and it is justified. The research proves that the project success factors may be the basis of the model, but at the same time the necessity to modify the conduct of the study is noted- the use of a different division of factors in the expert study and the involvement of a larger number of experts is considered. Other limitations identified in the study summary should also be considered in further development. By eliminating them, it will be possible to obtain a model correctly theoretically defined and possible to be implemented in practice, e.g. in production companies carrying out various types of projects. The model will be further developed. The assumptions of agents' activities will be expanded and an IT tool will be proposed that will ensure the application possibilities of the model. For full practical implementation, validation of the tool in real- life conditions will also be necessary.

Abstract

The article proposes a new method of assessing the ergonomics of workplaces using the theory of grey systems. The developed method allows the calculation of partial quantitative indicators of classification employee's position during work using grey number arithmetic and a standardized normal distribution cumulative. The selection of assessment criteria in the method includes the criteria contained in standardized guidelines. The presented method uses the data obtained from the chronological observation of work activities. The developed method allows for a assessment of the ergonomics of workplaces in terms of the risk of developing musculoskeletal disorders. For assessment, standardized ergonomics criteria for workstations were used based on PN-EN 1005-4 + A1: 2009 and ISO 11226:2000 standards. Assessment scales using grey numbers and a general algorithm for determining ergonomics indicators were developed. The finally developed method was used on a practical example of a production workstation on the assembly line.

Keywords: Grey System Theory, Ergonomic Evaluation, Ergonomic Evaluation Indicators, Ergonomic Criteria

Introduction

Ergonomics is defined as the level of adaptation of workplaces to the physical and mental capabilities of human. Due to the modern organization of production systems, excessive repetition of forced and unnatural movements and static body positions during work have become one of the most important ergonomic problems. Repeatability and unnaturalness of movements put a strain on the worker, reduces his productivity and increases the risk of musculoskeletal disorders (WRMSDs) from a long-term perspective (Punnett and Wegman, 2004). This phenomenon was described by Bernardino Ramazinni, but it was the later development of ergonomic risk prediction methods that gave the opportunity to value the risk (Franco and Fusetti, 2004). By using such methods, it is possible to identify the impact of work organization on the development of musculoskeletal disorders in

employees and to take actions to reduce ergonomic risk at various levels of the organization's functioning. The link between working conditions and real costs for enterprises is more and more often observed (Morse, Dillon, Warren, Levenstein and Warren, 1998). and ergonomic solutions are being implemented in various companies, e.g. with the use of Human-Centered Design (HCD). Such implementations are not always successful due to, among others, insufficient recognition of ergonomic problems and the lack of consideration of ergonomics at the initial stages of design- usually technical solutions are verified and validated after their implementation, in real industrial processes (Peruzzini, Carassai, and Pellicciari, 2016), This results in unnecessary costs that could be avoided by properly performed ergonomic analysis.

Ergonomic analysis results from the need to evaluate production situations and requires the introduction of indicators determining the ergonomic quality of workstations or tasks. Ergonomic assessment presents a major research challenge due to the complexity of the process of ergonomic risk assessment and the factors influencing it (Hales and Bernard, 1996), variability of which cannot be precisely predicted even with the use of relatively complex risk assessment methods This is due to the fact that in industrial conditions it is impossible to determine precisely the state of the assumed biomechanical criteria, especially the angular position of individual body segments. Therefore, there is a large uncertainty in the data collected in the assessment process. To solve this problem, it may be useful to use the theory of grey systems which is one of the approaches to uncertainty analysis. It is used in conditions of limited data availability in the analyzed system and determines the relationships between elements of this system.

Aggregated Ergonomic Assessment at Workstations

To assess the ergonomics of workplaces, normative guidelines are needed regarding the method of workplace evaluation, ergonomic design and evaluation of the results of ergonomic analyzes obtained. One of such standards is PN-EN 1005-4 + A1: 2009, which is used to assess designed machines and their components in terms of ergonomic risk associated with their subsequent operation by the worker or maintenance engineer. The standard specifies the rules for assessing the body posture and movements of the person operating the machine (Klembalska, 2011).

There are many methods to evaluate the different dimensions of human work. The assessed aspects of work can therefore be:

- the assumed (usually static) body postures at work assessed with the use of such methods as OWAS (Ovako Working Posture Analysis System) (Karhu, Kansi, Kuorinaka, 1977), REBA – Rapid Entire Body Assessment (Hignett and Mcatamney, 2000), RULA – Rapid Upper Limb Assessment (Mcatamney and Corlett, 1993),
- characteristics of manual works - Strain Index (Steinberg, 2005) or Key Indicator Method Manual Handling Operations (KIM MO) (Waters, Putz-Anderson and Garg et al., 1993), The Occupational Repetitive Actions Methods: OCRA Index - ISO 11228-3:2007,
- weight lifting - NIOSH Lifting Equation (Wickens, 2017),
- manual or forklift transport, for which the Snook and Ciriello tables (Snook and Ciriello, 1991) or the KIM method are used,
- energy expenditure assessed on a shift or momentary basis and the risk of fatigue as an important factor in fatigue management (Butlewski, Czernecka, Pojasek et. al., 2019),
- decision and operation processes, especially mental workload, which can be evaluated by NASA-TLX (Hart, Staveland, 1988) or Subjective Workload Assessment Technique (SWAT) (Reid, Nygren, 1988),
- subjective assessment of work strain for individual tasks - e.g. the Borg scale, where fatigue is assessed by selecting an appropriate statement describing the employee's perception. The evaluation scale in the Borg's approach relates to the employee's heart rate (Borg, 1982),
- aggregated methods of work evaluation taking into account a number of load factors, the result of which is a number interpreted as an ergonomic indicator of work severity - ERA or EAWS (Schaub, Mühlstedt, Illmann et. al., 2012),
- psychomotor load (Sadłowska- Wrzesińska, Gabryelewicz, Krupa, 2017).

Despite the existence of a significant number of methods, more are being sought that will allow a more accurate ergonomic assessment of workstations. Solutions that allow better prediction of the position of motor organs by modeling them, e.g. with the OpenSim program (Panariello, Grazioso, Caporaso et. al., 2019) as well as solutions leading to a better understanding of the reasons for the obtained differences in final ergonomic risk (Joshi and Deshpande, 2019) are sought after. The qualitative nature of the ergonomic risk factors, which is expressed in quantitative quazi indicators, causes the search for models of transition from the observed factors to the numerical value. An example of this can be the assessment of biomechanical loads using the QEC method or fuzzy logic techniques (Kose, Karabayir and Cevikcan, 2019; Akay, 2011; Akay and Kulak, 2007). In this article, it was decided to solve the problem of relatively quickly obtaining the cumulative value of ergonomic risk by using grey system theory and position classification methods according to ISO 11226 (PN-EN 1005-4+A1:2009) and the REBA method.

Grey System Theory and Grey Numbers

Over the last 30 years, Grey Systems Theory has found a number of applications (Bouzon, Govindan and Rodriguez, 2018; Sun, Zhang, Baleanu, 2018; Delcea, 2014). GST methods are used to solve a wide range of problems in technical, social and economic sciences (Liu, Lin, 2006). GST is particularly applicable to modeling systems with a high degree of uncertainty. This uncertainty is associated with incomplete information about the system, scarcity of information, or the risk of incorrect information (Liu, Yang and Forrest, 2016; Xie and Liu, 2010). This is due to the fact that when observing the functioning of systems, information about their boundaries, internal structure and their interaction with the environment is needed. However, to a large extent such information is incomplete and uncertain (Mierzwiak, Xie and Nowak, 2018). GST is suitable for analyzing this type of systems, with particular emphasis on testing problems on small samples and residual information. This theory analyzes partially information insecure systems by generating, extracting and detecting useful relationships from available information resources. Such actions enable previously impossible description and monitoring of operational behavior in systems. This allows GST to be widely used in business practice because, as a rule, social engineering systems are characterized by the fact that their quantitative description is characterized by a high level of uncertainty and a small amount of data possible to obtain (Mierzwiak, Xie and Dong, 2019).

One of the basic concepts of grey systems theory are grey numbers. They can be very useful in all assessment processes because they allow for easy modeling of approximate numerical evaluation of a given element or phenomenon. Approximations of this type are characteristic for evaluation of workstations' ergonomics.

The grey number $\otimes \in [a, b]$ is an unknown number d^* with the following known characteristics: $d^* \in Ra \leq d^* \leq b$. Basic arithmetical operations include addition, subtraction, multiplication, and division. These operations are performed on grey numbers in the way presented below.

The assumption is that there are the following two grey numbers: $\otimes_1 \in [a, b], a < b$ and $\otimes_2 \in [c, d], c < d$. The following basic operation rules for grey numbers apply (Sun, Zhang, Baleanu 2018; Delcea, 2014):

$$\otimes_1 + \otimes_2 \in [a + c, b + d] \tag{1}$$

$$\otimes_1 - \otimes_2 \in [a - d, b - c] \tag{2}$$

$$\frac{\otimes_1}{\otimes_2} \in \left[\min\left\{\frac{a}{c}, \frac{a}{d}, \frac{b}{c}, \frac{b}{d}\right\}, \max\left\{\frac{a}{c}, \frac{a}{d}, \frac{b}{c}, \frac{b}{d}\right\}\right] \tag{3}$$

$$\otimes_1 \cdot \otimes_2 \in [\min\{\mathrm{ac}, \mathrm{ad}, \mathrm{bc}, \mathrm{bd}\}, \max\{\mathrm{ac}, \mathrm{ad}, \mathrm{bc}, \mathrm{bd}\}] \tag{4}$$

$$-\otimes \in [-\mathrm{b}, -\mathrm{a}] \tag{5}$$

$$\otimes^{-1} \in [\frac{1}{\mathrm{b}}, \frac{1}{\mathrm{a}}] \tag{6}$$

An important operation that can be performed on grey numbers is whitening. This operation converts a grey number into the corresponding real number. Assuming that no additional information about the grey number $\otimes_1$ and $\otimes_2$ is available, the whitening operation proceeds according to formulas (7) and (8):

$$\otimes_1 \in [a, b] \Rightarrow \widetilde{\otimes}_1 = \frac{1}{2}(a + b) \tag{7}$$

$$\otimes_2 \in [c, d] \Rightarrow \widetilde{\otimes}_2 = \frac{1}{2}(c + d) \tag{8}$$

The above-described grey number whitening operation can be carried out with the use of special functions representing the experts' beliefs about a given phenomenon or object.

Materials and Methods

The methodology for evaluating workplace's ergonomics requires empirical data to be collected taking into account the guidelines included in ISO 1005 and ISO 11226 standards. Definition of the assessment criteria constitutes the starting point for the methodC_i (9):

$$C = \{c_1, c_2, \dots c_m\} \tag{9}$$

A detailed description of the criteria in accordance with the guidelines of ISO 1005 and ISO 11226 with an assessment scale using grey numbers is presented in Table 1.

Table 1: The fragment of the method for assessing criteria C_i adopted according to the criteria of the ISO 11226 standard (own preparation)

C_i	Name of the criterion/attribute	Visualisation of the attribute	Detailed description	Grey number value range
1	Twisted torso (left or right side)		from 60° to 90° (left or right)	[0.0, 0.2]
			from 40° to 60° (left or right)	[0.2, 0.4]
			from 20° to 40° (left or right)	[0.4, 0.6]
			from 10° to 20° (left or right)	[0.6, 0.8]
			from 0° to 10° (left or right)	[0.8, 1.0]
…	…	…	…	…

Using Table 1 it was possible to determine an assessment matrix according to formula (11). The data for this matrix was obtained from chronological observation with a fixed time interval. As a

minimum, the duration of observation covered one full work cycle. The values of attributes in individual criteria are determined in the time coordinates *T*.

$$T = \{t_1, t_2, \dots t_n\} \tag{10}$$

$$[\otimes G_{ik}] = \begin{bmatrix} \otimes G_{11} & \cdots & \otimes G_{1n} \\ \vdots & \ddots & \vdots \\ \otimes G_{m1} & \cdots & \otimes G_{mn} \end{bmatrix} = G \tag{11}$$

where:

$\otimes G_{ik}$ – the attribute value in the *i*-th criterion *C* in the *k*-th interval *T* expressed in terms of a grey number;

i = 1,2,…, *m;*

k = 1,2,…, *n.*

For each attribute C_j it is possible to calculate the arithmetic mean and standard deviation according to formulas (12) and (13).

$$\otimes \mu_i = \frac{1}{n}\sum_{k=1}^{n} \otimes G_{ik} \tag{12}$$

$$\otimes \sigma_i = \sqrt{\frac{\sum_{k=1}^{n}(\otimes \mathrm{G}_{ik} - \mu_i)^2}{n-1}} \tag{13}$$

To facilitate calculations, parameters $\otimes \mu_j$ and $\otimes \sigma_j$ are whitened according to formulas (14) and (15).

$$\otimes \mu_i = \left[\underline{\mu}_i, \overline{\mu}_i\right] \Rightarrow \mu_i = \frac{1}{2}(\underline{\mu}_i + \overline{\mu}_i) \tag{14}$$

$$\otimes \sigma_i = \left[\underline{\sigma}_i, \overline{\sigma}_i\right] \Rightarrow \sigma_i = \frac{1}{2}(\underline{\sigma}_i + \overline{\sigma}_i) \tag{15}$$

The next step in this method includes determining the partial evaluation indicators P_i^j, which determine the level of probability for the occurrence of each of the ranges of the five-point scale expressed in grey numbers $\otimes_j$, i.e. [0.0; 0.2], [0.2; 0.4], [0.4; 0.6], [0.6; 0.8] and [0.8; 1.0]. For the calculation of partial evaluation indicators, it is assumed that the value $\otimes G_{ik}$ is a random variable in the normal distribution (μ_i, σ_i). With this assumption and using the cumulative distribution function of a standardized normal distribution, five more indicator P_i^j can be determined in line with formula (16) to (20).

$$P_i^1 = P([0.0, 0.2]) = P\left(z_{\frac{0-\mu_i}{\sigma_i}} < Z < z_{\frac{0.2-\mu_i}{\sigma_i}}\right) \tag{16}$$

$$P_i^2 = P([0.2, 0.4]) = P\left(z_{\frac{0.2-\mu_i}{\sigma_i}} < Z < z_{\frac{0.4-\mu_i}{\sigma_i}}\right) \tag{17}$$

$$P_i^3 = P([0.4, 0.6]) = P\left(z_{\frac{0.4-\mu_i}{\sigma_i}} < Z < z_{\frac{0.6-\mu_i}{\sigma_i}}\right) \tag{18}$$

$$P_i^4 = P([0.6, 0.8]) = P\left(z_{\frac{0.6-\mu_i}{\sigma_i}} < Z < z_{\frac{0.8-\mu_i}{\sigma_i}}\right) \tag{19}$$

$$P_i^5 = P([0.8, 1.0]) = P\left(z_{\frac{0.8-\mu_i}{\sigma_i}} < Z < z_{\frac{1.0-\mu_i}{\sigma_i}}\right) \tag{20}$$

With the indicator P_i^j it is possible to determine the weighted average assessment coefficient P_i for each attribute C_i using formula (21).

$$P_i = \frac{a_1 P_i^1 + a_2 P_i^2 + a_3 P_i^3 + a_4 P_i^4 + a_5 P_i^5}{P_i^1 + P_i^2 + P_i^3 + P_i^4 + P_i^5} \tag{21}$$

The coefficients a_i are whitened values of relevant items of the scale $\bigotimes_j$ and their values are: $a_1 = 0.1$, $a_2 = 0.3$, $a_3 = 0.5$, $a_4 = 0.7$, $a_1 = 0.9$.

The result of these activities and their main objective is to enable the determination of an overall synthetic indicator for ergonomics assessment in accordance with the formula below (22):

$$P = \frac{m}{\sum_{i=1}^{m} \frac{1}{P_i}} \tag{22}$$

The indicator $P \in \langle 0,1 \rangle$ is thus a standardized indicator in the range from 0 to 1. The higher the indicator value and the closer it is to 1, the better the ergonomics is assessed. When analyzing the mathematical form of the indicator P, it can be noted that the poorer the evaluation of a given partial indicator P_i, the stronger its impact on the final result.

$\otimes\, \mu_i = \left[\underline{\mu}_i, \overline{\mu}_i\right] \Rightarrow \mu_i = \frac{1}{2}(0.68 + 0.88) = 0.78$

$\otimes\, \sigma_i = \left[\underline{\sigma}_i, \overline{\sigma}_i\right] \Rightarrow \sigma_i = \frac{1}{2}(0.22 + 0.22) = 0.22$

$$P(z_{-3.594} < Z < z_{-2.668}) = 0.4991 - 0.4961 = 0.003$$

$$P_1^2 = P([0.2, 0.4]) = P\left(z_{\frac{0.2-0.7764}{0.2160}} < Z < z_{\frac{0.4-0.7764}{0.2160}}\right)$$

$$= P(z_{-2.668} < Z < z_{-1.742}) = 0.496 - 0.4591 = 0.037$$

$$P_1^3 = P([0.4, 0.6]) = P\left(z_{\frac{0.4-0.7764}{0.2160}} < Z < z_{\frac{0.6-0.7764}{0.2160}}\right)$$
$$= P(z_{-1.742} < Z < z_{-0.817}) = 0.4591 - 0.291 = 0.1681$$

$$P_1^4 = P([0.6, 0.8]) = P\left(z_{\frac{0.6-0.7764}{0.2160}} < Z < z_{\frac{0.8-0.7764}{0.2160}}\right)$$
$$= P(z_{-0.817} < Z < z_{0.109}) = 0.291 + 0.0398 = 0.3308$$

$$P_1^5 = P([0.8, 1.0]) = P\left(z_{\frac{0.8-0.7764}{0.2160}} < Z < z_{\frac{1-0.7764}{0.2160}}\right)$$
$$= P(z_{0.109} < Z < z_{1.035}) = 0.3485 - 0.0398 = 0.3087$$

With partial indicators P_i^j, it is possible to determine the value of the indicator P_i for each criterion C_i according to the formula (21). The calculations depicting the process for the first criterion are given below:

$$P_1 = \frac{(0.1 \cdot 0.003) + (0.3 \cdot 0.037) + (0.5 \cdot 0.1681) + (0.7 \cdot 0.3308) + (0.9 \cdot 0.3087)}{0.003 + 0.037 + 0.1681 + 0.3308 + 0.3087} = 0.7136$$

The cumulative calculation results for the indicators P_i^j and P_i for all the assessment criteria are given in Table 3.

Table 3: Calculations results for indicator P_i and indicator P_i^j (own preparation)

C_i	P_i^1	P_i^2	P_i^3	P_i^4	P_i^5	P_i
1	0.0030	0.0370	0.1681	0.3308	0.3087	0.7136
2	0.0004	0.0164	0.1417	0.3851	0.3450	0.7381

4	0.0000	0.0018	0.0637	0.3907	0.4435	0.7836
5	0.0285	0.1021	0.2237	0.2812	0.2237	0.6326
6	0.0143	0.0789	0.2205	0.3137	0.2477	0.6603
7	0.0701	0.1644	0.2462	0.2177	0.1614	0.5549
8	0.0217	0.0986	0.2402	0.3068	0.2244	0.6376
9	0.0971	0.1818	0.2293	0.2177	0.1397	0.5280
10	0.0181	0.0910	0.2371	0.3145	0.2316	0.6458
11	0.0007	0.0174	0.1286	0.3531	0.3485	0.7431
12	0.0000	0.0009	0.0358	0.2861	0.4795	0.8102

The averaged ergonomics indicator P_i allows for a quick analysis of the ergonomics for the individual assessment criteria and the calculation of the overall ergonomics indicator using the formula (21). For the analyzed workstation, indicator calculations are shown below:

$$P = \frac{12}{\frac{1}{0.7136}+\frac{1}{0.7381}+\frac{1}{0.7380}+\frac{1}{0.7836}+\frac{1}{0.6326}+\frac{1}{0.6603}+\frac{1}{0.5549}+\frac{1}{0.6376}+\frac{1}{0.5280}+\frac{1}{0.6458}+\frac{1}{0.7431}+\frac{1}{0.8102}}$$

$$= 0.6731$$

The value of the indicator is between 0 and 1. The higher the indicator value and the closer it is to 1, the better the ergonomics is assessed. Partial indicators for each attribute should be interpreted similarly. The following criteria allow for a substantive and evaluative interpretation of these synthetic indicators P and partial indicators P_i (Kosacka, Golinska-Dawson and Mierzwiak, 2015; Więcek-Janka, Mierzwiak and Kijewska, 2015):

- a value above 0.7 informs of a good ergonomic quality of the workstation and thus no intervention in ergonomics is required,

- a value between 0.5 and 0.7 (inclusive) indicates an average ergonomic quality level of the workstation; interventions should be considered,
- a value between 0.3 and 0.5 (inclusive) is indicative of a low ergonomic quality level of the workstation; interventions in workstation are absolutely required,
- a value between 0 and 0.3 (inclusive) indicates extremely low level of ergonomic quality; it is necessary to stop work immediately.

Research Results

The set of partial indicators P_i allows for analytical interpretation according to individual criteria. With the use of analytical indicators, it is possible to set a priority for actions related to ergonomic interventions. The indicator P constitutes only a general and averaged representation of workstation's ergonomic quality and should be treated as an auxiliary value in the process of determining activities that must be taken.

Table 4 : Improvement proposals for the analyzed workstation taking into account the partial results obtained (own preparation)

C_i	Criterion name	P_i	The result of the analysis by the developed method	Description of improvements
Total indicator value $P = 0.6731$				
1	Twisted torso (left or right side)	0.7136	With this aspect, work does not require interventions	Inspection only is recommended
2	Torso extension/flexion	0.7381	With this aspect, work does not require interventions	Inspection only is recommended
3	Head - neck side bending	0.7380	With this aspect, work does not require interventions	Inspection only is recommended
…	…	…	…	…
6	Arm inward/outward rotation	0.6603	Work requires to consider interventions	Working in a line and the resulting positioning of the worker causes frequent stretching beyond the body axis. Spatial modification of the site should be considered.
7	Arm flexion/extension of shoulder joint	0.5549	Work requires to consider interventions	Work should be carried out in the so-called golden zone located at the elbow height.
8	Forearm supination/ pronantion	0.6376	Work requires to consider interventions	The gripping method should be taken into account, which allows to maintain a neutral position in the elbow joint

				(supination, pronation up to 45 degrees).
…	…	…	…	…

The significant limitations of the developed method include: the necessity of measuring constant time intervals and the limited number of ergonomic risk factors analyzed. The use of the REBA method as well as the ISO 11226 standard to develop the assessment model meant that the proposed approach did not take into account the repetition of movements and no other risk factors were included. In future studies, the assessment model could also take into account factors such as the microclimate at workstation or exposure to mechanical vibrations.

Conclusions

The aim of the research presented in this paper was to develop a quick method of assessing production workstations' ergonomics using the theory of grey systems. The developed method can be modified and improved by changing the evaluation scale to improve the accuracy of calculations. Due to the fact that the developed evaluation model is a quantitative model, it can be easily implemented in IT systems. The method allows for analytical and synthetic evaluation of the workstation.

An important direction for further research in the development of the proposed methodological solution is to compare the results obtained in the method with other assessment methods such as ERA, EAWS, QEC. Such a study would require collecting a large amount of data and developing methodological principles for comparing the results obtained from various assessment methods. This approach at the methodological level would therefore require the development of methodical triangulation procedures**.**

Aspects Regarding Some Theories Preceding the Emergence of the New Public Management

Florina POPA

Institute of National Economy, Romanian Academy, Bucharest, Romania,
florinapopa289@gmail.com

Abstract

The forms of manifestation of public administration, present until the end of the last century, were based on the traditional model, an expression of the principles of bureaucracy formulated by theoreticians of the time. The study follows the forms of approach of public administration and the theories that they were based on, prior to the emergence and development of the New Public Management (classical and neoclassical public administration, respectively, the theory of public choice, the new public administration, public management). Briefly, some elements of the theories formulated are presented, as well as their representatives, which generated the initiation of reforms and changes in the administration. The conclusions of the study point out, among other things, the fact that the management formula applied in the administration is not unique, but differs by countries, depending on the existing public administration and the priorities required for its proper functioning.
The aim of the paper was to capture the main moments and forms of changes in the administration that evolved towards the paradigm shift and the emergence of the New Public Management.
The research methodology was based on the identification and study of some materials from the foreign and autochthon specialized literature, corresponding to the chosen topic, the processing of the selected ideas and the author's own interpretation.

Keywords: Public Administration, Classical, Neoclassical, Theories.

Introduction

The great changes that have taken place worldwide in the context of globalization, as well as the diversification of services, were significant for the practice of traditional public administration, which is facing challenges.

Beginning with the last decades of the last century, the traditional model of public administration whose basic principle is Max Weber's bureaucracy theory has undergone changes by moving to a flexible public management model (Katsamunska, 2012). This meant moving away from the doctrines of traditional good administration of the progressive stage, with an emphasis on hierarchies, to a modern managerial approach, called the New Public Management, signifying a paradigm shift (Falconer).

The framework of the paper pursues forms of public administration approach and the theories that were underlying them, predecessor to the emergence and definition of the New Public Management; some elements of the stated principles, as well as their representatives who have generated reforms launch and changes in the administration are briefly shown.

The research is considered to be important from the perspective of knowing the main moments and forms of changes in the administration that preceded the emergence of the New Public Management, as an element of modernization of public administration.

Approaches to public administration prior to the New Public Management

Significantly for the emergence of the new current of thought was the change of the ideological perception concerning the state. As early as the eighth decade of the last century, the penetration of the neoclassical current and the transition to the new form of liberal government, which rejected the welfare state, led to the emergence of new reforms aimed towards reducing the public sector (whose superiority it denied), as well as the openness to market competition, at first, in developed countries [1]. (Świrska, 2014)

Regarding the origins of the New Public Management, Gernod Gruening (2001) shows that the opinions of theorists are different, for example:

- ✓ Some authors (Aucoin, 1990, pp. 115; Dunsire, 1995, pp. 21–29; Lueder, 1996, pp. 93; Naschold et. al., 1995, pp. 1–8; Reichard, 1996, pp. 245f; Schedler, 1995, p. 155) [2] argue that *public choice theory and managerialism* are at the origin of the New Public Management;
- ✓ Others (Aucoin, 1995, p. 3; Borins, 1994, p. 2; Kamensky, 1996, p. 250; OECD, 1995, pp. 8, 25; Osborne and Gaebler, 1993, p. 321; Reinermann, 1995, p.6) [3], considers that New Public Management represents *a paradigm shift*.

The author Marilena Ortansa I. Moraru (2012) shows that the New Public Management is based on *reforms regarding the role of government and public administration* in the delivery of public services, reforms that have taken place in Western Europe.

Currently, there is a general view that the New Public Management (NPM) is a *global paradigm* that emerges in response to the challenges produced by economic, institutional, political and ideological changes. The opinions that formed the basis of the NPM definition had as a common aspect "the implementation of management ideas from business and private sector into the public services" (Haynes, P., 2003) [4].

In essence, it can be considered that the New Public Management is based on a series of theories: classical public administration, neoclassical public administration, public choice theory, New Public Administration, political analysis, principal-agent theory, management theory and others (Gruening, 2001).

In the following, it is briefly presented the elements of some theories that preceded the emergence and development of the New Public Management.

Classical Public Administration

Against the background of some dysfunctions manifested in the public administration system (the distribution of posts, in the administration, on political criteria, the consequences being frequent changes of staff and an administrative system dominated by inefficiency and corruption) (Weber, 1956, p. 839; Van Riper, 1987; Stone and Stone, 1975; Schachter, 1989) [5], the progressive current emerged. The new movement pursued eliminating these shortcomings and stood out through initiating reforms that led to changes in the administration (Gruening, 2001, p. 3).

The *progressive* current (influenced by Frederick Taylor's scientific management practices) emphasizes efficiency, considered an important element in eliminating lack of training and qualification. To implement the objectives (efficiency, competence, elimination of corruption), practitioners of the progressive movement used performance indicators (Schachter, 1989) [6].

The science of public administration is established on the results obtained by the progressive reform. Practitioners of this science formulated *the organization theory* to which they added the concept of management, based on the following principles: division of labour and the specialization;

homogeneity, single command, hierarchy in the delegation of authority, responsibility, control of personnel (Gulick, 1937; Urwick, 1937; Mooney, 1937; Graicunas, 1937) [7].

References concerning the organization develop in the early twentieth century, along with the acceleration of industrialization and the emergence of large enterprises whereat capital (belonging to the owners) is dissociated from power (leaders). It is an empirical approach based on observation, belonging to industrialists and refers to *the rules of organization and rationalization of functioning* (Taylor, Foyol) [8].

The public managers within the organizational structures built on these principles came to certain functions: planning, organization, staff, guidance, coordination. (Gruening, 2001)

Among the representatives of the current are exemplified:

Frederick Taylor has as main element of the theory, "the standardization of work, the systematic control and the hierarchical organization"[9]. (Katsamunska, 2012, p. 77)

Henri Ford distinguished himself by standardizing the industrial production, introduced the working principles and the production chain, and implemented Taylor's scientific ideas with respect to the industrial administration of the organization (Bouri, 2016).

Herni Foyol introduced the modernization of management practices. He formulated the administration methods of an enterprise, establishing the principles underlying the administration and operation of the company: planning, organization of resource management, coordination, control (Bouri, 2016).

Max Weber supported a model of hierarchical administration of functions, competencies, control of the activity. Analyzing the interaction between the individual and the authority, he considered bureaucracy as an ideal way in the organizational field. Weber defined *three types of authority* within an organization (Bouri, 2016):

- *charismatic* refers to the natural qualities that an individual possesses, ensuring a potential for ascendancy in relation to others, such as, the situation of group leaders;
- *traditional* - authority is transmitted through tradition, as is the case of family businesses, through father-son succession;
- *rational or legal* [10] is in relation to the function; it occurs between management and the members of an organization; the latter perform the function established by the management authority.

The classical system of thought treated in correspondence with the economic and industrial structure of the era, also stood out by limits, such as (Bouri, 2016):

- it outlined the principles of an ideal, universal model of organization;
- neglecting the needs and interactions between individuals;
- neglecting the interactions between organization and environment.

Neoclassical Public Administration

After the Second World War, some criticisms of scientists, about the scientific nature of classical administration emerged, the orientation being towards *the neoclassical public administration*. In this sense, Herbert Simon (1976) [11] contributed by introducing new elements, such as:

- ✓ foundation of the public administration on scientific bases and on laws derived from the human behaviour;
- ✓ separating the facts from appreciations related to value.

Following these directions, scientific knowledge could lead to the observation and monitoring of the social environment.

Neoclassical public administration is based on elements of behavioural psychology, structural functionalism and systems theory and on the theoretical foundations of welfare economics and decision-making theory.

Although Simon's conception influenced many scientists in studies elaboration concerning the behaviour and decisions in administrative organizations, in the implementation of governmental reforms, the ideas of the progressive current and classical theory were taken into account. Also, it was aimed the organizations and jurisdictions simplification, strengthening and the unitary nature of the executive power.

Practitioners of neoclassical administration have improved the methods of analysis in measuring performance, audit, budgeting, streamlining jurisdictions and organizations and have sought to move to a more rational management style, different from the bureaucratic style (Gruening, 2001).

Not all specialists in the field have followed Herbert Simon's conception but the new scientific standards. There were scientists who refused to accept the separation of facts from values, considering that this will move away public administration from its foundations (political element and the public interest) (Waldo, 1965; Subramaniam, 1963) [12].

Thus, the classical approach was present both in the progressive structures of governmental practices and in the theory of public administration.

In the late 60s, of the last century, there were two schools of thought in the field of public administration, one *classical* and a *neoclassical* one, both based on the progressive orientation and objective knowledge (Gruening, 2001, p. 5).

Beside these approaches, new ones emerged.

The theory of public choice

It is based on the idea of the freedom of choice of individuals in their actions, in order to achieve their own objectives, in relation to their options. The term of *rationality*, in this theory, has a different meaning from that observed in Simon's conception, in the sense that in this theory, the rational behaviour is not related to an optimal level (from a theoretical point of view), but consists in the capacity of action of individuals in relation to the information they have, in order to achieve their goals (Tullock, 1965) [13]. In this sense, public choice theorists have tried to explain the social phenomena (Gruening, 2001).

Using this information, the scientists, follower of the theory of public choice, assessed the modern welfare state founded by progressive practitioners and those of public administration.

Public choice theorists have noticed some distinctions between the bureaucratic organizations and polycentric systems, as shown in the table below:

Table 1: Peculiarities distinguishing between bureaucratic organizations and polycentric systems

Bureaucratic organizations	Polycentric systems
- the traditional budgeting system can lead to inefficient use of resources (Niskanen, 1971) [14] or - an accumulation of tasks and resources, difficulties in performing certain tasks (Downs, 1966; Tullock,	- the existence of several decision-making centres; - decisions of individuals relate to the preferences and information they own (Hayek, 1960, 1969) [16];

1965) [15].	- the provision of services is separated from production; - there is competition in obtaining contracts between the producers from the private sector and those in the public sector.

Source: processing from Gernod Gruening (2001) "Origin and theoretical basis of New Public Management", International Public Management Journal 4 (2001) 1–25.

The component elements of the theory of public choice (methodology, recommendations, ethics) are opposed to the two currents of public administration - classical and neoclassical (Ostrom and Ostrom, 1971) [17]. Public choice theoreticians have contributed with a number of initiatives towards reform. Among the aspects concerned, these sighted the formation of a polycentric administrative system as opposed to the monocentric one (in the progressive version) (Gruening, 2001).

New Public Administration

There were a number of schools of thought that followed the classical and neoclassical public administration.

→ *The New Public Administration* (initiated by Dwight Waldo, 1968) meant a challenge for classical and neoclassical public administration. The concept includes elements from the *human relations segment and the political side* of public administration (Marini, 1971) [18].

In La Porte's opinion (1971, p. 31) "the purpose of a public organization is the reduction of economic, social, and psychic suffering, and the enhancement of life opportunities for those inside and outside the organization." [19]

The Human Relations Movement; Theorists

At this stage, the importance of the human factor and the tendency to humanize work relations increase.

Elton Mayo emphasizes the consideration of working conditions. Research achieved in the period 1927 -1932 referred to employee behaviour at the workplace [20]. His studies have shown that, unlike organizational, formal factors that can influence productivity increase in an organization, the employee behaviour can also be influenced by an informal system, respectively, feelings, as well as the way in which individuals interrelate; there is a positive correlation between the psychological factors and working conditions, with effects on productivity (Bouri, 2016).

The important element of novelty is the understanding of the importance of interpersonal relationships in workplace performance.

Maslow takes into account the secondary needs of employees. The analysis is focused on work motivation, establishing a pyramid of needs where it distinguishes primary and secondary needs. The motivation of an individual's work is determined by knowing how to meet his needs [21]. Among the needs of lower rank there are considered the psychological ones, security, respect and others.

Douglas Mac Gregor takes into account of the individual and organizational needs and formulates two theories regarding the different attitude of individuals towards work. (Bouri, 2016).

- Theory X - corresponds to the ideology and practices of the era; in the case of individuals with aversion to work, command, control of their activity, including coercive measures, are required. There are individuals who choose security, prefer to be directed and have no responsibilities;
- Theory Y - associates the individual needs with those of the organization. It is the situation of individuals who set their own goals, take over responsibilities and have the capacity for self-control. This category includes individuals who have an untapped knowledge potential, in reserve. (Bouri, 2016).

Chris Argyris At the heart of the organization is the individual and his knowledge. Organizational effectiveness depends on (Bouri, 2016):

- Satisfying the staff's need to self-manifest, by participating in the process of work conception, of decision.
- Ability to integrate change, organizational innovation.

Political Analysis

The discipline of political studies or political analysis emerged in the early '70s (Parsons, 1995) [22] and is focused on *two sides* of analysis concerning policies (Gruening, 2001):

⇒ pursuing practical policies, significant actors and results achieved (Anderson, 1975) [23]; it is oriented towards behavioural elements;

⇒ providing solutions for overcoming political problems (Nagel, 1980) [24].

Practitioners of political analysis considered this discipline to be modern, in relation to the public administration that focused on institutions (Lynn, 1996) [25].

✓ Philip Kronenberg and Orion White Rohr and others developed the *Blacksburg perspective*, which included elements of the New Public Administration (Wamsley et al., 1990) [26].

✓ *Communitarianism*, developed in the '80s, emphasized on the normative framework of the New Public Administration and had as its central idea, the high participation of individuals in political life, by creating some political and administrative structures with a higher degree of participation (Cooper, 1991; Barber, 1994) [27].

✓ *Public administration discourse theory* - another school of thought of the New Public Administration. Its representatives Fox and Miller (1995) [28] focused on the role of moderator of public administration in the sphere of public policies, in which individuals and organizations participate in solving public issues (Gruening, 2001).

The three schools of thought (Blacksburg perspective, communitarianism and discourse theory) had as basing element, the New Public Administration, the normative framework and reform proposals. These emphasize *participation, community, self-actualization and human resource development, as a central element of reforms in public and private organizations. It is considered that reality is based on social aspects.*

Public Management

It is an institutional approach that emerged in the '70s. The neoclassical research was implanted, through certain elements, in the private sector, and these were taken over in the public sector, through the public management. Taking over these elements from the private sector has two orientations (Gruening, 2001):

✓ *Rational or mechanistic* management styles and tools. It focuses on the measurement of performance and the remuneration of organizational leaders in relation to the results

achieved. It is highlighted through some policies: zero budgeting (Lerner and Wanat, 1992), management by objectives, techniques of performance measurement and accounting (Henry, 1990), public sector marketing (Kotler, 1975) and strategic, rational management (Wechsler and Backoff, 1986) [29].

- ✓ *Humanistic or organic* management styles and tools, such as [30]:
  - organizational development (Golembiewski, 1969);
  - Total Quality Management (Milakovich, 1991; Swiss, 1992);
  - strategic management (Moore, 1995).

From the above, one can signalize a close correlation between public management and public administration, accompanied, at the same time, by competition. The public management is considered by scientists to be *a new discipline, different from public administration*. (Gruening, 2001)

Conclusions

The manifestations forms of public administration, which crossed the last century were based on the traditional bureaucratic model having theoretical foundations in the United States, Great Britain and Germany (Fr. Taylor, W. Wilson, M. Weber) [31].

Considered a good way of organizing work, the classical administration is a hierarchic model of bureaucracy, based on centralized control, with a system of regulations, the professional bureaucrats being separated from the political system (Katsamunska, 2012).
Emerged after the Second World War, the neoclassical current sought the foundation of public administration on scientific basis, on rules and elements of human behaviour (Simon, 1976) [32].

A challenge for the two current of thought (classical and neoclassical) was the New Public Administration, scientists considering the change is necessary, a new direction in the administration thought, by creating democratic structures that emphasize participation, social equality (Gruening, 2001).

Public management, the new institutional approach of the '70s, meant taking over some elements in the public sector, from the private sector, being the expression of the correlation between the public management and public administration which is accompanied by competition (Gruening, 2001).

The process of change continued in the '80s - '90s, along with the emergence of the new managerial form in the public sector, called the New Public Management, in which the emphasis is on economy, efficiency, government efficacity, a higher service quality (Katsamunska, 2012).

There was no implemented a single formula of management in the public administration, the institutional reconstruction and finding the necessary solutions to solve the problems being different by countries, depending on the existing public administration and the priorities which it calls for its proper functioning against the background of administrative traditions (Naschold, 1996, p 19) [33].

One possibility may be to adopt a mix of changes that offer solutions to meet the interests of citizens, taking into account the need for an efficient public service.

Assessment of Modern Trends in The Development of Accumulative Pension Schemes in The Russian Federation

Yulia Y. FINOGENOVA

Plekhanov Russian University of Economics, Moscow, Russia
Finogenova.YY@rea.ru

Abstract

The paper discusses the possible transformation of the existing accumulative pension system in Russia, taking into account the concept of the guaranteed pension plan (GPP) announced by the Government at the end of 2019. The main difficulties of transition to the concept of GPP, taking into account the peculiarities of savings strategies of Russian citizens, are presented. The analysis of existing strategies for investing pension assets in mandatory and voluntary pension systems in Russia is carried out. As well as an analysis of foreign experience of pension savings' investment. The main ways of reforming the accumulative pension system are shown, as well as approaches to forming the structure of the investment portfolio of non-state pension funds are proposed.

Keywords: non-state pension funds, guaranteed pension plan, pension assets investments strategies, compulsory pension assets allocation, voluntary pension assets allocation.

JEL Classification: H55; H69; J26; J38.

Introduction

The global trend associated with the decline the role of the state in financing citizens ' pensions is becoming more noticeable during the crisis, when governments are trying to reduce the budget spending on social needs, as this becomes a very burdensome task.

At the end of Q3 2019, there were about 6.2 million people, or 8,2% of the economically active population, participated in the system of non-state pension provision (contributions at their own expense or within the framework of corporate pension programs). For comparison, in the system of mandatory pension insurance, where savings were formed at the expense of mandatory deductions of the employer before the "freeze" of 2015, implemented through the NPF, the number of insured persons was according to the Bank of Russia at the end of Q3 2019. 37,4 million people, which is 6 times more.

Against the background of a record drop in the consumer confidence index over the past five years, citizens will need additional incentives to encourage them to make voluntary contributions, in addition to the tax deduction, this is associated with a number of structural problems: low wages, high illegal employment, distrust of domestic financial institutions, etc.

The government of the Russian Federation has already made attempts to increase interest in the independent formation of pension savings among citizens in 2008 by offering a rather attractive program of co-financing pensions. For every 2 to 12 thousand rubles of annual voluntary contributions to the cumulative program of the compulsory pension system, the state was ready to add the same amount from the budget. Moreover, contributions could be made for 10 years from the date of entry into the program, the application period for joining which expired on December 31, 2014. Unfortunately, even a 100% return did not become a decisive factor for participation in pension savings. According to the Pension Fund of Russia, about 16 million citizens participated in the program, or no more than 12% of the economically active population at that time.

FINOGENOVA "Assessment of Modern Trends in The Development of Accumulative Pension Schemes in The Russian Federation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Another option that could potentially become an incentive for citizens to independently make pension contributions is the resuscitation of the decision announced in November 2019 to launch a guaranteed pension plan (further "GPP"). Recall that the pension moratorium, imposed in 2014, was then extended until 2022, which means that the insurance pension contribution bypasses the accumulative system goes to the insurance one. However, the question of how to properly manage the savings generated before 2015 remains open. Last fall, the Ministry of Finance proposed to transfer the savings formed in the mandatory pension system to the voluntary one, and the amount of contributions and their frequency in the new system is determined by the citizen himself. The transferred savings accounts will be registered in a single Central administrator, and the safety of pension savings must be guaranteed by the state (at the savings stage, full compensation for the amount of the nominal contribution with the established upper limit, and at the payment stage – the assigned pension also in the established guaranteed amount). Payments as in the state pension system are supposed to be indexed to a level not lower than inflation. GPP can be the first step towards the unification of pension programs, which means to increase the efficiency of investments in pension assets, provided that investment companies that manage these assets compete, and, most importantly, to better understand the essence of pension products offered on the market.[13]

In the accumulative pension system, the investment income received from pension savings is of particular importance, since the level of pension provision in this system depends on its size. Therefore, it is particularly important to develop investment strategies that would provide moderate risk in the long term with a return exceeding at least the return on banks' deposits.

Literature Review

In many researches, the main criterion for evaluating the effectiveness of investment portfolio management is the level of return received, as well as the need for regular pension contributions from the individual income. In the article of Martellini et al (2020) were considered, that in order to "supplement retirement benefits received from public and private pension systems, individuals need to make voluntary contributions and decide how to efficiently invest these contributions. Goal-based investing principles can be used to create retirement solutions that secure a minimum level of replacement income while delivering a high probability of reaching higher levels defined as aspirational goals".

In the study of Estrada and Kritzman (2018) was declared, that "the predominant metric for evaluating retirement investment strategies is the failure rate", but this rate "fails to distinguish between strategies that fail early in retirement from those that fail near the end of retirement" and "it fails to account for potential bequests". These authors proposed "a new metric, the coverage ratio, which is more comprehensive and informative than the failure rate", as far as it "measures the number of years of withdrawals (during and after retirement) supported by a strategy, relative to the length of the retirement period considered. Importantly, this metric accounts for everything the failure rate accounts for".

Another authors, for instance, Clare, Glover et al (2020) considered "the nature and importance of the concept of sequence risk, the risk that a bad return occurs at a particularly unfortunate time, such as around the point of maximum accumulation or the start of decumulation". They also proposed "three different measures of sequence risk, each of which is intended to inform investors of the probability that a chosen investment strategy may not deliver desired withdrawal rates, and hence these measures are intended to aid investment choices; conventional performance measures such as Sharpe or Sortino ratios are only indirectly related to this ability to achieve a given withdrawal experience"

Unfortunately, in the existing Russian reality, the savings rate of citizens does not exceed 3% of the income received, and the infrastructure of the investment market is not sufficiently developed. In addition, the constant transformation of pension legislation, as well as unresolved issues regarding assets formed in the mandatory pension insurance system for the "young" cohort of Russian citizens, do not add to confidence in pension savings.

Hypotheses

Currently, there are a number of possible directions for further development of the accumulative component of Russian pension system:

- continue to develop the mandatory accumulative element of the pension system (without GPP) through a return to its basic insurance principles of forming the pension system, the development of the accumulative component while maintaining its mandatory nature.
- to abandon the mandatory nature of the formation of the accumulative component of the pension system and switch to the principle of voluntariness, using the GPP model, in which a non-state pension in the GPP will exist along with other types of non-state pensions in the voluntary pension system;

In addition to the above hypotheses, it would also be possible to implement an option that would adopt a modified version of the GPP, which would develop a mechanism for possible financial participation of the employer in the financing of employee pension contributions. The employer will be given the right to choose: (1) to continue existing corporate programs, providing for the option of voluntary payment of pension contributions by the employee without participating in programs based on the GPP, and (2) to develop a new program based on the GPP, with the possibility of maintaining the previous programs.

Methodology and Data

Currently, one of the reasons for the lack of dynamic development of non-state pension provisions is the low level of wages of Russian citizens and the lack of necessary financial resources for their participation in voluntary pension programs, so the introduction of the GPP will not add to the number of non-state (voluntary) pension system participants. The issues of improving the living standards of the country's population should be resolved simultaneously with the reform of the wage system and increasing the share of wages in the country's GDP.

It is important to create a full-fledged three-level pension system (compulsory accumulative element, corporate pension programs, individual pension programs), which requires the creation of a system of effective incentives that encourage the employer to actively participate in the development of corporate pension programs for their employees, and the employee to participate in individual pension plans as well. Therefore, a set of measures is also needed to stimulate the development of individual pension insurance programs.

To increase the level of return on investments of pension funds, it is also necessary to fully develop the financial market with a variety of different financial instruments for long-term investment that provide returns above the level of inflation and have an acceptable level of risk.

The purpose of the GPP is to provide citizens "with the opportunity to form additional sources of funding for pension income through personal contributions in the NGO system, with the stimulating support of the state and strengthening mechanisms for protecting and guaranteeing pension rights.

The possibility of the employer's participation in the formation of pension contributions is not excluded, but the specific mechanism for this participation is not specified. Among the possible measures to encourage employer participation in the GPP, the following is mentioned: "the base for income tax can be reduced by the amount calculated depending on the listed contributions" , it is also proposed not to tax personal income tax on the amount transferred by the employer as co-financing of the employee's pension contribution (while a number of restrictions are introduced).

The concept of a guaranteed pension plan provides the number of incentives. In particular, for individuals, a tax deduction is offered for the amount of the contribution to the GPP, but no more than 6% of the income. For employers, when co-financing employee pensions, it is proposed to reduce the

tax base for income tax. One of the important points of the concept is the possibility for citizens to transform their pension savings into GPP within the framework of compulsory pension insurance

The compulsory insurance pension in RF is awarded upon reaching the age of 65 for men and 60 for women (taking into account the transition period until 2028). Her appointment requires at least 15 years of work experience (including the transition period until 2024) and a minimum amount of individual pension coefficients of 30 points (including the transition period until 2025). Now you can, if a citizen does not have enough experience or points to receive an insurance pension, "buy" them in the State Pension fund. To do this, an individual must voluntarily enter into legal relations on pension insurance and independently transfer pension insurance contributions. The period of payment of insurance premiums is counted in the insurance experience, the minimum payment for purchase per year in 2020 is just over 30 thousand rubles. This amount can be paid at once, in multiple payments, or monthly throughout the one year.

It is for the payment of these amounts that the funds generated in the GPP, including those converted from pension savings under the OPS, can be used.

If a Guaranteed pension plan is adopted, the role of the non-state pension funds (NPFs) is not fully clear, since the investment of pension savings will be carried out by management companies, accounting for accounts and pension schemes, and the pension operator. In these circumstances, the role of NPFs in the new pension system becomes redundant (see fig.1).

Fig. 1: Illustration of the proposed structure of Guaranteed pension plan (GPP) in Russia.
Source: compiled by the author based on [5]

In view of the planned introduction of the concept of GPP, it would be appropriate to use the experience of those countries where depositors (participants) of the pension fund are offered different risk portfolios depending on their belonging to a particular age category. Thus, more risky investment portfolios could be offered for younger participants, while conservative ones could be offered for older participants. With age, investment strategies for participants will change from risky to conservative, thus maintaining a balance of income growth and saving pension funds.

Obviously, in the accumulative pension system, the amount of return is important, but in the first place, nevertheless, the safety of pension savings, i.e. moderate long-term returns that exceed inflation, while meeting all the established requirements for such investment of pension assets by the state.

As indicators of the effectiveness of pension funds investment are used: indicators (annual, medium-term, long-term, for example, accumulated returns) of the return on pension funds; the growth rate of the investment portfolio (increase in the value of net assets in which pension funds are invested.

Currently, the Russian financial market does not provide the necessary financial instruments to fully diversify the investment portfolios of pension funds, and there are no long-term financial instruments that are adequate to meet the Fund's pension obligations in the time period.

The types of basic investment strategies used by NPFs are shown in table 1.

The time interval (long-term, medium-term and short-term periods) in which the effect of external factors is considered plays an important role. For example, the accumulated inflation of NPFs and their asset management companies may be bypassed in the long run, but in some years their profitability may be significantly lower than the level of inflation.

Over the 8-year period (2012-2019), the average accumulated return (67.28%) and the median return (72.32%) exceed the accumulated inflation for this period (65.57% For three years (2017-2019), accumulated inflation was about 10%, while the accumulated return on investment of pension assets (compulsory) is 16.74%, and pension assets (voluntary) is 15.74%.

The main goal of the non-state pension funds' investment strategy is to preserve pension assets, and this requires that the projected return is maintained at a level not lower than inflation; a certain level of liquidity is provided; the investment portfolio consists of securities with a high level of Issuer quality, low market and credit risks, and the investment/placement of pension funds is carried out in assets with high liquidity that bring stable, predictable income.

Table 1: Types of investment strategies used by non-state pension funds

Type of strategy	The share of investments	Minimum guaranteed return	Projected return (nominal)
Balanced (medium risk level)	Fixed income instruments 80-90%; promotions 5-10%	not defined	Up to 8%;
Basic (moderate risk level)	The fixed income instruments 70 - 80%; Promotions 10-20%	not defined	Up to 9%
Income guarantee (low risk)	Fixed income instruments 100%	Defined (may be revised due to changes in the key rate of the Central Bank of the Russian Federation	Up to 10%;

Source: compiled by the author, based on [1], [7], [11]

In order to provide long-term income, even though there may be short-term losses, the proposed structure of the investment portfolio could look like this: 10% (high-risk assets, risk portfolio) and 90% (non-high-risk assets, main portfolio). This structure allows you to generate additional income (at the expense of riskier assets), but in the event of their loss, maintain financial stability.

In addition, the list of permitted assets for the placement of pension assets in the compulsory system could be supplemented with investments in close-end mutual funds. The analysis of foreign experience has shown the active development of alternative instruments (which include hedge funds, private equity funds, which include venture funds, etc.) for investing pension funds (the share of which in investment portfolios can reach up to 30%). The return on such investments may be higher than in traditional investment objects. At the same time, there are problems of increased risks of such investments, such as the difficulty of exiting venture funds.

The structure of the investment portfolio of the NPF of the Russian Federation in relation to pension savings formed in the mandatory pension insurance system and pension reserves in the system of voluntary pension provision in non-state pension funds is shown in fig.2 and fig.3.

Fig. 2: Voluntary pension assets allocation [2], [3]

Fig. 3: Compulsory pension assets allocation [2], [3].

The analysis of private pension fund's returns showed that in the vast majority of economically developed countries that reported accumulated real returns in private pension funds, they were positive at 5-year, 10-year and 15-year intervals, which also affected the level of pension provision for Fund clients in these countries (in some of them, the aggregate pension replacement rate for lost earnings formed on the basis of a multi-level pension system reaches 90% or higher, such as in Portugal, Austria, Luxembourg, Italy etc.).

In a number of countries, the security of pension funds is determined in connection with either guaranteed returns or the avoidance of negative returns, and involves an annual review of the value of pension assets, taking into account the return over the past year. At the same time, the safety is adjusted to a certain level of profitability. It is very important that the reporting of pension funds in the OECD member countries involves, in addition to the nominal return (the actual investment result), taking into account an indicator of real return equal to the nominal return minus the inflation rate in a particular

country. The established guaranteed yield in the analyzed countries is usually set at 2-3% above the inflation rate (the indicator is calculated based on the average inflation rates for a certain period).

There are also various guarantee structures: floating or fixed minimum income, valid only at retirement or at each time interval, as well as their terms (calculated and paid annually or at the end of the accumulation period).

It is important to clarify that the safety of pension funds is considered in the long term (the minimum term of this perspective is 5 years, when the amount of pension funds is fixed in the accounts of the pension funds' clients).

In spite of the former conservative investment strategies of the pension funds, nowadays more and more pension assets are invested not in fixed-income instruments, but rather in the alternative instruments. The analysis confirmed that highly developed pension markets provide greater flexibility when it comes to investments not implying any restrictions on the structure of investment portfolios comprised of pension assets.

According to the reports of the OECD member countries, the concept of profitability is identified with the concept of "received result", and the result from investing pension funds can be either negative or positive. At that time, as a yield is a positive result from the investments of pension funds assets (see table 2).

Table 2: Return of pension assets in voluntary pension programs and the investment portfolio's structure in some OECD countries in year 2018 [10]

Country	In % of investment portfolio					Nominal investment return, %		Real investment return, %

If we look at the profitability of pension assets in Russia during the last three years in the state (compulsory) and non-state (voluntary) pension systems, we can see, that most of the time actual profitability was lower, then the forecasted profitability of the standard investment strategies. Moreover, the compulsory system demonstrated even better investment return in some years compared to voluntary system. In the same time, the return on the pension assets in the compulsory pension system was also greater for the last three years except the year 2018 (see table 3).

Table 3: Profitability of pension assets in Russian non-state pension funds for the years 2017 – 2019 compared to the required rate of return in the voluntary pension schemes and inflation rates

Rate of return and its comparison with the key benchmarks	Year 2019	Year 2018	Year 2017
Return on pension reserves (voluntary system)	*5,17*	*5,38*	*5,20*
Profitability spread (if annual return 6% required)	-0,83	-0,62	-0,80
Profitability spread (if annual return 8% required)	-2,83	-2,62	-2,80
Return on pension assets investments (compulsory system)	*9,46*	*0,79*	*6,49*
Profitability spread (if annual 6% required)	3,46	-5,21	0,49
Profitability spread (if annual return 8% required)	1,46	-7,21	-1,51
Inflation, %	*3,06*	*4,3*	*2,52*
Spread between inflation and investment return in the voluntary system, %	2,11	1,08	2,68
Spread between inflation and investment return in the compulsory system, %	6,4	-3,51	3,97

Source: compiled by the author based on [12], [3]

The weighted average return on investment of pension savings in the compulsory accumulative pension system on the basis if non-state pension funds was 10,5%, which is higher than the return on other financial instruments. The profitability of placing pension reserves in the framework of the voluntary pension system was lower only than the profitability of mutual funds and investments in gold.

The introduction of risk-based supervision funds, stress testing, fiduciary responsibility, a new system of compensation funds, the formation of each system risk management allowed the Bank of Russia (the state regulator) to expand the rights of non-state pension funds in terms of increasing their role in the management of pension assets and, in particular, to provide the funds the right to invest pension

reserves in any assets permitted by the Bank of Russia, whose list has expanded considerably. At the same time, the non-state pension funds retains the right to attract the asset management companies for the purpose of placing pension reserves in the voluntary pension system. Expanding the possibilities of self-placement of pension reserves helps to reduce the cost of non-state pension funds payments under trust management agreements and, accordingly, increase the amount of money transferred to the registered accounts of participants of the non-state pension fund.

Results and Conclusion

The results of the study showed that it is necessary to finalize the version of the GPP Concept, including the need to clearly identify and consolidate the role of non-state pension funds and their asset management companies in this system.

It also makes sense to expand the list of permitted assets for pension funds' investment for non-state pension funds and heir asset management companies. It also worth developing special financial instruments for the pension market (for example, pension bonds issued by the state with a long maturity of more than 15 years) with increased reliability (state and banks' guarantees, tax benefits to the issuer of such pension products) and guaranteed rates of return (at the level of inflation plus 1,5-2%).

It is also important to identify ways to further liberalize the requirements for pension funds' investment, thus focusing funds on the choice of real assets and long-term investment (for instance in the infrastructure projects);

In addition, it is important to differentiate the structure of risk-based supervision for different age groups of non-state pension funds' clients.

Discussion

It is important to identify the main priorities of the current stage of reforming the Russian pension system: the integration of non-state pension funds into the Russian economy, improving the living standards of pensioners, filling the budget of the State pension fund and reducing dependence on investments in it from the state budget. From the analyzed concept of the GPP it is not disclosed how the introduction of the GPP will affect the income of future pensioners.

As a solution to the problem with pension contributions to the State pension fund - the development of parity programs with the employer. We should also consider the possibility of co-financing the GPP program with the participation of the employee, the employer and the state, or the employee and the state (similar to state co-financing pension program). The total rate for pension contributions to the GPP (4-6% of the salary) can be distributed equally (2-3%) between the employee, the employer and the state, which will increase the rate of replacement of lost earnings by the received pension.

It is necessary to create an effective system of measures to encourage the participation of employees and employers in the GPP (voluntary non-state accumulative pension system) system:

- exclude any payments in the GPP system from the income tax base (personal income tax);
- withdraw from the taxable base of income tax pension contributions under contracts of GPP in favor of employees (you can specify this proposal by specifying the required work experience in the organization, for example, 5 years).

The Bank of Russia is once again trying to "restart" the motor of the accumulative pension system by agreeing to increase the size of the pension tax deduction to 52 thousand rubles per year by increasing the limit for calculating the tax deduction to 400 thousand rubles. If this limit is set separately for pension savings and a similar limit applies separately for other types of socially significant expenses (voluntary health insurance, education, etc.), then the potential maximum amount of tax deduction that citizens can receive will increase by more than 3 times compared to the current one.

In order to be entitled to the maximum tax deduction of 52 thousand rubles per year, a citizen must make monthly deductions of 4.3 thousand rubles. In principle, you can make deductions in a smaller amount, but then the maximum effect of the proposed innovation will not be achieved. And then the question arises, what percentage of the population is ready to make monthly contributions in this amount, for at least 15-20 years?

If we take official data on the average levels of nominal wages in Russia for the 1st quarter of year 2020, amounted 48 390 rubles, the size of pension contribution will be 8,9%. If we compare this value with the average amount of savings even for a relatively "prosperous" year 2019, it turns out that according to official data, citizens could save no more than 3% of their salary for the year. If we take into account the growing risks of unemployment and slowing economic growth due to the pandemic, then at the end of 2020, the savings behavior of Russian citizens is likely to be even more restricted.

Conclusions

The analysis allows us to conclude that a conservative portfolio for investing pension assets in NPFs may consist of the following assets: 30/70 ratio of shares and corporate bonds, while ensuring a return not lower than inflation. The share of state bonds and municipal bonds should not exceed 10%, and shares of Russian issuers should not exceed 10%, while shares of emerging market companies should not exceed 15%, and Russian corporate bonds should not exceed 65-70% of the portfolio.

The structure of a portfolio with an average level of risk may look like this: the ratio of stocks/bonds at the level of about 50/50. At the same time, Russian corporate bonds must account for at least 45%, shares of Russian issuers for at least 30%, and shares and bonds of emerging market companies for about 15% and 10%, respectively.

In the structure of a portfolio with a high level of risk and an investment horizon, the most optimal ratio of stocks and bonds is possible at the level of 70/30. The proportion of shares of Russian issuers at 50%; shares of emerging market companies 15%, corporate bonds of Russian companies 20%, bonds of emerging markets' countries 15%.

Abstract

Millions polyethylene terephthalate (PET) bottles are produced every day and get in landfills, rivers, seas and oceans. PETs lasts 700-800 years until they begin to decompose and will only disintegrate after about 1000 years. Although very difficult to disintegrate, PET is a 100% recyclable material. PET / recycled polyester is used as raw material for textile fibres or other PET packaging. Recycling is a solution both to reduce environmental pollution and to save natural resources. Recycling and selective waste collection is a major issue worldwide for which innovative technical solutions are sought. This paper presents the results of experimental research for an intelligent waste management system, conducted by a team of researchers in the frame of master's program Complex Projects' Engineering and Management from University POLITEHNICA of Bucharest. The customized macroplanning for the developed technical solutions with multiple design phases, was based on business strategy, needs analysis, concept generation and selection eventually ending up with the building and testing of a functional prototype. Also, based on a customized electrical and software architecture, a Smart Management Application for controlling the prototype is described in this work.

Keywords: Industry 4.0., New Product Development, Project-Based Pedagogy, Smart Management Application, Waste Compactor.

Introduction

The European Union aims to make all plastic packaging recyclable by 2030. Under current European legislation, all countries are required to recycle a certain percentage of the amount of waste from PET packaging. However, Romania recycles an insignificant amount of the entire volume of waste it produces, the rest being thrown in the landfill.

Polyethylene terephthalate (PET) packaging can be recycled and used for the manufacture of new containers or for raw materials in the textile industry. The diversity of types of packaging and the materials from which they are made complicates the recycling process. The recycling process sometimes becomes difficult and expensive. The quality and price of the recycled product compared to the original plastic is also a problem that complicates the recycling process.

A team of researchers from master program Complex Projects' Engineering and Management from University POLITEHNICA of Bucharest works to design and develop an innovative compactor system with selective waste collection controlled through a Smart Management Application developed in LabVIEW as a virtual instrument.

This paper is based on a master team research coordination regarding an initiative to empower and educate the public about the importance of recycling, providing effective means for selective waste collection with minimal user effort. This idea was generated in the frame of the master program Complex Projects' Engineering and Management from University POLITEHNICA of Bucharest. A key component of learning strategy is Project-Based Pedagogy (PBP) for a new product development according to ABAZA B. et al. (2015).

During last two academic years two master teams chosen to develop different innovative technical solutions for home use systems dedicated for compacting recyclable containers, designed with selective waste collection capability thus facilitating the recycling process. The development process included building and testing functional prototypes based on which the optimization of technical solution was made.

Initially student's research was focused on development of mechanical system architecture designing different technical solutions for compacting the waste and for selective waste collection. This paper investigates and propose solutions for the electrical architecture and for the software component which should be designed as a Smart Waste Management Application dedicated to be compatible with all these mechanical concepts but also to integrate Industry 4.0 concepts and principles.

Macroplanning

Based on customized macroplanning for new product development and PBP teams developed technical solutions which have gone through multiple design phases, while having continuous improvements made based on: business strategy, needs analysis, concept generation and selection eventually ending up with the building and testing of a functional prototype. Figure 1 explains the macroplanning defined according with academic program. This is another key element to take in account which influenced teaching activities and project development from the perspective of PBP integration, as Abaza mentioned (2020).

Fig. 1: Macroplanning

Preliminary Experimental Trials

To determine the forces required to compress the waste, a series of preliminary experimental determinations were made using a large variety of types of waste: cans, PET bottles, Tetra Pack, of different heights and thicknesses. It was used a Zwick/Roell ProLine table-top testing machine (Figure 2).

The results of the experimental determinations are presented in table 1.

Figure 3 shows the forces – deformation diagram during the experimental research, where:

- F1 – is the force required to initiate compression.
- F2 - the force at which the compression is performed.
- F3 - the maximum force it reaches at the end of the deformation.

Fig. 2: Zwick/Roell ProLine testing machine

Table 1: Experimental results

Waste Type	Material	Compression Ratio	H waste [mm]	v [mm/min]	F1 [N]	F2 [N]	F3 [N]
Can	Al	1/5	150	600	540	110	545
Can	Al	1/5	120	480	460	110	755
Bottle	Pet	1/4	330	1000	220	120	229
Bottle	Pet	1/5	355	1000	140	90	348
Bottle	Pet	1/5	350	1000	290	100	290
Tetra Pack	Paper	1/4	250	1000	100	150	170

Fig. 3: Force – deformation diagram

On the x-axis is deformation nominal D of the waste (bottle/can/tetra pack) in millimetres from start point until the point where the deformation was completed. On the y-axis is variance of force F in N during the deformation of the waste.

All experimental trials showed that during the deformation process there are 3 main forces thresholds to take in account: F1, F2 and F3. F1 is the spike of the force when initiating the deformation, F2 is the force during the deformation after F1 and F3 is the force at the end of deformation when there is no more volume reduction to be made. Based on this force variance the compactor should provide the F1 and F2 and to stop deformation just before F3. In this case the most relevant are the highest values for the force F1 required to initiate the deformation process. Based on the F1 values from all waste tested it results that the most disadvantaged case to be cover it is the case of the deformation of can where the force F1 it is about 600N. This is an important design input to take in account in the next design phases.

All experiments showed that stability of the waste is very important during deformation process and in any concept design of the compactor should provide solution for proper guidance and orientation of the waste.

Concept Generation

Based on these preliminary experiments the development process of the compactor followed all design phases according with macroplanning from figure 1.

Below in figure 4 is a selection of 2 design concepts for the compactor (Sevastian, 2019). The teams generate more versions but most of them used a screw nut mechanism for the compression subsystem of the waste. The screw is driven by an DC electric motor. Each concept proposes different solutions for compressing active parts taking in account the preliminary experimental trials.

Fig. 4: Concept design

The global design of the compactor (Figure 5) took in account the home use integration together with all main integrated functions: reducing the volume and selective waste collection.

Fig.5: Global design (Sevastian, 2019)

Development of Smart Management Application

Based on high accelerated development of Based on these preliminary experiments the development process of the compactor followed all design phases according with macroplanning from figure 4 (Sevastian, 2019)

Waste management domain is also affected by the high accelerated digital transformation proposed by Industry 4.0. A lot of research effort was focused on defining effective smart city concepts which integrate also wate management solutions. Basically, smart management applications use sensors to measure fill levels from waste container (bins) and generate different kind of notifications for assisting decision when to empty those bins and to collect the waste in an effective way. Many solutions where studied and developed using different kind of modern technologies like Cloud-based smart waste management (Aazam 2016) or Smart Waste Collection Monitoring and Alert System via IoT (Hisham Che Soh 2019).

This paper proposes a different development approach for the whole waste management ecosystem based on Industry 4.0 concepts and principles where the is a vertical integration with a hierarchical level component. It is about the integration of all IT system components at various hierarchical levels into one comprehensive solution. In our case these hierarchical levels are respectively the field level, the control level, the process line level, the operations level and the ecosystem planning level represented by the Waste Management Ecosystem (Figure 6).

Fig. 6: Waste Management Architecture

From this perspective our system will have similar levels like those from an automation pyramid:

1. Level one: sensors and actuators – connecting what should be connected at the level of compactor physical active parts representing the 'things and device' layer)
2. Level two: systems and internal services – monitor and manage in real time process at the level of the controller
3. Level thee: connectivity – connect for new applications and capabilities of the compactor
4. Level four: new services and ecosystems – transformation from the Waste Management Ecosystem.

Smart Waste Management and Execution Application plays a central role in development of the first stages of this approach based on Industry 4.0 transformation representing the digital hub of information and connectivity. In our case this will be represented by a virtual instrument software developed in LabVIEW able to cover all main roles and capabilities relates to:

- Remote control.
- Remote Diagnosis.
- Conditioning Monitoring.
- Systems Health Monitoring.

Smart Waste Management and Execution Application

Designing the Smart Waste Management and Execution Application was made based mechanical architecture of the compactors and based on electrical system architecture presented in the figure 7. Basically, this architecture describes the main components from level 1 and the way how these are interacting with components from level 2 from the automation pyramid.

Fig. 7: Electrical System Architecture

According to this figure, the software development should take in account interaction between main components from the level 1 with components from level 2 of the automation pyramid.

The components belonging to the level 1 in our case are:

- Limit switches which give the feedback about the position of the active compression plate.
- Active compression plate driven by screw nut mechanism. The 12V DC electrical motor will rotate the screw according with the compacting parameters given by the controller state machine through the motor driver connected between them. The nut will slide the active compression plate for producing the compression or for homing (repositioning to the home position).
- Confirm, Select and Abort buttons which allow to the user to select and interact with the compactor.
- 12V Power supply with power switch.
- Display connected to the controller. A local display is necessary even that the software may will have different remote interfaces on different devices.
- Safety devices like buzzer (generation of different audio signals), E-STOP button for stopping the compactor in any moment.

The main components belonging to the level 2 in our case are:

- Controller – in our case it was used and Aduino Mega 2560.
- WiFi Module type ESP8266 used for wifi communication.
- SD Card Module used for local logging data to the micro SD card.

Programming the Controller State Machines

Based on functional analysis and previous electrical architecture there were defined 8 states machines for the controller:

- DEBUG_STATE // 0 (System start-up and check all connected devices). In this state the system when is power up will check the status of all connected devices and will define the start-up states for all components. Figure 8 shows the interface for debug state when it can be seen that system by default will pass through automatically or, if necessary, it can be active the manual mode when a series of settings can be made for setting up the compactor: serial port selection (if wired connection is necessary), setup a new home position.

Fig .8: The interface for Debug State

- PET_STATE (Figure 9) // 1 (Compactor plate moves with to the left for compacting a pet). In this state the system will compact a PET moving the active plate, which generate the compression of PET, with a specific speed until the desired deformation is obtained. The speed is tuned using dedicated proportional–integral–derivative controller parameters (PID) for producing the proper speed of compressing plate to obtain deformation to a desired volume ratio compression. These parameters were defined based on experimental trials of the prototype for PET waste according with the combination of DC motor type, motor driver and mechanical components from the screw nut mechanism.

Fig. 9: The interface for PET state

- CAN STATE (figure 10)//2 (Compactor plate moves to the left for compacting a can). This is similar with the PET sate the difference being given by the PID parameters which are adapted for compressing a can.

Fig. 10: The interface for CAN state

- TETRAPACK_STATE (Figure 11)// 3 (Compactor plate moves to the right for compacting a tetra pack). This is similar with the PET sate the difference being given by the PID parameters which are adapted for compressing a can.

Fig. 11: The interface for TETRAPACK state

- HOLD STATE //4 (Hold a specific time the compactor plate is the position). When limit switch will be activated the active plate will stop and will remain hold in position for a defined time (1500ms).
- PREHOME_STATE (Figure 12) // 5 (Positioning to the neutral position -reference). In this state the active plate is start moving from current position to the home position (baseline) using dedicated home speed parameters.

Fig. 12: The interface for PREHOME state

- HOMING_STATE (Figure 13) // 6 (Compactor plate is in the neutral position waiting for a new compacting state). This is the state when the active plate is hold in home position waiting to start a new cycle. In this state the user can set parameters and insert a new waste in compactor.

Fig. 13: The interface for HOMING state

- OFF_STATE // 7 (System is freezing). This case freezes the compactor when an error occur or the E-STOP is activated. Is the safe mode state if anything happen and the user want to stop any activity.

Smart Waste Management and Execution Application was developed as a Virtual Instrument in the graphical programming environment LabView (Savu 2014). The virtual instrument is capable to integrate all roles and capabilities assumed for level 4 at the operational level from the pyramid with Waste Management Architecture presented in figure 5. This software application communicates and exchange data with the controller from level 2 integrating the level 3 represented by SCADA (Supervisory Control and Data Acquisition) (Abaza, 2014). A sample from the data flow programming code is presented in the Virtual Instrument Diagram (Spanu, 2018) from the figure 14.

Fig. 14: Sample of Virtual Instrument Diagram for Smart Waste Management and Execution Application

Statistics and data management is another section belonging to the Smart Waste Management and Execution Application. A sample of this is presented in the figure 15.

Fig. 15: The interface for Statistics

Actual version integrates basic functionalities for managing the loading status of the selective waste bins and can alert when the bin is almost full, and this can be empty. This functionality could be improved by integrating it in the whole process of monitoring a cluster of several compactors and to take operation decisions for collecting the compacted waste in an optimized way.

Based on logging and data exchange from all subordinate levels the system become capable to collects data from the sensors and states machines modes and more than that. This open another direction of development which is related to designing new graphical and data analysis tools relevant for the operational level.

Prototype Tests

Smart Waste Management and Execution Application presented in previous chapter was developed during the tests prototyping phase. According with the macroplanning the prototyping phase aims to reproduce and test the main function: reducing the waste volume. Another CAD version of the compactor was generated based on the materials and parts availability. In the Figure 16 is presented the CAD concept and the prototype made based on it.

Fig.16: CAD concept (Sevastian, 2019)

The prototype tests were aimed at assessing the behaviour of the comparator using all types of waste (figure 17). It has proven to be functional, successfully performing the functions for which it was designed. At the end of the test process, good behaviour in terms of noise and vibration during operation was observed, without the need for further improvements in this direction. In addition, several things have been identified that can be improved.

Fig. 17: Tests for different type of waste

Table 2 shows, by comparison, the initial dimensions with the dimensions of the compacted waste obtained from the testing of the prototype and using several types of waste.

Table 2: Dimensions of products

Waste Type	Material	Dimensions Initial [mm]	Dimensions after compacting [mm]	Compression ratio
Can 1	Metal	113	40	2.83:1
Beer Can	Metal	166	45	3.69:1
Can 2	Metal	131	40	3.28:1
Tetra Pack	Carton	202	40	5.05:1
PET 2l	Plastic	350	85	4.12:1
PET 1 0,5l	Plastic	187	65	2.87:1
PET 2 0,5l	Plastic	213	60	3.55:1

Product Optimization Analysis

According to the macroplanning the activity for product optimization analysis was performed during the prototyping process. It was used the method FMECA (Failure Modes, Effects and Criticality Analysis). The results of this analysis conducted to further development directions for the next version of the compactor and Smart Waste Management and Execution Application. Here are some relevant aspects:

- Reducing the section of the active pressure plate by using another nut with a larger flange diameter improving the position of stress concentrations and reducing stress in the holes areas. No residual deformations were found in the pressure plate, but at high stress it was elastically deformed.
- The possibility to reduce the section of the marginal plates. No deformations were found during the tests.
- Resizing the guide rods. Elastic buckling was found under conditions of maximum effort.
- Improving solution for evacuating air from waste during compression.
- Improving solution to protect the area where the lead screw is located from the pressing area.
- Modification in the architecture of the structure so that its stroke is not obstructed by the bearings and their fasteners.
- Improve PID adaptive optimization by extending the trials on different types of waste.
- Improve the customization and sensing for Controller State Machines. New interfaces can be developed for customization of PID and configuration parameters.
- Improve the usability of interfaces from Front Panel for the virtual instrument developed in LabView.
- Extend and improve tests of communication module. Testing them in different scenarios.
- Extend the cloud computing and analysis capabilities

The current chosen solution for compactor and Smart Management Application has gone through multiple design phases, while having continuous improvements made based on performed analysis and performance criteria, eventually ending up with the building and testing of a functional prototype.

Conclusion

This paper presented an educational development model of a Waste Management System. Based on a well-defined macroplanning different teams proposes concepts designs and technical solutions for waste compactors. Based on these a Smart Waste Management Application was developed synchronized with the same macroplanning.

The innovative system was developed based on Industry 4.0 concepts and principles.

Experimental research for prototype design has highlighted the forces needed for efficient compaction of different types of recyclable materials.

Based on the experimentally determined forces, the main mechanical and software components of the system were designed and optimized.

Smart Waste Management and Execution Application was developed as a Virtual Instrument based on Waste Management Architecture with a customised Electrical System Architecture and Programming Controller State Machines. The virtual instrument is capable to integrate all roles and capabilities from automation pyramid assumed for level 4 at the operational level. This software application communicates and exchange data with the controller from level 2 integrating the level 3 represented by SCADA.

Based on product optimization analysis performed during the prototyping process the actual version of Smart Waste Management Application integrates also basic functionalities for managing the loading status of the selective waste bins and can alert when the bin is almost full, and this can be empty. This functionality could be improved by integrating it in the whole process of monitoring a cluster of several compactors and to take operation decisions for collecting the compacted waste in an optimized way.

Based on logging and data exchange from all subordinate levels the system become capable to collects data from the sensors and states machines modes and more than that. This open another direction of development which is related to designing new graphical and data analysis tools relevant for the operational level.

This paper proved that iterative product development using Project-Based Pedagogy (PBP) synchronised with vertical integration approach from Industry 4.0 can become a new integrative education model for developing technical and transversal competences in engineering.

Non-Life Insurance Distribution Channels in Poland Compared to Selected European Countries

Anna SZYMAŃSKA

Department of Insurance, Faculty of Economics and Sociology, University of Lodz, Lodz, Poland,
E-mail: anna.szymanska1@uni.lodz.pl

Abstract

Increased competitiveness on the insurance market forces insurance companies to change their sales strategy. The development of domestic insurance markets and consumer preferences directly affect both the models of distribution of insurance services operating in them and the directions of changes in the structure of these channels. The aim of the paper is to compare the non-life insurance sales models in Poland with selected European countries. A research hypothesis was made that models of non-life insurance distribution channels on domestic European markets can be distinguished. Research results indicate three groups of countries in Europe with a similar level of development of non-life insurance markets. Four models of insurance sales have been distinguished on the market.

Keywords: Non-Life Insurance, Insurance Distribution

JEL codes: G22, M31, C38

Introduction

Domestic insurance markets are undergoing constant transformation which leads to changes in the way of purchase of insurance products by consumers. As a result, distribution channels in the insurance sector are changing rapidly. This is favored by dynamic technological changes. One of the most important trends in the financial services sector, including insurance, is the increasing use of new technologies by entities operating on the market (Waliszewski and Czechowska, 2019).

The form in which the consumer purchases an insurance service depends on many factors, such as the type of insurance, policyholders' preferences related to habits, and the availability and ability to use new technologies. According to Eurostat data, in 2017, the most common reason for not purchasing services via the Internet in EU countries was the preference for direct contact with the seller, loyalty to the seller and habit (69% of respondents), followed by fear about the security of such a transaction (25%) and the lack of sufficient skills (19%) (Szymańska and Klapkiv, 2019). Legal regulations on the domestic insurance market related to the protection of consumer rights are also of vital importance when it comes to choosing the distribution channel. Especially in the case of non-traditional distribution channels such as direct and bancassurance, there comes the risk to protect the interests of policyholders. In the case of the direct channel, for example, regulations on the possibility of withdrawing from the contract are mentioned, and in the case of bancassurance, it often happens that access to contract conditions is limited. Both in the case of non-traditional and traditional insurance distribution channels, legal regulations limiting the phenomenon of so-called *misselling*, i.e. offering products not adapted to the customer's capabilities or needs, are also important. It is also worth paying attention to trends outside the insurance market that affect the distribution of insurance. In Poland, there is an increase in insurance sales through the dealership channel in connection with the increase in sales of new cars or the use of leasing financing. The factors that affect the insurance sales strategy also include the economic situation directly affecting the demand for insurance services (Witkowska, 2016). All this influences the structure of domestic insurance distribution channels.

Cite this Article as: Anna SZYMAŃSKA“ Non-Life Insurance Distribution Channels in Poland Compared to Selected European Countries” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

According to the Global Insurance Pools McKinsey (2020) research, over the years the insurance industry in Europe has been dominated by direct sales through agents and brokers. However, new sales trends appear in the direct channel, also with the participation of "aggregators".

In Poland, agency sales have been the dominant insurance distribution channel for 20 years. Out of non-agency channels, the most popular is the sale of insurance in banks (Głowski, 2019 p. 14). It should be emphasized that, unlike banks, some insurance companies in Poland do not yet have a mobile application that would help clients, for example, in liquidation of claims or renewal of contracts. In Poland, sales of insurance via call centers were first introduced by LINK4 in 2003, and in 2005, sales via the Internet were offered by 25% of UKNUiFE insurance companies (2005). At that time, due to the growing access to the Internet, a significant increase in insurance sales via this channel was forecast. These forecasts turned out to be wrong. You can read more about the trends in changes in insurance distribution channels in Poland in the work (Laskowska, 2019). According to aleBank (2020), the coronavirus epidemic may have an impact on a more intensive than currently development of the insurance market sold remotely in Poland.

The aim of the paper is to compare the sales model of non-life insurance in Poland and selected European countries, taking into account the level of market development. A research hypothesis was made that models of non-life insurance distribution channels on domestic European markets can be distinguished.

The first part of the study is devoted to issues related to insurance distribution. The second part discusses the methods of assessing the degree of development of the insurance market. The research methodology is presented in the next section. The next part of the study is devoted to the analysis of the non-life insurance market in Poland against the background of European countries and the insurance sales models using cluster analysis. The last part of the work presents trends in the development of insurance distribution channels presented in available publications.

Insurance Services Distribution Channels

Distribution, in economic terms, is an activity consisting of the preparation, implementation and control of the flow of products or services from the place of their origin to the place of sale. Distribution is not only a way of delivering products or services, but also determining the place and method of contact with the customer. This is one of the areas of business activity that allows for the greatest diversification of activities towards clients. Distribution channels are independent entities involved in the process of making a product or service available for use, which create permanent links between the company and other entities, operate on the market and affect the economic results achieved (Kucka, 2009 p. 109).

Distribution of insurance services includes all activities related to planning, organizing, and especially transporting finished products from the insurer to the buyer (Otto, 2001 pp. 40-44). The most important activities in the field of distribution include: insurance protection, insurance risk, insurance consultancy, information, payments, negotiations, conclusion of insurance contracts, insurance documents, claims settlement and promotion. The distribution channels themselves are defined differently in the literature on the subject. On the one hand, these are all entities that participate in distribution, and on the other, the number and sequence of intermediaries involved in moving the product from the manufacturer to the buyer (Ostrowska and Jamróz, 2016 p. 128). It is a mistake to identify the sales channel of insurance services with the distribution channel. The sales channel is only a subsystem of the distribution channel. However, in most works, these terms are used interchangeably. In this paper, the terms of distribution and sale will be used to refer to the method of selling insurance.

There are many classifications of insurance service distribution channels. Most often, distribution channels are divided into direct, where there is direct contact between the insurance company and the policyholder, and indirect, where the service is provided with the use of third parties (Otto and

Materka 2003). Traditional forms of direct distribution include the sale of insurance services by full-time employees of insurance companies employed in the branch network. Insurance companies may also employ agents on a full-time basis with fixed or mixed remuneration (monthly fixed remuneration plus commissions depending on sales results). A non-traditional channel of direct distribution is the sale of services over the telephone and the Internet, often referred to as the direct channel. The indirect channels include insurance agents, multiagents, insurance brokers, banks and other institutions (Bojanowska and Wójcik, 2015 p. 427). Bancassurance, which is a combination of banking and insurance services, is becoming an increasingly important channel here. You can read more about insurance mediation, for example, in the works (Bednarczyk, 2016 pp. 126-144; Carter and all, 2009; Mehr, 1969).

Digitization is changing insurance distribution channels. A new model of insurance sales is a hybrid model in which the client is obtained traditionally or on the Internet, while the agent prepares the contract and sends the policy in an electronic version for signature. Another popular model is the mixed model (ROPO - research online, purchase offline), which consists in searching for an offer on the Internet, for example using a comparison engine, and then finalizing the contract in traditional channels, most often multi-agencies. These models are reported differently by insurers, which distorts the statistical data. So-called internet "aggregators", ie entities initially specializing in one area, are gradually expanding their offer also with insurance, such as the German portals Check24 and Verivox and the British MoneySuperMarket. This sales model is gaining ground in Western Europe, especially in the UK. According to McKinsey's analysis in Great Britain, in 2017 aggregators became the primary distribution channel for motor insurance in direct sales (53%) (Rychlik et al., 2019).

In each country, insurance distribution is subject to separate legal regulations, which directly affects the development of individual distribution channels. In Poland, in 2017, the Insurance Distribution Act (the Act of 15 December 2017 on Insurance Distribution) was adopted, which implements the provisions of the Directive of the European Parliament and of the Council (EU) on insurance distribution (Directive of the European Parliament and of the Council (EU) 2016 / 97). The EU's IDD (Insurance Distribution Directive) aims to increase the protection of consumers concluding insurance contracts and to harmonize the provisions on insurance mediation. The Act on Insurance Distribution covers all entities distributing insurance, regardless of the distribution channel.

Measures for Assessing the Maturity of The Insurance Market

Assessing the degree of development, or in other words, the maturity of the insurance market is not easy. The most frequently conducted research analyzes: the share of the gross written premium of a given country in the global premium, for example for the whole Europe, the gross written premium rate *per capita*, the insurance penetration rate and the CRx insurance market concentration factor.

The ratio of gross written premiums *per capita*, often called the density index, is the ratio of gross premiums written to the number of inhabitants of the country (total premiums per inhabitant). The insurance penetration rate is the ratio of gross written premium to GDP (total Premium to GDP). The degree of market concentration is reflected by the CRx concentration ratio, i.e. market share, measured by the gross written premium, of the x largest insurers of the Central Statistical Office (2018).

Often, surveys also assess the number of insurance companies authorized to conduct insurance business in a given country, which allows to assess the competitiveness on the market. The degree of maturity of the insurance market can also be measured by the number of insolvencies of insurance companies (Balas-Noszczyk, 2019).

Research Methodology

The research was carried out on the basis of quantitative data taken from Polish and European public statistics: GUS[1], KNF[2], PIU[3] and Insurance Europe[4].Due to the lack of data for 2018, the data from 2017 was analyzed. It should be emphasized that the data published on the Insurance Europe website is incomplete, which makes statistical analysis difficult. There is no data for all European countries, and many countries are sampled. Not all countries collect data on distribution channels, and the records themselves are imprecise and interpreted differently by supervisory authorities (Gąsiorkiewicz, 2016 p. 22). In Europe, premiums written are broken down into five primary distribution channels: direct sales, agents, brokers, bancassurance and other distribution channels. This makes it difficult to analyze sales data in online channels or in a mixed model.

Statistical methods of structure analysis and cluster analysis were used in the research.

The main purpose of cluster analysis is to study the similarity or distinctiveness of objects. The aim is, therefore, to divide the objects into classes containing objects that are similar due to the observations on variables, and different from each other (Gatnar and Walesiak, 2004, p. 318).

One of the classification methods was used for the research, which is the two-stage cluster analysis, which is quite resistant to assumptions about the distribution of variables, allows to assess the quality of grouping using the Silhouette measure and enables automatic determination of the number of groups.

After elimination of missing data, the study analyzed 16 European countries, including Poland.

Results

The study consisted of two stages, including the classification of European countries in terms of the degree of development of the insurance market and the structure of non-life insurance distribution channels.

In the first stage of the research, a two-stage cluster analysis was carried out in order to divide countries into groups with a similar degree of development of the non-life insurance market. The following variables were used for the classification: density index and penetration index. As a result of the classification, three clusters were obtained for which the measure of cohesion and distinctiveness was at a good level (the Silhouett measure was 0.7), which proves a good division of the studied countries into groups. The importance of the classifying variables was 1 for the penetration index and 0.95 for the density index. The results of the classification are presented in Table 1.

group [%]			
Average value of the density index in the group [euro]	330,25	1028,33	1420,00

Source: own calculations using IBM SPSS Statistics

The applied classification method enabled to distinguish three groups of non-life insurance markets, as presented in Table 1. The first group includes countries with density and penetration indicators below the average for the EU non-life insurance market (EUR 919 and 2.27% respectively).). Among them, Poland. The second group includes countries with a high penetration rate and a density index above or slightly below the EU average. Great Britain, France and Germany are here. According to Insurance Europe data, in 2017 these countries were leaders in the EU in terms of written premium, with a total share of 60.1% of the premium. The third group consist of two countries: Luxembourg and Malta, with a high density and low penetration rate.

In the next stage of the research, a two-stage cluster analysis was carried out in order to distinguish classes of countries with a similar structure of non-life insurance distribution channels. The following classification variables were used: direct sales, agency sales, broker sales, bancassurance. The variables determined the share of gross written premium obtained in a given distribution channel in the premium of a given country. As a result of the classification, four clusters were obtained. The measure of consistency and distinctness indicates a good fit of the model (Silhouette value 0.6). The importance of the predictors was: 1 for the broker channel, 0.74 for direct sales, 0.7 for bancassurance and 0.57 for the agency channel. The results of the classification are presented in Table 2.

Table 2: The results of the classification of European countries in 2017 in terms of non-life insurance distribution channels

Cluster number	**1**	**2**	**3**	**4**
Countries by clusters	**Belgium, Bulgaria, Malta, United Kingdom**	**France, Spain, Portugal, Turkey**	**Germany, Poland, Slovenia, Italy**	**Croatia, Finland, Ireland, Luxembourg**
Average share of the brokerage channel in the group [%]	53,92	18,39	14,69	7,26
Average share of direct sales in the group [%]	24,7	17,65	13,17	50,40
Average share of bancassurance sales in the group [%]	3,84	14,62	4,29	3,17
Average share of agency sales in the group [%]	20	45,84	66,45	24,47

The analysis of the classification results presented in Table 2 and Figures 1-4 allows us to conclude that there are four models of distribution channels in the European non-life insurance market. The first one is characterized by a vast majority of sales by brokers (on the domestic market on average 53.92%). The second one, with sales in the bancassurance channel relatively high to other models (14.62% on average). The third model is the dominant agency sales (66.45% on average). The last, fourth model - countries with a clearly dominant direct sales channel.

In 2017, Poland recorded gross premiums written in Section II at the level of over EUR 8.9 billion, which accounted for 1.9% of the entire EU premium written, amounting to EUR 470 billion of PIU (2018). Poland has the penetration rate of the non-life insurance market similar to the so-called "new" EU members (1.9% for Poland, 3.1% on average in the EU), ie much below the EU level. Non-life gross written premium *per capita* amounted to EUR 234 compared to the EU average of EUR 919 and it was a better result than in the countries of the "new Union". In the structure of Section II insurance distribution channels, sales through insurance agents dominate. Germany, Italy and Slovenia have a similar distribution model.

Trends in The Development of Distribution Channels

According to specialists „*Key to the success of an insurer is the ability to establish cost-effective distribution channels to enable it to make contact with potential policyholders for the sale of its products"*. (Carter et al.,2009).

You can read about the future of the development of distribution channels in Europe and in the world both in scientific studies (Laskowska, 2019; Bhattad, 2012; Marzai, 2018), and in various reports (Capgemini, 2017; McKinsey, 2020; KPMG, 2018).

The Capgemini advisory agency in its publication (2017) lists four basic trends in changes in insurance distribution:

1.Rise in customers' use of the internet to buy insurance products,
2.Increased use of social media as a distribution channel.
3.Rise in usage of SaaS solutions to enable the insurance distribution process across multiple channels.
4.Rise in usage of technological solutions to automate the underwriting process and increase direct sales.
According to the study, the preferences for purchasing insurance will change with the new generation of insurance consumers. The use of the Internet in selecting insurance offers and purchasing insurance is expected to increase. However, this trend is not as growing as expected a few years ago

due to the lack of appropriate distribution networks in developing economies and consumer habits. In the case of life insurance, customers still prefer the advice of agents, but for less complex products, such as motor and property insurance, they increasingly choose the Internet. The challenge for insurers is acquiring customers through social media such as Facebook, LinkedIN and Twitter. Social channels will be gaining ground in the insurance industry. As the number of distribution channels grows, insurers have to implement new technologies and automated insurance systems into their online sales processes.

McKinsey & Company (2020) in the report presented trends and forecasts for the insurance industry, including the development of distribution channels. According to this study, the current trends indicate a clear change in the approach to insurance sales, both in traditional and direct channels. In the future, sales in direct channels are expected to slow down in most European markets.

Summary

Nowadays, insurers use many distribution channels, from traditional ones, such as agents and brokers, to modern ones, such as call centers, bancassurance, the Internet, and mobile. Unfortunately, changes in statistical reporting have not kept pace with the development of new distribution channels. Not all European countries systematically collect data on sales channels, and published data is often estimated. Therefore, it is difficult to say what the exact shares of each channel in the distribution of insurance on domestic markets are. On the basis of Insurance Europe data, four models of insurance distribution were distinguished for the non-life market in Europe, which allowed for a positive verification of the research hypothesis put forward in the paper. European countries can be divided into those where the market is dominated by the sale of non-life insurance through brokers, into those where agency sales with a significant bancassurance channel dominate, then into countries with a clear dominance of the agency channel and those where the market is dominated by direct sales with a significant share of agency sales. However, on the basis of the available data, it is not possible to unequivocally link the type of insurance distribution model to the level of market development. The most important predictive variable in distinguishing the sales model classes was the market share of the brokerage channel. This shows the greatest diversity of the surveyed countries in this area.
It is a pity that the availability of statistical data does not allow for more accurate research in this area.

Peculiarities in the Development of Investment Processes in the Russian Arctic

Natalia A. SEROVA

Luzin Institute for Economic Studies of the Federal Research Centre "Kola Science Centre of the Russian Academy of Sciences", Apatity, Russia

nataleks13@yandex.ru

Abstract

The research is aimed at defining possibilities of increasing the investment activity in the Russian Arctic. It involves an economic and statistical analysis of the investment process development in the Russian Arctic for 2000-2018, including the investment structural analysis in terms of financing sources, forms of incorporation and investment media. Main trends observed in the field of investments in the studied regions and Russian Arctic in general are revealed during the research. These include a 15,3 times increase in the inflow of investments over the study period, a growing share of own funds in the cumulative investments indicative of the improvement of financial stability in the majority of arctic regions and a rising portion of investments to the core capital of joint ventures with Russian and foreign ownership that suggests an efficient development of the public and private partnership. It is concluded that the Russian Arctic has a substantial potential for the activation of investment activities.

Keywords: Arctic Zone of The Russian Federation, Regions, Investments.

Introduction

Investments constitute an integral part of any economics and the most significant factor of the socio-economic state systems. Quantitative changes in investments affect all fields of national economies reckoning the issues of their attraction among the most essential objectives of the governmental investment policy.

In Russia, main consumers of investments are represented by regions, where the Arctic zones of the Russian Federation (RFAZ or Russian Arctic) are of particular importance for the development of national economy. Due to the special nature of arctic territories, which include extreme climate and environmental conditions, remoteness from national economic centers, infrastructural underdevelopment, peculiarities of settlement, unattractiveness of living conditions causing the migration outflow, etc. (Zaykov et al (2019); Kondratov (2017); Shelomentsev et al (2018); Moskalenko and Kropaneva (2013); Badylevich and Verbinenko (2017); Pavlov and Selin (2016)), their exploration and development is not possible without encouragement of investments.

Results and Discussion

The earlier investigations of the methods designed for the management of investment activities in the Russian Arctic (Serova (2019); Serova (2020); Skufina et al (2019)) demonstrated that the investment policy of Arctic regions was aimed at the activation of investment processes. In order to reveal possibilities of increasing investment activities in the Arctic regions, the author has analyzed the development of investment processes in the Arctic regions for 2000-2018.

Cite this Article as: Natalia A. SEROVA "Peculiarities in the Development of Investment Processes in the Russian Arctic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

Analysis of the dynamics of investments to the core capital

The volume of investments to the core capital for the Russian Arctic in general in 2018 was RUB 2 367.5 billion (13.5% in the All-Russian volume of investments), of which 59.3% (RUB 1 275.3 billion) covered the wholly Arctic regions (Murmansk Region, Nenets, Yamalo-Nenets and Chukotka Autonomous Districts) and 46.1% (RUB 1 092.3 billion) accrued to the partly Arctic regions (Arkhangelsk Region, Krasnoyarsk Territory, Republics of Komi, Karelia and Yakutia). The largest volume of investments (43.3% in the cumulative investments to the Russian Arctic) was traditionally accumulated in the main gas-producing region of Russia – the Yamalo-Nenets Autonomous District.

The analysis has shown that for the Russian Arctic in general, the incoming investments for 2000-2018 grew 6,1 times. The greatest grow was typical of the Chukotka Autonomous District with a gold-mining industry as a basis of the economics (incoming investments to the region for the whole study period increased 7,3 times) and of the Nenets Autonomous District with an oil and gas production industry as a core business (incoming investments grew 5,9 times). Despite the investment expansion having been observed in these regions since early 2000s, the relative share of the cumulative investments to the Russian Arctic still remains the lowest among all Arctic zones (except for the Republic of Karelia) (Table 1). The investment rates to the level of the year 2000 below the average Russian value have been demonstrated by the Republic of Komi (131,3 %) and Karelia (168,8 %) due to the lack of large-scale investment projects in these regions that could be of interest for potential investors.

Table 1: Relative share of the region in the cumulative investments to the Russian Arctic, %

	2000	2005	2010	2015	2016	2017	2018
Wholly Arctic regions							
Nenets Autonomous District	2.3	5.6	4.0	6.1	3.7	4.5	3.9

Republic of Sakha (Yakutia)	9.5	12.2	12.3	10.6	12.0	16.2	17.0
Source: calculated by the author.							

There is a negative trend expressed in a reduced inflow of investments over recent years and related to the deterioration of the geopolitical environment, oil price downturn, imposition of Western sanctions and other adverse factors, which significantly limited the investment opportunities of the Arctic regions (Vyakina (2017); Serova (2019); Baqheri and Akbarpour (2016); Tyll et al (2018)). In particular, sanctions mean prohibition of supplies of tailored offshore oil-and-gas production machinery and technologies to Russia and force many international companies to suspend or significantly reduce participation in various projects on the Russian Arctic shelf (Krapivin (2014)).

Analysis of the structure of investments to the core capital

In terms of structure, the largest share in the Russian Arctic falls at the investments to mining (56.9 %) and this value is even higher (75.5%) in the wholly Arctic regions. These investments are mainly concentrated in the Nenets Autonomous District (relative share of mining as a type of business in the cumulative investments of the region in 2017 was 93.0 %), on Yamal (79.5 %), in the Republic of

Komi (55.6 %), Chukotka (51.3 %), and Yakutia (46.2 %). The analysis of the investment distribution in terms of forms of incorporation is indicative of mainly Russian investments arriving to the Russian Arctic. Notably, in 2000 these mainly prevailed in the east (for example, in Yakutia, the relative share of Russian investments was 99.6% in the total volume for the region), but in 2017 this trend shifted to the west of the Russian Arctic. As well, an increase in the joint form of incorporation in the distribution of investments comes under notice particularly in the Yamalo-Nenets Autonomous District suggesting an efficient development of the public and private partnership in the region.

The trends observed in the structure of investment sources for the Russian Arctic have their own specific nature. In the developed countries, where internal (own) company's sources cover the financing of the demand for investments at 70-80%, during the economic recovery and growth periods, the share of internal sources reduces against the rise of external (attracted) funds (Igonina and Opryshko (2011)). In Russia, the economic revival during the period of overcoming the consequences of the global economic crisis was not accompanied by the reduced share of own funds in the Arctic regions. Moreover, their relative share in the cumulative investments to the Russian Arctic for 2000-2017 was on average only 41.7%.

However, the majority of Arctic regions have recently demonstrated an emerging trend of increasing share of own funds in the structure of investment sources (Table 2) to imply the improvement of their financial stability (Naumov (2013)). The most noticeable changes over the whole study period are common for the Nenets Autonomous District, where the share of own funds in the cumulative investments of the region grew 3.1 times. The opposite trend is observed in the Krasnoyarsk Territory (share of own funds reduced from 70.8% to 46.7%), Yakutia (60.3% to 38.2%), in the Murmansk Region (62.2% to 56.8%), and Yamalo-Nenets Autonomous District (26.6% to 23.1%).

Table 2: Share of own funds in the investments to the core capital, %

	2000	2005	2010	2015	2016	2017
Wholly Arctic regions						
Nenets Autonomous District	24.9	33.1	66.9	65.5	63.8	79.0
Murmansk region	62.2	61.9	34.9	43.4	53.3	56.8
Yamalo-Nenets Autonomous District	26.6	43.2	26.9	34.7	23.1	23.1
Chukotka	37.5	9.4	34.4	45.1	24.7	44.9
Partly Arctic regions						
Republic of Karelia	54.8	41.9	39.2	42.7	51.6	61.4
Republic of Komi	57.5	33.7	31.2	53.8	43.4	72.3
Arkhangelsk region	46.6	31.3	50.4	61.4	52.5	60.9
Krasnoyarsk Territory	70.8	61.5	58.4	51.1	49.5	46.7
Republic of Sakha (Yakutia)	63.0	55.3	46.3	56.3	44.2	38.2
Source: calculated by the author.						

A negative trend may be seen in the share of budgetary funds in the investment structure reduced from 14.5% in 2000 down to 13.1% in 2017. This mainly happened due to the decline in the relative share of budgetary allocations in the cumulative investments of Yakutia (from 29.3% in 2000 down to 8.2% in 2017) and Yamalo-Nenets Autonomous District (8.4% to 2.6%).

Conclusions

The analysis of the development of investment processes in the Russian Arctic in 2000-2018 has demonstrated that the Arctic regions have a significant potential for the activation of investment activities. Despite the sanction pressure and departure of international partners from joint ventures on the Russian Arctic shelf, the international cooperation in the Arctic region continues and the volumes

of national investments are growing year by year. However, due to the fact that the significant part of investments to the Arctic region was generally aimed for the development of mining, the issue of the balanced development of the investment climate in the Russian Arctic still remains urgent and requires improvement of the mechanism for the formation and implementation of a regional investment policy.

Advantages and Limitations to Application of Telematics Systems in The Road Transport Industry in Poland

Wojciech Zalewski

Nicolaus Copernicus University, Toruń, Poland

w.zalewski@umk.pl

Abstract

The article attempts to make an in-depth analysis of the level of application and use of telematics systems based on GPS/GSM/GPRS technology in Polish road transport companies, which support transport in the implementation of goods deliveries in integrated supply chains. The article is based on a survey conducted in 2019 based on a group of 500 Polish road transport companies. The presented results clearly show a relatively low level of the use of telematics systems in management by Polish road transport companies, with a simultaneous significant level of awareness of managers as to the need to use them in the context of contractors' requirements. Based on the results of the survey, it was shown that the application of these solutions, despite the observed barriers, leads to companies obtaining significant added value in the quality of services provided. The SEM structural equation model was used to assess the impact of customer requirements and barriers to the application of solutions, as well as to assess the value added.

Keywords: Road Transport, Telematics, GPS, GSM, SEM Model.

Introduction

Today, globalization processes in the world economy have set new demands for modern transport systems. Currently, in many parts of the world, almost 80% of the mobility needs of people and goods are met by road transport. Therefore, the effective use of this mode of transport, the improvement of its forms of operation, the creation of more and more modern transport systems and the constant modernization of transport means and road infrastructure is an inevitable process.

In Poland, international road transport has become one of the most dynamically developing sectors of the economy. The proper functioning of a transport company on the international or intra-Community transport market, its financial and human resources stabilization, financing its activities, dynamics of development, the use of modern conceptual, technical and technological solutions, depend mainly on the professionalism of the company's management staff. In the light of the rapidly growing competition and the situation caused by the COVID-SARS2 pandemic, the chance to improve both the efficiency and safety in road transport, and thus the company's survival on the economic market, is created by modern telematics and IT systems, which are becoming a very important executive tool of modern supply chains, Deshpande (2012), Singh and Teng (2016). Technologies that use telematics solutions based on GPS (Global Positioning System) and GPRS (General Packet Radio Service) are of major importance in the supply chain, where road transport plays a key role.

The study is a continuation of the research and the presentation of its results related to the use of telematics systems in international and domestic road transport enterprises in Poland (Zalewski, 2019). The research objective of the article is an in-depth analysis of the level and scope of the use of telematics systems based on GPS/GSM/GPRS technology by road transport companies in Poland as well as to show to what extent barriers in the application of these solutions affect the scope of their use and the obtained added value for the company. The novelty of the paper lies in the application of recently surveyed primary data and estimation of a structural equation model (SEM) to investigate causal relations among the scope of use, contractors' requirements, value added and barriers to a wide exploration of telematics in management.

Cite this Article as: Wojciech Zalewski " Advantages and Limitations to Application of Telematics Systems in The Road Transport Industry in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The achievement of the intended objective resulted in the formulation of the following two research hypotheses:

1. Barriers in the use of telematics devices affect both the scope of their use in the company and the requirements for their use by contractors.
2. The requirement to use telematics devices by contractors and the scope of their use in a company have an impact on the added value achieved by them.

The research methodology included the analysis of the available literature as well as primary data obtained as a result of a survey conducted in 500 road transport companies in Poland.[1]

Telematics in Road Transport

Telematics makes it possible for road transport to use technologies and methods of remote access to vehicles or loads via a wireless teleinformatic network. As one of the logistics executive tools, it serves not only to support management processes, but also to increase the efficiency and competitiveness of the transport market. Thanks to the use of telematics elements (ICT networks, traffic control systems, electronic systems for locating vehicles and loads, electronic exchange of documents), it is possible to optimize vehicle routes (Cattaruzza *et al*., 2017), which significantly contributes to reducing the time of cargo transport (Schuessler and Axhausen, 2009). Telematics technologies that are used to track vehicles and loads are of particular importance in the transport of hazardous and high-acid materials (Minni, 2013).

The use of telematics solutions in road transport allows obtaining a lot of data, extremely useful in a transport company. Combining this with their processing by modern IT systems allows the following:

- planning optimal transport routes with the use of accurate digital maps and regularly updated system data,
- analysis and control of the routes of movement of vehicles or loads, including the minimization of their length, time and costs of transport, elimination of fraud, and, consequently, more dynamic handling of transport orders,
- registration of the basic operational parameters of the vehicle, *i.e.*, speed, distance travelled and route, engine speed, fuel consumption, axle loads, as well as monitoring the condition of the cargo space, control of on-board operation systems, *etc.*;
- control of the driver's work in the light of the regulations on maximum driving times, as well as in the scope of using the optimal driving technique ensuring economic operation of the vehicle, *etc*.,
- increasing the broadly understood safety in transport;
- precise determination of the dates of loading, customs clearance, deliveries, *etc*., and thus the optimal implementation of the goods distribution process.

When analysing the presented scopes of application of telematic systems in road transport as well as the literature in this area, we can divide these applications into the following research areas:

- the research area related to ITS (Intelligent Transport Systems) Sowman J., Box S., Wong A., *et al*. (2018), Novikov A., Pribyl P., Vasileva V., *et al.* (2017), Santa J., Fernandez P. J., Zamora M.A. (2016).
- the research area related to safety, infrastructure charges, road congestion, vehicle flow control, Khaalil Omar. K. (2017), Moriarty P., Honnery D. (2013), Mishra S., Bhattacharya D., Gupta A. (2018).
- the research area related to vehicle navigation systems, technical and telematics equipment, vehicle on-board equipment, autonomous vehicles and their control and others, Ballarin C.,

[1] The research was financed by the Scientific Grant Miniature 2 of the National Science Centre, Poland, no. 2018/02/X/HS4/00107, entitled 'Support for logistic processes in road transport using telematics systems'.

Zeilinger M. (2017), Szigeti S., Csiszar C., Foldes D. (2017), Di Fazio A., Bettinelli D., Louette E. , *et al.* (2016).

In the literature, it is difficult to find research describing the level of application of telematics systems in road transport, which, as mentioned above, is a basic component of supply chains. In many publications, including Pflaum *et al*. (2020), Kolar *et. al*., (2010), Michel (ed.) (2017), Saenz (2019), Guhathakusta (2017), authors describing the use of modern technologies that support supply chain management using the general term digital supply chain, and on this basis analyse their efficiency or digital integration. The exception is the study by Kiba-Janiak and Tronina (2017), in which the impact of selected telematics systems on the improvement of transport tasks was assessed. The use of telematics in transport is the subject of an article by Minea and Surugiu (2013), presenting research related to transport in supply chains as the most time-consuming and cost-generating factor and the possibility of real-time analysis of events occurring in distribution processes.

The use of telematics systems in road transport in the light of the survey research carried out

The achievement of the assumed research objective, which was to determine the level and scope of the use of telematics systems by road transport companies, as well as the verification of the hypotheses proposed was, as mentioned in the adopted methodology, to conduct a survey on the basis of a specially prepared questionnaire. The study was conducted using the CATI method in 500 randomly selected road transport companies in 2019.

The study was performed on a sample of companies taken from the database of members of the Association of International Road Transport Carriers in Poland (ZMPD) and from the databases of regional associations of road carriers. The characteristics of the research sample are presented in Table 1. As a result, by combining the databases of ZMPD and the regional associations, 4,500 companies were pulled together for selection. The number of 500 respondents selected for the survey purposes was dictated by the adopted assumption of obtaining an estimated error of no more than 5%.

Table 1: The structure of the studied sample due to the selected criteria

Participation of companies due to the form of conducted activity	**[%]**	**Share of companies in terms of the number of employees**	**[%]**
Entry into the business register	40.4	Up to 49 employees	63.8
Limited liability company	36.2	50 up to 249	31.2
Joint-stock company	2.8	250 employees and more	5
Other (limited partnerships and other)	20.6		
Experience in running a business	[%]	Number of transport units	[%]
More than 10 years	60.6	From 1 to 9	49.4
From 5 up to 10 years	22.8	From 10 to 19	25
From 3 up to 5 years	12.4	From 20 to 49	6
Up to 3 years	4.2	From 50 to 100	6
		Above 100	3.8
The range of services	[%]	The leading direction of the service portfolio	[%]
International transport	66.2	Poland - other EU countries	57.8
Domestic	23.4	Poland	33
Regional	7.1	Poland - Eastern European countries	4.8
Local	3.3	Inside the EU - outside Poland	4.4

The share of companies due to the homogeneity of the conducted activity	%	The nature of the transport	%
At least 80% of revenues generated from transport activities	49.2	Universal	91.0
Less than 80% of revenues generated from transport activities	50.8	Special	9.0

Source: own study

By analysing the data presented in Table 1, it can be concluded that the sample of 500 companies selected for the study reflects the structure of transport companies providing transport services in domestic and international transport, in line with the data presented in the report https://gitd.gov.pl/fileadmin/user_upload/BTM/ZEZWOLENIA_ZAGRANICZNE/Dane_statystyczne_dotyczace_transportu_miedzynarodowego_w_2019_r..pdf. Therefore, the results of the research can be generalized to the entire population of transport companies in Poland. In addition, the analysis of the sample showed that in 85% of cases, companies had a license for domestic and international transport, and only 15% of transports were carried out for purposes of the so-called own needs.

One of the key elements of assessing the level of application of telematic solutions and, at the same time, the level of support in management processes was data analysis, which resulted from the answers to the questions to what extent Polish companies use their telematics systems. The second important measurement was the determination of the independence of the characteristics in relation to the number of vehicles (the company size), the form of business or the scope of transport orders. The majority of the information on the analysis of these data and the results are presented in the article by Zalewski (2019).

Fig. 1: The scope of application of telematics systems (numbers in %)

Source: Own study based on survey research and Osińska, Zalewski (2020).

Analysing the data presented in Figure 1, it can be concluded that despite the widespread use of telematics solutions (92% of respondents possess telematics systems) their scope and level of use is low and mainly focuses on three basic elements related to the implementation of the transport task by

the driver and the vehicle. This is the knowledge about the current condition of the vehicle (the vehicle is on the move or on a stop) - 95% of respondents consider this element important. What is the current position of the vehicle in relation to the digital map - 87% of respondents consider it important, as well as the amount of fuel consumed per 100 km - 57.8% of the answers in the affirmative. The remaining variables are less or completely irrelevant to the respondents. Information about the timely implementation of transport tasks, *i.e.*, the level related to the supply chain and the possibility of digital analysis of planning and execution, is important for only 42.2% of respondents. The result of this variable may come as a real surprise because it is closely related to the timeliness of the services provided.

In order to achieve the research objectives of this study, further analysis of the data obtained from the survey was carried out. The analysis of descriptive statistics data performed with the support of the SPSS 2.6 system allowed to state that:

- In most cases, customers do not require the carrier to have telematics systems for the implementation of transport tasks. This is the opinion of 63.2% of the respondents, 36.8% indicated such a necessity (answers on the Likert scale ranging from 1 to 7). Moreover, 31% of respondents indicated the need to present and share data online with their principals.
- 53.6% of the respondents agree with the statement that the possession and use of telematics systems is important for acquiring new orders and clients. However, taking into account the fact that the use of the systems, their scope, is at a low level, it could be concluded that it is rather a marketing benefit and not a real willingness to use.
- An important scope of using telematics systems was the question to what extent the use of telematics systems affects the support of management processes in the company. 59.4% respondents believe that this impact is important, which may confirm the level of awareness regarding the support of management processes in various systems with a high technological level, but again contradicts the findings regarding the level of application of these solutions.
- It is worth noting that 49% of the respondents did not have a dedicated TMS IT system that would cooperate with the telematics system, 52% of the respondents were not integrated with cooperating systems and in 81% of cases there was no person employed in the company who would be dedicated to carrying out analyses of the effectiveness and profitability of transport tasks using telematics data. This fact indicates that despite the management's awareness of having systems, they may not have sufficient analytical knowledge due to the lack of staff that deals with these problems. Confirmation in this case is obtained from the analysis of the question about the active participation of managers in the analysis of telematics data. Almost half (49.8%) do not participate in this process.

The key element for the implementation of the objective set out in this study was the determination and indication of the size and significance of the added value obtained by the company due to the use of telematics solutions. 51.2% of the responses indicated that the use of these solutions increases the quality of transport orders implementation through the real-time tracking of transports by customers. Similarly, over 54% of respondents believe that the systems allow to forecast the punctuality of deliveries, which directly affects their harmonization. 50.8% of entrepreneurs also indicate a significant improvement in the security of supply as a result of the use of telematic systems and over 50% indicate an improvement in flexibility and speed of response in emergency and unforeseeable situations. In addition, over 48% of respondents believe that customer relations are improving and the level of information flow increases significantly.

With regard to the physical use of the systems indicated, a question arises about the barriers to their application. In this regard, in the seven-point Likert scale, the questions were defined as to what barriers are important for entrepreneurs. Over 50% of the respondents consider the high level of investment necessary to implement the system and the current operating and maintenance costs to be the most important barrier. Moreover, the study has identified other barriers and limitations, such as the complexity of the systems proposed by suppliers, the need to employ dedicated service personnel, reluctance of drivers to be controlled by forwarding services, or difficulties in setting data standards for analysis. The share of responses pointing to these limitations did not exceed 30%.

Structural equations in the assessment of barriers and the added value of using telematics systems in road transport

In order to verify the research hypotheses put forward in the study regarding the impact of barriers and customer requirements on the use of telematics solutions, as well as the requirement of their use by contractors on the level of obtained added value, it was decided to propose a structural equations model (SEM), which is used to test hypothetical relationships between observable and latent variables.

Since both the barriers to the use of telematics devices, contractors' requirements and the scope of use of these devices cannot be measured directly with one observable variable, they must be treated as latent variables. Each of these factors should therefore be measured with the help of several observable variables, verified in terms of scale reliability. Table 2 contains the final list of observable variables selected by confirmatory factor analysis and constituting a given latent variable to ensure the highest possible level of reliability, as measured by the Cronbach's Alpha statistic.

Table 2: Latent variables including the observable variables and the Cronbach's Alpha statistics

Factor	Observable variables*	Cronbach's Alpha
Barriers to the use of telematics devices	P26_2, P26_3, P26_5	0.90
Contractors' requirements to use telematics devices	P12_1, P13_1, P14_1	0.94
The scope of use of telematic devices	P17_2, P17_3, P17_4, P17_5	0.87
The added value of using telematics devices	P24_1, P24_2, P24_3, P28_2	0.97

**Full description is presented in the annex.*
Source: Own study

All of the considered factors reached the value of the Cronbach's Alpha statistics above 0.7, which confirms the high reliability of the scale and the correctness of including a given set of observable variables as components of individual latent variables (Żurek, 2016).

Structural econometric models (SEM) allow for the recognition of latent variables in the model of a cause-effect nature. For this reason, it was decided to use them for further data analysis. The SEM model developed to verify the hypotheses posed is shown in Figure 2.

Fig. 2: Hypothetical SEM model. (Full description observable variables is presented in the appendix).

Source: Own study.

The assumed model was estimated in the SPSS AMOS v. 16 package using the maximum likelihood method with the assumed significance level at 0.05. The results of the estimation of the external SEM model, *i.e.*, the factor analysis, are included in Table 3. The results of the internal (cause-and-effect) model in Table 4, and the measures of the degree of model fit to the data in Table 5.

Table 3: Estimation results of the external SEM model

Relation	Parameter	Parameter evaluation	P Value
P26_5 ← Barriers to application	α_1	0.454	
P26_2 ← Barriers to application	α_2	0.764	0.000
P26_3 ← Barriers to application	α_3	0.751	0.000
P12_1 ← Contractors' requirements	α_4	0.946	
P13_1 ← Contractors' requirements	α_5	0.881	0.000
P14_1 ← Contractors' requirements	α_6	0.829	0.000
P17_2 ← Scope of use	α_7	0.862	
P17_3 ← Scope of use	α_8	0.787	0.000
P17_4 ← Scope of use	α_9	0.917	0.000
P17_5 ← Scope of use	α_{10}	0.881	0.000
P24_1 ← Added value	α_{11}	0.926	
P24_3 ← Added value	α_{12}	0.902	0.000

Table 5: Measures of the degree of fit of the SEM model

Model	IFI	NFI	RMSEA	CMIN/DF
Estimated	0.966	0.947	0.076	2.731
Saturated	1	0.000		
Independent	0	0.000	0.139	7.688

Source: own study based on the results of the study.

The results obtained for the external model presented in Table 3 indicate that all factor loadings are statistically significant. Some parameters do not have a given *P* value, which is due to the need to assign a constant value to some parameters in order to ensure the traceability of the model (Byrne 2010).

When interpreting the results obtained, it should be noted that the barriers to application of telematics devices significantly increase the contractors' requirements in this respect (β_1) and the scope of their use by transport companies (β_2). Furthermore, as expected, the contractors' requirements for transport companies are reflected in the use of telematics devices in a given company. The relationship between these factors was statistically significant (β_3). However, increasing the scope of using telematics devices influences the growth of the added value generated by them (β_5), which fully verifies the proposed research hypotheses.

Despite the fact that the direct impact of the contractors' requirements on the added value turned out to be statically insignificant with the assumed significance level at 0.05 (β_4), it should be remembered that their influence is indirect through the scope of use.
The value of the IFI index is 0.966, and the RMSEA is at the level of 0.076, which allows to conclude that the model is correctly fitted to empirical data.

Conclusion

The research objective of the study was to assess the scope and degree of use of telematics systems based on GPS/GPRS technology, which are used by Polish road transport companies that carry out the transport of goods services, which are the main processes of supply chains. Despite the widespread use of systems and the significant share of transport in the European market, the scope and level of use of data obtained from telematics systems is still very diverse and very low in the elements of key importance for the functioning of supply chains. The low level of use of telematics solutions may be caused by the need to employ an additional person who will conduct data analysis and inform management boards of companies about it in order to take corrective actions. Moreover, an important

element may also be the lack of standardization in the telematics systems used, which makes it difficult to present a comparable format of results.

In Polish road transport companies, there is a significant popularity of having telematics solutions based on GPS/GSM/GPRS technologies, which is confirmed by the research results obtained (92%). The scope and professionalism in the use of the systems is, however, at a very low level, despite the fact that the awareness of the management of enterprises is at a high level as to the need for increasing integration with contractors in supply chains. The results presented in the paper clearly show that the knowledge about the status of the vehicle, its current position, fuel consumption and the time remaining to be used by the driver on a given day is still important for entrepreneurs. The punctuality of deliveries, the size of delays, the efficiency of using the driver's working time or matching the places of return loads are much less important. This is due to the lack of reporting of such data to principals or a low level of awareness among managers of the impact of these elements on the quality of services provided.

The estimated model (SEM) clearly shows that an increasing motivator to use the full potential of telematics solutions are primarily customers ordering transport services, who in the era of significant restrictions resulting from the situation related to the COVID-SARS2 pandemic will want to use remote tools to monitor and analyse deliveries by carriers. Furthermore, transport companies see that the added value in the form of an increase in the quality of transport services that they obtain as a result of having solutions allows them to reach new sources of transport orders. The proposed model of the structural equation also allowed, first of all, to verify the hypotheses and, based on the observable variables, indicated the indirect impact of the requirements of contractors on the generation of added value in their logistic service. Similar models can be used to identify factors influencing defined variables in other sectors and countries. The research carried out and the results obtained indicate a further necessity to conduct research in this field. The author's new research (which has not been published yet) indicates a significant change in the application of telematics solutions that the author will probably soon describe.

Appendix: Observable variables (on Likert scale from 1 to 7)

Observable variable	Question
P12_1	Please indicate how often your customers require telematics systems for transport.
P13_1	How often do your customers request you to provide data about the vehicle that carries out the order for them (visualization on the map plus data related to the time of loading or unloading)?
P14_1	Please indicate to what extent the possession of telematics systems in your vehicles is important for getting new orders and transport contracts.
P17_2	Control of the number of kilometres travelled by the vehicle in accordance with the mapped route.
P17_3	Matching return loads after unloading to vacant vehicles.
P17_4	Ensuring efficient use of working time by the driver.
P17_5	Analysis of the legitimacy of stoppages during the execution of the order.
P24_1	Improving the quality of the execution of transport orders by enabling the customer to track transports.
P24_2	Forecasting on-time delivery in the supply chain, which affects the harmonization of supplies.
P24_3	Increasing the security of supply.
P26_2	Availability of systems on the market
P26_3	The complexity of the systems proposed by the vendors
P26_5	Reluctance of drivers to supervise their work by forwarding services
P28_2	The system allows you to track transport tasks on an ongoing basis in the context of mileage control, the quality of order fulfilment and thus costs.

Abstract

The purpose of this work is to establish whether the placement by the author of his own digital copyright assets (DCA) in the microstock portfolio can be considered as an investment. The second goal is related to the fact that the leading intermediary companies of this type entered the stock market, and their publicity made possible fundamentally different ways of implementing investments. Therefore, part of the work is devoted to the analysis of problems and paradoxes of publicity. The research methodology is based on comparative analysis using the so-called Howey test. As a result of the analysis, it was found that DCA meet the criteria for belonging to investment activities, and can be considered as a new promising investment resource.

Keywords: Digital Copyright Asset, Howey Test, Investment, Public Company, Risk.

Introduction

In recent years, quite a few scientific publications have appeared on the analysis of investment opportunities for using digital financial assets (DFA) - cryptocurrency, smart contracts and all kinds of derivatives based on them. However, this article focuses on another class of digital assets, namely, digital copyright assets (DCA). It should be noted that there is practically no literature on the analysis of investment opportunities for using such assets. At the same time, in the work on DFA, some techniques were successfully used that can be applied to the analysis of DCA. In particular, the so-called Howey test was applied. So, for brevity, called the legal criterion used by the US Supreme Court and the Securities and Exchange Commission (SEC) to determine whether a particular transaction, security or asset relates to investment activities (Gabaldon, 2000; Telpner and Ahmadifar, 2017). The criterion has been applied since the late forties of last century, and its starting points are quite simple: in order for a transaction or instrument to be classified as an investment one, four conditions must be met:

- It is an investment of money;
- There is an expectation of profits from the investment;
- The investment of money is in a common enterprise;
- Any profit comes solely from the efforts of a promoter or third party.

Further in the article, each of these conditions will be considered from the point of applicability for the analysis of DCA.

Another aspect of this work is related to the analysis of the impact of the entry of intermediary companies on the stock market. There are very few such companies so far, and this paper considers only those of them that form the market turnover of such copyright assets as stock digital images, sound and video files. That is, we are talking about the so-called microphotostocks. Today, Shutterstock Ink and Adobe Stock are present on the stock market. The question of the influence of the company's publicity on the investment opportunities for using assets of this class is of great scientific interest. Therefore, further in the work, the analysis within the Howey test will be combined with the analysis of problems and paradoxes of publicity.

An Investment of Money

The first test condition has not been considered in such a limited way for a long time. In various documents of the US Supreme Court and SEC, as well as in scientific works, a broader interpretation of the possibility of investing both cash and non-cash funds, and various classes of assets of a tangible and intangible nature was given (Telpner and Ahmadifar, 2017).

In our work, we consider intellectual property - copyrights in digital form, which, like any property that has a monetary value, certainly belong to assets. Such assets are specially prepared digital files of images, video, sounds, text, as well as composite objects that include the listed elements. The value of such assets depends substantially on the quality of preparation that the author/investor is able to undertake in order for the asset to be brought to the market. This aspect, in principle, is associated with the creation of an intellectual asset as property that has a monetary value. The fact is that until the mid-2010th in the scientific literature, questions have been discussed about whether a "private" file with a text or image recording can be considered an asset, and from what moment such a file can be considered an asset.

At present, with the accumulation of more experience, we can more confidently indicate the stage in the sequence of the investor's actions, as a result of which a "raw" file of this type is transformed into a more complete asset. Namely, in order for the attributes of property to become an integral part of the latter, they must be included in its information (documentary) structure. The file should be structured, for example, in accordance with the electronic document standards (ISO 10303-21:2016; ISO 8879:1986). The essence of these standards is that such a file can have both content and descriptive sections (metadata sections) in its structure. Then, in addition to the actual pictorial or literary content, it can include sections of metadata, including those that specify the attributes of property.

Modern technologies form the specified sections of an electronic document file in such a way that some of them are created automatically, and some must be filled with data manually, or programmed to perform this function for a large number of similar files belonging to one author/investor. For example, when generating an image file, a digital camera, regardless of the shooting scene, automatically generates several such sections, recorded in special generally accepted formats. In particular, in EXIF (Exchangeable Image File Format) the camera enters metadata about its own parameters (Camera data 1), and image parameters (Camera data 2). In IPTC (International Press Telecommunication Council) format, the camera prepares (but does not fill in) sections with full information about the image itself (including keywords) and copyright (see Table 1).

Table 1: Standard digital image metadata structure

Camera Data 1 (EXIF)	Camera Data 2 (EXIF)	Description (IPTC)
1	**2**	**3**
Make: NIKON CORP. **Model:** NIKON D3200 **Date:** 2019-01-27T14:37:04+03:00 **Exposure Program:** n/d **F-Stop:** f/8.0 **Max Aperture Value:** f/4.8 **ISO Speed Ratings:** 100 **Focal length:** 122.0 mm Etc.	**Pixel Dimension X :** 6016 **Y:** 4000 **Orientation :** Normal **Resolution X:** 300 **Y:** 300 **Resolution Unit:** Inch **Compressed Bits per Pixel:** 4.0 **Color Space:** sRGB **Light Source:** Unknown **File Source:** DSC	**Document Title:** Squirrel **Author:** nickname **Description:** Black squirrel in city park, close-up. **Description Writer:** nickname **Keywords:** animal; forest; fur; nature; park; sciurus; sciurus niger; summer;…(etc.) **Copyright status:** fixed **Copyright notice: -** **Copyright info URL: -**

Source: compiled by the authors based on own research

At this point, the resulting "raw" file may already be of some value and have a value estimate. In particular, we can indirectly judge that a file created with an amateur camera may have less value due to less volume and lower image quality.

However, the whole value of the received file can be realized and it can be put into commercial circulation only by filling additional attributes and fixing the author/owner, therefore, the following metadata must be included in the descriptive section of the received file (see "Description" column in Table 1):

- information about the author/owner;
- title;
- description of the plot;
- keywords;
- copyright information.

It is quite obvious from the description of this section why no machine (yet) is able to fill it in automatically. Only after the completion of this transaction, the asset can be legally recognized and its sale (transfer of rights) becomes possible. In addition, it becomes possible to search for it in a huge array of similar assets stored in databases (portfolios) of authors, owners, and most importantly, in portfolios of market intermediaries who organize the investment process. However, running a little ahead, we note that this completes only the first stage of asset preparation.

The Investment in a Common Enterprise

In the classic version of test, the second condition on common enterprise implies that investors unite their funds or assets into a common pool, and (possibly) divide the profits made in proportion to their participation. In order to correlate this condition with investing in DCA, it is necessary to clarify now which investors work with such assets and how the investments are made, i.e. what is the investment process?

Let's start with the fact that in relation to the DCA of the studied class, investors can be:

- authors who created these assets;
- any market participants who legally obtained or acquired the rights of ownership (disposal) of these assets;

- companies that create such assets on an industrial level, have their own photo, video, sound production or acquire rights from direct authors. At the same time, we note that copyrights by law may remain with the authors for life.

The investment process consists of several stages, the first of which consists in obtaining a DCA and its preparation. Otherwise, as noted above, it cannot acquire full investment characteristics. Thus, the production or acquisition of the original ("raw") digital file and the initial preparation of the corresponding sections of its metadata is an integral part of the investment process.

The next stage is the conclusion of a contract with a network financial intermediary, who organizes the market of the DCA. Note that digital copyright assets are now operated by new institutional intermediaries that emerged in various e-commerce segments in the mid-2000s. Their appearance, in fact, marked a kind of investment breakthrough in the intellectual property market. New intermediaries operate ultra-large DCA portfolios. For comparison, it can be shown that if the investment portfolios of large technology companies and patent intermediaries (aggregators) include tens of thousands of patents and other industrial property assets, then the portfolio of only one network company (microstock) Shutterstock Ink., by the beginning of 2020, confidently exceeded a mark of 300 millions of DCA (see Table 2).

The conclusion of a contract with a network intermediary implies that the author/investor agrees to fulfill the necessary requirements of the latter. Basically, these requirements relate to the quality of the preparation of the DCA, including the quality of metadata. Some requirements may relate to the content and thematic of assets, interaction with payment services and tax authorities.

After the conclusion of the contract, the author/investor gets the right to transfer his DCA to the intermediary. However, this stage also begins with the preparation of metadata. The transfer process itself is organized in such a way that it is impossible to upload a file to the intermediary's portfolio without filling in another one, this time an external metadata section, which will be stored on the intermediary's servers. This section contains data: on thematic categories the image will be exhibited by the mediator; whether the image is raster or vector; what sizes (in mega pixels) and in what formats (jpg, tiff, etc.) the images will be offered to the market; what price frames can be set for licenses of different types, etc. Each company can have this set individually, but the stage itself is mandatory.

Table 2: Largest microphotostocks as in 2020

№	Microstock	Portfolio, millions of DCA.	Author's contingent	Stock ticker
1	Shutterstock	330	More 1 million	SSTK
2	Adobe Stock	200	-	ADBE
3	Dreamstime	140	640 thousand	-

Source: compiled by the authors based on own research

Formally, after the completion of this stage, the intermediary brings the asset to the market, and the author/investor gets the hope to expect receiving investment income, which happens in practice. Thus, the third condition of the Howey test is also satisfied. However, due to many individual characteristics of the DCA, the investment process with their use has very individual features.

Expectation of Profit

First of all, we note that unlike ordinary securities, foreign currencies, and even more standardized financial derivatives, each DCA is, in fact, an author's work, reflecting the individual (including genre) preferences and creativity of the author. Moreover, compliance with this quality is one of the requirements of the intermediary, i.e. by definition, there cannot be two identical DCA in the

portfolio of the same intermediary. From this point, the pool of assets operated by the intermediary is not depersonalized, as is the case of traditional investment funds.

The next feature concerns the ability of the author/investor to manage their individual portfolio. The fact is that after concluding a contract with an intermediary, the author/investor gets at his disposal a personal account with many convenient functions. Guided by his own strategic motives, the author/investor transfers his portfolio to the intermediary, and then may not take any action, for example, not replenish it with new assets. The mediator, performing his part of the work, carries out market exposure, promotion (marketing) of all DCA at his disposal using the modern network technologies available to him. As a result of the implementation of this, the simplest strategy, the market demand for DCA may appear, and the sale of licenses for their use may occur. We are talking specifically about the sale of licenses, since the ownership rights to the DCA in this case generally (there are exceptions) remain with the authors/investors. The intermediary, in turn, has the right to sell licenses for the use of each asset multiple times, and undertakes to pay the authors/investors a predetermined portion of the income (net of commissions and other expenses), but only if the income take place.

The latter circumstance is the most significant, since the risks and uncertainties associated with digital, as well as with any other intellectual assets, are known to be the highest in the economy. Let us repeat once again that, in our opinion, this factor is one of the most significant for confirming belonging to investment activities in terms of the riskiness of obtaining the expected investment income from a common enterprise. Returning to the Howey test, we also note that the high risks inherent in the activities of an intermediary (promoter) or third party, according to many researchers, confirm the fulfillment of the last, fourth condition of the test (Telpner and Ahmadifar, 2017).

The Efforts of a Promoter or Third Party

In our opinion, the principle of participation of shares (portfolios) of individual authors/investors in the aggregate portfolio of an intermediary should be attributed to the justification of the same condition. Here, the broker's portfolio as a whole should be viewed as the aggregate intellectual capital in digital form that generates profits. In order to maintain and improve the return on investment, the intermediary commits itself to apply reasonable management efforts that affect the success of the enterprise, and the authors/investors reasonably expect a return from these efforts.

However, in addition to the general goal of profit growth, there is also a contradiction between the authors/investors and the intermediary. In particular, the intermediary is interested in multiplying the total portfolio of the company, and seeks to solve this problem in any way, including by attracting new participants. For example, the contingent of authors/investors officially registered by the aforementioned Shutterstock Ink by the beginning of 2020 exceeded 1 million people (see Table 2). The continuous expansion of the intermediary's portfolio, as in the case of a regular joint-stock company, leads to a dilution of the shares of individual participants. To mitigate this effect, they have to take steps to increase their portfolios. This is the simplest and most obvious way to preserve the return on investment, but due to the risks and uncertainties inherent in intellectual assets, even a proportional increase in individual portfolios does not guarantee that income will be maintained. In this area, as noted above, other market laws are in force.

Other important aspects of the intermediary's activities are, firstly, the development, creation and improvement of the network itself (network platform). Authors/investors expect the intermediary to further develop the network in order to ensure the growth of its value and profitability. Secondly, the task of the intermediary is, in principle, to create and then develop the market of the corresponding DCA and the formation of market prices. In particular, the intermediary is engaged in marketing, publishes its price lists in order to form market representations of the current prices of the DCA in various thematic and price categories. The intermediary also plays a key role in establishing the rules for the network trade turnover, price and other categories of the DCA, and criteria for their quality. Finally, he also conducts all transactions related to the DCA trade. Thus, it is the intermediary work to ensure the liquidity of the DCA.

The authors/investors expect that, receiving the part of the profit, the intermediary will direct it, among other things, to expand the network, which will ultimately lead to an increase in the company's total capitalization. The intermediary also assumes responsibility for ensuring the information security of the entire network. He also undertakes to control the protection of copyright (i.e. intellectual property rights of the DCA owners), and by his authority and concrete actions seeks to ensure control over their observance.

So, back to the description of the investment process algorithm, which we interrupted on the fact that the authors/investors have the right to expect receiving a specified part of the income, but only if it takes place, i.e. there have been events of (licenses) sale of their DCA. This moment is interesting in that it marks the appearing of the third, most important, administrative section of metadata for each DCA (Voronov et al., 2017). This section is also external, stored on the intermediary's servers, and the following data is automatically entered into it:

- how many times licenses for a particular DCA were sold;
- how much revenue was received from each sale. The fact is that this value is not constant and depends on a combination of many factors;
- by what keywords the buyers were looking for the asset, and which of these words are in the primary metadata section formed by the author;
- what formats and sizes were in demand, etc

Thus, if the sale of licenses for a specific asset has occurred, then due to the formation of the third (administrative) section of metadata, its value increases significantly. This is because the market sees sales data and it is a clear signal that a particular asset has moved into a higher probabilistic demand category. Uncertainty about the investment attractiveness of such a DCA decreases, and the likelihood of additional income increases with each sale. The mediator continues to add metadata to the administrative section continuously. It should be noted that if without the creation of the first, internal (see Table 1) and the second, external descriptive sections of the DCA metadata, in principle, it is impossible to bring DCA to the site of an intermediary, then the appearance of an administrative section can significantly increase its investment attractiveness, and, consequently, profitability.

The creation and improvement of all three sections of metadata can be roughly called the "Information Enhancement" of a particular DCA, by analogy with the well-known financial term "Credit Enhancement". At the same time, as in finance, information improvement can be both internal and external.

In the process of studying the strategic possibilities of managing portfolios of the DCA, we identified the momentum effect, both in individual assets and in portfolios of a similar class in general. In its most simplified form, this property consists in the fact that a portfolio, brought to a certain level of income, continues to generate it even in the absence of any control actions from the author/investor. The presence of momentum in DCA has been proven on the basis of more than 10 years of observations on the digital images portfolio as a whole, and on individual record-holding assets, demonstrating clear historical series of returns. We used the obtained experimental data to develop a generalized structural model of DCA portfolio, as well as to study financial risks using Bayesian network models (Voronov et al., 2020).

Paradoxes of Publicity

So, the analysis based on the Howey test generally confirms that the placement by the author of his DCA in the microstock portfolio meets the criteria for belonging to investment activity. However, as shown in Table 2, the leading microstocks have already entered the stock market and went public. This means that, on the one hand, any investor, regardless of whether he owns a DCA, can freely purchase microstock shares and become a participant in the intellectual property market. On the other hand, participation in the aggregate intellectual capital of a microstock is available only to authors/investors who own the DCA. This paradox leads to the fact that two diverse groups of investors have different rights to participate in equity and intellectual capital.

Another problem is that microstock equity investors are better protected because their earnings are affected only by market fluctuations in the value of the company's shares. The public microstock cannot arbitrarily lower the profitability of its shares. At the same time, as shown above, the microstock does not have any obligations regarding the share of sales revenue distributed to authors. As a result, for example, Shutterstock cut royalties by three times in 2020. Earlier, income was $ 0.25-0.33 from the sale of one license for an image by subscription, but now this value has dropped to the base $ 0.1. In response to this, a number of authors/investors turned off their portfolios in order to "wait out losses", but this is unlikely to affect the company's policy, since there are not very many of these among 1 million authors. Of course, Shutterstock is guided by its own corporate strategy, and with a portfolio of 340 million assets, there is little risk. Most likely, this is just an attempt to fix its financial problems, to which the company has every right.

In conclusion, we note one more unusual feature of microstocks, associated with the fact that, due to the fixed value of the DCA, the total value of the company's digital asset portfolio is practically independent of fluctuations in the stock market. Obviously, such companies may be of interest to hedge funds looking for opportunities to invest in assets and companies whose value is less dependent on stock market fluctuations.

Conclusion and Further Research

Finally, applicability analysis of the Howey test to digital copyright assets (DCA) showed the following:

The investigated digital copyright assets are a kind of intellectual property - copyrights in digital form, which, like any property that has a value, are classified as assets. A feature of DCA forming process is the need for special preparation of digital files in order to introduce property attributes and other metadata into their information structure. The last, administrative section of metadata is formed based on the results of asset sales, if any.

Investing in a common enterprise is carried out using the organizational structure of specialized market intermediaries, which bring the DCA of individual authors/investors into a common pool, and ensure the subsequent investment process. However, unlike ordinary financial assets, DCA are not depersonalized in the process of marketing and trading. The risk of investing in DCA significantly exceeds the risk of investing in conventional financial assets.

The intermediary allows the author/investor to independently vary the strategies for managing the DCA portfolio. At the same time, the revealed momentum effect in DCA portfolios allows generating income even in the absence of control actions. The momentum property in DCA has been confirmed by our long-term observations of digital image portfolios. Despite the fact that the momentum effect of standard financial assets has been discovered for a long time (Asness et al., 2013), there have been no reports of such a property in the DCA in the literature. Therefore, the aspect of momentum, in our opinion, is promising for further research. Among other things, in public companies, different properties of this effect can be used by both ordinary investors who own shares (for example, of microstocks) and authors/investors who manage DCA portfolios. In particular, stockholders can feel the momentum effect in the price trend of their securities, and authors/investors can use the momentum of their portfolios when choosing strategies for replenishing them with new assets.

As the leading microstocks have already entered the stock market and went public, then on the one hand, any investor, regardless of whether he owns a DCA, can freely purchase microstock shares and become a participant in the intellectual property market. On the other hand, participation in the aggregate intellectual capital of a microstock is available only to authors/investors who own the DCA. This leads to the fact that two diverse groups of investors have different rights to participate in equity and intellectual capital.

Abstract

National culture is a master variable that defines ways in which societies function and differ one from another. Organizations competing on the global market need to take national culture into account when organizing their daily operations. There exists a significant body of literature that deals with different ways in which national culture affects organizations. The aim of this paper is to analyze national culture as a moderator in organizational research. In order to systematize the most recent findings we analyzed relevant literature since 2010 with a special emphasis on methodological and theoretical implications of using national culture as a moderator. Our paper identifies key research areas and avenues for future research of the moderating role of national culture in organizational research and provides methodological and theoretical suggestions for scientists entering the field.

Keywords: national culture, moderator, organizational research

Introduction

Activities and processes within an organization are influenced by various factors from its surroundings. One of the most important factors is the national culture within which an organization does business. National culture influences an organization through the dominant norms and values of its employees, management, owners and founders. The construct itself has origins in cultural anthropology and works of Kroeber & Kluckholn (1952) and Inkeles & Levison (1969) which hypothesized that national culture can be observed as a set of values that explain ways in which individuals form their attitudes towards authority, gender roles in a society and conflict resolution. Before the 1980-s national culture was viewed as an exogenous and unidimensional variable in organizational research. Hofstede (1983) was the first to define and quantify national culture as a multidimensional construct consisting of value dimensions. Over the course of time different scientists proposed similar models of national culture (Schwartz, 1994; Trompenaars & Hampden Turner, 1997; House et al., 2002). However, these models define and measure national culture in similar fashion as Hofstede's model and are all focused on societal values. Some scientists argue that analyzing national culture only through the lens of societal values is somewhat vague (Caprar et al., 2015), but this approach is still dominant in business research and our paper will also focus on national culture value dimensions as moderators in organizational research.

Cite this Article as: Mate DAMIĆ, Dora NALETINA And Luka BUNTIĆ "National Culture as a Moderator in Organizational Research" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

National culture value dimensions are derived from key societal issues that exist in a society and they reflect the way members of a society tackle these issues. Hofstede's national culture value dimensions model identifies six different dimensions. Power distance measures how willing are the less powerful members of a society to accept and expect that power is distributed unequally. Individualism versus Collectivism is the second dimension of Hofstede's national culture dimensions model. Societies that rank high on individualism have a stronger preference for loose social connections and individuals in these societies are expected to take care of themselves. Collectivist societies on the other hand prefer a tighter social structure and take care of the members of a wider social group. Masculinity versus Femininity is the third dimension of the model. Societies that are more masculine have a higher preference for goal achievement, assertiveness and rewards for success. Feminine societies on the other hand have a preference for cooperation, caring for other members of the society and focus on the quality of life. Uncertainty avoidance is the fourth dimension of the model and it measures how societies cope with uncertainty and ambiguity. This dimension should not be confused with risk aversion. Long term versus Short term orientation is the fifth dimension of the model. Long term oriented societies are viewed as being more pragmatic, as they easily give up tradition in order to embrace new practices that are better than the existing ones. Short term oriented societies are more focused on tradition and do not prefer social change. The sixth dimension of the model is called Indulgence versus Restraint. Societies that score high on Indulgence do not oppose leisure and are more open to activities related to enjoying life. More restrained societies do not promote leisure and are keener to regulate it by social norms.

Schein (1983) theorized that a business organization reflects different components of its external surroundings, and above all else the nationality of the management and founders of the organization. Laurent (1983) also hypothesized that assumptions and values of the local population will have a significant influence on management behavior in organizations competing on the local market. Differences in national culture often led to different outcomes of various initiatives and processes in an organization. The interest for the construct of national culture has led to a large body of literature, and a number of research streams. Two broad research streams that can be identified are the main effect and moderator studies of national culture at the individual, organization and country level of analysis (Kirkman et al., 2006). The main effects studies are dominant in the literature, and Kirkman et al. (2017) proposed that more research should focus on the role national culture plays as a moderator of different relationships within an organization. In this paper we tried to identify relevant moderator studies since 2010 with a focus on the organizational level. We hope our findings will offer a good starting point for scientists preparing to enter the research of national culture.

Methods

In order to analyze the most common theoretical and methodological approaches used we conducted a bibliography analysis using key words related to moderation, national culture and organizational research. We searched the Web of Science Social Sciences Citation Index with the year range from 2010. Our search produced a total of 22 papers which was significantly lower than expected. Kirkman et al. (2006) state that there is a lack of studies on the moderating role that national culture plays in organizations. However, there seems to be a relatively small number of contributions to this research stream, although it provides an interesting avenue for inter cultural research.

After analyzing the topics and findings of the papers we included a total of 10 papers in our literature review. We find that these paper offer relevant insights into the moderating role of national culture in organizational research. These papers also provide sound theoretical foundations for the analysis of the moderating role national culture plays in organizational research and can therefore be used as a good starting point for future cultural research. The main contribution of this paper is the systematization of a number of relevant research studies that analyze the moderating role of national culture in organizational research as well as the identification of key research areas and limitations related to existing research.

Literature Review

A number of critiques for the use of Hofstede's national culture model can be found in the literature. Taras et al. (2016) state that many other dimensions shape culture more than the nation, primarily socioeconomic and demographic factors. In addition, they conclude that national culture dimensions represent average values and do not take into account many variations that exist within a national culture. One of the problems that often occurs in intercultural research is the assumption that the influence of national culture equals the influence of the country. National culture can be seen as the most important informal institution of a country, and the dominant features of national culture are often reflected in the design of formal institutions and the way organizations operate in a country. Nevertheless, the overall national effect consists of a number of institutional and other factors, so it is very important to correctly assess not only whether national culture is important, but also to what extent it is important, i. e to assess the strength of the cultural effect (Kirkman et al., 2017). Kirkman et al. (2006) state that the common issue with the use of Hofstede's model in scientific research is that country scores cannot be lowered to the level of organization and individual directly from the national level, i.e generalize that what is valid for the country level is valid at lower levels. In addition to this, Hofstede et al. (2010) explain that national culture dimensions should only be used in studies that evaluate country differences as they represent a national average and are usable only when compared to other national averages, and not on their own. According to Steel et al. (2010) the power of prediction for cultural variables increases with the level of observation. The reason is probably that aggregating the data reduces the measurement error. Therefore, studies of the relationship between national culture and organizations should avoid ecological fallacy, i.e. assigning values from higher levels to lower levels, as well as atomic fallacy, i.e. assigning values from lower to higher levels. Taking all of this into account, and following advice from Kirkman et al. (2017), more research should focus on exploring the role of national culture as a moderator in various organizational processes and activities. An overview of relevant research that analyzed the moderating role of national culture on organizations can be found below.

Naor et al. (2010) used hierarchical linear modelling to draw conclusions about the impact of organizational and national culture on production plant performance. In doing so, they come to the conclusion that there is no significant influence of the national on the organizational culture. This result of the analysis can be partly explained by the fact that the analysis was conducted in the production facilities of large multinational companies that "imported" their organizational practices and values and in no way adapted to national culture.

Engelen (2010) analyzed the moderating role of individualism and power distance on the relationship between organizational structures, organizational culture, leadership style and entrepreneurial orientation in China and Germany. He theorizes that if there is a strategic fit between observed organizational factors and national culture, that their effect on entrepreneurial orientation will be stronger than in the absence of such fit.

In a more recent work, Engelen et al. (2015) analyze the moderating impact of individualism and uncertainty avoidance on entrepreneurial orientation. In doing so, they conclude that a combination of institutional factors has a stronger effect on organizational outcomes than each factor individually, and that it is important to observe layers of cultural values to clarify their impact on organizational outcomes.

Wiengarten et al. (2011) analyzed the impact national culture as a moderator of the relationship between investment in quality practices, factory and equipment investment on the operational performance of enterprises. They concluded that the low level of individualism has a positive effect on investments in production equipment as well as in quality practices. On the other hand, low levels of masculinity and uncertainty avoidance only affect investments in quality practices.

Engelen et al. (2012) analyzed the impact of inter-functional integration, defined as the process of interaction and collaboration between functions in an organization and organizational and national culture. In doing so, the authors show that there is a positive impact of the collectivism dimension on the relationship between interaction and collaboration between functions in the organization and the success of new products, while the impact of organizational culture was significantly smaller. On the other hand, the stronger the organizational culture itself, the stronger the positive moderating effect of collectivism in the organization.

Škerlavaj et al. (2013) analyzed the moderating impact of national culture on organizational learning culture, where organizational learning culture consists of obtaining and interpreting information as well as behavioral and cognitive changes in the organization. Research has shown that there is a moderating effect of power distance on the relationship between information interpretation and behavioral and cognitive changes, while individualism, masculinity, and uncertainty avoidance have had a negative impact on the relationship.

Černe et al. (2013) analyzed how managerial innovation affects the propensity to innovate and innovative performance in terms of commercialization and whether this relationship is affected by individualism. In doing so, they take the position that individualism has a different role in different phases of the innovation process, and especially that the impact of individualism will depend on the breadth of the definition of innovation. Based on the analysis conducted in thirteen countries, they conclude that individualism helps greatly in the invention phase, while collectivism has shown a positive impact in the commercialization phase when the company's cooperation with other stakeholders is more important.

Unger et al. (2014) analyzed the relationship between organizational culture and strategic fit of projects that an organization is engaged in. In doing so, they observed the influence of the dimensions of national culture as potential moderators of that relationship. According to the authors, masculinity, collectivism and people-orientation proved to be significant moderators of the relationship between organizational culture and strategic compliance of the project and explained a good part of the model variance.

Bachmann et al. (2016) conclude that the relationship between strategic planning and the entrepreneurial orientation of an organization will be more pronounced if the organization operates in a national culture characterized by a high level of uncertainty avoidance, collectivism and a low level of masculinity. They also state that the constructs observed at the organizational level are grounded in the interaction of variables at higher levels. A result of this is that it is often possible that observing models at only one level will lead to overlooking important factors of an observed relationship. A similar recommendation is made by some other authors engaged in national culture research (Gelfand et al., 2006; Kirkman et al., 2017;).

Strese et al. (2016) analyzed the impact of national culture on the relationship between organizational culture and the absorptive capacity of the organization. They state that power distance has a significant impact on vertical communication in an organization, individualism on the horizontal exchange of information, while uncertainty avoidance has an impact on the general attitude towards new ideas. In addition, they show that the relationship between each type of organizational culture and potential absorptive capacity is very stable regardless of national culture. However, when looking at the realized absorptive capacity, it can be concluded that a high level of power distance negatively moderates the relationship between market culture and realized absorptive capacity. Also, it can be concluded that the relationship between adhocracy culture and realized absorptive capacity is positively moderated by both high levels of power distance and uncertainty avoidance.

Based on the above, it can be concluded that a number of authors have analyzed the influence of national culture as a moderator of various organizational relationships. In doing so, they all used Hofstede's model

of national culture value dimensions. Majority of the studies has shown that national culture has an influence on different organizational processes and outcomes. The theoretical foundation for analysis of national culture as a moderator in organizational research can be traced to the contingency theory and the Venkatraman's (1989) contingency model of „fit for moderation“.

According to the contingency theory, national culture can be seen as a superior system which influences the subordinate system, i.e. the organization that operates within in. The traditional contingency model for analyzing the impact of external factors on an organization will therefore consist of three sets of variables: application of an organizational practice, contingency factors, i.e. national culture, and organizational performance following the application of the organizational practice. Following the contingency model of „fit for moderation“, the influence of an independent variable on a dependent one can vary depending on the different value of the moderator. In the case of national culture as a moderator, the strength of the effect on an organization will depend on its strategic fit (Strese et al., 2016), i.e. the degree of correspondence between organizational and national culture.

Two most commonly used methods for the analysis of national culture as a moderator in organizational research are moderated regression and hierarchical linear modelling (Kull & Wacker, 2010; Strese et al., 2016;). These methods allow the researchers to avoid ecological and atomic fallacy. Hierarchical linear modelling allows for testing of multiple research models. The testing usually starts with the null model, which is also called the no-limit model. The goal of the null model is to determine the variability in dependent variables with respect to intra-group and inter-group components and it does not contain defined predictors. After that, variables are added to the model at the first level of analysis. Following the contingency model, these variables will usually be the organizational practices and outcomes of the practices. At the first level of analysis, constants and regression coefficients are estimated. In the next step, variables of the second level of analysis are added to the model. In the case of national culture these will be the measures of different national culture value dimensions that are expected to influence the relationships defined at the first level of the model. The aim of the second level model is to examine whether the dimensions of the national culture within which a company operates affects the strength of the relationship between different organizational practices and outcomes. It is important to note that the use of hierarchical linear modelling is independent of the number of analyzed organizations from a particular country, which is very useful when conducting intercultural research (Kull and Wacker, 2010). However, the research sample should include at least ten different countries.

Conclusion

National culture is one of the most important external factors influencing organizations. It is present in the values, norms and behavior of employees, management and the founders of an organization. The dominant view on national culture is still the Hofstede value dimensions model, which was first proposed in the 1980s. This models presents national culture as a six dimensional construct, and provides country measures that make inter country comparison possible and easy. National culture literature can be broadly divided into main effect and moderator studies. The main effect studies outnumber moderator studies significantly. However, analysis of national culture as a moderator is an interesting avenue for future research due to a number of reasons.

The common issue in national culture research is that scientists tend to equate country scores with organizational and individual scores. However, values at the national level cannot be transferred to lower levels and vice versa, since doing so would mean committing either ecological or atomic fallacy. Observing national culture as a moderator can therefore be used as an elegant solution for this common issue. Another recommendation for national culture research is to try and take as many countries as possible into the research sample. Although this may lead to difficulties in data collection, national

culture dimensions should only be used in studies that evaluate country differences, and observed as national averages.

The theoretical foundations for observing national culture as a moderator in organizational research are solid, and the methods are well established and allow the researchers to avoid ecological and atomic fallacy, some of the most common issues in intercultural research. Future research should also try to focus more on similarities and differences of culture effects on different levels, therefore, hierarchical linear modelling is perhaps the most appropriate quantitative method for use in national culture research.

Future research should also try to broaden the construct of national culture. A number of authors have proposed interesting new ways of looking at national culture. Gelfand et al. (2006) proposed a cultural framework of loose and strict societies that could be used to expand the national culture value dimensions model. Leung et al. (2005) propose that future research should be more qualitative and experimental in nature since most national culture studies are quantitative and use self-reported measures. As we stated earlier in the paper, researchers should bear in mind that national culture is one among many external factors influencing organizations. Market competition, legal framework, macroeconomic environment and state institutions also have a significant impact on activities of an organization. Therefore, it is always important to measure the strength of the effect of national culture on an organization.

Changes in The European Audit Services Market

Malgorzata KUTERA

Jagiellonian University, Cracow, Poland
malgorzata.kutera@uj.edu.pl

Abstract

In-depth changes are now taking place in the audit services market in Europe. They are mainly caused by the implementation of new rules laid down in European regulations. However, Member States have relatively broad freedom in drafting detailed regulations. In light of the above, the main purpose of this article is to identify disparities between financial audit systems in different European countries and to assess them in the context of changes introduced in the EU as a whole. Particular attention is paid to aspects connected with the organisation and the structure of the audit services market. Rules applicable in 30 countries have been analysed and differences identified concerning the scope of Public Interest Entities, the obligatory audit firm rotation, the ban on providing selected non-audit services, and joint audits. Disparities were found in key aspects of statutory auditor activities which are still very controversial. The biggest ones concern the obligatory auditor rotation and the maximum duration of engagement by a given entity. This has a negative impact on the effectiveness of the whole market and its competitiveness.

Keywords: Statutory Audit, EU Audit Reform, Audit Firm Rotation, Non-Audit Services.

Introduction

A series of scandals stemming caused by falsifying corporate financial results has significantly undermined trust in auditors globally. They started in 2001 with the collapse of Enron and the situation deteriorated further during the last economic crisis. As a result, the last several years have seen a process of in-depth changes to the financial audit system. In the European Union, this mainly entails implementing new regulations which became binding in audits of 2017 financial statements. The above regulations significantly impact formal aspects of practising the profession of a statutory auditor and the operation of audit firms. They concern, among other things, precisely defining the role of the statutory auditor, effectively preventing conflicts of interest in the provision of various services and restricting market concentration. There have also been major changes to the supervision system of statutory auditors and the rules of reporting audit results.

Directive 2014/56/EU and Regulation 537/2014 form the legal grounds for the most recent system changes. The Directive lays down a number of guidelines concerning all obligatory audits in a given country, while the Regulation introduces additional requirements for auditing the statements of Public Interest Entities (PIEs). These new regulations apply within the European Union as well as in Iceland, Liechtenstein and Norway, which are members of the European Economic Area (EEA). Even though the UK has recently left the EU, it has also implemented them.

Still, it must be said that the above regulations leave a lot of leeway in setting national rules. Altogether, they contain about 50 different options to choose from. Member States were happy to use these options and have actually implemented highly varied rules, including those governing matters that are key for the organisation of the audit services market. Significant discrepancies between national financial audit systems hinder harmonising the market within Europe as a whole and definitely reduce its efficiency. What is of fundamental importance in this context are, in particular, the regulations adopted on the scope of Public Interest Entities (which have always been subject to more detailed and demanding rules of auditing), the obligatory rotation of audit firms and the maximum duration of engagement by the client, the ban on providing certain non-audit services and the rules of conducting joint audits.

Cite this Article as: Malgorzata KUTERA "Changes in The European Audit Services Market" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In the light of the above, the main purpose of this article is to identify disparities between financial audit systems in different European countries and to assess them in the context of systemic changes made in the EU as a whole. Particular attention is paid to aspects connected with the organisation and the structure of the audit services market. In the introduction, EU regulations are analysed in detail, mainly to determine the degree of decision-making freedom during their transposition into national law. Then, the rules adopted by individual countries are verified in depth and key differences between them are identified.

The following research questions have been formulated:

1) What is the scope of Public Interest Entities implemented in EU countries?
2) How did individual countries approach the problem of market concentration when implementing regulations on the obligatory rotation of audit firms and the maximum duration of their engagement?
3) Which non-audit services were ultimately prohibited in the EU?
4) What solutions for joint audits have been adopted by Member States now?

In this context, there has always been a significant problem with the relatively high concentration of the audit services market, which inhibits its competitiveness. This is why the final solutions adopted by countries in this regard, including those concerning joint audits, are particularly interesting. However, the starting point of an analysis of the situation is the definition of public interest entities, as only for this group of entities is auditor firm rotation obligatory.

Theoretical Background

Serious changes to the financial audit system in Europe were initiated in 2006 as a result of very public scandals involving the falsification of company results in the early 21st century. Directive 2006/43/EC introduced a series of regulations governing the provision of statutory audits, the organisation of audit firms, introducing public supervision of statutory auditor activities and the cooperation between supervisory organisations in the EU, as well as the systematic and obligatory training of statutory auditors. More stringent requirements for audits of public interest entities were also introduced, e.g. the application of uniform standards during these audits (International Standards on Auditing) or the greater liability of statutory auditors. However, these changes turned out to be insufficient, particularly during the last financial crisis. There were widespread concerns about insufficient information in auditors' reports, lack of credibility of their contents (particularly with regard to financial accounts of banks, financial institutions and listed companies), too cosy relationships between audit firms and entities they audited, doubts as to the actual objectivity and independence of auditors, as well as the high concentration of the audit services market increasing systemic risk. In response to these concerns, another reform was carried out at the EU level, by adopting Directive 2014/56/EU and Regulation 537/2014.

The new audit regulations came into effect on 17 June 2016 and applied to the financial year starting after this date. An exception was made for the obligatory audit firm rotation, the implementation period of which was extended. However, the implementation of these regulations in individual countries followed very different paths and has still not been completed. By June 2016, 12 EU Member States had implemented the revised regulations, a year later the number was 25, and in June 2018 there were 27 such EU states. The last country in the EU to implement these regulations was Slovenia. As of July 2020, of all obligated states, the new rules had not been completely implemented yet by Norway.

Matters addressed by these new legal regulations have been the subject of many research projects over many years. In the context of this article, the most important subject is the concentration of the audit services market and the problem of auditor independence. The dominance of several audit firms significantly limits the unbiased selection of an auditor and leads to systemic risk. It also directly drives the prices of services provided by statutory auditors and the quality of their work. This is because an excessively long engagement of an auditor by their client may also limit the objectivity and the professional scepticism of the statutory auditor. This is why new EU regulations have introduced

mandatory rotation of audit firms auditing the financial statements of key entities in every Member State. Other new rules require joint audits, which force statutory auditors to cooperate, and ban the provision of certain services to the audited economic operators.

The concentration of the audit services market concerns, in particular, the services provided to the largest economic operators in each country (Simunic, 1980, pp. 161-190). The market is significantly dominated by the Big 4 audit firms. It is worth remembering that significant mergers and acquisitions occurred in the group of the largest global audit companies, which exacerbated this unfavourable development further. This has been confirmed in the research of, among others, Minyard and Tabor (1991, pp. 79-90), Wootton et al. (1994, pp. 58-74), Choi and Zéghal (1999, pp. 1-21) and Pong (1999, pp. 451-475). Institutions responsible for the security of trading have been warning for years that this high concentration may have a negative impact on price competition, the unbiased choice of an auditor and the quality of statutory auditors' work (FRC, 2006; Oxera, 2006, 2007; OECD, 2009). These warnings were particularly resounding at the beginning of this century, right after a series of spectacular company collapses initiated by the bankruptcy of Enron in 2001. However, the reforms made then in the audit services market turned out to be ineffectual, and the very same problem reappeared during the 2008 financial crisis. Analyses continued confirming the high concentration of the statutory auditor market and linking it directly with the systemic risk of the financial sector (European Commission, 2010; Oxera, 2011; Treasury Committee, 2008). It is worth noting that in the literature, the concentration of the audit services market was mainly studied from the perspective of various competition factors. In particular, its impact on the price of financial statement audits and the quality of statutory auditors' work was analysed.

Statutory auditors' independence is also the subject of many research projects. The important analyses in this context concern the prohibition on providing non-audit services to the client whose financial report the firm audits and the obligatory rotation of audit firms. However, the results are not clear cut. Some studies demonstrate a negative relationship between non-audit services provided by a statutory auditor and the quality of the annual audit of the financial statements of the entity (Sharma & Sidhu, 2001, p. 563-594; Kinney et al., 2004, p. 561-588; Khurana & Raman, 2006, p. 977-1016). On the contrary, other studies show that providing non-audit services does not actually impair the accounts auditing process (DeFond et al., 2002, p. 1247-1274, Knechel & Sharma, 2012, p. 60-81, Koh et al., 2013, p. 1-33). For example, DeFond proved that there is no significant relationship between the fees charged by auditors for non-audit services and their tendency to express other than positive opinions on the audit of the annual financial statements of the same clients.

Another aspect connected with the independence of auditors is their obligatory rotation and the maximum duration of their engagement by a given entity. In this context, both the change of the key audit partner and the rotation of the entire audit firm are analysed. The obligatory change of the key audit partner had already been introduced before. The current regulations govern the rotation of audit firms. Most scientific research does not support the thesis that a longer duration of auditor engagement by the audited company has a negative impact on the quality of services provided. On the contrary, research more often indicates a positive relationship between these aspects (Johnson et al., 2002, p. 637-660; Myers et al., 2003, p. 779-799). For instance, Myers has proven that the longer the engagement of the auditor by the company, the more sceptical the auditor is about risky decisions taken by the board of the audited entity. There are also other studies demonstrating that in the early years, the quality of financial statement audit is worse than later (Geiger & Raghunandan, 2002, p. 67-78).

The last element is the joint audit. Some analyses of this subject proved that the obvious increase of the fee for this type of audit does not necessarily lead to better service quality (Guo et al., 2017, 1595-1627). Other researchers have, for example, carried out a broad comparative analysis of joint audits in France and single audits applicable in the United Kingdom. A clearly higher level of the total fee paid in France was observed, but there was no significant improvement in the quality of the service provided (Andre et al., 2016, p. 245-274). Similar conclusions are drawn from Deng's research. He analysed the results of work of individual pairs of audit firms involved in joint audits and demonstrated that the joint work of a smaller firm and a Big4 firm does not necessarily improve the final audit quality (Deng et al., 2014, p. 1029-1060).

Methodology of Research

The main purpose of this article is to identify disparities between financial audit systems of individual European countries, particularly with regards to the organisation of the market for audit services.

First, EU regulations are analysed, mainly to determine the degree of decision-making freedom during their transposition into national law. The verification concerns mainly the provisions of Directive 2014/56/EU and Regulation 537/2014 which define a public interest entity, lay down rules of audit firm rotations, the ban on non-audit services, and regulate joint audits. This is followed by an in-depth analysis of legal texts governing the financial audit system in all obligated countries in which the reform has already been completed. This research thus covers EU Member States, the UK, Island and Liechtenstein, i.e. altogether 30 states. It excludes Norway, as the implementation in this country has not yet finished.

Detailed rules of audit service provision in individual countries were also identified by analysing secondary data, mainly form reports of the European Commission, of public authorities supervising activities of statutory auditors and of global audit firms.

Research Results

One major aspect of the audit market reform was to define Public Interest Entities (PIEs). Principally, the scope of PIEs in the new directive is not significantly different than in previous European regulation. However, Member States were given the opportunity to broaden the set of such entities and make it more precise. It should be noted that this is of key importance for the interpretation and adoption of other regulations connected with the reform. This is because the second document adopted by the EU– Regulation 537/2014 – contains important solutions envisaged specifically for the PIE group, so delineating the scope of Public Interest Entities is a starting point for implementing further changes in the audit market.

According to the definition form the directive, all the following should be treated as Public Interest Entities (Directive 2014/56/EU, article 2):
- entities governed by the law of a Member State and listed on regulated markets in the European Union;
- credit institutions operating within the EU, regardless of whether they are listed on a regulated market;
- insurance undertakings operating in a Member State, also regardless of whether they are listed on a regulated market and of their business line (i.e. type of insurance);
- other entities included in this group by individual Member States due to their significant public relevance (because of the nature of their business, their size, or the number of their employees).

The last item of the aforementioned provision offers complete freedom to expand the scope of PIEs. The majority of EU Member States took advantage of this opportunity, which led to significant differences between the criteria adopted. Consequently, attention must be paid to the definition adopted in a given country, particularly when considering the activities of multinational corporations. The conditions defined for PIEs apply to every individual company domiciled in a selected Member State regardless of where its mother company conducts its business and whether the latter is also treated as a PIE.

Of all the countries obligated to reform the system, 19 have extended the scope of Public Interest Entities while 11 adopted the definition from the EU directive. The relevant details are presented in table 1.

Table 1: Scope of Public Interest Entities

PIE defined according to the EU directive	Extended scope of PIEs
1. Ireland	1. Portugal
2. United Kingdom	2. Spain
3. Netherlands	3. France
4. Germany	4. Malta
5. Denmark	5. Slovenia
6. Finland	6. Italy
7. Estonia	7. Croatia
8. Greece	8. Austria
9. Cyprus	9. Czech Republic
10. Liechtenstein	10. Hungary
11. Luxembourg	11. Poland
	12. Bulgaria
	13. Romania
	14. Slovakia
	15. Latvia
	16. Lithuania
	17. Belgium
	18. Sweden
	19. Iceland

Another important but controversial aspect of the reform of the financial audit system in Europe is the obligatory rotation of audit firms. It applies only to services provided to Public Interest Entities. Consequently, the change of the audit firm is not obligatory for other entities, even if they are subject to the statutory duty of having their financial statements audited. The basic rule of the EU law stipulates that after 10 years of service, the audit firm must be obligatorily changed (Regulation 537/2014, article 17). The key audit partner representing a given audit firm and auditing the statements must be changed after the maximum 7 years. If a company wants to bring back its former audit company, it must wait at least 4 years before doing so.

However, the regulations have given Member States many additional possibilities of modifying this obligation, particularly during the interim period of implementing the new regulations. Namely, it its legislation, every country can:

- extend this basic duration once by another 10 years under the condition that the audited entity carries out an independent tendering procedure (so the maximum duration of engagement will amount to 20 years);
- extend this period once by another 14 years if the engagement is based on a joint audit;
- shorten the period of obligatory rotation to below 10 years.

It should also be added that authorities supervising the financial audit system in a given state may, in exceptional cases, permit the 10 year duration of engagement of the audit firm by the audited company to be prolonged by another 2 years (upon a request of the audited entity). This can, for example, occur when the entity underwent some complex restructuring processes or there were serious problems with the tendering procedure conducted.

An analysis of rules finally adopted by individual Member States shows major discrepancies between them. Limits concerning the obligatory auditor rotation are summarised in Table 2.

Table 2: Rules of audit firm rotation (in years)

Country	Minimum engagement duration	Maximum engagement duration	Possible engagement extension (by tendering)	Possible engagement extension (by joint audit)
Austria	1	10	Not possible***	Not possible***
Belgium	3	9	9	15
Bulgaria	1	7	Not possible	Not possible
Croatia	1	10	10	10
Cyprus	1	10*	10*	14**
Czech Rep.	1	10	10	Not possible
Denmark	1	10	10	14
Estonia	2	10	10	Not possible
Finland	1	10	10	14
France	6	10	6	14
Germany	1	10	10**	14
Greece	1	10*	10	Not possible
Hungary	1	10*	Not possible	Not possible
Iceland	1	10	10	14
Ireland	1	10	Not possible	Not possible
Italy	9	9	Not possible	Not possible
Latvia	1	10	10	Not possible
Liechtenstein	1	10	Not possible	Not possible
Lithuania	2	10	Not possible	Not possible
Luxembourg	1	10	10	Not possible
Malta	1	10	10	Not possible
Netherlands	1	10	Not possible	Not possible
Poland	2	5	Not possible	Not possible
Portugal	2	8 or 9	1-2	Not possible
Romania	1	10	10	Not possible
Slovakia	2	10	10	Not possible
Slovenia	3	10	Not possible	Not possible
Spain	3	10	Not possible	4
Sweden	1	10	10**	14**
UK	1	10	10	Not possible

** other rules for banks and financial institutions*
*** not possible for banks, insurance undertakings and pension funds*
**** possible for contracts concluded in 2003-2014*

The above data clearly shows that individual countries have made significant use of the scope of freedom they were afforded when implementing EU legislation. With regards to the minimum duration of audit firm engagement, most countries adopted 1 year (20 states). Only 10 countries adopted other rules, with Italy and France choosing the most demanding ones. With regards to the maximum engagement duration, the solution adopted in EU regulations is the most popular (10 years). However, there are also clear restrictions: the shortest duration of engagement is effective in Poland, namely 5 years. There are much greater disparities in the rules allowing the possible extension of the engagement duration of the audit firm. For normal audits, this possibility was generally not introduced in 11 countries, and for joint audits in 20. An overall analysis of data shows that Europe now has about 17 different solutions for the obligatory audit firm rotation adopted by the total of 30 countries. It should be noted that these rules apply only to PIEs, but the definitions of a PIE differ in various states. This brings about major disparities between national systems of financial audit.

The third aspect of the reform of the audit services market concerns the prohibition of providing certain types of services to entities whose financial statements are audited by the specific audit firm. This prohibition applies only to selected non-audit services provided to Public Interest Entities and their affiliates.

Under EU rules, the provision of the following additional services to the audited company is prohibited (Regulation 537/2014, article 5):

a) within the scope of tax and tax compliance services:
   - preparation of tax forms;
   - payroll tax;
   - customs duties;
   - identification of public subsidies and tax incentives – unless the provision of this service by the auditor is required by law;
   - support and client representation during tax inspections by state authorities – apart from exceptions defined by law in which representation by the auditor is obligatory;
   - calculation of direct and indirect tax and deferred tax;
   - tax advice;
b) valuation services;
c) accountancy, keeping books of accounts and executing financial reports;
d) payroll services;
e) designing and implementing internal control or risk management procedures related to financial information or designing and implementing financial information technology systems;
f) internal audit activities;
g) legal services:
   - the provision of general counsel;
   - negotiating on behalf of the client;
   - acting in an advocacy role in the resolution of litigation;
h) promoting, dealing in, or under-writing shares in the audited company;
i) human resources management services with respect to:
   - exerting significant influence over accounting or the preparation of financial statements (e.g. searching for or recommending candidates for the financial department);
   - structuring the organisation design;
   - cost control;
j) other services:
   - related to financing, capital structure and investment strategies of the client;
   - involving the auditor in the client's management and decision-making processes.

It should be noted that the regulations have left certain freedom to Member States in fine-tuning their regulations also in this area. In addition, every state may define other prohibited services and lay down more restrictive rules of providing non-audit services. What is more, the state may permit the provision of services related to tax law and asset valuation, on the condition that

- they have no direct or have immaterial effect on the audited financial statements;
- the estimation of the effect of these services on the financial statements is comprehensively documented and explained in an additional report to the audit committee;
- the principles of auditor independence are fully complied with.

In every case, the audit committee is obliged to set additional, detailed conditions for the provision of these services by the audit firm.

When analysing the rules adopted by individual Member States, it should be noted that they generally followed two approaches: either only defining prohibited services in their legislature (“black list”), or presenting a clear, exhaustive list of allowed services (“white list”). The second solution is obviously

more restrictive, as it severely curtails the scope of non-audit services. However, it has been applied in some cases. A full list of solutions applied in this area is given in Table 3.

Table 3: Implementation of rules on non-audit services

Country	Restrictions in line with EU regulations	Conditional provision of tax and valuation services
Austria	Yes	Yes
Belgium	Yes	Yes
Bulgaria	Yes	Only tax services
Croatia	Yes	Yes
Cyprus	Yes	Yes
Czech Rep.	Yes	Yes
Denmark	Yes	Yes
Estonia	Yes	Yes
Finland	Yes	Yes
France	No (additional prohibitions)	No
Germany	Yes	Yes
Greece	Yes	Yes
Hungary	Yes	Yes
Iceland	Yes	Yes
Ireland	Yes	Yes
Italy	Yes	No
Latvia	Yes	Yes
Liechtenstein	Yes	Yes
Lithuania	Yes	Only tax services
Luxembourg	Yes	Yes
Malta	Yes	Yes
Netherlands	No (white list)	No
Poland	No (white list)	No
Portugal	Yes	No
Romania	Yes	Yes
Slovakia	Yes	Yes
Slovenia	Yes	No
Spain	Yes	Yes
Sweden	Yes	Yes
UK	No (additional prohibitions)	Yes

The above table clearly shows that most countries adopted rules identical with EU solutions. Only four countries decided to expand the scope of prohibited services, including two which created white lists. With regard to the conditional provision of tax and valuation services it is clear that the majority of countries decided to adopt a flexible solution in this regard. A definite ban on the provision of these services was imposed by only 6 countries.

The last part of changes in the audit services market which significantly impacts its structure is the explicit introduction of a joint audit, i.e. an audit of financial statements conducted independently by two audit firms. This auditing model had been followed before and was particularly popular in France. The new regulations emphasise its importance in the context of improving the credibility of auditors' work. However, there is no obligation to introduce joint audits, even under engagements by Public Interest Entities. Member States enjoy complete freedom in this regard. To date, joint audits have been introduced as obligatory in three countries: France, Bulgaria and Croatia. In France, they are obligatory for auditing financial statements of all PIEs, in Bulgaria – only for banks, insurance undertakings and

pension funds, while in Croatia – for the largest PIEs (when conditions concerning employment or total assets are met). In other countries joint audits are optional, but some are trying to promote this form of cooperation between audit firms, e.g. by extending the time before the obligatory auditor rotation.

Conclusions

Research results presented above answer the key research questions asked in the introduction to this article. Member States adopted different definitions of a Public Interest Entity. In 19 of them the scope of PIEs is now definitely broader than proposed by the EU directive. Only 11 adopted a definition identical as in European regulations. This ultimately means that in individual states, different groups of economic operators are subject to more stringent rules of financial statement auditing. Even greater disparities were identified between solutions concerning the obligatory rotation of audit firms. An analysis of the minimum engagement duration shows that only 10 countries adopted a duration greater than 1 year. In the majority, the auditor must be changed after 10 years, which is what was proposed in the directive. However, there are also countries in which the change must occur earlier (e.g. after just 5 years in Poland). Significant discrepancies are also visible when one analyses the rules for extending the auditor engagement. For normal audits, no such possibility is envisaged in 11 countries. On the other hand, 19 countries introduced conditions for extending the engagement, but these are quite diverse. In case of joint audits, longer engagement is impossible in 20 countries. Only 10 decided to intentionally promote this form of financial statement auditing and introduced some criteria for extending the auditor engagement in this regard. In most cases, the ban on providing selected non-audit services is equivalent to the proposal from the directive. Four countries introduced more stringent restrictions. There are greater discrepancies concerning the conditional provision of tax and valuation services by an audit firm. A outright ban on their provision was adopted by 6 countries, while the remaining ones allow it. The last research question related to the organisation of joint audits. In this context, it is worth noting that this solution was not adopted generally as obligatory. Only 3 countries chose it (France, Bulgaria and Croatia), and to very different extents. In the remaining countries joint audits remain optional.

To summarise the results of this research, it should be said that European countries adopted solutions for the financial audit system that differ quite a lot in many aspects. This also applies to key issues related to the activities of statutory auditors, which have led to many controversies over the years. Consequently, the audit services market in Europe cannot be called fully harmonised. The discrepancies certainly limit its effectiveness and negatively impact the level of competition. However, one should add that this this reform represents another good step in improving the transparency of audit firms' activities and the quality of services they provide.

Abstract

Students belong to population groups that have a high risk of health problems and risky behaviors. The use of the Health-promoting lifestyle profile allows the identification of factors influencing health keeping behavior. The study involved 205 students from various Russian universities, 97 of them were domestic students, 108 – international students. Participants filled out the Health Promoting Lifestyle Profile. According to the results, both groups of students had sufficient resources to maintain psychosocial well-being. The adherence to a healthy lifestyle in the groups of domestic and international students had its own gender and age specifics. The reason for these differences may be not only cultural factors associated with religious, educational, health-improving traditions. The differences may also be based on economic factors.

Keywords: Health Promoting Lifestyle, Domestic Students, International Students, Russia.

Introduction

Despite their young age, students belong to those population groups that have a high risk of health problems and risky behaviors (Chistopolskaya et al., 2016; Chistopolskaya et al., 2017). The origins of such health disorders in students can lie both in the specifics of relationships in the parental family (Nikolaev et al., 2016), and in the influences of the modern social environment, pushing young generations to excessive using mobile communication devices (Nikolaev and Kulygina, 2019).

The use of the Health-promoting lifestyle profile (Walker et al., 1987) allows the identification of factors influencing health-promoting behavior. This questionnaire is widely used in the world in many languages - Malay (Kuan et al., 2019), Russian (Petrash et al., 2018), Turkish (Soylar et al., 2017), Farsi (Baygi et al., 2017), Kurdish (Kamali et al., 2016), Spanish (Mullins et al., 2013), Chinese (Meihan and Chung-Ngok, 2011), and others. It serves as a tool for studying healthy lifestyles of population, in particular, students in Saudi Arabia (Alzahrani et al., 2019), Croatia (Mašina et al., 2017), South Africa (Roomaney et al., 2017), sailors in Iran (Baygi et al., 2017), pregnant women in Turkey (Soylar et al., 2017), postmenopausal women in Sri Lanka (Rathnayake et al., 2020).

Cite this Article as: Evgeni NIKOLAEV, Elena LAZAREVA, Nadezhda LANTSOVA, Lyubov ROMANOVA and Rahmatulla YAKUBOV "Health Promoting Lifestyle among Domestic and International Students in Russia: A Comparative Analysis" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

This work is an attempt of a comparative study of health-promoting lifestyle profile in two groups of university students living and studying in Russia. The first group - students from different regions of Russia, the second group - students who came to study at a Russian university from abroad. These university students have the same conditions of study and living. Possible differences between groups can only be related to socio-cultural specifics.

Method

The study involved 205 students aged 17 to 27 years from various Russian universities, who studied full-time at different faculties. 115 of them were women (56.10%), 90 were men (43.90%). 97 students (47.32%) were citizens of Russia, 108 (52.68%) were citizens of Azerbaijan, Egypt, Kyrgyzstan, Tajikistan, Turkmenistan and Uzbekistan. In the groups of domestic and international students, there were no significant differences in the ratio of subjects by sex and age ($p > 0.05$).

To study health promoting lifestyle among domestic and international students, study participants anonymously filled out the Russian version (Petrash et al., 2018) of the Health Promoting Lifestyle Profile (Walker et al., 1987). The standard values of the questionnaire scales obtained by the authors of the questionnaire validation in Russia in St. Petersburg (Petrash et al., 2018) were taken into account in the comparative analysis of the data obtained in this study.

Statistical analysis was carried out by using basic statistics and comparing mean values and standard deviations with a normal distribution of indicators using the Student's t-test at a significance level of p not less than 0.05.

Results

Comparison of the indicators of healthy lifestyle in domestic and international students of Russian universities with the normative sample data of the HPLP Russian version showed that statistically significant differences in behavioral activity are identified (Fig.). In particular, domestic and international students reliably more often have a more responsible attitude to their health and more often understand how important it is to maintain and improve their health ($p<0.001$). Domestic ($p<0.05$) and international students ($p<0.001$) are significantly more likely to have regular physical activity. Following a certain nutritional system and choice of certain foods that support health are reliably more often found in international students in comparison with the norm ($p<0.05$).

The cognitive and emotional components of healthy lifestyle in domestic students do not differ from the normative data. In the group of international students, significant differences with the norm were revealed according to the characteristics of spiritual growth ($p<0.05$) and stress management ($p<0.001$), which is manifested by their greater desire in self-realization and developing internal resources and taking more active measures to overcome stress and relieve emotional tension.

Generalized characteristics of healthy lifestyle in domestic and international students also significantly exceed the normative indicators. Significant differences are more pronounced in international students ($p<0.001$) than in domestic students ($p<0.05$).

Fig. Health-Promoting Lifestyle Profile in domestic, international students and normal sample

At the next stage of the analysis, a comparison was made between the indicators of healthy lifestyle in domestic and international students. Significant differences between the studied groups on the scales of Physical Activity ($p<0.001$), Interpersonal Relations ($p<0.001$) and Stress Management ($p<0.001$) are revealed. The results indicate that international students are more likely to exercise regularly than domestic students, they are better able to recognize sources of stress and take measures to eliminate it. At the same time, international students are less able to use interpersonal communications to establish close relationships.

Further, a comparison was made between domestic and international students in gender subgroups. As the analysis showed there are no significant differences between male domestic and male international students in characteristics of healthy lifestyle. In female subgroups significant differences are revealed in parameters of Physical Activity ($p<0.05$), Interpersonal Relations ($p<0.001$) and Stress Management ($p<0.001$).

In line with this, male domestic and international students share the same models of health promoting behavior. Female international students have more physical activity through regular exercise. They are also better able to recognize stress and take measures to eliminate it. Domestic female students are more likely to use communication to build close relationships.

The study of the healthy lifestyle among domestic and international students was also carried out taking into account the age factor. Thus, it is found that at the age of 17-20, international students not only more often resort to regular physical exercises to maintain health ($p<0.001$) but also manage stress better than their Russian peers ($p<0.05$). At the same time, domestic students use communication skills better than international students for close and trusting contacts ($p<0.05$). At an older age of 21-27, international students cope with stress better than domestic students of the same age ($p<0.001$).

Conclusion

From the results obtained, it is obvious that in the studied groups of domestic and international students in Russia the health promoting lifestyle is well formed and both groups of students have sufficient resources to maintain psychosocial well-being. However, the adherence to a healthy

lifestyle in the group of domestic and international students has its own specifics. Overall, healthy lifestyle indicators are more pronounced among international students. Domestic students, in comparison with international students, can better use communication skills to maintain close relationships. This is more pronounced among younger female domestic students. International students are more eager to maintain good physical shape through regular exercise, as well as deal better with emotional stress and stressors. These features are more pronounced among young international students and among female students. Older international students are more likely to have more developed stress management abilities.

The reason for these differences may be not only cultural factors associated with religious, educational, health-improving traditions of a particular country from which the student comes. The differences in the healthy behavior of students may also be based on economic factors, explaining the greater attention of international students to health issues by the need to protect it in terms of payment for medical services. All this should be the subject of further comparative studies.

Abstract

The purpose of the research is a comparative study of the psychosocial characteristics of health related behavior in undergraduate students with diverse cultural background who live and study in one cultural reality. A group of 97 native students and group of 108 foreign students of several Russian universities took part in an anonymous survey through social networks. Students motivated to healthy behavior prevail among the studied university undergraduates. The revealed specific psychosocial risk factors for native and foreign students may become a guideline for cultural relevant preventive programs and regular activity of university medical and psychological services.

Keywords: Health, Psychosocial Risk Factors, University Undergraduates, Native Students, Foreign Students, Cultural Background.

Introduction

Behavioral health risk in undergraduate university students is the subject of research by scientists from many countries (Kang et al., 2014; El Ansari et al., 2018; Di Benedetto et al., 2020). The researchers focus on the issues of illegal drug use by students (El Ansari et al., 2020) and use of other psychoactive substances (Delgado-Lobete et al., 2020), attitudes towards death (Chistopolskaya et al., 2016) and suicidal behavior (Chistopolskaya et al., al., 2017), eating behavior (Kabir et al., 2018) and specificity of body weight control (Alipour et al., 2015), determinants of health-related lifestyles (Aceijas et al., 2017) and mobile phone use related anxiety (Nikolaev et al., 2018).

At the same time, psychosocial health issues are closely related to the specifics of the family environment (Nikolaev et al., 2016) and the cultural context (Powell, 2018). That is why the purpose of the research is a comparative study of psychosocial characteristics of health related behavior in groups of undergraduate students with diverse cultural background who at the moment live and study in one cultural reality.

Method

The study, which was conducted in the form of an online survey, was attended by students studying at Russian universities. The first research group, representing native Russian students, consisted of 97 people with an average age of 19.96 ± 2.49 years. These students were residents of Russia. The proportion of men in the group was 42.27%, women - 57.73%. The second research group of 108 participants was represented by foreign students who came to study at Russian universities from 6 countries of Central Asia and the Middle East. The average age of students was 20.53 ± 1.87 years, the proportion of men - 45.37%, women - 54%. Students received an offer to take part in an anonymous survey through social networks in Internet. The questions of the online-form dealt with student's socio-demographic status and attitude to health-risky behaviors. The primary data obtained were processed using common statistical techniques including descriptive statistics, chi-square test and correlation analysis..

Results

Comparative analysis of socio-demographic characteristics of native Russian and foreign students reveals significant differences in adherence to religion (χ^2=137.48; p<0.001), employment (χ^2=6.59; p<0.05), place of residence (χ^2=118.46; p<0.001). The distribution by sex and age in these groups does not have significant differences. The majority of foreign students (94.44%) are adherents of Islam, the majority of native students (75.26%) are Orthodox Christians. The percentage of students consider themselves to be non-believers is about ten times higher in native students (11.34%) than in foreign students (1.61%). More than three quarters of native and foreign students do not work (76.29% and 89.81%, respectively). At the same time, native students are more likely to work officially (9.28% vs. 4.63%) or officially and periodically (14.43% vs. 5.56%). The overwhelming majority of foreign students live in a hostel (92.59%). More than half of native students live in their own housing (57.73%), less often in rented housing (23.71%) or in a hostel (17.53%).

The specificity of the cultural background also manifests itself in undergraduate university students in differences in perceived stress (χ^2=35.41; p<0.001). More than half of native students (56.7%) experience moderate and 22.68% high levels of stress. While foreign students are more likely to rate perceived stress as insignificant (38.89%) or high (26.85% of students) (Table).

The study of attitudes towards suicide among native and foreign undergraduate students shows that the majority of students in both groups believe that suicide is unacceptable behavior (91.75% and 84.26%, respectively). At the same time, 12.96% of foreign students consider suicide acceptable and 7.22% of native students believe that suicide can be a way out of an unsolvable situation.

In the course of further analysis, significant differences are obtained between native students and foreign students in consumption of alcohol (χ^2=8.53; p<0.05) and other psychoactive substances (χ^2=5.71; p<0.05). Most of the surveyed students do not smoke cigarettes (84.54% and 83.33%, respectively) and hookah (70.10% and 67.59%, respectively). Among native students 6.19% often smoke cigarettes, 13.89% of foreign students rarely smoke cigarettes. Hookah is rarely smoked by 29.90% of native students and 26.85% of foreign students. Hookah is often smoked by 5.56% of foreign students. In general, native and foreign students are more inclined to smoke hookah than cigarettes, possibly considering this type of tobacco intake as safer for health.

Table: Psychosocial characteristics related to health in groups of students (%)

Indicator	Variables	Native students	Foreign students
Conventional and electronic cigarette smoking	often	6,19	2,78
	seldom	9,28	13,89
	none	84,53	83,33
Hookah smoking	often	-	5,56
	seldom	29,90	26,85
	none	70,10	67,59
Alcohol consumption	often	2,06	2,78
	seldom	38,14	19,44
	none	59,80	77,78
Other psychoactive substances consumption	often	-	-
	seldom	-	5,56
	none	100,00	94,44
Attitude towards suicide	suicide is permissible	1,03	12,96
	suicide can be a way out of an insoluble situation	7,22	2,78
	suicide is unacceptable	91,75	84,26
Perceived stress level	none	2,06	14,81
	low	18,56	38,89
	moderate	56,70	19,44
	high	22,68	26,86

Significant differences are determined in the attitude of undergraduate university students to alcohol consumption: native students are more inclined to drink alcohol in comparison with foreign students. 59.79% of native students and 77.78% of foreign students do not drink alcohol. 38.14% of native and 19.44% of foreign students rarely drink alcohol. Alcohol is often consumed by 2.06% and 2.78% of students, respectively.

To determine the content of the relationship between the studied parameters in cultural groups of students, a correlation analysis is carried out separately. Thus, in the group of foreign students, significant interrelationships are revealed between the level of stress and suicidal ideations ($r=0.27$; $p<0.01$), the level of stress and the use of psychoactive substances ($r=0.29$; $p<0.01$), suicidal ideations and cigarette smoking ($r=0.29$; $p<0.01$), hookah smoking ($r=0.23$; $p<0.001$), frequency of alcohol consumption ($r=0.28$; $p<0.01$), frequency of other psychoactive substances consumption ($r=0.43$; $p<0.01$). In the group of native students, the number of reliable relationships is much less. Positive correlations of suicidal ideations with cigarette smoking ($r=0.41$; $p<0.001$) and alcohol consumption ($r=0.42$; $p<0.001$) are revealed.

Conclusion

The presented research has shown that students motivated to healthy behavior prevail among the studied university undergraduates. This applies to both native students and foreign students. However, differences in cultural background are accompanied by differences not only in sociodemographic characteristics, but in psychosocial characteristics related to health as well.

If the values and behavior of native students are more connected with Orthodox traditions, Islamic traditions occupy an important place in the life of foreign students. These influences, in our opinion, are manifested in the fact that foreign students perceive stress to a lesser extent and more often than native students refuse alcohol. This is on the one hand. On the other hand, Islamic traditions do not have an absolute protective effect. Every twentieth foreign student uses psychoactive substances other than tobacco and alcohol. Every fifth of them uses alcohol with varying frequency; every sixth of foreign students lacks an anti-suicidal barrier. Especially alarming is the relationship between suicidal ideations, stress and substance use, incl. tobacco and alcohol.

These psychosocial risk factors for native and foreign students should be taken into account by university authorities. They can also become a guideline for cultural relevant preventive programs and regular activity of university medical and psychological services.

Abstract

This study aims to analyze the effectiveness of using Social Media Marketing Activities (SMMA) on brand equity and customer response in the aviation industry. The survey was conducted on 173 respondents who knew the ad of the travel fair program through social media and had made purchases at the travel fair program. The method used to analyze data is Structural Equation Modeling (SEM). Where the results of the study indicate that SMMA influences brand awareness, brand image, and customer response both directly and indirectly.

Keywords: Social Media Marketing Activities, Brand Awareness, Brand Image, Customer Response.

Introduction

The digital age has changed consumer behavior. Various information and offering that are presented through social media and various applications have changed the shopping behavior of consumers. At present the use of social media marketing has penetrated to the aviation industry. Social media marketing is a media that is considered capable enough to inform and promote a program to the public with an exponential effect. Various data shows that most tourists have conducted various information searches on tourism destinations to accommodation facilities using digital media. The digital lifestyle that occurs in most tourist behavior is a reason why airline companies have websites and social media as media in marketing activities. One of the aviation promotions programs that has recently come under the spotlight of young people is the travel fair program. Where in the travel fair program, the public gets information about airlines that offer special prices for next year's flight schedule to various foreign destinations.

For young people, traveling is not just a pleasure but a lifestyle. If previously it was considered a luxury item, but now it is considered a mass luxury. The life of young people who cannot be separated from social media and the desire to display the latest photos is one of the drivers why the number of tourists traveling the world is dominated by young people (Starcevic, Konjikusic, & Metropolitan, 2018). Local airlines such as Garuda Indonesia and AirAsia Indonesia also hold regular travel fairs where prospective tourists get more information through social media such as Twitter, Facebook and Instagram. Even some foreign airlines, such as Singapore Airlines, Japan Airlines, Cathay Pacific, Silk

Cite this Article as: Terrylina Arvinta MONOARFA, Rahmi RAHMI And Nofi Dewi MUSTOFAH "The Effectiveness of 'Travel Fair' Social Media Marketing Activities towards Customer Response in the Airlines Industry" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Air, All Nippon Airways (ANA), Asiana, Korean Air, Thai Airways, now routinely hold travel fairs in Indonesia by collaborating with several banking companies in Indonesia and Indonesian travel agents as a partner program.

It is undeniable that the existence of social media has the opportunity to increase Brand Awareness and Brand Image, even further able to increase Customer Response. This is in line with studies conducted by Kim & Ko (2012) in testing the role of social media marketing activities of leading fashion brands (LV) in Korea, as well as research on the existence of social media on several well-known brands (Burberry, Louis Vuitton, Dior, Gucci , and Hermes) who are able to have a positive influence on Brand Equity (Brand Awareness and Image) and Customer Responses (Preferences, Premium Prices, and Loyalty) also have been conducted by Godey et al. (2016). In addition, Seo & Park (2018) in his research on the aviation industry has tested the effectiveness of social media and its effects on Brand Equity (Brand Awareness and Image) and Customer Response (e-Word of Mouth and Commitment) on airline companies in Korea.

In this case, what needs to be addressed is whether the strategy to increase the ease of accessing air transportation modes through the travel fair program can be an effective step for Indonesia to increase its tourism appeal to drive its economy. Meanwhile, foreign airlines are also implementing the same strategy in Indonesia, by offering more diverse foreign flight routes and competitive flight facilities.

Based on the phenomena that occur in the aviation industry in Indonesia, which are then corroborated by several studies that have been done before, the researcher wants to evaluate the effectiveness of social media, especially in the travel fair program in the aviation industry in Indonesia. Whether when a customer makes a purchasing decision at a travel fair, it can be said that Social Media has been effective in encouraging the formation of Brand Equity (Brand Awareness and Image) and providing an optimal influence on the Customer Response, both directly and indirectly.

Literature

Social Media Marketing Activities (SMMA)

Richter and Koch describe social media as an online application program, platform, or media that facilitates interaction, working together, or sharing content (Kim & Ko, 2012). In other words, social media is a space to express opinions openly or comment on anything raised by others, whether in the form of text, images, sound, or video. Communication that occurs on social media is two way. This communication creates community quickly because of the same interests with each other (Kotler & Keller, 2019). Social media marketing is the latest addition in the world of marketing, which is used to establish communication on an integrated marketing plan. Hemsley & Dann (2014) defines it as a commercial marketing event or process that uses social media in an effort to positively influence consumer buying behavior. Lee classifies Social Media Marketing Activities (SMMA) in the form of communication, information providers, carrying capacity of daily life, media promotion and sales, as well as forms of social response and activity response. Nowadays, consumers tend to trust information obtained through social media more than advertising in a marketing or promotional activity (Seo & Park, 2018).

Kim & Ko (2012) have described Social Media Marketing Activities (SMMA) into several dimensions, such as entertainment, interaction, and word of mouth, on the objects of research in the fashion industry in Korea. Godey et al. (2016) in the same industry added dimensions of trendiness and customization. Whereas Sano (2014) in a study of insurance companies in Japan, has added the dimension of perceived risk in explaining SMMA. Seo & Park (2018) in his research on the aviation industry in Korea, explained SMMA through several dimensions, namely: entertainment, interaction, trendiness, customization, and perceived risk.

Manthiou, Chiang, & Tang (2013) mentioned that entertainment is an important dimension to measure SMMA. That a person often uses social media for reasons of seeking pleasure and the virtual

community that is in it that has presented something and gives attraction. Furthermore, in the dimensions of interaction Delerue, Kaplan, & Haenlein (2012) explain that social media is an interaction space so that between brands and customers or between customers can meet, discuss, exchange ideas in virtual communities (Seo & Park, 2018). Muntinga, Moorman, & Smit (2011) explain that the trendiness of social media drives consumer behavior, such as the desire to see new things, curiosity for something new, and the desire to get information before making a purchase decision. Customization, according to Nam & Yeo, is a tool for companies to communicate the uniqueness of their brands (Seo & Park, 2018). Perceived risk is used as a dimension of SMMA where it is explained that social media serves to reduce customer concerns for a brand (Sano, 2014).

Brand Equity and its drivers

Bong na, Marshall, & Keller (1999) explain that brand equity is divided into brand awareness and brand image. Customer-based brand equity is defined as the differential effect of brand knowledge on consumer responses to brand marketing. So that the explanation of brand knowledge is divided into two components, namely brand awareness and brand image. Brand equity is formed in consumers' memories as a unique value that distinguishes one brand from another by combining various brand properties.

Brand Awareness

Brand awareness is the ability of consumers to recognize a brand (brand recognize) and recall a brand (brand recall) in a particular product category (Atilgan, Aksoy, & Akinci, 2005; Bong na et al., 1999; Keller, 2005). In other words, that the level of one's brand awareness of a product can be measured when consumers are able to recognize and recall a brand at different times. Brand awareness has four levels namely unaware brand is the lowest level in the brand pyramid, where consumers are not aware of a brand. Brand recognition is the minimum level of brand awareness which is important when a consumer chooses a brand when making a purchase. Brand recall is a reminder of a brand without passing assistance / stimulation to mention certain brands in the market. Top of mind is the brand that first appears in the minds of consumers and is mentioned when asked about a product category on the market.

Brand Image

Brand image shows something positive about a brand. Brand image can be made when the association linked to the brand is in a profitable, strong, and unique position; which refers to brand networks in the minds of consumers, because brand knowledge is seen from the perspective of associative network memory models (Bong na et al., 1999; Keller, 2005; Pappu, Cooksey, & Quester, 2005). Additionally, creating a profitable, strong, and unique brand image uses for sustainable competitive advantage with attractive economic returns. Brand image is formed from the following factors: 1) Quality, related to the quality of products offered by producers with certain brands; 2) Trusted or relied upon, related to opinions or agreements formed by the public about a product consumed; 3) The usefulness or benefits, associated with the function of a product that can be utilized by consumers; 4) Price, which in this case is related to the high or low of the amount of money spent by consumers to influence a product, can also affect the long-term image; and 5) The image of the brand itself, which is in the form of views, agreements and information relating to a brand of a particular product.

Customer Response

Customer response is measured through customer preferences, willingness to buy premium prices, and customer loyalty. Parguel, Delécolle, & Valette-Florence (2016) explain that preference for a brand is a condition where among the many brands competing in the market, a consumer only chooses one main brand choice based on the knowledge and feelings consumers have towards that brand. Yann, McColl, & J. Kitchen (2010) explain that the measurement of preferences can be done by asking consumers questions to show which brands are consumers' favorite among several categories or brands.

Willingness to pay is a form of buying behavior where there are conditions in which consumers are willing to pay whatever price is offered, when compared to other brands (Godey et al., 2016; Netemeyer et al., 2004). Jacoby illustrates that customer loyalty to a brand is a form of buying behavior (consumer response) in which of several existing brands, a consumer only focuses on one brand. Some literature states that loyalty is a psychological process in which consumers have made purchases and plan to make repeat purchases in the future (Godey et al., 2016).

Design of Hypotheses

Mangold and Faulds explain that social media in their activities is part of the marketing mix in communicating a brand. Similarly, Bruhn et al. stated that social media had a significant impact on brand equity, specifically brand awareness (Godey et al., 2016). Hutter, Hautz, Dennhardt, & Füller (2013) in his research stated that social media user interaction influences brand awareness and purchase intention of MINI Cars. Likewise, (Seo & Park, 2018) in his research concluded that social media marketing activities have a positive effect on the formation of brand awareness. Furthermore, brand awareness has a positive effect on customer response. The hypotheses in this study are:

H1: Social Media Marketing Activities have a positive effect on Brand Awareness.

Social media has a dramatic impact on a brand's reputation. As concluded from his research that customers will respond positively to a brand's reputation when a company has social media (Kim & Ko, 2012). This is in line with Godey et al. (2016) and Seo & Park (2018) explained that social media had a positive effect on brand image formation and subsequently brand image had a positive effect on customer responses. The hypotheses in this study are as follows:

H2: Social Media Marketing Activities have a positive effect on Brand Image.

Seo & Park (2018) in a research on the aviation industry in Korea, concluded that Brand Awareness has a positive effect on customer commitment which is one form of Customer Response. Godey et al. (2016) in his research concluded that the brand equity measured has a positive influence on customer responses in the fashion industry. The hypotheses in this study are as follows:

H3: Brand awareness has a positive effect on customer responses.

Brand image as a variable forming brand equity has a positive influence on Customer Response (Godey et al., 2016). This is in line with research conducted by Seo & Park (2018) that Brand Image has a positive influence on commitment and e-WOM which is the variable forming Customer Response.

H4: Brand Image has a positive effect on Customer Response.

According to Kim & Ko (2012) in his research it has been proven that Social Media Marketing Activities effectively have an indirect effect on Customer Response manifested in the Purchase Intention variable. Next, Sano (2014) in a research on an Insurance company in Japan also concluded that Social Media Marketing Activities had a direct or indirect effect on Customer Response manifested in the Positive Word of Mouth and Commitment variables. Godey et al. (2016) also agreed that Social Media Marketing Activities contribute to an increase in customer response, both directly and through Brand Equity variables. Likewise Seo & Park (2018) has concluded that Social Media Marketing Activities indirectly have a positive effect on Customer Response as measured through Commitment and Electronic Word of Mouth. Thus, the hypothesis in this study are:

H5: Social Media Marketing Activities have a positive effect on Customer Responses.

Methodology

This research is a qualitative method with a descriptive approach. The data collection technique used is purposive sampling technique by setting certain criteria in selecting respondents. The respondent is someone who has seen the promotion of a travel fair program on social media and has purchased flight tickets through a travel fair program. The number of respondents in this study were 173 people. The data analysis method in this study is to use Structural Equation Modeling (SEM) using Amos 18. All

scale was adapted from previous research and measured using five-point Likert scale ranging from 'strongly agree' to 'strongly disagree'. Social media marketing activities used five dimensions (entertainment, interaction, trendiness, customization, perceived risk) adapted from Seo & Park (2018). Brand equity explained brand image and brand awareness adapted from Godey et al. (2016) and Seo & Park (2018). Customer response was measured by three indicators (preference, willingness to pay, loyalty) and adapted from Godey et al. (2016). A pilot test was carried out 30 participants who had experience dealing with 'Travel Fair' social media activities. According to their comments and feedback obtained from the participants, some modification was made on the arrangement of the questionnaire.

Figure 1: Research model

Table 1: Questionnaire Items

Concept	Construct	Items
SMMA (Seo & Park, 2018)	Entertainment	1. The social media of this airline is enjoyable. 2. The content shared about by the social media of this airline is enjoyable.
	Interaction	3. Information sharing is possible in the social media of this airline. 4. The discussion and exchange of opinions is possible in the social media of this airline. 5. The expression of opinions is easy in the social media of this airline.
	Trendiness	6. The information shared in the social media of this airline is up to date. 7. The use of social media by this airline is fashionable.
	Customization	8. The information that I need can be found in the social media of this airline. 9. The social media of this airline provided the information that I needed.
	Perceived risk	10. The social media of this airline alleviated my concern(s) regarding the airline's service. 11. The social media of this airline alleviated my concern(s) about using the airline.

Brand Equity (Seo & Park, 2018)	Brand Awareness	1. I am always aware of this airline's brand when I come to the travel fair event. 2. I am aware of the characteristics of this airline when I come to the travel fair event. 3. I can always remember the logo of this airline when I come to the travel fair event.
	Brand Image	4. This airline is a leader in the industry. 5. I have an impressive memory regarding this airline. 6. This airline is customer-centered.
Customer Response (Godey et al, 2016)	Preference	1. Although another brand has the same features, I would prefer to purchase from this airline. 2. It seems smarter to purchase from this airline. 3. Although there is another brand as good as this airline, I prefer to buy from this one.
	Willingness to pay	4. When brand x increases the price a little bit, then I will keep brand X. 5. I am willing to buy any price offered from brand X 6. I am willing to buy from brand X, although other brands offer better promotions.
	Loyalty	7. I will suggest brand X to other consumers. 8. I would love to recommend X brand to my friends. 9. I regularly visit brand X. 10. I intend to visit X brand again. 11. I am satisfied with brand X with every visit. 12. Brand X would be my first choice. 13. Brand X is my choice in a future.

Table 2: Profile of respondents

Sample Characteristic (N=173)		
Categories	N	%
Airline using social media		
Garuda Indonesia	96	55.5
Singapore Airlines	31	17.9
AirAsia Indonesia	32	18.5
Japan Airlines	11	6.4
Cathay Pacific	3	1.7
Gender		
Male	78	45.1
Female	95	54.9
Age		
30 or younger	64	37.0

31-40	60	34.7
41-50	38	22.0
51 or older	11	6.4
Marital Status		
Married	102	59.0
Single	71	41.0
Occupation		
Employee	86	49.7
Entrepreneur	10	5.8
Public Employee	27	15.6
Students	13	7.5
Housewife	36	20.8
Others	1	0.6

Exploratory Factor Analysis

This analysis is used to classify variables based on similarity. The similarity is shown by the high correlation value. Validity and reliability tests were measured using factor analysis. The first thing to note is to test the KMO (Kaiser-Meyer-Olkin) value.

Table 3: Exploratory Analysis

	Customer Response	SMMA	Brand Awareness	Brand Image
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.	0,947	0,863	0,890	0,827
Bartlett's Test of Sphericity (Sig.)	0,000	0,000	0,000	0,000
Cronbach's Alpha	0,964	0,911	0,918	0,881

It can be said that each variable represents a statement on the questionnaire that can form factors or dimensions. Where the KMO value >0.5 and the level of significance in the Bartlett's Test of Sphericity is <0.05. The results of the factor analysis that formed the variables look valid in this test. In addition, through Cronbach's Alpha it can be concluded that all statements used to measure variables are reliable.

Confirmatory Factor Analysis

This analysis is used to identify the relationship between variables by conducting a correlation test. Second order construct is used to test the model per variable which consists of several dimensions and indicators to get a fit model according to index criteria.

Table 4: Confirmatory Factor Analysis

	Customer Response	SMMA	Brand Awareness	Brand Image	Cut-Off Value	Evaluation Model
P	0,250	0,512	0,222	0,214	≥ 0,05	*Fitted*
CMIN/DF	1,130	0,969	1,397	1,451	≤ 2,00	*Fitted*
TLI	0,996	1,001	0,992	0,991	≥ 0,95	*Fitted*
CFI	0,997	1,000	0,997	0,996	≥ 0,95	*Fitted*
RMSEA	0,028	0,000	0,048	0,051	≤ 0,08	*Fitted*

Based on the following table describes the results of the Second Order Construction test produced by the variables in the research model. As a result of testing the model obtained from research in accordance with the criteria, which proves that the model is in accordance with existing data.

Empirical Results

Table 5: Fitted Model

	Dependent Variable		Independent Variable	*Regression Weights Model*	
				C.R	Result
H1	Brand Awareness	<---	SMMA	5.124	Accepted
H2	Brand Image	<---	SMMA	3.410	Accepted
H3	Customer Response	<---	Brand Awareness	5.595	Accepted
H4	Customer Response	<---	Brand Image	5.951	Accepted

Figure 2: Hypothesis Testing Result

Result and Conclusion

This study investigated the impact of social media marketing activities about airlines travel fair which can drive the improvement of brand awareness and brand image, also customers response. The result of this study can summarize as follows: *First,* SMMA has a positive and significant effect on Brand Awareness, with C.R value of 5.124. *Second*, SMMA has a positive and significant effect on Brand Image, with C.R value of 3.817. *Third*, Brand Awareness has a positive and significant effect on Customer Response, with C.R value of 5.595. *Fourth,* Brand Image has a positive and significant effect on Customer Response, with C.R value of 5.951. *Fifth*, SMMA has a positive and significant effect on Customer Response, with C.R value of 4.939.

Abstract

It is determined an interdependence of the amount of receivables and its management. It is substantiated that timely and appropriate measures taken to settle the optimal amount of receivables lead to the financial recovery of all activities of the enterprise and ensure its financial security. It is investigated that the issues of the optimal amount of receivables at the enterprise are very important and relevant for the activities of any enterprise. An economic and mathematical model of calculation the optimal ratio of receivables is proposed, which will help in the management of receivables at the enterprise and increase the efficiency of its activities.

Keywords*:* Management, Current Assets, Accounts Receivable, Modeling, Optimization.

Introduction

At the current stage of economic development, enterprises are not able to effectively manage their receivables, which make a significant share of the current assets. Most enterprises practically are not able to normally function due to the receivables, as this withdraws funds from the turnover. Under such circumstances, the role of effective accounts receivable management, its timely return and prevention of bad debts increases significantly, and it cannot be done without proper analysis and use of economic and mathematical modeling.

It should be noted that the problems of accounts receivable management, its availability and amount at the enterprise are considered in the researches of many foreign and domestic economists, but the issue still remains topical, and the definition of its optimal ratio at the enterprise is becoming urgent in the current conditions of managing a market economy.

Literature Review

The study of literary sources on the accounts receivable management and the determination of its influence on the enterprise activities, as well as its functioning in modern economic conditions, showed a variety of approaches to study of this issue. Thus, the analysis of domestic scientists who considered the above-mentioned issue in their works showed the following:

Chukhno (2014) defines that receivables can have a significant influence on the volume and structure of the money supply, payment turnover, the rate of funds turnover at the enterprise. At the same time she states that the increase in accounts receivable and its share in the current assets of the company indicates the unconscionable credit policy of the company with regard to buyers or the increase in the volume of sales of goods, or indicates the financial insolvency of some buyers. It is indicated that a long-term non-return of accounts receivable causes a cash deficit that can reduce the financial activity of the enterprise. The author also notes that an important stage in the accounts receivable analysis is the factorial analysis, which is aimed at quantifying the impact of various factors on the level of receivables. It is also noted that enterprise managers must explore the amount of their receivables in different ways. Very often they do not pay due attention to the implementation of a comprehensive financial analysis of the company, which is very important as the accounts receivable management requires a truly well-considered scientific approach.

Khokhlov (2017) also emphasizes the importance of the accounts receivable management. In his works he examines the main stages and models of accounts receivable management at the enterprise, highlighting its main advantages disadvantages. The author notes that the financial resources management of the company is closely connected with the optimal ratio of accounts receivable, as well as its size, the term of its payment and the impact of such receivables on the financial support of the enterprise. Investigation of this issue also focuses on the fact that the excessive receivables lead to an outflow of equity, while its excess to a certain extent can cause both a loss of liquidity and a stop of the production at the enterprise. In addition, accounts receivable management is defined as a process of development and implementation of managerial decisions regarding the coherence of its size and turnover ratio to provide the necessary profit from activities and obtain the optimal amount of available funds at the enterprise.

Sarapina (2014) pays considerable attention to the methods of managing receivables at the enterprise. In particular, she notes the importance of determining the optimum size of receivables, which would not prevent the normal functioning of the enterprise. Also, in her studies it is noted that insignificant amounts of receivables may indicate a low sales of company, but significant volumes will indicate a large amount of cash outflow from the company. Both of these will significantly affect the economic activity of the enterprise.

In particular, Sobekova-Majkova and Ključnikov (2017) identified in their research the risk of insolvency of small and medium enterprises and their problems with the receivables, noting its significant impact on their development and functioning.

Siekelova et al (2017) also consider the accounts receivable management in their research work. The authors note that its timely payment plays a positive role in economic activity, but the presence of a significant amount of debt leads to the risk of delayed payments, as well as additional costs associated with the accounts receivable management. It is being noted that the capital invested in receivables does not bring income to the enterprise. Also, the authors point out that the accounts receivable management is a very powerful tool for the elimination of the non-payments risk, being an integral part of the financial management of any enterprise. They consider the optimal ratio of receivables size and assessing the creditworthiness of buyers to be the basis of the research. Since receivables for goods, works and services are an integral part of an enterprise's assets, its availability and size are extremely important to control.

Kubíčková and Souček (2014) in their studies pointed to the importance of the availability and use of accounts receivable in the management system of companies, paying particular attention to the forms and methods of managing it.

Casalin et al (2017) note the importance of researching relations between suppliers and buyers of material assets, in particular, they analyzed such an interconnection on the example of Chinese industrial relations, using different approaches to analysis of the impact of receivables and payables on the activities of the enterprises.

Kojo et al (2017) analyzed the determination of the place of working capital and its individual components in the enterprise management system, using the regression date analysis.

Sutjiati Njotoprajitno (2017) emphasizes that in the modern realities of settlement relations when the receivables are an integral part of the economic life of the enterprise, accounts receivable management is of particular importance. In the author's opinion, enterprises, which activities lead to an increase in receivables, have a greater potential to increase their income. At the same time, if there is an existing receivable that is uncontrolled by the enterprise, it can lead to financial problems and, eventually, even to bankruptcy. In the course of the research, the emphasis is made on the importance of managing receivables, establishing a link between it and the turnover of assets at an enterprise, and determining the impact on the efficiency of the activity and the equity capital use.

The above mentioned studies are of unquestionable importance but it should be noted that there continues to be a need for further research on the accounts receivable management at the enterprise, determination of its optimum ratio, in particular, using the economic and mathematical methods.

Objectives Statement

Accounts receivable affects the economic activity of the enterprise in such a way that it is almost always a probability that it will remain unrecoverable for a certain period of time, and this, in the first place, leads to a crisis in the financial state of the company, as there is a situation of shortfall in available cash. Therefore, the purpose of the study was to find the directions of the effective available receivables management at the enterprise through the application of economic and mathematical modeling.

Methods

During the study, a number of methods were used, in particular, statistical method, graphical method, methods of regression analysis, method of simultaneous equations solution.

Results and discussion

In the process of assessment, an enterprise is considered as a business entity and, at the same time, is a property complex consisting of elements that can be assessed more or less independently of each other. Among these elements, it is common to distinguish the tangible ones, such as land, real estate, equipment, liquid assets, accounts receivable, and intangible ones, namely an image, business reputation, technical competence, and the quality of enterprise management. The importance of these issues is substantiated by Demchenko (2011). An important indicator characterizing the enterprise activity is the state of settlements with debtors. Accounts receivable of the enterprise arises as a result of non-cash settlements with buyers, contractors, depositors, accountable persons etc. The incurring of debts is due to the coincidence of the moment of finished products shipment, performance of works or delivery of services with the time of their payment. Significant amounts of accounts receivable lead to working capital redistribution. The issue of the optimum amount of receivables at the enterprise is very important and relevant for the activity of any enterprise, especially in the current conditions of economic performance.
Size of available receivables leads to the need for an optimal risk management and profitability management solution. It is important to consider the comparison of the benefits that an enterprise wants

to receive by investing funds in accounts receivable, with the costs that it will incur as a result. The accounts receivable management includes special procedures and models of company behavior in regard to buyers and customers while selling them the assets with a payment delay and control of its final receipt.

To improve the efficiency of the enterprise in the current conditions of management and taking specific management decisions on the availability and size of receivables, it is advisable to analyze the availability and change of accounts receivable at a specific Ukrainian company “Agroservice” LLC of Odessa region and to determine the directions of forming its optimal size for the economic process optimization.

The analysis of the receivable’s status of the “Agroservice” LLC as a whole and in the context of individual articles is shown in the table 1.

Analyzing these indices, it can be noted that the main part of the receivables in the "Agroservice" LLC make other current accounts receivable. As a whole, this type of receivables has increased from UAH 20147 in 2014 to UAH 92400 in 2019. The average annual amount of receivables of all types in this case in 2019 amounted to UAH 132570, which is UAH 103331 more than in the base year of 2014. As it can be seen, the size of settlements receivable decreased, namely, the prepaid expenses receivables – by 20 thousand UAH. The average annual amount of accounts receivable for products, goods, works and services increased significantly by UAH 30860.

An important index of the accounts receivable analysis is its turnover. Its acceleration helps to reduce the duration of its repayment, which allows improving the payments quality and indicates the improvement of payment discipline.

Table 1: Composition and dynamics of accounts receivable of the “Agroservice” LLC, thousand UAH

Index	2014	2015	2016	2017	2018	2019	2019 to 2014, (+;–)
Accounts receivable for products, goods, works, services	8640	7380	107	22992	36557	39500	30860
Settlements receivable							
incl. due for taxes, levies and other statutory charges paid	414	255	1384	582	547	650	236
prepaid expenses	38	1376	651	1087	19	20	-18
Other current accounts receivable	20147	20070	35739	39426	91047	92400	72253
Total	29239	29081	37774	64087	128170	132570	103331

Source: calculated according to the financial statements of the enterprise

To analyze the dynamics of the receivables turnover ratio and the duration of its payment at the "Agroservice" LLC, let us consider the data given in Table 2.

Table 2: Receivables turnover ratio dynamics at the "Agroservice" LLC

Index	2014	2015	2016	2017	2018	2019	2019 to 2014, (+;–)
Net income (revenue) from sales of products (works, services), thousand UAH.	10600	15637	29261	44105	52361	54212	+43612
Average annual amount of receivables, thousand UAH.	30008	29160	66855	50984	96128	101230	+71222
Receivables turnover ratio	0,35	0,54	0,44	0,87	0,54	0,53	0,19
Duration of accounts receivable payment, days	1033	681	834	422	670	695	-338

Source: calculated according to the financial statements of the enterprise

The net income of "Agroservice" LLC for 2014-2019 increased by UAH 43.6 million, while the increase in average annual receivables amounted to UAH 71.2 million, that is, more than three times. This led to a low value of the receivables turnover ratio, an as a result the period of receivables payment in 2014 was 1033 days, and in 2019 - 695 days.

Since the accounts receivable make a certain share of current assets, there is a correlation between the working capital value and the amount of receivables. The simplest and, at the same time, objective enough to detect a correlation relationship between the investigated values is the regression analysis method.

Data analysis showed the importance of receivables in 2014. It can be assumed that this is due to the complex social and political situation in Ukraine, caused by events in the East of the country.

The dependence of average annual receivables (AAR) on the average annual value of working capital ($AVWC$) (Fig. 1) was obtained using the linear regression method. In order to find the linear regression coefficients, we used the least squares method, according to which the model parameters are chosen in such a way that the sum of squares of empirical values deviations from the model ones is minimal according to Kovaliov (1997).

$$AAR = 3203{,}287 + 0{,}798 \cdot AVWC \quad (1)$$

Fig. 1: Dependence of average annual accounts receivable on average annual working capital value

To evaluate the model quality, we calculated the determination coefficient (for linear regression it is equal to the squared multiple correlation, which value ranges from 0 to 1 and the more it approaches to 1, the more appropriately the model describes the empirical data.

The determination coefficient for the model (1) equals to $R^2 = 0{,}999$. The determination coefficient does not differ much from one, indicating that the conditional variance of the model differs little from the real significance variance and with a sufficient probability indicates that the model is not bad enough to describe the data.

The coefficient of argument in dependence (1) is equal to 0.798, that is, with the increased working capital cost by 1 UAH, the amount of accounts receivable increases by UAH 0.798.

Settlements with debtors are of dynamic character, and therefore require constant control of the company management. This activity is inextricably connected with the processing of large streams of economic information, which largely depends on the accounting system efficiency of the enterprise. For proper management and functioning, it is necessary to have reliable and timely information on the status of accounts receivable, legality and verifiability of economic operations. Thus, the study of the optimal ratio of receivables available at the enterprise is one of the key tasks in solving problems that arise during the current management of the enterprise, including from the position of liquidity.

To develop an economic and mathematical model, we assumed that the impact of liquidity on the enterprise profitability is statistically significant. At the same time, the growth of the liquidity ratio leads to an increase in the profitability of assets, but to a certain limit, after which the connection becomes inverse. Consequently, at the functional dependence of the current assets profitability ratio on the liquidity ratio the maximum value should be observed.

Fig. 2 shows the dependence of the current assets profitability ratio (*APR*) on the total liquidity ratio (*TLR*).

Fig. 2: Dependence of the current assets' profitability on the total liquidity

The regression curve has been found using the least square method

$$y = -8{,}65 \cdot 10^{-5} \cdot x^4 + 0{,}01022 \cdot x^3 - 0{,}37559 \cdot x^2 + 4{,}06554 \cdot x + 11{,}42979. \quad (2)$$

The determination coefficient $R^2 = 0{,}986$.

The maximum values of the general liquidity ratio cannot be considered as a result of the absence of experimental points nearby. Thus, the profitability ratio reaches its maximum value at $TLR = 7{,}6$.

Fig. 3 shows the dependence of current assets profitability on the intermediate liquidity ratio.

The regression curve

$$y = -1{,}46 \cdot 10^{-4} \cdot x^4 + 0{,}01474 \cdot x^3 - 0{,}46610 \cdot x^2 + 4{,}32245 \cdot x + 12{,}59064 \quad (3)$$

The determination coefficient $R^2 = 0{,}984$.

The profitability ratio reaches its maximum value at $LPR = 6{,}4$.

Fig. 3: Dependence of the current assets profitability on the intermediate liquidity ratio

Figure 4 shows the dependence of the current assets profitability on the absolute liquidity ratio.

Fig. 4: Dependence of the current assets' profitability on the absolute liquidity ratio

The regression curve

$$y = 1{,}596 \cdot 10^8 \cdot x^3 - 1{,}87 \cdot 10^6 \cdot x^2 + 5564{,}098 \cdot x + 18{,}659. \quad (4)$$

The determination coefficient $R^2 = 0{,}616$.

The determination coefficients' value indicates the high quality of the models and the close relationship between the factors.

The profitability ratio reaches its maximum value at $APR = 0{,}002$.

Using the maximum points of functional dependences (2), (3) and (4), three equations can be written for estimating the optimal ratio between receivables and other components of current assets.

$$TLR = \frac{CA}{CO} = 7{,}6;$$
$$LPR = \frac{MA+AR}{CO} = 6{,}4;$$
$$APR = \frac{MA}{CO} = 0{,}002,$$

where CA means current assets; MA means monetary assets and their equivalents; AR means accounts receivable; CO means current (short-term) obligations.

The following ratios can be easily found from these equations:

$$\frac{AR}{MA} = 3200;$$
$$\frac{AR}{CA} = 0{,}84.$$

In accordance with these ratios, the monetary assets should be in 3200 times less than the accounts receivable, and the latter should make 84% of the current assets volume.

In order to construct the models of accounts receivable management, it would be useful structural models proposed by Omelyanenko et al (2019). They demonstrate the structure of the system, which is the subject of the survey, its internal parameters, and features of external fluctuations. These models are reasonable to create the optimization models.

Conclusions

At the enterprise a certain amount of receivables will always be present, as it is the result of its financial and economic activity. At the same time, important for the company managers should be not the problem of its complete elimination, but optimization of its volume. The tools for managing and controlling the level of accounts receivable and its structure should be developed at the enterprise. In addition, the main factors that have a significant impact on its dynamics and structure should be taken into account. The accounts receivable management essentially depends on the analysis of such factors, and it, in turn, affects the entire financial activity of the enterprise.

The values of the optimal amount of receivables in the enterprise are very important and relevant for the activities of any enterprise, especially in the current conditions of the economy. The received assessments of the optimal ratio between the accounts receivable and monetary and working assets cannot be considered accurate. But one can make a fairly sure conclusion that accounts receivable cannot be less than the sum of all other components of current assets. This is primarily due to the issue of the expediency of large stocks storing at the enterprise, as it is better to sell them and have a certain amount of receivables than hold significant volumes of finished stock products.

The use of the developed economic and mathematical model of the optimal accounts receivable ratio will have a positive impact on the enterprise management as a whole and the improvement its financial status in particular.

Abstract

At present higher educational institutions are integrating into the global educational space. As a result, e-learning implemented at various levels of Crimean educational institutions becomes relevant. Technology as the area of big opportunities for improvement in higher education impacting the development of new ways of assessment can enhance motivation, self-reflection, and washback.
The research aims to determine the capabilities of open educational resources implemented in the educational process for Bachelor's / Master's Degree Programmes based on the data obtained at the Sevastopol State University. Viewing integration of digital and web technologies in the educational process in terms of developing students' and professors' new skills and professional competencies, the paper describes the benefits and challenges of e-learning assessment resources. The analysis of literary sources and conducted empirical study allows presenting and substantiating e-learning features, various examples of electronic resources, their efficiency, and feasibility in developing the modern digital educational environment. It is stated that the effective implementation of the electronic assessment depends on the federal, regional, and local legal framework; personnel qualification, technical equipment, access to technology; quality methodological support; teachers' and students' readiness to electronic assessment application. The practice-based look reveals the potential of online testing in foreign philology education as an instrument of the students – academic staff – authorities interaction along with evaluation, whose strong points include enhancement of communication where fast feedback based on reliable statistics is needed; saving time for live interaction both in real classroom and in synchronic teaching/learning sessions in remote education; individualization of studies.

Keywords: Assessment, Assessment Mode and Tools, Remote Teaching, Higher Education.

Introduction

Over the past 20 years, Higher Education in Russia has changed greatly. Samoylenko N.B. (2018) mentioned that with the transition to e-learning format of the 21st Century class, educators' attention has been drawn to studies of the characteristics of new online and real communication; the

importance of changing interaction and autonomous learning; the issues of conducting effective learning.

In a research study by Harrison, L., Heikoop, W. (2016) new ways of assessing are described. The new context allows pointing out assessment as the area of modern technology that can have a direct impact on the teaching-learning process and its result. Technology can offer affordances that provide new ways of assessing. We can now assess and evaluate students in ways that simply were not available to us even ten years ago.

The introduction of new technology at all levels of education at the Sevastopol State University has been boosted by COVID-19 pandemic. On the one hand, like in all higher educational institutions, the lockdown has emptied campuses, but on the other hand, it impacted on how students access the courses and how academics work across all disciplines.

The learning process at all educational levels will be considered complete after evaluation whose essence lies in establishing feedback ("student – lecturer") and informing the lecturer on how successful the process of mastering new knowledge, and developed skills is. The introduction of new pedagogical technologies in the educational process as well as changes in the format of all types of classes have led to a discrepancy between the national assessment system and the modern requirements of the education system.

We note insufficient consideration of age and individual characteristics of the students; standardization and formalization of the assessment tools; the predominance of episodic assessment; pronounced subjectivism; psychological discomfort of the students while being assessed; limited possibilities of the assessment scale; the absence of an optimally objective mechanism for summing up assessment results.

In the Federal law "On education in the Russian Federation" (2015) the digital educational environment is presented. Functioning of the digital educational environment, in our opinion, became possible due to the implementation of educational programs based on the application of e-learning and distance learning technologies. E-learning, by article 16 of the Law "On education in Russian Federation" (2015), refers to the organization of educational activities with the application of the information contained in databases and used in educational programs; information technologies and technical means ensuring its processing; as well as information and telecommunication networks used for the transmission of this information via communication lines for the interaction of students and teaching staff.

Recommendations of the UNESCO policy in the field of mobile learning (2015) stress that E-learning implies the use of the Global Internet and/or local area network of educational institutions and media.

We believe that the evaluation system at the present stage should not be reduced to mechanical fixation of results. Borissova, D. and Keremedchiev, D. (2020) mentioned that rather, it is a continuous process of collecting, analyzing and systematizing information about the educational, cognitive, scientific and practical activities of students, which allows determining the level of their knowledge and developing recommendations for possible educational process adjustments. In this regard we analyzed the assessment methods that proved to be practically effective for online training.

Purpose and Objectives of The Research

The aims of our study are to describe theoretical and practical aspects of assessment in remote teaching contexts in higher education; discover assessment mode and tools, the benefits and challenges of e-learning assessment; investigate the guidance from experienced test developers and international assessment experts; to explore and present practical ways of assessing skills which we use in our classroom.

We focus on ways of defining what is meant by student experience and how it may be measured. We situate the student experience in our context and examine ways of measuring aspects of the student experience including effectiveness of methods and tools for evaluation.

In the book by Jen Harvey (1998) one of the aims of evaluation is highlighted as clarification if tests have a positive or negative influence where we teach and why. When we plan an evaluation, we must consider the purposes, the interests of those involved and the practical limitations.

Literature Review

In the Draft Recommendation on Open Educational Resources (2020) New System of Higher Education is recommended as open, flexible, user-friendly, and attractive system for students to meet their needs. It should also support the interactive style of learning. Moreover, according to UNESCO Draft Recommendation on Open Educational Resources "in building inclusive Knowledge Societies, Open Educational Resources (OER) can support quality education that is equitable, inclusive, open and participatory as well as enhance academic freedom and professional autonomy of teachers by widening the scope of materials available for teaching and learning".

At the same time, "Open Educational Resources (OER) are learning, teaching and research materials in any format and medium that reside in the public domain or are under the copyright that have been released under an open license, that permit no-cost access, re-use, re-purpose, adaptation and redistribution by others". It is also associated with popular e-learning, distant learning, web-based learning, and online learning practices.

From the proposed tools we choose the digital platform to use – Institution's LMS; the tutors use the publicly available platforms – Google Classroom, Microsoft Teams; try to agree with colleagues on the platform, to share materials/cooperate in creating materials with colleagues. In a research study by Erzsébet Csibi (2020) the recommendations offered to professionals are described. From the recommendations we consider the most important are: plan and set up your course; consider timetable, content, assessment, communication; think over the way to communicate with your students; use the educational platform, to deliver the content: short videos, readings, critical thinking problems, research, consultation hours; search or create your additional resources if necessary; share knowledge.

The requirements of New Federal State Educational Standards of Higher Education 3+, 3++ and laws in Russia underline the importance of e-learning implementation starting from the Bachelor's Degree Programme through all further stages (Federal State Educational Standards of Higher Education (Bachelor's Degree Programme) 3++, 2019). Researchers, scientists, and educators integrate digital technologies and web opportunities in the learning process at Russian universities developing new skills and professional competencies for students and professors.

In our opinion improving the effectiveness of using e-learning assessment resources can be achieved due to the skillful combination of the application of such resources that would suit the demands of the three main participants (students, academic staff, authorities) of the educational process and implementing the electronic testing platforms which are either provided by universities as an integral element of their LMS or are chosen by educators from the range of open resources (mostly cloud technology).

Methodology

The study involved students of Bachelor's, Master's Degree Programs (Sevastopol State University in 2018-2020). Most of them are ESL students. These students were randomly selected from ESL 9 courses designed as content or non-content-based.

The research was organized to identify the examples of open assessment online resources and technologies in the educational process and to analyze their effectiveness in teaching procedures and developing students' learning autonomy.

The study is based on the results of the empirical study devoted to the implementation of remote learning into the educational process.

The problem of professional online assessment process is relevant. We analyzed the opportunities for implementation of online assessment tools for the improvement of online education in the foreign language teaching process.

We researched on the use of online assessment tools in English language class on a group of students in higher educational institution learning. We analyzed the role of students' digital skills and new trends of online education in a higher educational institution.

We would like to describe the opportunities for virtual education and communication. It is obviously necessary to generalize today's students' skills for providing education online course.

The goal of this study was to identify whether the use of online assessment tools in learning process has positive response on students' skills.

Results

The study aimed to identify the advantages and disadvantages of using such assessment methods as testing, portfolio, oral survey, survey with digital applications in electronic educational environment (table 1).

Table 1: Advantages and disadvantages of methods for assessing the level of students' knowledge using electronic educational technologies

№	Method	Type of control	Advantages	Disadvantages
1	Testing	Current, intermediate, final	• Standardization, ability to ensure validity of content and measurement, practicality; • insignificant time spent on conducting, analyzing results, getting instant results for students; • possibility of statistical processing on the computer; • creating equal conditions for students; • objectivity of the obtained results; • relative accuracy of determining the level of students' achievements.	• Preparation of high-quality tests by a lecturer; • assessment of students' general knowledge; • lack of ability to evaluate higher-level thinking skills; • limited time frame; • no "lecturer-student" contact; • no choice of multiple answers; • full dependence on technical conditions; • exposure to man-made accidents and catastrophes.
2	Portfolio	Final	• Continuous accounting of quantitative and qualitative achievements of students in various activities, their personal achievements, metasubject results, self-assessment/mutual assessment of students; • creating equal conditions for	• Possible negative attitude of "age-related" lecturer; • lack of study time; • lack of uniform requirements for the structure, content, and design of the portfolio; • exposure to man-made accidents and catastrophes.

			students; • focus on checking the reproductive level of information, on the cooperation of all participants in the educational process: lecturer-student-parents; • personal contact “lecturer-student”; • self-analysis and self-control of the student; • ability to explain when defending/presenting your portfolio online.	
3	Oral interview	Current, intermediate, and final	• Personal contact “lecturer-student”; • the opportunity to correct, clarify, respond the student in real time; • development of the student's speaking skills.	•Much time spent on the preparatory stage (selection of questions, etc.); • the teacher's authority pressure; • significant amount of time for individual interviews; • exposure to man-made accidents and catastrophes.
4	Survey (digital: smartphone apps, QR codes, Google forms, and other resources)	Current, intermediate, and final	• Ability to reach all students and get an instant response; • reduced time for verification; • creating equal conditions for students; • evaluation in % ratio of the completed tasks to the total with subsequent transfer to the traditional domestic 5-point scale; • completing the state standard requirements.	• Possible absence of apps on students' mobile devices; • exposure to man-made accidents and catastrophes.

The analysis of the advantages and disadvantages of assessment methods used in electronic educational environment has led to pointing out the unsolved questions of 1) simplification of the learning process; 2) cheating and plagiarism prevention; and 3) motivation of "aged" lecturers to use technology.

In a research study by Zharko L. N. (2018) the effective implementation of the mentioned methods is revealed. It is possible under the application of specific organizational and pedagogical conditions (Figure 1).

Figure 1: Organizational and pedagogical conditions for implementation of methods for assessing the level of students' knowledge using electronic educational technologies

Thus, assessment of students' achievements can be viewed as a tool for measuring the efficiency of the educational process, means of transforming roles of its participants, and a condition for quality improvement of online learning. At present, the emphasis is placed on the dynamics of changes in the achievements of students as active participants of the assessment process. Their involvement in self-assessment, stimulation of responsibility and independent planning of actions help to obtain quality results.

The university platform (http:// testmoodle.sevsu.ru) presents in the distance learning environment of the Sevastopol State University online courses, created by lecturers and professors in different areas of university students training: Institute of Humanities and Pedagogy, Institute of Information Technologies and Management in Technical Systems; Institute of Finance, Economics and Management; Institute of Nuclear Energy and Industry; Maritime Institute; Polytechnic Institute; Law Institute.

The lecturers and professors of the Sevastopol State University learned: how to design the course; prepare and organize students for distance learning and interaction with the tutor; place the materials (lectures, files, books from electronic library, assignments, tests, etc.) in LMS Moodle; they studied the organization of testing and assessment; how to analyze the educational process; they studied the legal resources of the use of distance learning technologies and e-learning in the Russian Federation.

In the process of online courses learning for various programs, they learned the technology of creating electronic training courses in the distance learning system, received practical recommendations for working in the Moodle system, they were presented with the format of the course; technology for designing testing and assessment materials for the distance learning system, and the organization of testing and assessment in the distance learning system.

We present the example of one of the courses "Technology of Teaching Foreign Languages at the University" (https://testmoodle. sevsu.ru/course/view.php?id=872) for first-year master students by the "Philology" specialist. It includes a promo video about the course, lecture material, interactive lectures and assignments, professionally oriented assignments, development of lesson fragments, a glossary, 60 tests, microteaching tasks.
The results of learning at these courses can be set off for the disciplines implemented at the university: code and training specialty; the name of the discipline and its place in the curriculum of the educational program; level of education; the form of training; the curriculum position; basic or

optional part, elective discipline or elective; the number of credits and hours for the discipline within the curriculum.

Implementation of remote learning in traditional higher education is provided regarding the demands of the ministry and corresponding decisions made by university authorities. Gotskaya, I.B. et al (2013) mentioned the choice of the technical platform, which entails the benefits and limitations the academic staff will have to cope with, and is made at the level of the institution. It is regularly a Learning Management System (LMS) like Moodle, Edmodo, WebTutor, or Prometheus used for administration and control of the education process. From a functional perspective, the platforms serve to automate the tasks of delivering educational content to the right people at the right time, monitoring the use of learning resources, administration of individual students and groups, organization of interaction with the teacher, making reports. The range of the instruments offered by such platforms must be mastered by the academic staff and students to meet the new demands of the teaching/learning process. Haphazard actions at the technical level may seriously affect the result. Thus, obvious becomes the need for theoretically substantiated decisions.

Teaching/learning process is a vibrant interaction of the three main parties (student (learner), academic staff, and university authorities), whose communication under the current circumstances occurs through the introduction of remote learning in the traditional educational environment. Fast transition from common pedagogical practices (everyday live classroom communication) reveals the need to find a way that would open new opportunities for constructing efficient interaction. Knowing whether the students have learnt, whether teaching has been effective, and how to address students' needs best are the teachers' concerns that are not new but require choosing adequate approaches and technology. In other words, the situation requires the development of the evaluation system.

The term "evaluation" in teaching foreign languages is used along with "assessment" and "testing", but they are technically different. Evaluation surpasses the student's achievements to consider all aspects of teaching and learning and is used to look at how educational decisions are made. Desheng, Ch. et al (2013) described assessment as an ongoing process of gathering data to measure students' progress which has multiple forms: a) formative assessment (administered during the learning process with the aim of using the results to improve instruction); b) summative assessment (performed at the end of a course often for purposes of providing aggregate information on program outcomes to educational authorities); c) traditional test-based assessment (involving written or oral tests); and d) task-based assessment (which are activity-based tasks, and includes teacher-student interaction, student-student interaction, body movement, teamwork, portfolios, and other language requirement and activities). Evaluation is the process that follows this collection of data, including analysis and reflection, as well as decisions based on the data. From Hughes A. point of view (2003) testing is the process of applying tests that in language teaching are generally viewed as instruments of evaluation that measure ability, knowledge, or performance by eliciting observable behavior from the test taker. Thus, a test can be considered as a minimal unit of the assessment process that provides information meaningful for the general evaluation of a student's foreign language performance.

Under the new circumstances, the application of tests in teaching implies wide use of electronic testing platforms. The effectiveness of evaluation founded on the application of such resources depends on their availability and reliability as well as characteristics that would suit the demands of the three main participants (students, academic staff, authorities) of the educational process.

In the book by Bulanova-Toporkova, M.V. (2002) electronic testing platforms are analyzed in technical terms. The electronic testing platforms are either provided by universities as an integral element of their LMS or are chosen by educators from the range of open resources (mostly cloud technology). Application of a testing platform in the educational process presupposes the development of the subject content base whose stages include: 1) choosing the task content; 2) choosing the task presentation; 3) creating instructions and descriptions; 4) practical assessment (collecting empirical data); 5) processing the collected data; 6) interpreting the processed data; 7) test quality assessment.

In the paper by Georgiadi A.A. and Georgiadi A.K. (2019) the test content inputting into the system is viewed as a time and energy-consuming process carried out by the academic staff which can become useless in the current geopolitical situation. Using open cloud resources (chosen by university or individual) is risky because it can be easily restricted by sanctions.

A significant effort made by universities to take control of the education transition into its new format should be accompanied by well-balanced decisions regarding information security. One of the possible solutions can be the development of the university's testing platform. An attempt to create a system targeted at the needs of students and academic staff was the development of the UWebTutor testing system by Apatova, N.V. et all (2017). The web application written in the PHP programming language with elements of JavaScript whose test and user data are stored in a MySQL database powered by the InnoDB engine is a product of student-professor collaboration.

Another reason to create the university's testing platform lies at the organizational level. Educational process based on remote learning/teaching implies specific interaction of its participants where statistics becomes an important element. The statistical data can be used by a student, a group, a teacher, a chair, or authorities as a source for self-evaluation, evaluation, and reflection. An important characteristic of a platform to choose is the ability to request detailed statistics of test completion by students where a teacher can review the grades a student has received, as well as the time they have taken to complete the test. Apatova, N.V. et all (2017) highlighted that along with statistics for individual students, the system should allow access to overall statistics for groups and tests which would provide a quick assessment of the results of all students on a certain topic. The feature is not provided by open platforms as it presupposes the transfer of administrator rights from the owner to the user. This could be the fertile ground for university authorities' initiating development of safe university testing platforms by teams of university engineers.

Basically, modern electronic testing platforms provide templates for multiple choice, multiple answer, true/false, and direct input of information tasks. These essential instruments can serve various educational purposes, but they are often viewed as a rigid set of opportunities (but for direct input) that enables students' remembering the order of questions and answers while doing the test and technical processing the information by guess rather than thinking. The foreseen problem can be avoided by question mixing and provision of a relatively bigger bank of tasks. The solution was tried out within the UWebTutor system, where each test taken by a student is in a way unique: questions are randomly selected from a question bank (the number of questions in the bank is higher than the number of questions presented in the test), and answers to the questions are presented in random order. In a research study by Georgiadi A.A., and Gavrikov I.V. (2016) this feature is mentioned as the one which also allows extending the system's functions from control to self-control and learning through testing.

Teaching practice in the context of remote learning became an area of implementing testing in the preparation of the second-year undergraduate students of the Sevastopol state university. The practice (216 hours (6 credits)) took place in the fourth semester after the course of «Fundamentals of counselor activity». The entrance test was introduced to determine the quality of the students' preparation for counseling activities in a children's health camp.

The test located in Moodle electronic educational environment was offered to 102 students from 6 groups of 44.03.01 Pedagogical education direction. The tasks contained 54 open and closed questions, as well as compliance tests. The results of testing in Moodle showed that 56% of students passed the entrance test with good and excellent results; 44% received satisfactory marks; and 87% of students passed the test on the first try. The test results showed that students are better at coping with theoretical questions than practical ones. The most difficult were open tests on solving pedagogical situations. The questions aimed at checking skills and abilities of interaction with children, team organization, overcoming problems and making independent decisions, preventing and resolving conflicts in a group of children. The difficulty in solving pedagogical situations can be explained both by the lack of practical experience of work with children and practice-oriented preparation for

counseling activities on the part of students. Thus, the testing provided information about the level of the students' preparation for the teaching practice.

The results of the teaching practice were presented in the form of the electronic portfolio. The program of the pedagogical practice describes the students' results assessment system (table 4).
The public presenting of the practice results took place online in Skype relying on the above-mentioned rating system.

Table 4: Assessment of students' practice results

№	Assessment materials	Scores	Checked Result Codes
1.	Portfolio	0-20	PC-6 - Able to design and implement educational programs that contribute to the development of students' cognitive activity, independence, initiative, creativity, the formation of a civic position, the ability to work and life in the modern world, the formation of a healthy and safe lifestyle among students; PC-8 - Able to interact with parents and cooperate with teaching staff.
2.	Report	0-20	
3.	Student' teaching practice review	0-20	
4.	Practice diary	0-20	
5.	Presentation	0-20	
	Total	100	

Thus, the use of testing in theoretical courses has shown its limitations as regular templates (true/false, multiple choice, and multiple answer tasks) need extracting specific information on the discipline content. Depending on the purpose, the tasks are either questions eliciting information about students' general understanding and knowledge of the subject (used before or during the lecture) or glossaries that serve to diagnose the result of teaching/learning (control of the basic knowledge). Deeper evaluation in theoretical disciplines requires other assessment procedures of knowledge and skills.

Testing is a tool of evaluation that can be used in different organizational forms and at different stages of the teaching/learning process at university. Its strong points include a) enhancement of communication where fast feedback based on reliable statistics is needed; b) provision of space for live interaction when transferred outside the classroom (both real classroom and synchronic teaching/learning sessions in remote education); c) creation of conditions for individualization of studies. Possible limitations of test application lie in the sphere of organization (availability of good testing platforms at the university's LMS), technical issues (availability of the Internet connection as well as the necessary hardware and software); and contents of the discipline (purposes and logic of the teaching/learning process presuppose the use of a much broader range of instruments; testing cannot be a substitute for teaching/learning). Despite the weak points, the potential of testing for evaluation in foreign language teaching needs more research. As a fast-developing sphere of technology, it has become part of our everyday life and the number of ways, templates, and fields of its application is sure to grow.

Conclusion

The results of the research reveal important conclusions. To organize successful teaching and learning at university there must be approved free access to applied electronic resources, integrated into the courses.

Moreover, it is recommended to present full course structure, possible reporting forms, set deadlines, assessment details/criteria, forms of control. Methodological support and consultation by professors are key issues in e-learning implementation at universities.
Potentially the efficacy of evaluation based on the use of modern remote learning technology depends on the choice of a testing platform that must be 1) constantly available for all the participants of pedagogical interaction (students, academic staff, and authorities must be able to use them with the

help of available hardware and software at any time and place); 2) reliable in terms of the information storage (the importance of the content bank should not be underestimated as it becomes a valuable instrument of the uninterrupted educational process); 3) technically correspond the demands of the pedagogical interaction in regard to collecting and processing statistical data both for personal and organization use, sustaining the testing procedure.

The research data clarify that methods of managing students learning are focused on taking into account the individual characteristics of participants in online learning, their needs and the implementation of the principles of the organization of practice-oriented learning.

The Assessment of The Image of a Non-Public Higher School – A Case Study

Radosław Ryńca and Robert Łojko

Wroclaw University of Science and Technology, Poland

Radoslaw.rynca@pwr.edu.pl; robertlojko@interia.pl

Abstract

The changes taking place on the market of educational services require changes in the way higher schools are managed. The key to success is to find and undertake solutions that will allow a higher school to maintain a good competitive position. It seems that image activities carried out by tertiary education institutions may be of great importance, as a result of which it will be possible to satisfy the needs and expectations of various higher school stakeholders. This article aims to present the assessment of the image of a non-public higher education institution as well as to offer the proposal of the improvement measures. Based on the surveys carried out, the authors identified the factors which have a decisive influence on the image of a higher school.

Keywords: higher school image, higher school image improvement

Introduction

The dynamic and unpredictable situation brought about by the first half of 2020 caused unprecedented changes in the surrounding reality of tertiary education institutions. In the conditions of intense competition between both public and non-public higher schools (Olędzki, Tworzydło, 2009), the importance of the image of higher education institutions is continually growing. Such an image enables them to stand out from the group of other higher schools, which affects the decision-making process of students (Barich, Kotler, 1991). Those tertiary education schools which have strong, distinctive images are in a better position (Azuory, Daou, El Khury, 2014) which allows them to compete more effectively on the market of educational services. During the times of the population decline, the best reputable organisations with a strong image are the least affected by the fluctuations in demand due to high buyer loyalty (Obłój, 1998). A positive image is associated with the credibility of the organisation and the services it provides to its environment. The image that precisely positions a higher school in the target awareness of its stakeholders is a significant source of competitive advantage (Altkorn, 2004). The studies conducted in this field (Alves, Rapso, 2010) contribute to a better understanding of the image of a higher school and its importance for higher education institutions in keeping and attracting new students.

As results from the studies on this issue (Cercincova, Mugur, Palea 2015), growing competition and integration in the European Higher Education Area make image creation an essential process for most European tertiary education institutions. The changes occurring during the first decade of this century have led to the fact that higher education institutions have allocated more resources to strengthening and consolidating their images (Curtis, Abratt, Minor, 2009). It was shown in the study by Perozo and Alcala (2008) that the image of a higher school is essential both for its source-organisation and for the addressee, *i.e.* the entity that receives its components from the stimuli, which directly affects the effectiveness of the organisation (Druteikiene, 2011). According to several studies conducted in this field, the image has a significant impact on the Reputation of higher schools.

The resulting evidence (Del-Castilo-Feito, Blanco-Gonzales, Gonzales-Vasquez, 2019) about the relationship between the image and Reputation allows developing and implementing the strategies

Cite this Article as: Radosław Ryńca and Robert Łojko "The Assessment of The Image of a Non-Public Higher School – A Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

used for managing these values. This creates the opportunity to benefit from the synergy and increase the efficiency of the practices with the concurrent reduction of the costs of managing these assets, which is a crucial aspect of attracting and retaining stakeholders (Plew, Ho, Conduit, Karpen, 2016).

Numerous studies (Duarte, Alves, Rapso, 2010) on the importance of the image for higher education institutions indicate the need for more and more in-depth analyses as well as empirical research which would enable a better understanding of what elements and strategies may be crucial for the effective management of the higher school image. The current contemporary interest in the image (Helgesen, Nesset, 2007) translates into the possibility of identifying the practical features of the image of higher schools. Some studies (Weissman, Petruzzellis, Romanazzi, 2010) indicated a vital role of higher school image in the development of educational service management strategies, thereby confirming the validity of the additional analysis of the concepts used as positioning tools which influence the choice of a higher school.

Generally speaking, the purpose of this article is to analyse and assess the image of a non-public higher education institution located in Wrocław, which belongs to the largest group of private higher schools in Poland. For this reason, the article provides a description of the importance of the higher school image. Moreover, it presents an analysis and assessment of higher school image, based on the example of a non-public tertiary education school. Finally, the article also offers some proposals for improvement measures.

Higher School Image – Literature Review

The image (*imago*) is a holistic picture of an organisation; it is variable and depends on subjective experiences (Widerski, 2015) created in the consciousness of the environment (Alvesson 1990), which is the entirety of direct and indirect experiences and feelings (Cian, 2011). The image is a cumulative effect of the organisation's impact (Zawadzka, 2010). Most organisations have a distinctive image (Aaker, Keller, 1990) which can be relationally perceived (Kazoleas, Kim, Moffitt, 2001) as positive, neutral or negative. In the course of the studies into consumer behaviour (Knoll, Tankersley, 1991), it was found that consumers have many images of organisations that are continually changing (Knoll, Tankersley, 1991). The image is (Wiśniewska, 2012) a cumulative effect of the influence of the organisational behaviours and its visual identification system. The image is the sum of beliefs, attitudes and impressions a person or group has about a given object. The object may be an enterprise, product, brand, place or person. Impressions can be real or false, real or imaginary. A good or bad image guides and shapes behaviours (Kolter, 1991).

The image is an essential tool of market impact (Kall, 2001); it is an attribute resulting from conscious or unconscious communication activities undertaken by higher schools. Image creation, in which two primary groups of factors are involved (Wójcik, 2013) (the state of the organisation and the intensity and quality of communication) is strategically important for many organisations, especially for those which are service providers (Zabala, Panadero, Gallardo, Amate, Sanchez-Galindo, Tena, Villabla, 2005). A positive image (Kończak, Bylicki, 2018) requires systematic commitment and consistency in its creation; it is a set of unique, distinctive features, reflecting individual character (Dewalska-Opitek, 2010). It is an added value (Ociepka, 2003) which increases the level of buyers' satisfaction. Moreover, it is a source of buyers' loyalty and the guarantee of the good quality of the services provided (Budzyński, 2002).

In the context of tertiary education, the image (Duarte, Alvaes, 2010) is the result of all the individual person's opinions about a higher school. It is the audience that is the actual creator of the image (Avenarius 1993). For a higher education institution (Theus, 1993) that seeks to improve its image or create a new one, it is necessary to take into account the diversity of the organisation stakeholders and the effects of the influencing factors, mainly of an organisational, situational, personal and business nature. The research carried out in this field (Kazoleos, Kim, Moffitt, 2001) shows that the organisational structure, apart from the environmental factors, is the most basic and critical factor for the image of a higher school.

The image of a tertiary education institution represents the perception of students (Sung, Yang, 2008) and the frequently rare concepts which should be introduced in the higher education sector. The statistically significant differences identified (Perez, Torres 2012) in the perceived organisational image of higher schools indicate that each of them has different levels of the organisational image as a result of the perception of students and teaching staff as well as other stakeholders. The image may vary depending on the environment or context (Figiel, 2013). It may vary depending on the geographic market concerned. It may also differ on the same market of the educational services provided since different stakeholders can identify the organisation differently. According to the studies (Rozwadowska, 2002), depending on image type as well as the context and addressees, who subjectively filter the information reaching them, the image of the organisation will be different.

What is clearly visible on the market of higher schools is that there is competition (Olędzki, Tworzydło, 2007) for candidates for studies, teaching staff, research funding, external funding, statutory objectives or sponsors. According to the research (Foroudi, Yu, Gupta, Foroudi, 2019, Krzyżak, 2009), the data obtained from current students and graduates are quite frequently a source of information shaping the image of a given tertiary education institution. Higher schools use their images to attract new students (Ivy, 2008). They rely on the fact that their images directly translate into student loyalty (Helgesen, Nesset, 2007).

The Analysis and Assessment of The Image of a Non-Public Higher Education Institution – A Case Study

Study Method

The study aimed to assess the image of a non-public higher school. The assessment of the image of the entity under analysis involved the analysis of image creation instruments used by the higher school. What was also investigated was the importance of the image of higher schools for the respondents' decision related to the choice of studies in a given higher school.

In the study, the test sample was randomly selected. The survey questionnaire contained twenty questions about the research problem and five metric questions. The survey included closed alternative questions as well as a disjunctive and conjunctive cafeteria. A survey to assess the image, including the instruments used, was conducted in January 2019 in the form of an anonymous questionnaire distributed among one hundred and twenty-seven students of the higher school.

Following the typology of questionnaires developed on the basis on the ways, in which they are submitted (Kaczmarczyk, 2003), the survey under analysis was conducted as an auditorium survey, during which the respondents are gathered in one place. The individuals taking part in the survey were informed about the anonymous nature of the survey and its purpose.

The results of the survey

As already mentioned, one hundred and twenty-seven higher school students took part in the survey. Most of the respondents (82%) are women while 18% of them are men. The majority of the respondents are between twenty-six and thirty years old and constitute 35% of the respondents. Another group in terms of the age of its members includes people between thirty-one and thirty-five years old who constitute 24% of the respondents. The third group, including 16% of the respondents, is composed of people between thirty-six and forty years old. The fourth group is made up of the respondents whose age rages from twenty-one to twenty-five years old; they constitute 12% of the respondents. In the fifth group (8% of the respondents), there are people under twenty years. The sixth age group is made up of people over forty-one years old.

The majority of the individuals who participated in the study are those with higher undergraduate education (bachelor's degree) – 72% of the respondents. 19% of the respondents completed secondary education while 9% are those who completed their studies and obtained their master's

degrees. When asked about their work, the largest number of the study participants (57% of the respondents) work on the basis of an employment contract, 24% are employed under a contract of mandate or contract for a specific task, 13% of the respondents have their own businesses while 6% of the respondents did not work professionally during the survey.

When asked what industry they currently work in, 29% of the respondents indicated that they work in commerce, 23% in the finance sector, 17% in marketing, 17% of the study participants indicated other answers and 6% of them – at the time of the survey – did not work.

Among the respondents, 49% of those surveyed assessed the current image of the higher school as good whereas 34% of them as very good (Chart 1).

Chart 1. Answer to the question: How do you assess the current image of University in Wroclaw?

Source: The authors' own study based on the survey data.

When asked about the way, in which the respondents found out the most about University' offer, 82% of the survey participants pointed to Internet advertising, 48% pointed to radio advertising, 47% found out about the university's offer from friends or family. On the other hand, 43% of the respondents learned about the offer of the studies thanks to the information on banners and city lights while 24% of them learned this information from press advertisements (Chart 2).

Chart 2. Answer to the question: How did you find out about the offer of studies at University in Wrocław?

Source: The authors' own study based on the survey data.

According to 78% of the surveyed respondents, an attractive study offer was the main reason for choosing this university. 76% of those surveyed said that the university is highly prestigious. For 68%, the reason for choosing the university was the competitive amount of the fee for studies. 53% of the respondents were persuaded by third parties when choosing the university. 19% justified their choice by the proximity of the university (Chart 3).

Chart 3. Answer to the question: What was your reason for choosing studies at university in Wrocław?

Source: The authors' own study based on the survey data.

When asked about what form of reaching out to future students with the educational offer of the university is in their opinions the most effective, 40% of the respondents indicated social media advertising, 23% – radio advertising, 12% – another form of Internet advertising, 10% of the respondents indicated billboards and city lights while 3% had no opinion on this issue (Chart 4).

Chart 4. Answer to the question: What form of reaching out to future students with the educational offer of university in Wrocław is – in your opinion – the most effective?

Source: The authors' own study based on the survey data.

As shown in Chart 5, 73% of the respondents positively assessed the educational offer of the university. Only 15% of respondents are dissatisfied.

Chart 5. Answer to the question: How do you assess the offer of the fields of study/specialisations offered by University in Wroclaw?

Source: The authors' own study based on the survey data.

63% of the respondents also positively assessed the promotional activities conducted by the university. 17% of the respondents assessed it on the average level while less than 11% of the respondents assessed negatively the promotional activities performed (Chart 6).

Chart 6. Answer to the question: How do you assess the activities carried out by the university aimed at promoting the image of University in Wrocław?
Source: The authors' own study based on the survey data.

When asked if you are satisfied with the choice of studies at in Wroclaw, 37% of respondents answered that they are satisfied with the choice of university, 31% are satisfied with the choice of the field of study and 24% with the choice of specialization, 4% of the respondents believe that they are not is satisfied with the choice of the faculty, 3% of respondents do not feel satisfied with the choice of specialization, and 2% of respondents are not satisfied with the choice ofuniversity.

Chart 7. Answer to the question: Are you satisfied with your choice of studies.
Source: The authors' own study based on the survey data.

When asked if you would recommend studying at, 88% of respondents answered yes, while 12% of respondents do not recommend studying at the university.

Proposals for Improving the Image of The University Under Analysis

What emerges from the survey data it that – from the perspective of the respondents – the surveyed university has a positive image. This is the result of over 20 years of intensive activities and investments in this area. Therefore, in the opinion of the authors of the article, it is reasonable to maintain the current image as well as to continue the activities in the realm of public relations. It would therefore be advisable to organise, among other things, conferences on the practical aspects of business, such as the Congress of Family Businesses which was held last year and which attracted much interest from its participants. The positive reception of the congress indicates high demand for such projects in the region. The university should also intensify its cooperation with the companies which are the leaders in particular fields and which stand out in terms of innovation and investment in technology development.

What is more, the first academic LTE technology laboratory in Lower Silesia which has been opened this year, is highly popular. It prepares students to work in the 5G super-fast Internet environment. Thanks to the efforts of the university authorities, students studying at Lab powered by Nokia based in the studied university will learn about the technologies that will revolutionise Internet and telecommunication services in the coming years.

The group of proposals for improving the image should also include the activities which, in the opinion of the respondents, may positively influence the perception of University in Wrocław. The educational offer should be continuously improved so that it meets the expectations not only of graduates but also of potential employers. Therefore, it seems appropriate to establish cooperation with employers through regular meetings.

The sponsorship and patronage of cultural events granted by the university should also be taken into consideration. Likewise, conducting image campaigns outside the period of recruitment for studies should also take place. The proposal to improve the image of the studied university should also be accompanied by the possibility to participate in sports competitions organised in Wrocław and Lower Silesia. What is worth considering is the participation of the university team in sports events which are very popular, such as, for example, Wrocław Night Half-Marathon, Wrocław Marathon or Company Race which are organised on a regular basis. These events are of interest to tens of thousands of people. They are broadcast on the radio and television. Among the proposals to improve the image of the university, it is also worth considering offering courses and workshops for secondary school students in their final years to make it easier for them to prepare for the secondary school final examinations as well as to learn about the educational offer of the university. As results from the answers provided by the respondents, the university should improve the functioning of MojaUczelnia mobile application and Moodle platforms. More than half of the respondents had reservations about the functioning of the application – about its readability and liquidity. What is worth emphasising is the high level of students' satisfaction (which was confirmed in the research) with the choice of the educational offer of University in Wrocław.

Concluding Remarks

The growing role of competition on the market of educational services, the population decline and the increasing difficulties in obtaining a service recipient have led to the fact that a number of higher schools started attaching particular importance to their images. The essence of these activities is to communicate systematically with the internal and external environment in order to gain (meet or exceed its expectations) and thus achieve an advantageous market position. Shaping the image of the university in a proper manner requires performing monitoring activities and carrying out regular analyses as to whether the activities undertaken are appropriate for achieving the assumed results. According to W. Budzyński, shaping the image of an organisation should include several actions aimed, among others, at diagnosing the initial situation, thanks to which it will be possible to answer the following questions: what is the current competitive position of the image of the higher school in the different groups of its environment and what are its strengths and weaknesses. Additionally, it is

also vital to have an action plan which would allow determining what image the organisation intends to create and by what means it wants to do so. The actions undertaken should shape and promote a positive image of the higher school. Therefore, contacts with both high school students, who will be the potential customers of a higher education institution in the future, as well as higher school graduates and employers seem to be necessary. Higher education rankings also play an essential role since they constitute a valuable source of information for higher school candidates.

The authors are aware that the tested research sample could be larger. However, due to the COVID pandemic, it was not possible to collect a larger number of completed surveys. The aim of further work will be an attempt to compare the obtained research results with the research conducted in public and other non-public universities of a similar profile.

To sum up, the article aimed to analyse and assess the image based on the example of a non-public higher school. Based on the surveys carried out, the authors identified the factors which have a significant influence on the image of a higher school. An indirectly achieved objective was also to offer some actions which would improve the image of a non-public higher education institution.

Abstract

Primary school education is one of the basic issues in society. The effectiveness of schools and the extent of its impact on society are measured on the basis of teachers' loyalty, love, attachment to school and their desire to continue their work in the school. This gets reflected in the increased level of creativity in displaying scientific material and its delivery to students clearly. The current study is aimed at identifying the degree of organizational loyalty among teachers in Aleamid School for boys and girls and the most important obstacles that lead to weak organizational loyalty.

Keywords: Organizational Loyalty, Emotional Dimension, Constant Loyalty, Standard Loyalty.

Introduction

Organizational loyalty is one of the important topics of concern among business organizations, thanks to its implications and influence in increasing productivity. It is a vital topic characterized by originality and innovation while it is linked with many new concepts which an organization experience. If an organization desires to carry out its work successfully, it must strike a balance between its goals on one hand and the goals of organizational employees on the other hand. This fine balance remains a reason to satisfy the needs of working individuals which contributes in the development of their loyalty towards the organization. Further, this phenomenon reflects positively upon the organization and helps in achieving its goals. It is an inevitable fact that human element is the most important resource for any organization to produce renewable intellectual energy. Human resources ensure that the work is continued without any flaws. So, those organizations that possess highly efficient human resource and high degree of organizational loyalty exhibit positive performance, while at the same time, it also increases the company's efficiency in a sustainable way (Kim et al, 2016).

Organizations, irrespective of whether service-oriented or goods manufacturer, compete among each other to achieve excellence in the services provided or the goods produced. The organizations rely on their employee's competitive capabilities. In any organization, workers represent the backbone of their competitive capabilities because of their role in achieving their goals. Therefore, majority of the management concepts revolve around working individuals. These concepts are conceived to enhance their role in raising the efficiency of the organization, and improving their performance to fulfill the required role to the fullest extent. In order to maintain and develop a role, the organizations seek to ensure that its employees are closely related to their organizations, making keen observations on them, ready to do everything so that they can achieve success, elevate them to higher levels in the organizational hierarchy and remain on top compared to other organizations. One of the most important directives and determinants of job performance for an employee is the value that the manager holds and adheres to, when executing multiple tasks. The values of the leaders are also considered as the core structures in shaping the organization's culture (Cha& Hwang, 2018), (Suker, 2018).

Organizational Loyalty

Organizational loyalty is considered as one of the basic concepts in administrative and behavioral sciences. This concept focuses on understanding the feelings and behavior of an employee towards their organizations in which they work. In other terms, organizational loyalty is a collective term to denote the degree of loyalty, fulfillment, and connection that an individual feels with the organization where he or she works (Ghreeb, 2012), (Bae & Kim, 2019).

Organizational loyalty is the willingness of an employee to take utmost effort for the organization and his/her strong desire to stay in it. The employee tends to accept the organizational goals and values which can be understood from his/her unwillingness to leave the organization for reasons related to increase in salary, job position, professional freedom, or issues related to work. Organizational loyalty is associated with the concept of organizational symmetry. This concept represents a certain degree of belonging and loyalty where the workers experience that the organization creates opportunities for them to accomplish and create self-development practices. The organization has powers within the organization and when there is no contradiction in executing these powers, the degree of organizational loyalty tends to increase dramatically. Therefore, organizational loyalty is the degree to which an individual corresponds to his organization and the strength of his/her association with it. Organizational loyalty can be considered as a sort of psychological bond between individuals and the organization at all levels (Eazima et al, 2007), (Rodivilov & Shin, 2019).

Researchers (Al-Rousan, Al-Amoush, (2013); Sukor et al, (2020)) mention that Organizational loyalty is a state of mind which unites the worker with organization where he or she is employed. It connects the employees' goals and their desires with that of the organization and maintain their employment in the company. It creates a sense of positive feeling in the employee towards his or her organization. Organizational loyal further enhances the commitment of an employee towards his/her company values and devotion to achieve its goals. It acts as a lasting sense of association between the employee and the organization. Organizational loyalty is based on three areas for instance, organizational emotional loyalty is one the areas which gets reflected through the individual's affiliation with the organization and his/her association with its goals and the pursuit of it.

Dimensions of Organizational Loyalty

According to various researchers (Kazim, (2014); Hasan, (2016); Owais, (2019); Mahmoud & Jar, (2019); (whiting et al, 2008)), organizational loyalty is decided based on three dimensions continuous loyalty, coherent loyalty and directed loyalty. Among these, the first one is intended to devote one's life and sacrifice his/her interests for the survival and continuity of the organization. In the goal dimension, i.e., coherent loyalty, the employee intends to practice social relations that bind the individual with others in a manner that results in cohesion and continuity of the group. The third dimension is directed loyalty which refers to the individual's attachment based on the values and principles of the organization. Organizational loyalty studies used the term 'loyalty' instead of 'commitment' since there is a great rapprochement present between these terms. Loyalty expresses the strength of commitment as this concept stems from the emotional commitment and normative commitment as long as there is a rapprochement with values and the principles of the organization. So, loyalty represents the highest degree of commitment towards an organization. Based on this point of view, the three most common dimensions, used by the researchers, and considered in the current study are presented here.

1. Emotional loyalty: This loyalty is an affiliation of employees with the organization and their awareness of distinctive characteristics of their work in terms of degree of independence, importance of the job, required skills, availability of supervision and direction. This loyalty type indicates the level of sense and awareness of the employee about his or her job's distinctive characteristics and their compatibility with the job. This loyalty type allows the employee to participate effectively in administrative activity. Further, this dimension is influenced by the degree of individual awareness about the distinctive characteristics of his/her work, to the degree of independence, importance of the job, diversity of skills, proximity to supervisors and clear

instructions to work. These variables develop an organizational climate which is equivalent to all its employees and has a positive impact on their level of loyalty.

2. Standard (moral) loyalty: This loyalty type denotes employee's commitment and how they feel attached with the organization through the promotion and supporting of the organization well. The loyalty is found among its employees when it allows them to participate in socially-interactive events.
   In addition to the implementation of work procedures, the employees feel connected to the company by knowing their contribution in the development and achievement of company's goals, planning and organization policy.
   It is the employee's sense of commitment towards continuing their work at the organization. In other terms, it denotes an employee's sense of morality to stay back in the organization without looking at utilitarian aspects that can be achieved in case of joining another organization. This type of loyalty reflects a sense of responsibility and commitment towards the institution. This loyalty makes the employee stay with the organization and pay back what the organization provided to him. An employee feels this way only based on the values that stem from their background such as family or social normalization (or after joining the organization) before joining the organization or during organizational normalization.
3. Continuous loyalty refers to the value of investment that can be achieved if an employee continues to stay with the organization or the amount of loss if he/she decides to join another organization. It indicates the degree to which the employees understand the benefits that can be attained if they stay back and continue, rather than the loss which they may undergo when they leave the organization. This component is based on the assumption that organizational loyalty expresses the accumulations of common interests such as promotions, compensation and rewards between the individual and the organization, more than being an emotional or moral process. These three components affect each other and a common bond present among these three components is 'perception' that loyalty is a psychological state which expresses the relationship between an employee and his/her organization. The authors find that the nature of psychological state is different among the previous types. So, the employee who has emotional loyalty has a desire to achieve something alike those who have strong and continuous loyalty.

Methodology

Research assumptions and purpose

Schools are one of the most important educational institutions. The efficiency and effectiveness of schools depend mainly on how the schools are administered and how does the principal perform his/her duties with teachers in the school? The success of a school administration is decided based on the extent of their efficiency in achieving the required goals, proper planning to execute their efforts, increase cooperation and harmony, connect all the stakeholders of the institutions, nurture loyalty among the employees of the organization, increase their commitment towards the values of the school, efforts taken to make the organization successful and spread a spirit of enthusiasm among the teachers.

By clarifying the purpose of this study, it can be observed that organizational loyalty is an important measure to assess the extent of harmony among the individuals with one another and with their organization. It represents the extent of sincerity and integration that the individual exerts towards their organization. Organizational loyalty includes basic components such as feeling safe, participation in business plan implementation, belonging to the organization, complacency, desire of an individual to take responsibility, feel valued and respected. Therefore, the importance of the current research is evident from the following points.

1. Disclosure of organizational loyalty to teachers
2. Identify the most influential dimensions in increasing organizational loyalty

Research sample and tools

Al-Ameed Primary School for Girls and Boys is one of the distinguished private schools in Karbala/Iraq and is affiliated with Imam Abbas Holy Shrine, Karbala/Iraq. The shrine supervises the school directly. This school surpassed rest of the schools in terms of performance in the recent years while it is deemed to be one of the best schools in existence. A high success rate was achieved during the previous years. The school introduced e-learning in teaching processes, added advanced curricula in teaching, and competed with both private and government schools in the region. Therefore, the current study is aimed at understanding the experiences of this school and introduce new proposals to further develop their work while at the same time, circulate these experiences to rest of the schools for them to incorporate. A questionnaire was used to collect data and Likert scale was used to generate results for the practical side. Table 1 shows the sample size of the study i.e., 119.

Table 1: research sample

Aleamid school for boys and girls									
Number of years of service			**Academic achievement**		**Sex**		**age categories**		
- 21 more	-11 20	-1 10	master	Bachelor	female	Male	more - 46	45 - 35	Less than 35
1	17	101	3	116	77	42	8	19	92

The table is prepared by researchers.

In order to achieve the best results, an already-established scale used in different studies earlier ((Al-Rousan& Al-Amoush, 2013); (Kazim, 2014); (Jahjouh, 2014)) was used in the current study too with few minor modifications to suit the current study objectives. The scale has three dimensions such as emotional dimension, constant loyalty and standard loyalty. The scale is included as a practical aspect.

Research hypothesis

The main hypothesis in this study is that there is a significance difference in organizational loyalty between males and females. There are three sub-hypotheses present for this main hypothesis.

H1: There is a significance difference in emotional dimension between males and females
H2: There is a significance difference in constant loyalty between males and females
H3: There is a significance difference in standard loyalty between males and females

Statistical Analysis

The current study used few statistical techniques listed herewith.

1. Descriptive statistics for demographic variables (frequencies & percentages)
2. Descriptive statistics for main variables (means & standard deviations)
3. Pearson correlation
4. Mann Whitney U test

Table 2: Frequencies and Percentages for Years of Experience

Experience	Freq. (%)
1-10	101 (84.87%)
11-20	17 (14.29%)
21 or more	1 (0.84%)

Fig 1. Pie chart for Years of Experience

Table (2) shows the frequencies and percentages for 'years of experience'. It can be understood from the table that the respondents with 1-10 years of experience possessed the highest frequency and percentage (101, 84.87%) in the study. The next level of experience was 11-20 years with a frequency and percentage (17 and 14.29%). Finally, there was one respondent with 21 or more years of experience with 0.84%. Figure 1 shows the results as a pie chart.

Table 3: Frequencies and percentages for academic achievement

Academic achievement	Freq. (%)
Master	3 (2.52%)
Bachelor	116 (97.48%)

Fig 2. Pie chart for Academic achievement

Table (3) shows the frequencies and percentages for academic achievement. The table infers that the 3 respondents hold master's degree as their academic achievement with 2.5% percentage frequency. The respondents who hold bachelor's degree were 116 in number with the greatest frequency of 97.48% in the study. Figure 2 shows the results as a pie chart.

Table 4: Frequencies and Percentages for Sex

Sex	Freq. (%)
Male	42 (35.29%)
Female	77 (64.71%)

Fig 3. Pie chart for Sex

Table 4 shows the frequencies and percentages for gender. Most of the respondents were females i.e., 77 in total with a frequency of 64.71% whereas the male respondents accounted for (35.29%) i.e., 42 respondents. Figure 3 shows the results as a pie chart.

Table 5: Frequencies and Percentages for Age Category

Age Category	Freq. (%)
Age Category	**Freq. (%)**
Less than 35	92 (77.31%)
35-45	19 (15.97%)

Fig 4. Pie chart for Age Category

Table (5) shows the frequencies and percentages for age category. The respondents aged above 35 were high in number with great frequency i.e., (92, 77.31%). The respondents in the age range of 35-45 were 19 in number with a frequency of 15.97%. The final category respondents belonged to age range 46 or more years with 8 respondents and a frequency percentage of (6.72%). Figure 4 shows the results as a pie chart.

Table (6) shows the descriptive statistics for items of the study. The range of the mean was between (4.39- 3.08). This denotes that agreement about the questions of the study was higher. The values of Standard Deviation (SD) were in the range of (.875-1.527). This denotes that there existed some deviations in the respondents' answers.

Table 6: Descriptive Statistics for items of the study

No.	Item	Mean	SD
q1	Employees feel the desire to spend the remainder of their career in the organization	3.46	1.103
q2	Staff speak with pride about the organization	3.55	1.226
q3	The organization has a high position in the hearts of workers	3.56	1.293
q4	Staff treat the organization's problems as their personal problems	3.73	1.430
q5	I feel that I would be happy to work for the rest of my life with this organization	3.62	1.426
q6	Enjoy the discussion about the organization with people outside	3.32	1.127
q7	I feel that the organization's problems are among my own problems	3.94	1.019
q8	The organization's concerns are among my interests	3.95	1.268
q9	I feel a strong sense of belonging to this organization	3.80	1.176
q10	I feel that the advantages offered in this organization are greater than those offered in other organizations	3.49	1.213
q11	I feel that many things will be affected by my life if I decide to leave the organization	4.39	.875
q12	I am afraid of leaving the organization because it is difficult to find another job	3.32	1.142

No.	Item	Mean	SD
q13	I feel that my stay in the organization stems from my need to work in it	3.33	1.113
q14	I feel that leaving the organization at the moment will cost me a lot	3.08	1.527
q15	I feel the necessity of commitment and loyalty to the organization	3.53	1.103
q16	I feel that moving to another organization is unethical	4.08	1.161
q17	I feel a moral obligation that motivates me to continue working in this organization	4.19	.941
q18	I feel guilty if I left the organization	4.20	.917
q19	I feel that the organization deserves sincerity and loyalty to her	4.26	1.029
q20	I feel a sense of commitment and responsibility towards some of the employees, which motivates me to stay with the organization	3.81	1.361

The table is prepared by researchers.

Table 7: Ranking Criteria for the Selection of Items

Variable	Item	RII	Ranking by category	Overall ranking	Importance level
Emotional dimension	q1	0.692	8	16	H-M
	q2	0.710	7	13	H-M
	q3	0.712	6	12	H-M
	q4	0.746	4	10	H-M
	q5	0.724	5	11	H-M
	q6	0.664	9	18	H-M
	q7	0.788	2	7	H-M
	q8	0.790	1	6	H-M
	q9	0.760	3	9	H-M
Constant loyalty	q10	0.698	2	15	H-M
	q11	0.878	1	1	H
	q12	0.664	4	18	H-M
	q13	0.666	3	17	H-M
	q14	0.616	5	20	H-M
Standard loyalty	q15	0.706	6	14	H-M
	q16	0.816	4	5	H
	q17	0.838	3	4	H
	q18	0.840	2	3	H
	q19	0.852	1	2	H
	q20	0.762	5	8	H-M

The table is prepared by researchers

According to Chen et al. (2010), the importance levels in table (7) from Relative Importance Index (RII) are derived as follows:

Table 8: Importance Levels

Importance Levels	Range
High (H)	0.8 < RII < 1.0
High-Medium (H-M)	0.6 < RII < 0.8
Medium (M)	0.4 < RII < 0.6
Medium-Low (M-L)	0.2 < RII < 0.4
Low (L)	0.0 < RII < 0.2

The table is prepared by researchers.

The results of Relative Importance Index are reported in table (7) along with corresponding ranking and their importance level. It is evident from the ranking table that five items were identified as 'High' importance levels and were considered of prime importance for the selection of its constructs. These 'High' importance indicators attained RII in the range of 0.806-0.878. However, the remaining 15 items were identified as 'High-Medium (H-M)' importance levels with secondary importance in the selection of its constructs. These 'H-M' importance indicators had RII in the range of 0.616-0.790.

Table 9: Descriptive statistics, test of normality, and correlation matrix

Variable	Mean	SD	K-S Test	1	2	3	4
Emotional dimension	3.6601	.59683	.066	1			
Constant loyalty	3.5227	.65722	.092*	.499***	1		
Standard loyalty	4.0126	.54035	.093*	.456***	.496***	1	
Organizational Loyalty	3.7318	.48512	.089*	.805***	.840***	.782***	1
*P < 0.05, **P < 0.01, ***P < 0.001.							

The table is prepared by researchers.

Table 9 is divided into three parts; the first part is concerned with descriptive statistics. Among the three dimensions of organizational loyalty, standard loyalty achieved the highest mean and least SD, i.e. $(M = 4.01, SD = .54)$, whereas emotional dimension secured second position with $(M = 3.66, SD = .597)$. The third was constant loyalty with least mean and highest SD of $(M = 3.52, SD = .657)$. One sample Kolmogorov-Smirnov (K-s) test was conduct to test the normality in the second part of table 9. The results indicate that the two dimensions of organizational loyalty were not normally distributed alike the main variable i.e. organizational loyalty, since the p-value was less than 0.05. So, it can be firmly concluded that the data was not normally distributed.

Table 9 also shows the matrix of Pearson correlation coefficients among the variables in the study. The correlation coefficients suggest that there is a significant positive correlation among all the variables. Pearson product-moment correlation coefficient was calculated to confirm a significant, positive and moderate correlation between emotional dimension with constant loyalty, where $(r = 0.499, P < 0.001)$, and standard loyalty, where $(r = 0.456, P < 0.001)$. The correlation between constant loyalty and standard loyalty was computed as $(r = 0.496, P < 0.001)$. Finally, there was a strong positive and a significant correlation exists between the organizational loyalty with its dimensions where $(r = 0.805, P < 0.001)$ for emotional dimension, $(r = 0.840, P < 0.001)$ for constant loyalty, and $(r = 0.782, P < 0.001)$ for standard loyalty.

Testing of hypothesis

In order to test the main hypothesis, the sub-hypotheses were tested as shown below

Fig. 5: The distribution of emotional dimension for males and females

Table 10: Independent-Sample Mann Whitney U test between males and females for emotional dimension

Total N	119
Mann-Whitney U	2,064.000
Wilcoxon W	5.067.000
Test Statistic	2,064.000
Standard Error	179.420
Standardized Test Statistic	2.491
Asymptotic Sig. (2-sided test)	.013

The table is prepared by researchers.

Figure 5 shows the distribution of emotional dimension for males and females. It can be understood that the distributions of males was somehow normal and consistent while the distribution of females left skewed. Table 10 shows the results of Mann Whitney U test between males and females for emotional dimension. The results suggest that there is a significance difference between males and females since $(U = 2064, p = .013)$. *So, the first sub-hypothesis is confirmed.*

Fig. 6: The distribution of constant loyalty for males and females

Table 11: Independent-Sample Mann Whitney U test between males and females for constant loyalty

Total N	119
Mann-Whitney U	2,335.500
Wilcoxon W	5,338.500
Test Statistic	2,335.500
Standard Error	179.028
Standardized Test Statistic	4.013
Asymptotic Sig. (2-sided test)	.000

The table is prepared by researchers.

Figure (6) shows the distribution of constant loyalty for males and females. It can be inferred that the distributions of males was somehow normal and consistent, while the distribution of females left skewed. Table (11) shows the results of Mann Whitney U test between males and females for constant loyalty. The results suggest that there is a significance difference between males and females, since $(U = 2335.5, p < 0.001)$. *So, the second sub-hypothesis is confirmed.*

Fig. 7: The distribution of standard loyalty for males and females

Table 12: Independent-Sample Mann Whitney U test between males and females for standard loyalty

Total N	119
Mann-Whitney U	2,204.500
Wilcoxon W	5,207.500
Test Statistic	2,204.500
Standard Error	178.970
Standardized Test Statistic	3.283
Asymptotic Sig. (2-sided test)	.001

The table is prepared by researchers.

Figure (7) shows the distribution of standard loyalty for males and females. It can be observed that the distributions of males was somehow normal and consistent, while the distribution of females remained skewed. Table (12) shows the results of Mann Whitney U test between males and females for standard loyalty. The results suggest that there is a significance difference between males and females, since $(U = 2204, p = 0.001)$. *So, the third sub-hypothesis is confirmed.*

Fig. 8: The distribution of organizational loyalty for males and females

Table 13: Independent-Sample Mann Whitney U test between males and females for organizational loyalty

Total N	119
Mann-Whitney U	2,312.500
Wilcoxon W	5,315.500
Test Statistic	2,312.500
Standard Error	179.827
Standardized Test Statistic	3.868
Asymptotic Sig. (2-sided test)	.000

The table is prepared by researchers.

Figure 8 shows the distribution of organizational loyalty for males and females. It can be understood that the distributions of males was somehow normal and consistent, while the distribution of females got skewed. Table (13) shows the results of Mann Whitney U test between males and females for organizational loyalty. The results suggest that there is a significance difference between males and females, since $(U = 2312.5, p < 0.001)$.

Table 14: Hypothesis Test Summary

	Null Hypothesis	Test	Sig.	Decision
1	The distribution of emotional dimension is the same across categories of Gender.	Independent-Samples Mann-Whitney U Test	.013	Reject the null hypothesis and **accept** the alternative hypothesis
2	The distribution of Constant loyalty is the same across categories of Gender.	Independent-Samples Mann-Whitney U Test	.000	Reject the null hypothesis and **accept** the alternative hypothesis
3	The distribution of Standard loyalty is the same across categories of Gender.	Independent-Samples Mann-Whitney U Test	.001	Reject the null hypothesis and **accept** the alternative hypothesis
4	The distribution of Organizational Loyalty is the same across categories of Gender.	Independent-Samples Mann-Whitney U Test	.000	Reject the null hypothesis and **accept** the alternative hypothesis
Asymptotic significances are displayed. The significance level is .05.				

The table is prepared by researchers.

Table 14 summarizes the testing of both main and sub-hypotheses for the study. The null hypotheses were rejected while the alternative hypothesis i.e., difference between males and females regarding organizational loyalty and its dimensions got accepted.

Conclusions and Discussion

The respondents participated in the study expressed their desire to work with the school and expressed organizational loyalty. It was found that there are significant correlations among the dimensions of organizational loyalty. Based on the statistical analysis, it is found that all the dimensions of organizational loyalty got fulfilled which, in other terms, all the research hypotheses got fulfilled. The teachers, both women and men, are ready to work with a high moral spirit since they possessed organizational loyalty within themselves towards the school. Since the teachers feel comfortable with the work environment, they desire to work in the school itself. The statistical ratios attained infer that the school administration showed much interest in providing a comfortable work environment for employees in terms of tools, devices, programs and means of communication. The school administration further provides means of transportation, put great efforts in clarifying the school's policies, objectives and procedures for teachers, making them accept decisions and all practices and generate high organizational loyalty among them.

In order to increase the proportion of organizational loyalty to higher levels, the leaders must work hard to raise the morale of teachers by increasing material rewards. Further, they should also design a fair incentive program for teachers and increase their participation in decision-making, since it is important in enhancing organizational loyalty. Further the leaders should also emphasize the activation of human relations among teachers in the work environment. The leaders must work out new mechanisms for promotion based on competency of the teachers. The teachers must be educated to increase their positive participation in achieving the goals of the school. The teachers further should be encouraged and urged to learn positive thinking in order to increase their loyalty to the school. The leaders should work to develop challenges that are appropriate to the aspirations of teachers. The teachers should get motivated out of this challenges so that their thinking, creativity and loyalty towards the school are increased.

Abstract

Currently in Ukraine, the problems of external financial vulnerability, assessment of external stability of the economy, analysis of monetary and financial and debt risks do not attract due attention of specialists and civil servants. Based on this, Ukraine is gradually but surely immersed in a new economic and financial crisis, one of the causes of which is the COVID-19 pandemic. *The aim of the article* is to identify the level of financial invulnerability of Ukraine in modern conditions and under the presser of world pandemic. *Methods / approaches*: research methodology based on methods of statistic, correlation and comparative analysis; logical and heuristic; extrapolation; Feedback. *Results*. Is was identified what the most suitable instrument for analyzing the situation in financial system of Ukraine in the international context is the Macroeconomic Imbalance Procedure. The mane indicators of this procedure show what with a high level of external debt burden, the national economy is characterized by low and unstable growth rates, as well as significant vulnerability to external factors Particularly dangerous is the so-called avalanche effect, when high credit risks of investors push up market interest rates, which, in turn, cause an increase in the debt burden, thus triggering a spiral of crisis events. It is determined that a significant trade deficit, low level of international reserves, the negative balance of the international investment position, excessive foreign debt of Ukraine and the unbearable burden of debt payments signal the possibility of a debt crisis and balance of payments crisis in Ukraine in the near future. *Conclusions.* Thus, the analysis shows that the process of macro-financial stabilization in Ukraine is quite unstable and can be destroyed at any time under the influence of large-scale external shocks or internal shocks. In particular, it is dangerous to reduce the absolute and relative indicators of international reserves; the size of the external debt burden remains at a critically high level, and the amount of short-term debt continues to increase. What is why when it is necessary to choose a methodology for assessing the vulnerability of the financial system and identifying indicators that may indicate its stability, it is impotent to use not individual, but a system of indicators. containing directly as elements of the financial and macroeconomic sector.

Keywords: Financial Invulnerability, International Factors, Accounting Methodology, Macroeconomic Imbalance, Indicators, Financial Regulators.

Introduction

Ukraine's financial system has suffered losses due to previous crises, continues to lose due to the global pandemic at COVID-19, and further trends in the global and national economy do not allow us to hope for optimistic expectations. Therefore, there is a high probability of another global financial crisis and the need to assess the readiness of Ukraine's financial system. It is the identification of key vulnerabilities of the financial system of Ukraine that allows us to determine the right tactics to protect against instability and adjust to the situation in international financial markets.

Ukraine is twice as vulnerable to external financial instability as its neighbors (Europe and Central Asia), and four times more vulnerable than low- and middle-income countries (in terms of GDP per capita) (Zimovets, 2019). Over the last ten years, business financing models have been gradually tested and introduced in Ukraine, which mainly minimize losses and quickly take capital out of the country's financial system. And hence the risks of capital outflows in 2019. were significantly higher than in the two previous crises. Today, offshore big business plays a key role in the international capital cycle in Ukraine. Therefore, the stability of the country's financial system increasingly depends on the efforts of big business to change the location of its capital. Over the last ten years, the share of large and medium-sized enterprises controlled from offshore has increased from 26% to 36% (Zimovets, 2019). Therefore, a natural consequence of the use of withdrawal schemes was an artificial shortage of equity in the country.

Traditionally in Ukraine, the problems of external financial vulnerability, assessment of the external stability of the economy, analysis of monetary and financial and debt risks do not attract due attention of specialists and civil servants.

However, a review of economic activity published by the Ministry of Economic Development, Trade and Agriculture (Macroeconomic analysis, 2020) indicates a reduction in Ukraine's GDP in January-May 2020 by 5.9%. Based on this, Ukraine is gradually but surely immersed in a new economic and financial crisis, one of the causes of which is the COVID-19 pandemic. The new agreement with the International Monetary Fund should help Ukraine get out of the crisis with the least losses, but whether the proposed program will be realistic for the current conditions of Ukrainian business is not yet clear.

Ukraine has agreed with the IMF on a new $ 5 billion loan program. Of this, the country has already received $ 2.1 billion, and will be able to receive the remaining funds in four tranches over the next year and a half (IMF memorandum, 2020). These funds are needed for Ukraine to finance budget and balance of payments deficits, due in particular to COVID-19.

The IMF has identified four priorities for Ukraine: 1) to support households and businesses during the crisis; 2) preserve the independence of the National Bank of Ukraine; 3) recover state losses from the owners of bankrupt banks; 4) continue anti-corruption measures. Two of the four priorities concern the financial sector, which the International Monetary Fund considers most vulnerable.

The National Bank of Ukraine promises to keep inflation within the 5% target range, maintain a flexible exchange rate and buy currency to replenish reserves. Among the priorities of the state: strengthening the capital requirements of banks after the crisis; reduction of non-performing loans and return of assets of bankrupt banks; reforming state-owned banks; improving the finances of the Individual Deposit Guarantee Fund; development of the non-banking financial sector.

At the same time, in its communication, the International Monetary Fund paid unusually much attention to the risks of the program on the part of Ukraine, says the head of the macroeconomic research department of the ICU group (Nikolaychuk, 2020).

In particular, it is about the uncertainty of the government's economic policy, the potential impact of related interests and the adoption of populist decisions instead of prudent structural reforms. An important priority of the new program with the IMF is the return of bank funds lost due to the past crisis. No less important is another task - to reduce the level of problem loans in state banks.

The President of the Ukrainian Society of Financial Analysts Yu. Prozorov considers the implementation of the program of the Cabinet of Ministers of Ukraine, which would focus on the development of Ukrainian industry, export support, the functioning of the Development Bank, economic diplomacy (Kislyak, 2020), to be an alternative to cooperation with the IMF. On the positive side, the first tranche of the loan went to the budget to finance domestic expenditures, not to the NBU's international reserves. In this case, Ukraine's credit ratings will rise.

Results

Preventing excessive volatility of the main indicators of the stability of the financial system of Ukraine, increased sensitivity to fluctuations in global conditions requires coordination of actions of the authorities to counteract existing and potential imbalances. This will require cooperation between the National Bank of Ukraine and the executive within a single system for identifying and overcoming macroeconomic imbalances, which should include testing of draft state budgets, decisions on setting the discount rate, planned actions of the government and the National Bank of Ukraine in the foreign exchange market, public debt in terms of their likely effects. on macroeconomic stability and financial stability. In view of this, we consider it expedient to introduce a system for detecting macroeconomic imbalances and crisis prevention on the European model. An important component in the structure of European economic governance is the Macroeconomic Imbalance Procedure which is created to analyze macroeconomic imbalances. As a monitoring mechanism it is aimed to discover potential risks at early development stages to prevent negative macroeconomic imbalances and correct already formed adverse situations (Eurostat, 2016; Eurostat, 2012; The Macroeconomic Imbalance Procedure, 2016). Macroeconomic Imbalance Procedure as part of financial and economic management has three components:

- notification mechanism that facilitates early detection and monitoring of imbalances based on qualitative economic analysis and financial evaluations;
- a system of indicators, which is a set of indicators and indicative thresholds used in the first stage of detection of external and internal imbalances and which are differentiated for the Eurozone countries and other non-member countries;
- an in-depth review aimed at identifying or identifying at an early stage whether potential imbalances are benign or problematic (Eurostat, 2016).

The dispute over the Macroeconomic Imbalance Procedure shows both the disadvantages and advantages of this mechanism. They concern both the order and the choice of indicators. In particular, the usefulness of the procedure for EU candidate countries has been proven, but on the other hand it is considered that this procedure does not take into account the specifics of catching-up countries. The discussion continues.

The list of indicators selected for the Macroeconomic Imbalance Procedure was formed based on four principles (Shumska, 2018):

1) the choice of indicators focuses on the most relevant aspects of macroeconomic imbalances and losses of competitiveness (with special emphasis on ensuring the proper functioning of the euro);
2) indicators and thresholds in the table are selected so as to provide reliable signals regarding potential imbalances and losses of competitiveness at an early stage of their occurrence;
3) the table plays an important role of communication. To this end, the table includes a limited number of indicators, their selection and conversion should be as simple and easy to reproduce by third parties, and statistics should be available;
4) indicators should be based on high statistical quality data and ensure comparability for different countries (Eurostat, 2016; Eurostat, 2012).

As a result, the list of indicators includes indicators that reflect external imbalances, competitiveness positions and internal imbalances. This combination of indicators and the format of their calculations can reflect both short-term rapid deterioration and the gradual accumulation of imbalances in the long run (Eurostat, 2012).

The European documentation describing the procedure for assessing imbalances often emphasizes that the indicators included in the system should not be taken purely mechanically, but additional information should be taken into account to draw conclusions in a broad financial and economic context. The setting of indicative thresholds is not very strict, it is aimed at avoiding a significant number of false alarms, but also to identify problems as soon as they arise. The thresholds were determined by European experts on a detailed analysis of the results of existing empirical research.

The threshold limits for changes in financial indicators in European practice are as follows (Shumska, 2018):

- net investment position: -35%;
- credit to the private sector: + 14%;
- private sector debt: 133%;
- debt of the general government sector: 60%;
- total liabilities of the financial sector: 16.5% (Eurostat, 2012; The Macroeconomic Imbalance Procedure, 2016).

Threshold values of indicators are not constants, they are periodically revised depending on other factors influencing the functioning of the financial and economic system.

Currently, Ukraine's financial system is not ready for future global (international) challenges, but has become a vulnerability (Zimovets, 2019):

high level of external debt dependence, which has grown from 91.5% to 98.4% of GDP over the past 10 years. According to this indicator, Ukraine is twice as vulnerable as in Europe and Central Asia and has significantly less reserves to cover external debt compared to the same countries (reserves cover only 15.7% of external debt, which is three times less than in the above-mentioned countries);

progressive dysfunction of the banking system of Ukraine, a manifestation of which is the curtailment of business lending against the background of inertial stagnation of the banking resource base. Imbalances between the size of public debt and domestic sources of its financing are 142.2% and almost three times higher than the maximum allowable value;

shifting the focus of currency risks in the sector of non-financial corporations, which accounts for 84% of the country's short-term external debt. The share of total foreign currency debt in total business financing is 19.1%, which means that the majority of Ukrainian business is controlled by non-residents.

In the first half of 2020, a number of negative trends were observed in Ukraine, indicating a deterioration in the country's international liquidity and solvency, and a deepening balance of payments imbalances. Among them: the widening of the trade deficit and weak inflows of foreign capital, the reduction of international reserves and the growth of short-term external debt, the preservation of a high level of debt burden and the actualization of the problem of external debt service.

At the same time, the imposition of global trends on domestic realities will yield disappointing results. Thus, the reduction of portfolio investment in the world with low credit ratings of Ukrainian economic entities will lead to the prolongation of the dependence of the financial condition of the state on attracting external official financing.

The current account balance, the country's net international investment position, the size of external aggregate debt and short-term debt, the volume of external debt payments and the level of official foreign exchange reserves are generally accepted indicators of external vulnerability or resilience to external shocks. Table 1 shows a standard set of indicators of external stability, calculated for the period 2015 - 2019 on the basis of data from the National Bank of Ukraine.

Table 1: Financial indicators of Ukraine's external stability and their limits

Indicators	2015	2016	2017	2018	2019	Limits
Gross external debt,% of exports of goods and services	248	246	216	210	205	200
Gross external debt,% of GDP	130,4	121,8	103,9	100,3	97,1	60
Short-term debt,% of gross external debt	43,3	41,6	40,1	40,6	34,1	20
Short-term external debt,% of exports of goods and services	107,3	102,7	86,9	88,0	78,1	40
External debt payments,% of exports of goods and services	58,3	29,4	28,1	27,1	26,1	25
International reserves,% of short-term external debt	25,9	32,9	40,2	38,5	35,7	100
International reserves, months of imports	3,2	3,6	3,6	3,4	3,2	3,8
Current account balance,% of GDP	1,8	-1,4	-1,9	-0,3	-0,1	-2,3
Net international investment position,% of GDP	-41,7	-37,1	-23,7	-23,3	-22,1	-35

Source: developed by the authors on the basis of official data of the National Bank of Ukraine

The obtained quantitative values of the indicators were compared with the limit values (last column of the table), which were determined according to the Alert Mechanism of the European Commission and the statistical department of the Central Bank of Indonesia (Alert mechanism report).

When these limit values were exceeded, the corresponding indicators were marked as signaling an increased level of danger. According to the results of the analysis, in 2019, out of nine indicators of external stability, only two - the current account balance, the net international investment position - showed a low degree of vulnerability to the impact of shock situations. According to other indicators of the size of external debt, debt payments and the size of the country's international reserves, the level of relevant risks is assessed as very high.

Thus, a significant trade deficit, low international reserves, a negative international investment position, excessive foreign debt of Ukraine and the unbearable burden of debt payments signal the possibility of a debt crisis and a balance of payments crisis in Ukraine in the near future.

In 2018, Ukraine, together with China and Argentina, is ranked among the most vulnerable among the developing countries among the developing countries in terms of external financing needs, adequacy of international reserves, asset valuation and foreign trade stability (Shavalyuk, 2020).

Thus, Ukraine's cooperation with the IMF and maintaining foreign economic and debt stability should become one of the priorities of the state in the short term. But in the medium term, to balance the country's financial and foreign economic imbalances, it will be of paramount importance to rehabilitate the institutional system and pursue an active structural policy that ensures the development of domestic entrepreneurship and the departure from the raw material model of the economy.

In our opinion, a very important aspect that should be taken into account in the process of Ukraine's interaction with the IMF is that the Fund does not have a permanent set of measures to achieve the goals of macro-financial stabilization in a particular country. IMF specialists can quickly adjust the initial parameters of stabilization programs while justifying by the national government measures / criteria different from those proposed by the IMF, but effective enough to bridge the existing gaps in public finances, monetary and external sectors. Therefore, in order to achieve the long-term goals of socio-economic development and restore the full sovereignty of the state, it is undeniable to develop an active position of state institutions in problematic issues of cooperation with the IMF and professional advocacy of national economic interests.

According to the latest data from the World Bank, in 2016 the ratio of external debt to exports in Ukraine (233.7%) was more than twice as high as for low- and middle-income countries (106.7). And the Ukrainian ratio of external debt to gross national income (127.8%) exceeded the average level in low-income countries by almost five times (Figure 1).

Figure 1 shows the main external debt indicators of Ukraine in the dynamics from 2014 to 2019. These data indicate that all of these indicators of the external debt burden of Ukraine significantly exceed the threshold values.

Fig. 1: External debt indicators of Ukraine in 2014-2019

Source: developed by the authors based on World Bank data

With a high level of external debt burden, the national economy is characterized by low and unstable growth rates, as well as significant vulnerability to external factors - fluctuations in interest rates, exchange rates, prices for exported goods, the level of demand in partner countries. In addition, the high amount of external debt requires significant costs for its maintenance. Particularly dangerous is the so-called avalanche effect, when high credit risks of investors push up market interest rates, which, in turn, cause an increase in the debt burden, thus triggering a spiral of crisis events.

Discussion

Ukraine's national financial system is currently showing much greater resilience than on the eve of the 2008 global crisis. This fact, according to experts, there are certain reasons for the development of the domestic economy, namely (Shemaueva, 2020):

1) the international reserves of the NBU have significantly increased in recent years. At the beginning of March 2020, they amounted to 26.6 billion dollars. US and increased over the year (compared to March 1, 2019) by 6.4 billion dollars. US dollars (at the beginning of 2008 the reserves amounted to 32.5 billion US dollars);

2) in 2019, the capitalization of commercial banks significantly improved. Balance sheet capital increased by a third, from UAH 155.7 billion to UAH 200.9 billion. During the recovery, weak banks were withdrawn from the market, the total number of banks decreased to 75, of which only 6 were unprofitable (at the beginning of 2008 there were 214 banks in Ukraine). Confidence in banks is growing: the volume of hryvnia deposits of the population for the year increased by 17%, foreign currency - by 15%. The share of non-performing loans in the loan portfolio of banks in 2019 decreased from 52.9 to 48.4%;

3) in the structure of commodity exports 44.3% were agricultural and food products, the elasticity of demand for which in the crisis period is insignificant (in 2007 42.2% of exports were metallurgical products, 17.2% - machinery and instrumentation, demand for which fell sharply due to the global crisis).

4) Ukraine has a moderate level of debt burden: in 2020 the planned cost of repayment and servicing of public debt is UAH 375 billion, of which the share of external debt is about UAH 160 billion. Gross external debt amounted to 121.7 billion dollars as of December 31, 2019. US dollars and increased by 6.1% over the year (in 2007 - 80.0 billion US dollars, an increase over the year was 46.7%);

5) there was a significant strengthening of the hryvnia against major currencies. Thus, in 2019 against the US dollar the hryvnia rose by 18%. At the same time, the consumer price index decreased to 4.1% from December to December (16.6% in 2007).

Thus, there are grounds to state the existence of a certain "reserve" of strength accumulated by the Ukrainian financial system, which can withstand both short-term fluctuations in global markets and the inhibition of economic activity within the country. But we must keep in mind that this stock is not unlimited.

In order to minimize the vulnerability of the financial system of Ukraine, it is necessary at the level of state regulation to take measures to:

1. Restoration of the functionality of the country's banking system by reducing public debt and directing the released capital to lending to productive sectors of the economy;
2. Creation of special foreign exchange reserves sufficient to compensate for possible capital outflows through the productive sector of the economy, and taking into account the trends of progressive offshoring of business, the level of corporate debt refinancing that have developed during previous financial crises;
3. Increasing the liquidity of the banking system to the level of meeting the hectic demand of the productive and non-financial sectors of the economy in the face of various global challenges.

Therefore, in Ukraine it is time to develop a clear action plan to prevent the likely development of future crises under pessimistic (unfavorable) scenarios (Ukraine 2030, 2017). The main guideline for future development doctrines should be a clear definition of potential sources and specific regulatory mechanisms for the formation of financial reserves and liquid sectors of the economy. This is not possible without a methodology for taking into account existing signs of vulnerability and indicators of stability and steadfastness of the financial system. Of course, the national methodology of each country is based on the ideology of its own and international scientific schools, which should be based on certain principles of thinking and recognized ways of action that are not related to personal or social benefit, but only to the principles (Vugalter, 2007):

the axiom that deprives a priori of the assessments formed by modern scientific schools is not tied to anyone or anything, but only to the axiom that the best theory cannot give more than it already has in reality;

truthfulness, which explains reality based on the results of specific research conducted by man, who builds a logical model of existing (true) reality. So, following Aristotle - no other scientific model, recognized in the world, cannot correspond to the existing nature of things and cannot be plausible (Aristotle, 2001);

productivity - proves that every scientific theory should be aimed at establishing bridges between idea and reality, ie to build a productive model as close as possible to the truth. And hence - for each country there are different methodological approaches;

limitations - emphasizes the presence of the development process, which should gradually lead to negative (negative indicators). So, if this does not happen, then in reality we are dealing with erroneous dogmatic ideas;

plurality, which emphasizes the impossibility of recognizing any alternatives as equivalent, equivalent and relevant to the existing reality. However, without multi-valued explanatory methodologies, it is not possible to solve any problem and achieve productivity (as close as possible to reality);

subjectivism, which is based on the economic behavior of a person (individual) or a typical average subject, his psychology and is not related to the analysis of certain facts;

objectivism - tied to the behavior and psychology of the masses, intergroup relations, takes into account social facts and other interdisciplinary aspects (Calinescu, 2014) that can explain the economic phenomena that occur in modern reality.

Despite the existence of generally accepted methodological provisions and methods of accounting, each country in the formation of the national accounting system focuses on the characteristics of its own economy, a set of principles; valuation of assets and liabilities and methods of their recognition; existing methods of unification of accounting procedures; forms of financial statements, etc. Today, Ukraine is in the process of harmonizing accounting to the requirements of the European Union and other international institutions, resulting in the active introduction and use of International Financial Reporting Standards. In this regard, it should be recognized that the accounting methodology is a general scientific concept that goes beyond its perception only at the national level, and therefore should determine the main starting points through the prism of principles, valuation techniques, financial reporting structure that exist in other countries. Europe and the World Economic Community. It is taking into account the general international approaches that each country should determine its own harmonious set of methodological tools for the national accounting system.

Quite common national accounting systems implemented by various financial regulators are the following (Getmanchuk, Parieva, 2016):

continental (introduced in European countries and based on state regulation of accounting standards);

British-American (used in the United States and the United Kingdom and focuses on a professional approach to the development and approval of accounting principles);

South American (common in South America: Argentina, Brazil, Chile, etc., takes into account and evaluates the conditions of inflation),

Islamic model (characteristic of the East and takes as a basis the rules of the Qur'an).

This division of accounting systems allows us to identify the characteristics that are more appropriate to use in different countries and to identify the nature of their development at the international level. The definition of accounting methods becomes even more relevant in the context of the use of digital technologies (Calinescu, Likhonosova, Zelenko, 2019) of accounting and reporting.

Conclusions

Thus, in recognizing and choosing the methodology of accounting for financial vulnerabilities should be based on the state of the economy, the economic nature of the objects, the nature and content of the subject of study. It should be developed in close connection with the development of national and general international theory and practice, which, together with a harmonized legal and legislative framework, will help level the internal and external factors influencing the financial vulnerability of Ukraine.

When choosing a methodology for assessing the vulnerability of the financial system and identifying indicators that may indicate its stability (or volatility) in the long run, it is necessary to use not individual indicators of the financial system and its institutions, but a system of indicators containing directly as elements of the financial sector economics (in particular, the share of overdue loans, the level of deposits, interest rates on loans and deposits, others) and macroeconomic (such as the dynamics

of prices, exchange rates, balanced movement of goods and capital, fiscal discipline, etc.). It is the choice of such a methodology for assessing the stability of the country's financial system that will reveal its ability to absorb negative unforeseen consequences and correctly identify (sufficiently) those regulators that will help stabilize the financial system at the national level.

Thus, the analysis shows that the process of macro-financial stabilization in Ukraine is quite unstable and can be destroyed at any time under the influence of large-scale external shocks or internal shocks. In particular, it is dangerous to reduce the absolute and relative indicators of international reserves; the size of the external debt burden remains at a critically high level, and short-term debt continues to grow. Restoration of the external stability of the economy, reduction of currency and debt risks require a new quality of macroeconomic regulation and the development of a comprehensive program of revival and restructuring of the financial sector of Ukraine.

All this is really necessary so that after the end of the COVID crisis, the country can return to the trajectory of sustainable economic growth. However, any progressive changes, even minor ones, affect the interests of different groups. Although the risks to Ukraine's implementation of the IMF program remain. The COVID-19 crisis may deepen and the global economic and financial environment may worsen.

Abstract

In today's economic environment, performance measurement is important for industries to grow especially for SMEs in order to sustain in the global market. This study is focused on the Malaysian SMEs' strategic approach to managing KPIs for their business performance. The strategic approach here is looking at business strategy, communication method and monitoring approach that support for the internal business processes with the development of KPIs. This study is based on a quantitative approach where the survey questionnaires were distributed among SMEs in Malaysia. The findings show that most of the SMEs put more attention to measuring the financial and customer perspective performances. In addition, the strategic approach includes the business strategy, communication method and monitoring tool that are implemented to manage the related business performance. Moreover, the finding also shows that SMEs lack of attentiveness on the monitoring and evaluation of a real time-factor KPIs. Communication among staff within the organization was found that had a significant relationship with managing the SMEs' business performance. In this study, communication methods implemented by SMEs are at a moderate level. The management has clarified the KPIs in the company and all employees understood the proposed KPIs.

Keywords*:* Key Performance Indicators, Small and Medium Enterprises, Strategic Planning.

Introduction

Rapid market change and global competition create an environment where organizations have to act responsively and comprehensive. In Malaysia, SMEs are facing the challenge from the domestic company as well as the international competition and new competitors (Saleh & Ndubisi, 2006; Podmoskovnov, 2018). Yet, the industry is fairly small. The impressive track records demonstrated by these competitors pose more pressure for the SMEs to enhance their competitive edge. To cope with today's market, SMEs need to radically improve its operating performance in order to sustain. Here, SMEs need to clearly understand how to deliver outcomes efficiently and effectively (Soosay et. al., 2016). Furthermore, Wu (2009) stated that performance measurement is a tool that can help an organization to identify the weakness in the business process and continuous improvement. In the performance field, numerous performance models have been introduced to enable companies to assess their performance. The most notable model is the Key Performance Indicators (KPIs). KPI attempts to overcome the limitations of financial instruments in measuring performance. Furthermore, a set of structured KPIs helps companies to figure out the key indicators that are critical for the success of the organization (Kaganski, Snatkin, Paavel, & Karjust, 2013). SMEs in some developing countries such as China (Chen, 2011) and Thailand (Phusavat & Manaves, 2008) have implemented key performance indicators and benchmarking mainly to identify the opportunities for improvement in the business process. However, there is still a lack of research about Malaysian SMEs. It seems that key performance indicator remains an untapped field of inquiry in the industry, thus it motivates this study's exploration of the subject.

Problem Statement

Many studies have shown that the strategic planning process is the basis for an organization to set up and manage business performance. The organization's strategic approach is designed to address the needs of an organization to measure and monitor the performance continuously. Eckerson (2009) stated that efficient KPIs must be supported by the organizational strategy, planning and management process. Even though the research by Char, Yasoa, and Zakiah (2010) showed that there is 76 percent of Malaysian SMEs have implemented strategic planning in their organization, however, this study is limit the sample to the northern states of Malaysia (Kedah, Perlis, and Penang). The result cannot show that all the SMEs in Malaysia will be the same of the characteristics. In addition, the ways of the Malaysian SMEs link their planned strategy of managing the business performance is need to be further studied. SMEs have a simple organizational structure and their management is always controlled by the owner-manager (Giannopoulos, Holt, Khansalar, & Cleanthous, 2013). Therefore, the method of managing business performance is probably different. However, Parmenter (2015) suggested the KPI design in SMEs follows a similar process to the large firm includes of identifying the strategic planning process, assigning the KPI team to support the KPIs, and set up the system of managing KPIs. The key difference between SMEs and large firms is the duration of the process. The process in SMEs always quick because there are fewer employees and generally less complex if compared to the large firms. Therefore, the strategy of SMEs communicating and monitoring KPIs need to be further studied (Bhuinyan *et. al.*, 2019)

Literature Review

Key Performance Indicators (KPIs)

Goodpasture (2003) defined the KPIs as tools for delivering measurement systems and the management is needed to understand what is important to the organization, various techniques to assess the business present state and its key activities with the selection of performance indicators. “KPIs are used to evaluate the factors or of a particular activity that is critical and crucial for the current and future success of an organization” (Verzola et al., 2009; Bhuinyan *et. al.*, 2019). As identified from the above definition, KPI has been developed mainly to enable measurement of organizational performance and it can be used to identify opportunities for improvement through comparison both within the organization over time or between different units or companies. In the research by Wu (2009) has set out a list of performance indicators mainly employed by SMEs in Australia and South China.

Business Strategy

The management play a vital rule to clarify and manage business strategy includes of planning, establish goals, translates the vision into strategy, align the strategy of initiatives, and get feedback and continuous improvement. The research by Kaplan and Norton (2001) was stated that only 5 percent of the workforce understands the strategy and 15 percent of executive teams spend more than one hour per month discussing strategy. Meanwhile, Parmenter (2015) pointed out that the KPIs enable the organization to keep aligned with its strategic objectives. KPIs must emanate from vision level and cascade through the organization. We can see that translating the organization's vision into KPIs and key action initiatives requires several intermediary steps such as leadership, customer focus continuous improvement and business results.

Communication Methods

KPIs should be fully understood and integrated into management in order to maintain a successful performance measurement system. Therefore, Parmenter (2015) suggested a KPIs reporting line, the KPI project team must have excellent communication skills, knowledge about the organization, ability to drive change and mix of old experienced people of the organization. The KPIs project team

needs to report directly to the CEO and there should not be any intermediate barrier in between them. However, the interaction of the process will be different depends on the size of the organization (Kaplan & Norton, 2001). According to the research by Singh (2015), SMEs have much less complexity in performance measurement to manage and continuously monitor the system. Therefore, with the low number of employees in SMEs, the method of interaction KPIs in the organization will different from the large organization (Basuony, 2014).

Monitoring System

According to Parmenter (2015), the KPI dashboard can be employed in monitoring the overall business performance. A good KPI dashboard will show the right direction and confidence in the management to know whether their strategy is being implemented in the right way. So that, the organization can directly look at the graphic and device improvement for the process that is underperforming. Parmenter (2015) added that the critical success factors are daily basic operational activities and a past indicator cannot be a "key" for a business. So, a good dashboard requires a timely measure and the KPI team must be experts in graphical displays ensuring. However, Wu (2009) stated that SMEs usually have no time to conduct real-time performance measurements. Moreover, the size of the organization will influence the complexity of performance measurement and monitoring system (Singh, 2015; Hammerl *et. al.,* 2019; Md Sapry, Mohamed Yusof., 2019). But Parmenter (2015) suggested that the monitoring system of SMEs have the same characteristics as other large organizations.

Small and Medium Enterprises (SMEs)

According to the National SME Development Council Official Website, SMEs divided into two sectors: (1) manufacturing, manufacturing-related service and Agro-based industries, and (2) services, primary agriculture and information and communication. Table 1, show the details of the new definition for SMEs in Malaysia.

Table 1: New Definition of Small and Medium Enterprises (SMEs) for Malaysia

Category	Micro	Small	Medium
Manufacturing	Sales turnover of less than **RM300,000** OR employees of less than **5**	Sales turnover from **RM300,000** to **less than RM15 mil** OR employees from **5 to less than 75** Sales turnover from **RM300,000 to less than RM3 mil** OR	Sales turnover from **RM15 mil to not exceeding RM50 mil** OR employees from **75 to not exceeding 200**
Services and Others Sectors	Sales turnover of less than **RM300,000** OR employees of less than **5**	employees from **5 to less than 30**	Sales turnover from **RM3 mil to not exceeding RM20 mil** OR employees from **30 to not exceeding 75**

Methodology

The quantitative research method was employed in this research by distributing questionnaires to collect the data from SMEs. Questionnaires were distributed through email to obtain the data. After that, SPSS v21.0 was employed to interpret all the data obtained. Descriptive and inferential statistics were used to describe the current status of SMEs' strategic approach towards managing business performance. Lastly, discussions were made about the theories and the actual situation. According to SME Corporation Malaysia official website, there are 155 manufacturing SMEs in Batu Pahat that are registered under SME Corporation, however, after communicating with the officer of SME Corporation Malaysia, the list was created in 2014 and not updated. Therefore, this study followed the population in the list and selected the target sample to study. Moreover, this study is concerning the micro, small and medium-sized enterprises in with the number of employees from 1 to not exceeding 200. Owner managers, managers, supervisors and any full-time employees were selected as the respondents for this study.

The given population is 155 companies, by referring to the table developed by Krejcie and Morgan (1970), the sample size would approximately be 110 companies. For this research, a random sampling method was used to select the respondents from the population. Each population has an equal chance of being selected to become a sample in this study.

Survey Questionnaire Design

In this research, a questionnaire is formed to gather the information needed. The questionnaire consists of 5 sections as shown in Table 2.

Table 2: Survey Questionnaire Structure

Section	Content	Data Categories
A	Demographic of respondents and company profile	Nominal Scale
B	Business performance	Likert Scale
C	Business strategy	Likert Scale
D	Communication method	Likert Scale
E	Monitoring system	Likert Scale

In section A, the information about the respondent and company profile was gathered by using a nominal scale with a few variables to get clear information. While, for sections B, C, D and E, there were given in the form of a Likert scale with seven scales from strongly agree to strongly disagree. This research attempts to identify the significant level of SME's strategic approach towards managing business performance.

Figure 1: Research Framework

H1 - There is a significant relationship between business strategy and business performance.
H2 - There is a significant relationship between the communication method and business performance.
H3 - There is a significant relationship between monitoring tools and business performance.

16 sets of the survey questionnaires were distributed to the 10 SMEs by email and interview. These pilot test results were indicated in the table below.

Table 3: Reliability analysis from Pilot Study

Items	No of Question	Cronbach Alpha
Business Performance	8	0.84
Business Strategy	6	0.88
Communication	7	0.91
Monitoring	5	0.76

According to the Table 3, there were a total of 26 questions and a total of 16 respondents took part in this pilot study. The Cronbach's Alpha value for business performance, business strategy and monitoring tool are 0.839, 0.881 and 0.860 respectively. This showed that the questions are understandable by the respondents participated. For the communication method, the Cronbach's Alpha value is 0.910 which means that the design of the questionnaire excellent and high in reliability allow in the real study.

Reliability Analysis of Administrative Questionnaire

There were a total of 62 respondents who took part in the data collection. The reliability analysis was conducted according to the items asked in the questionnaire. Business performance obtained 0.805 of Cronbach's Alpha value where the communication method obtained 0.890 of Cronbach's Alpha value.

Table 4: Test reliability

Items	No of Question	Cronbach Alpha
Business Performance	8	0.87
Business Strategy	6	0.76
Communication	7	0.87
Monitoring	5	0.77

These two items obtained the result of good in the internal consistency level. However, for the business strategy in section C and section D (monitoring tool) obtained the result of acceptable internal consistency with Cronbach's Alpha value was 0.805 and 0.872 respectively. This proved that the data collected in the real study is valid and reliable.

Data Analysis

The number of registered SMEs in Batu Pahat under SME Corporation was 155 and the sample used in the study was 110. Among the 110 questionnaires distributed, 62 were returned with a return rate of 56.36%.

Demographic Analysis

Referring to Table 5, the frequency of the female respondents is 37 out of 62 respondents. Female respondents occupied 59.7% in this survey. Besides, there were 25 (40.3%) male respondents. All the respondents' ages were within the range of 18-60 years old. The ages of the respondents are mostly between 26 – 35 years old with 23 (37.1%) respondents involved in the survey. This is followed by 16 (25.8%) respondents are within 18 – 25 years old age group. Besides, for ages between 36 – 45 years old, there are 14 (22.6%) respondents involved in the survey. There are only 9 (14.5%) respondents that age between 46 to 60 years old. Table 5 shows a summary of the background of respondents.

Table 5: Summary of Respondent's Background

Items		Frequency	Percentage
1	Gender		
	Male	25	40.3
	Female	37	59.7
2	Age		
	18 – 25 years old	16	25.8
	26 – 35 years old	23	37.1
	36 – 45 years old	14	22.6
	46 – 60 years old	9	14.5
3	Current Position		
	Owner	5	8.1
	Manager	7	11.3
	Supervisor	18	29.0
	Officer	32	51.6

Items		Frequency	Percentage
4	Number of Employees		
	1 to 5	12	19.4
	6 to 75	35	56.5
	76 - 200	15	24.2
5	Industry		
	Paper	8	12.9
	Food and Beverage	4	6.5
	Chemical	16	25.8
	Rubber and Plastic	14	22.6
	Others	20	32.3

On the other hand, all 62 respondents were holding different job positions as well. By referring to Table 5, the highest position of the respondents that are involved in the study is the staff and officer position with 32 (51.6%) respondents in it. The second highest is the supervisor position with 18 (29.0%) involved in the survey. 7 (11.3%) respondents are involved in this survey are managers and followed by the owner-manager position with 5 (8.1%) respondents. In this survey, the numbers of employees at the company that the respondents currently work with are within the range of 1-200. There were no respondent workings at the company with more than 200 employees. According to the table above, the number of employees in the manufacturing firm that took part in the survey was quite small. The highest response was from the small-sized manufacturing firm with 6 to 75 employees, with 35 (56.5%) of the returned questionnaire. Then, it is followed by manufacturing size with 76 – 200 employees and 1-5 employees with 15 (24.2%) respondents and 12 (19.4%) respondents respectively.

Last but not least, the highest category of manufacturing firms involved in the survey is the “Others” category which achieved 32.3% of the response. The “Others” category includes manufacturing of electronic products, metal products, non-metallic mineral products, machinery equipment, palm oil and transport equipment. This is followed by 16 (25.8%) respondents from chemical products and man-made fibers category. Next, there were 14 respondents from the rubber and plastic products category which is 22.6% of the overall number. About 12.9% or 8 respondents were from paper products and printing categories. Category of food products and beverages achieved the lowest number, with 4 (6.5%) respondents involved.

Descriptive Analysis of the Variables

In this study, the statistical descriptive analyses were used on the data collected to observe the frequency, means and standard deviation.

Business Performance

Table 6 shows the mean and standard deviation for every question related to the business performance of SMEs.

Table 6: The mean and standard deviation of types of KPIs

No	Items	Mean	SD	Mean Interpretation
1	Customer satisfaction	5.27	1.22	High
2	On-time deliveries	5.58	1.37	High
3	Share market	3.73	1.47	Moderate
4	Employee Turnover	4.73	1.22	Moderate
5	Revenue	5.69	1.26	High
6	Revenue growth from new products	5.31	1.26	High
7	Quality	5.47	1.38	High
8	Corporate responsibility	4.61	1.38	Moderate
Total Mean				High

The average mean for the business performance is 5.05, which proved that SMEs who took part in the survey were already employing distinct KPIs in the business. The dispersion of data is at a moderate level, with 1.30 of standard deviation value. There are three items with moderate in mean tendency level which were asked items about the evaluation on employee turnover rate, evaluation on market share, and corporate responsibility. This shows that these three business performances are relatively less measured when compared to other business performances.

Business Strategy

Table 7 shows the mean and standard deviation for every question related to business strategy.

Table 7: The mean and standard deviation of business strategy

No	Items	Mean	SD	Mean Interpretation
1	Critical Success factors	4.37	1.47	Moderate
2	Establish goals and strategic initiative	4.68	1.34	Moderate
3	Vision	4.27	1.50	Moderate
4	Vision into strategy	4.26	1.49	Moderate
5	Feedback to enhance strategy	4.06	1.49	Moderate
6	Continues improvement	4.77	1.19	Moderate
Total Mean				Moderate

From the table above the average mean for the business strategy is 4.40 which shows a moderate tendency level. This shows that the level of implementing the business strategy of SMEs have to be enhanced in order to link with managing the business performance. The dispersion of data is at a high level, with 1.41 of the standard deviation value.

Communication Method

Table 8 shows the mean and standard deviation for every question related to the communication method.

Table 8: The mean and standard deviation of the communication method

No	Items	Mean	SD	Mean Interpretation
1	Clarification of KPIs from the management	4.81	1.21	Moderate
2	All employees understand the purpose KPIs	4.60	1.09	Moderate
3	Employes and their role about KPIs	4.77	1.24	Moderate
4	Training and empowerment to support KPIs	4.73	1.09	Moderate
5	KPIs and team	4.16	1.24	Moderate
6	KPIs and team training	4.47	1.02	Moderate
7	KPI within stakeholders	4.85	1.16	Moderate
Total Mean				Moderate

By referring to the Table 8, the average mean of communication methods is 4.63 with the mean tendency level being moderate. This shows that communication of KPIs within the organization had to improve, especially in terms of appointing staff to the KPI team which obtained the lowest mean score. Besides, the dispersion of data is at a moderate level with a 1.15 standard deviation value.

Monitoring Tool

Table 9 shows the mean and standard deviation for every question related to the monitoring tool.

Table 9: The mean and standard deviation of the monitoring tool

No	Items	Mean	SD	Mean Interpretation
1	The management and financial review	5.43	0.99	High
2	The management and non-financial performance	5.08	1.14	High
3	KPIs dashboard – to monitor performance	3.95	1.36	Moderate
4	Immediate action on KPIs performance	4.22	1.25	Moderate
5	Day to day monitoring	4.11	1.29	Moderate
Total Mean				Moderate

From the table above, the average mean of monitoring tool is 4.56 which indicates a moderate mean tendency level and the dispersion of data is also at a moderate level with 1.21 of standard deviation value. However, two items obtained high tendency levels which were management has periodically reviewed financial and non-financial performance, with obtained 5.43 and 5.08 respectively. This is indicating that these two practices have been implemented by the SMEs to monitor business performance.

Normality Test

Before proceeding to correlation analysis, the data collected have to be tested for its normality. Table 10 shows the result of the normality test for business strategy, communication method and monitoring tool.

Table 10: Result of the normality test

Items	Kolmogorov		Supiro	
Business Strategy	0.26	0.00	0.94	0.04
Communication	0.20	0.00	0.91	0.00
Monitoring	0.19	0.00	0.92	0.02

The table above shows that the p-value is lower than 0.05. This indicated that the data distribution is not normal. Therefore, a non-parametric test was used to identify the direction and the strength of the relationship that exists between all three variables and business performance.

The Relationship between Business Strategies towards Business Performance

Hypothesis 1:

There is a significant relationship between business strategy and business performance.
There is a significant relationship with the p-value is 0.006 and with the correlation coefficient of 0.344. This value indicates that there is a significant but low positive relationship between business strategy support and business performance.

The Relationship between Communication Method towards Business Performance

Hypothesis 2:

There is a significant relationship between communication methods and business performance.
There is a significant relationship with the p-value is 0.005 and the correlation coefficient of 0.327. This represented that there is a significant but low positive relationship between communication methods and business performance.

The Relationship between Monitoring Tool towards Business Performance

Hypothesis 3:

There is a significant relationship between monitoring tools and business performance.
There is a significant relationship with a p-value of 0.05 and the correlation coefficient of 0.349. This means that there is a significant but low positive relationship between monitoring tools and business performance.

Summary of Hypotheses Testing

With respect to the objectives of this study, the following findings were obtained as shown in Table 11.

Table 11: Summary of hypotheses testing result

H1	There is a significant relationship between business strategy and business performance.	Accepted
H2	There is a significant relationship between communication methods and business performance.	Accepted
H3	There is a significant relationship between monitoring tools and business performance.	Accepted

These three dimensions, business strategy, communication method and monitoring tool have shown a significant relationship with business performance. The significant value achieved was less than 0.05. This was able to support the relationship between organizational strategic approaches toward managing KPIs in SME's business performance.

Discussion of Findings

Based on the finding of this research, KPIs belonging to the customer and financial and perspectives appear to have more attention from the participating SMEs than that of the internal business and learning perspectives. In this study, SMEs are concerned about the revenue growth, quality of products and customer satisfaction. This could be attributed to the nature of Malaysian SMEs in measuring business performance. There is a need for more appreciation of innovation and human capital. This finding was consistent with the findings of other researchers who stated that the key non-financial indicators usually will not be so concentrated by SMEs (Phusavat & Manaves, 2008; Wu, 2009; Zahid et. al., 2017)

The second part looked at the business strategies by the SMEs towards managing the KPIs. Business strategies include implementing the BSC to develop the strategy. In this study, the business strategy implemented by SMEs is at a moderate level. This shows that the level of implementing the business strategy of SMEs has to be enhanced in order to link with managing the business performance. This is also consistent with that of Giannopoulos et al. (2013) who produced evidence from UK SMEs that only 25 percent of the companies used BSC to develop a strategy in the performance measurement system.

In addition, the finding also shows that SMEs in this study is the lack of attentiveness on the monitoring and evaluation of a time-factor KPIs. Management has periodically reviewed the financial and non-financial performances. They are lack of monitoring on the real-time performance and daily basis. This result supports the studies by Hudson, Smart, and Bourne (2001) which indicated that SMEs usually use historical data to measure business performance.

Communication among staff within the organization was found that had a significant relationship with managing the SMEs' business performance. In this study, communication methods implemented by SMEs are at a moderate level. The management has clarified the KPIs in the company and all employees understood the proposed KPIs. A training program is provided to support the KPIs. Therefore, the communication method suggested by Parmenter (2015) applies to the SMEs managing KPIs.

Limitations

In order to contact each of the respondents, communications are to be established one by one. This method would not be an ideal way also due to the sheer size of the number is extremely time-consuming. Moreover, some respondents were unaware that they are measure one of the KPIs in the performance measurement system. Time constraint is a major consideration due to the limited time

given to complete this research. Besides, most of the companies will not give cooperation in taking part in this survey. Thus, many methods were used to collect the questionnaire in order to acquire sufficient data for the SPSS to analyze.

Recommendation and Conclusion

If the organization intends to enhance the performance measurement system, it would need to plan the strategic approach of managing the KPIs' efficiency and effectiveness. Good preparation is needed for organizations to enhance the SME's business performance. This can be prepared from the business strategy support. The management should establish goals and translate them into a strategy. In addition, training and education need to provide for the KPI team to empower employees to support the KPIs. After the organization has installed the system, continuous communication and monitoring are needed to support the KPIs performance. This study had small sample sizes that are gathered from manufacturing SMEs in Batu Pahat only. Therefore, future researchers can consider gathering data from SMEs in the whole of Malaysia. It is best if the future researcher can focus on a sector. Future researchers can also use a mixed approach rather than only the quantitative method. It can incorporate interviews into the research as well as having a quantitative approach.

Annotation

The article discusses theoretical approaches to the study of social capital. Conceptualization of social capital always includes “trust”, which can be interpreted from the perspective of various sociological paradigms. By viewing trust as recognition of obligations and expectations as well as their concentration, we move to the level of strategies analysis of social agents. Subjective assessment of trust in authorities, institutions, organizations, movements, associations and commissions shows the extent to which social agents perceive the results of various social institutions’ functioning, how they evaluate them and whether they rely on them. This, in turn, influences the chosen strategies of social agents in various fields of social space.

Keywords: Social Capital, Distrust, Trust, Social Connections.

Statement of the Research Problem

Social capital is a multicomponent subject of sociological, anthropological, sociocultural, economic and political research, aggregating the problems of various scientific approaches (Burkinskij, Gorjachuk, 2013). It includes conventionality and the importance of social norms, necessity, impossibility or contingency of certain (social) ties, their stability and reproducibility, ways of correlating the formal and informal. This follows from contingency which, in the language of N. Luhmann, is an immanent property of the social. Social capital also regards vertical and horizontal social relations and inclusion in social groups, constructivist and structural, i.e. collective agents and individual actors, subjective and objective, arbitrary-spontaneous and deterministic. The complexity of a given object is explained not only by the variability in the choice of sociological theoretical constructions for further empirical sketch but also by the integrity of the concept itself, meaning its validity when applied to questions of the essence of economic, political, culturological, etc. This explains the popularity of “social capital” in the rationale for resource allocation, civil society, policies of openness and representation, democratic institutions, pluralism and tolerance.

In the same way that M. Weber spoke about the "ethos of economic thinking", scientists referred to "trusting relationships", inscribed in social ties and in the principles of their effective mobilization (Weber, 1990). J. Coleman notes the dual structure of social capital and then approves the relationship between obligations and expectations at the micro level and the reliability of the system at the macro level (Coleman, 2001). If obligations and expectations for their fulfillment take the form of an informal “trust receipt”, the very reliability of the system presupposes production methods and assimilation of value patterns and attitudes, as a result of which a complex of expectations about “outstanding credit” occurs, i.e. obligations. As in the case of R. Putnam and F. Fukuyama, we are talking about "trust", which can be both a cause and a consequence of stable social relations networks functioning (Putnam,

1996; Fukuyama, 2008). In this understanding, social capital is the implementation of norms and trust in various social situations that seem possible for a particular subject due to its involvement in certain systems of relationships.

As J. Coleman writes, the definition of social capital can be derived from its functionalist approach (Coleman, 2001). P. Sztompka proposed to consider trust and its (dis)functionality according to the principles of R. Merton, that is, the principle of functional relativity (trust in one institution may be dysfunctional, in another - functional) (Sztompka, 2012). If only its functional properties in the sense of R. Merton are considered, in our research we come to what F. Fukuyama says, characterizing social capital as a connecting link of trusting and normative-regulatory relations that constitute liberal, democratic, representative and civil society (Fukuyama, 2008). At the same time, the research axiomatic position is that in the social groups, formal and informal institutions we are analyzing, whether it be labor collectives, cooperatives, trade unions, associations, social movements, in predominantly horizontal relations, and in state, political, legal institutions, - in vertical relations, a functional (contributing to the support and adaptation of this system) set of stable expectations is always produced and reproduced, forming and strengthening trust (Krivopuskov, 2013).

Considering the consistency of different interpretations of trust-based interaction, we can refer to its phenomenological interpretation as an institutionalized process of social interaction. It contains self-evident and habitualized typification schemes with their everyday grading according to pragmatic interests. This interaction also includes knowledge of recipes for interpreting the intended interaction outside the assumption of a crisis with the corresponding legitimations. On the other hand, it is a more systemic interpretation of N. Luhmann, according to which trust is the minimization of risks (Berger, Lukmann, 1995; Luhmann, 2002).

In the first case, trust excludes or presupposes the exclusion of a partial crisis from everyday life; in the second case, it presupposes system operations reducing the complexity of the surrounding world and subsequent operations of (repeated) selection of the elements, minimizing risks. Trust, in both cases (phenomenological and systems theory), contains schemes of interpretation assimilated by the subject / system which through description refer a particular social situation to the code of trust and distrust. Social capital, therefore, acts not only as effectively mobilized social ties for the accumulation of other types of resources and their conversion but also as a product of internalized schemes of assessment, perception and action, in accordance with which these social ties are constructed and classified.

Combination of these schemes of assessments, perceptions and actions generates stable social ties that are in a specific relationship with those being actually constructed, and the ones already constructed - already established social relationships between agents that affect their habits and vice versa (Bourdieu, 2002). If we imagine various social structures in the form of collective agents who delegate rights and corresponding competences in their own representation to a certain person or group of persons, we can conclude that the accumulation of symbolic capital by a representative of a given collective allows it to maximize benefits and minimize costs in their favor. This implies redistribution of trust and distrust, recognition and non-recognition. The agents included in this collective can judge the legitimacy of this appropriation, recognition and non-recognition, trust and distrust, even though this occurs in terms and categories of the collective itself (Bourdieu, 1985).

We proceed from the position that social institutions, represented by collective agents, are capable of accumulating and monopolizing symbolic power, influencing the social capital of agents and their strategies. Thus, our research problem is to determine the factors influencing redistribution of trust and distrust, affecting the strategies of social agents.

The aim of the work

is to determine the key factors, influencing distribution of subjective trust and distrust in the Russian Federation.

The theoretical basis of the study

Almakaeva A., Volchenko O., Belyaeva L., Petro N. (an authentic structural study of social capital in one of the regions of the Russian Federation can be found in his works), Schrader H. (Almakaeva, Volchenko, 2018) studied social capital and its transformation in Russia.; Belyaeva, 2016; Petro, 1999; Schrader, 2004). We have chosen the theoretical constructions of P. Bourdieu from the fundamental sociologists (Bourdieu, 2001). Referring to the work of V. Radaev, trust, in our case, is defined as “concentration of expectations and obligations” (Radaev, 2003). But it should be noted that they can occur in qualitatively different situations. L. Théveno and L. Boltanski wrote about this, speaking of different ways of judging “fair”, which take place in different situations. (Boltanski, Théveno, 2013).

We argue, relying on P. Bourdieu, that the concentration of expectations and obligations presupposes recognition and non-recognition (symbolic capital), in accordance with which any concentration of these expectations and obligations is possible in general (Bourdieu, 2002). The first level of such recognition and non-recognition is the "matrix of social relations" in the language of P. Berger and T. Lukman, or "official", "state", in the language of P. Bourdieu (Berger, Lukman n 1995; Bourdieu, 2016). Indeed, to judge recognition and non-recognition, obligations and expectations, it is necessary to act in the logic of the space that forms the taxonomic principles, “codes”, in accordance with which any recognition and non-recognition is then possible. To trust someone, one must trust the very trust schemes by which other agents are judged in the categories of recognition / non-recognition (Bourdieu, 2002). The second level of such recognition is "mundane", where agents are already acting in accordance with their strategies in one field or another. That is, the first level is theoretical for the agent. It is reflected in his categories, which he combines.

It can be said that social agents concentrate their obligations and expectations in accordance with the recognition and non-recognition of one instance or another, that is, an increase in the recognition of an instance by social agents will mean both increased obligations in relation to this instance and increased expectations.

The more agents are inclined not to recognize this instance at the level of strategies as a legitimate representative of the values of the first level of recognition, the less they are inclined to implement strategies aimed at fulfilling obligations in relation to this instance and the fewer expectations will be placed on the functioning of this instance.

Trust, including a complex of obligations and expectations, implying recognition or non-recognition of their significance, is at the heart of not only social capital as a network of social connections between social agents located close to each other in the social space we have constructed. This will mean closeness and possible structural homogeneity of the totality of social, cultural, economic capitals. Trust is also at the heart of symbolic capital, making it possible to establish social ties for their further use (conscious or unconscious) in obtaining maximum benefits.

If the expansion and accumulation of social contacts depends on symbolic capital and its volume, then the possibility of further recognition and non-recognition within the framework of the constant expansion, maintenance and accumulation of social ties depends on social capital and its constant maintenance, like the circulation of gifts (Bourdieu, 2002).

There is a relationship between symbolic capital, often manifested as social capital. Social capital is practical, involving constant work to maintain and accumulate one form of capital in favor of another - and vice versa (Bourdieu, 2002). In our opinion, every instance, be it a state, educational, church institution, is always in the process of constant production and reproduction, which presupposes self-legitimation and all the tools necessary to accomplish such legitimation, which is a second-level construct that supports the institutional order itself – the first level construct (Bourdieu, 2016). Such social institutions within the framework of the sociocultural environment under consideration should accumulate symbolic capital of the supra-individual level, create millions of “weak” ties, which, by recognizing this institution, will legitimize its existence in various forms - as institutions, authorities, commissions, departments, ministries. Using this logic, trust relationships between institutionalized

political, legal, economic platforms and external social agents, not directly being part of a closed group of functionaries, party members, parliamentarians, judges and big businessmen, legitimize the existence of such an institution not only as a closed sect. It also legitimizes it as a “relatively open”, “reciprocal”, “transparent” system. It means that the social base increases, inclined to fulfill additional obligations for this institute and which expects it to fulfill its expectations.

The Results of The Study

The respondent's subjective assessment of trust in the direction of a social institution or authority may indicate what a person expects from this or that institution and what obligations he is ready to fulfill so that the institution can make the expected changes. Sociological structuralism, especially in its structural-functionalist branch, does not view the agent's strategies as meaningful. However, structuralist constructivism tries to understand first, generating social action structures and, secondly, how structures are realized in these actions, that is, to interpret the functioning of structures in the strategies of agents (Bourdieu, 2001). We want to understand what factors influence distribution of trust and mistrust in the social space, what social institutions comes the recognition and non-recognition of obligations and expectations from, related to these and other institutions. This, of course, affects the design of agent strategies that can exclude the significance of the institution by virtue of its non-recognition (and vice versa - to enhance its importance.

In our study we use the information provided by the WVS (World Values Survey), namely, the seventh wave of the study, conducted in 2017-2020 (methodology in the source) (Inglehart et al., 2020). Considering our theoretical part, we decided to analyze the data set on the Russian Federation obtained during the seventh WVS wave. The indicators of subjective trust were the respondents' answers regarding trust in their family, friends, neighbors, people they know personally, as well as those regarding trust in various instances - the state, political parties, churches, universities, etc. To determine the factors affecting the distribution of trust and distrust in the Russian Federation, we used the factor analysis procedure for the data set, provided by WVS as a data packet in SPSS. There were 1810 (N = 1810) respondents from the Russian Federation.

The suitability of a factor analysis is described, using the Kaiser-Meier-Olkin (KMO) sample adequacy test at 0.898 with the Bartlett sphericity test of 300 at a significance level of $p = 0.000$ with approximate chi-square of 15973.048. Factor analysis by the method of principal components identified 6 main factors, the first of which explains 28.563% of the total variance, the second - 8.669%, the third - 6.768%, the fourth - 5.045%, the fifth - 4.504%, the sixth - 4.349%. Together, six factors explain 57.898% of the cumulative variance. We used the varimax rotation method with Kaiser’s normalization, the rotation was converged in 9 iterations. The results of the factor analysis are given in two tables, representing the component matrix (Table 1) and the rotated component matrix (Table 2). To extract the factors, the following variables were used: subjective trust in the family, neighbors, acquaintances, strangers, people of other nationalities and religions (this forms the micro-level of perception and interaction). Further, the macro level of perception and interaction with organizations, institutions - trust in the church, the armed forces, the press, television, trade unions, the police, the legal system, the state, political parties, parliament, civil services, universities, the electoral system, large corporations, banks , conservation movements, women's movements, charities and regional organization.

Confidence: Major regional organization (combined from country-specific)	.239	**.688**	.077	.142	-.021	.095

Values in bold are critical factor loadings for definition and interpretation. The obtained 6 factors can be classified as follows (Table 3):

Table 3: Obtained factors and their interpretation

Trust in structures (macro level)	Trust in agents that implement structures in strategies (micro level)
Factor 1 influence on the distribution of trust and mistrust on the part of political and legal institutions that are interested in maintaining the official and its reproduction.	**Factor 4** influence on the distribution of trust and mistrust on the part of people with a different nationality and religion
Factor 2 influence on the distribution of trust and mistrust on the part of social movements, associations and regional campaigns	**Factor 5** influence on the distribution of trust and mistrust on the part of the people around who interact with the subject
Factor 3 influence on the distribution of trust and distrust of information institutions and channels.	**Factor 6** influence on the distribution of trust and mistrust on the part of the family - the closest group of people

It should be noted that the attitude towards people of a different nationality and religion depends on internalized structures which are then implemented in social practices. Distribution of trust and distrust, as we can see, depends on the variables loading the given factor the most. It can be noticed that the field of economic collective agents in the form of large corporations and banks does not load any factor sufficiently. Therefore, we can say that they do not have such an impact on the distribution of trust and distrust as political and legal institutions, public organizations, media and the immediate environment of the agent, which he interacts with intensively on a daily basis. Likewise, we do not notice a significant factor load on the part of the church, military forces, universities - probably because they are perceived as part of political and legal institutions. But we cannot assert this with certainty without additional data. This hypothesis is opposed by the performed correlation analysis, not showing a single significant correlation (> 0.7), except between the variables "trust in people of other nationalities" and "trust in the church."

The study shows that trust and distrust as a combination of obligations, expectations and recognition, are formed mainly by 6 factors, taking into account their division into the structural level (macro) and the strategic level (micro), at which the structures perceived by the agent are implemented. This is closely related to social capital, which is a group resource, but is used by a single agent. On our part, such structures as the state, represented by a certain group of agents, also have their own social capital, “credit of trust”. It may seem that "social capital" as a concept can only be applied in considering the strategy of social agents. But if we break with structuralism towards constructivism, we notice that structures are represented by different people and different groups of people. They are delegated the rights to speak on behalf of the entire group, that they are a concentrate of the symbolic capital of this group, allowing them to mobilize social ties to allocate resources in their favor. Empirical research presupposes making such a gap. Otherwise the theoretical constructs of the "state" may remain only constructs without the possibility of research.

We can say that the distribution of trust and distrust in the Russian Federation is influenced by the factors we have identified. This affects the strategies of agents, which, in turn, affect the attitude towards authorities, commissions, institutions, movements, organizations - how this or that institution can be represented and what expectations it will fulfill in exchange for fulfilling the obligations of social agents.

Discussion and conclusion

The main element of social capital is trust as a concentration of obligations and expectations, implying a symbolic minimum of generating this type of relationship - recognition. Consideration of trust in this respect is fundamental in the study of social capital.

The concept of "social capital" can be applied in studying the structures and strategies of their perception, assessment and action. Distribution of trust and distrust in the society shows the tendency of social agents to fulfill obligations in relation to the authority in return for fulfilling expectations. Of course, this requires recognition, but it often acts as a construct of the first level, as something without which it is impossible to perceive the social and the entire surrounding world. With such an approach it is possible to explain, for example, particularistic or communitarian value attitudes, crime and deviations in general. Obligations in relation to political and legal institutions, in this case, are unfulfilled due to non-recognition of the second level construct (legitimation) or collapsed expectations in relation to this institution. Formalization and transparency, and, of course, implementation of structures in the strategies of social agents, especially in a theoretical sense, can be also explained by it.

If it is possible to investigate strategies of social agents and the place of various authorities in their lives, relationships with different variables can be found, reflecting the intensity of interactions between social agents and authorities. The preference of one instance or another in the eyes of respondents can be determined, that is, social capital can be studied according to a structural methodology, not institutional one.

Resumen

El artículo presenta, desarrollado por los autores, el método de asignación de fondos presupuestarios por deportes (federaciones deportivas). La metodología se basa en el conocido enfoque de costo-beneficio en economía, es decir, el criterio principal para determinar la cantidad de fondos para un deporte en particular para el próximo año calendario serán los resultados logrados por los atletas en períodos anteriores (lapso de tiempo - 4 años) en competencias de varios niveles. El uso de métodos de la teoría de la probabilidad y la estadística matemática le permite evaluar cuantitativamente un resultado deportivo específico y monetizarlo. Por lo tanto, es posible realizar fácilmente el control público y el examen de la validez de los gastos presupuestarios destinados a apoyar un deporte específico (federación deportiva).

Palabras clave: Deportes, Financiamiento Presupuestario, Distribución Del Financiamiento.

Introducción

Muy a menudo, cuando se distribuye apoyo financiero para el desarrollo de industrias con orientación social, especialmente si este apoyo proviene de los presupuestos estatales o regionales, surge el problema de la distribución de los recursos asignados.

En la Rusia moderna, una parte significativa de estos sectores de la economía nacional está sufriendo serias dificultades en la financiación presupuestaria, a pesar de la existencia de varios programas específicos y el deporte no es una excepción. Una de las principales razones de la mala gestión del deporte en las regiones rusas es la falta de criterios matemáticamente justificados para usar los recursos disponibles y, sobre todo, financieros. Es muy difícil desarrollar y financiar simultáneamente decenas de deportes diferentes en el nivel necesario. El procedimiento existente para la distribución de la financiación presupuestaria por deportes en las regiones se caracteriza por un bajo nivel de objetividad, transparencia y eficacia. Por lo general, se da prioridad a la práctica de deportes (fútbol, hockey, baloncesto, voleibol), pero no se tienen en cuenta los intereses de deportes más exitosos y efectivos. Tambien es importante el estatus y cargo que ocupa el titular de la federación deportiva correspondiente, así como su relación con las autoridades autonómicas.

Modelos De Financiación

Como se sabe, en la práctica mundial hay dos modelos principales de financiación deportiva: europeo y americano [5]. El modelo europeo (Rusia) asume una financiación mixta con un predominio significativo de los fondos presupuestarios. El modelo estadounidense (EE. UU.) se caracteriza por la falta de apoyo directo al deporte desde el presupuesto nacional y la presencia de un gran número de

ARKALOV " Metodología Para Optimizar La Financiación Presupuestaria Del Deporte En Rusia: El Aspecto Regional" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

incentivos fiscales para la inversión en el deporte por el sector privado. Ambos modelos de financiación implican la implementación de funciones para asegurar las siguientes áreas del deporte: deportes de masas, deportes de élite (olímpicos) y profesionales [1].

La clasificación de deportes también es una práctica generalmente aceptada en la mayoría de los países del mundo, pero no existe un enfoque uniforme para la clasificación. Cada país procede de sus propias características de financiación deportiva.

Los intentos de crear métodos que resuelvan el problema de asegurar una distribución objetiva, equilibrada y transparente de los fondos presupuestarios por parte del deporte no son nuevos. Muchas regiones de Rusia están desarrollando y aprobando sus propios sistemas para clasificar los deportes basándose en los fondos presupuestarios asignados. Al mismo tiempo, los principales criterios de clasificación son: disponibilidad de instructores, base material y técnica, componente nacional y cultural del deporte, logros en competiciones de varios niveles, etc. La mayoría de estos métodos son bastante subjetivos, ya que se basan en el juicio de expertos y no están respaldados por cálculos y conclusiones matemáticos.

Una de las formas de resolver este problema es la metodología propuesta por los autores será la suma de indicadores que tengan un cierto peso específico, que se calcula por los resultados de los períodos anteriores (lapso de tiempo es 5 años) [2]. La solución está basada en el conocido enfoque 'costo-beneficio' en economía, es decir, el criterio principal para determinar el volumen de financiamiento para un deporte en particular para el próximo año calendario. El uso de métodos de la teoría de la probabilidad y la estadística matemática le permite evaluar cuantitativamente un resultado deportivo específico y monetizarlo. Por lo tanto, es posible realizar fácilmente el control público y el examen de la validez del gasto presupuestario asignado para apoyar este deporte o federación deportiva en particular [4]. La metodología se basa en un algoritmo de distribución de fondos entre las federaciones deportivas en base a los puntos ganados en función de los resultados de su trabajo en el año anterior al previsto. Para evaluar los resultados del trabajo, se seleccionan indicadores que están contenidos en los datos oficiales de observaciones estadísticas estatales. Por un lado, ellos permiten hacer una valoración bastante completa de los resultados en cada deporte; por otro lado, estos indicadores están disponibles, son fácilmente verificables y no requieren fondos adicionales para recolectar información.

Metodología de financiación

La novedad científica del método propuesto es la siguiente:

- por primera vez en la práctica rusa, la distribución de la financiación presupuestaria por deporte se calcula basándose en un modelo matemático que tiene en cuenta datos fácticos objetivos sobre los resultados (logros) de los representantes de un deporte en particular;
- basándose en los formularios de informes estadísticos estatales, se han desarrollado criterios para evaluar la efectividad y eficiencia del trabajo de las federaciones en diferentes deportes;
- se ha escrito el código y se ha desarrollado un software que permite automatizar completamente el proceso de asignación de fondos presupuestarios por deporte.

De manera convencional, todos los indicadores de la metodología se dividen en los siguientes grupos:

1. El número total de atletas involucrados en deporte particular;
2. El número de atletas de la región incluidos en los equipos nacionales;
3. Infrastuctura y personal del deporte;
4. Coeficiente olímpico / paralímpico.

Consideremos el algoritmo de cálculo de puntos utilizando indicadores individuales como ejemplo.

Sea 'N' el promedio para un cierto período base (t años) el número de atletas involucrados en un deporte en particular:

$$(1)\ N = \frac{\sum_{i=1}^{n} M5\ (SFi)}{t},$$

donde,

i de 1 a n – número de deportes;
M_5(SFi) – número de atletas en un deporte en particular;
t – franja horaria.
y k_j – el número de victorias que se suman para todas las federaciones deportivas registradas en la región. En este caso, los puntos se calculan en base a los resultados mostrados en las competiciones durante el período base de acuerdo con el algoritmo que se muestra en la Tabla 1.

Tabla 1: algoritmo para el cálculo de puntos basado en los resultados de victorias en competiciones

Lugar	Victorias totales	Puntos	
1	k_1	(2)	$x_1 = \frac{N}{k_1 + 1} + x_2$
2	k_2	(3)	$x_2 = \frac{N}{k_2 + 1} + x_3$
3	k_3	(4)	$x_3 = \frac{N}{k_3 + 1} + x_{4-6}$
4–6	k_{4-6}	(5)	$x_{4-6} = \frac{N}{k_{4-6} + 1} + x_y$
Participación	k_y	(6)	$x_y = \frac{N}{k_y + 1}$

Además, por ejemplo, el valor de puntos del personal (entrenadores) se calcula como la cantidad media de entrenadores ($COACH_{5av}$) por la cantidad media de atletas (M_{5av}) que practican deportes de manera organizada y participan en competiciones durante el período base.

$$(7)\ \mathrm{COACH} = \frac{\mathrm{M_{5av}}}{\mathrm{COACH_{5av}}},$$

Se propone que el 'coeficiente olímpico / paralímpico' se tome como una unidad sumada al recíproco de la relación entre el número de deportes olímpicos y paralímpicos y todos los deportes desarrollados en una región o área en particular:

$$(8)\ \mathrm{O(P)C} = 1 + (1 - \frac{\mathrm{OSD+PSD}}{\mathrm{SD}});$$

где:
O(P)C (Olympic/Paralympic coefficient) – coeficiente olímpico;
OSD (Olympic sport disciplines) – los deportes olímpicos;
PSD (Paralympic sport disciplines) – los deportes paralímpicos;
SD (sport disciplines) – los deportes inscritos en El Registro de deportes de toda Rusia.

Después de calcular todos los indicadores, se calcula la suma de los puntos total ganados por una federación deportiva en el i-ésimo deporte,

El volumen de financiación presupuestaria destinada a un deporte específico (federación deportiva) se calcula de acuerdo con el siguiente algoritmo.

a) Calculación de la suma de puntos total:

$$(9)\ \mathrm{SUMtotal} = \sum_1^n \mathrm{SUMtotal(SFi)}\ ,$$

donde:
SUM_{total} – la suma de puntos total ganados de todas las federaciones deportivas;
$SUM_{total(SFi)}$ – puntos totales ganados por una federación deportiva individual.
b) Calculación de valor de un punto:

$$(10)\ \mathrm{VAL(1\ point)} = \frac{\mathrm{BF}}{\mathrm{SUMtotal}},$$

donde:
VAL(1 point) – valor monetizado de un punto;
BF – volumen de financiación presupuestaria.

c) Calculación de volumen de financiación presupuestaria para un deporte (federación deportiva):

$$(11)\ FUND(SFi) = VAL(1\ point)*SUMtotal(SFi),$$

donde:

FUND(SFi) – volumen de financiación para un deporte (federación deportiva) dentro de las asignaciones presupuestarias.

La tarea de evaluar adecuadamente estos resultados y traducirlos en puntos condicionales es, quizás, la más difícil en el desarrollo de esta metodología. Para solucionarla, se hicieron los siguientes supuestos:

- cuanto menos probable es la victoria en una competición, más valor esa victoria tiene. Asimismo, un evento deportivo realizado en el territorio de una región se califica cuanto más alta es la probabilidad de que este evento se realice en esa región en particular;
- la probabilidad de ganar coincide aproximadamente con la frecuencia relativa de las mismas victorias en competiciones similares durante el período base;
- la probabilidad de celebrar un evento a nivel ruso en el territorio de la región es inversamente proporcional al número total de regiones rusas en las que podría realizarse este evento;
- los valores acumulados se utilizan al calcular los puntos.

Riesgos potenciales

El volumen de financiación presupuestaria destinada a un deporte específico (federación deportiva) se calcula de acuerdo con el siguiente algoritmo:

a) calculación de la cantidad total de puntos ganados por todas las federaciones;
b) calculación del valor de un punto (monetización);
c) calculación del volumen de la financiación para un deporte específico (federación deportiva).

También notamos que el uso de esta metodología puede estar asociado con el surgimiento de algunos problemas que requieran investigación adicional.

En primer lugar, es necesario comprender si tal situación es posible cuando una o más federaciones deportivas actúan juntas, es beneficioso para ellas distorsionar la información, logrando así puntuaciones más altas y, en consecuencia, mejor financiación. Por ejemplo, ellas podrían retrasar deliberadamente el envío de información, negarse a realizar eventos deportivos en el año en curso para recibir más puntos más por su celebración en el futuro, etc. Hay que hacer siguientes comentarios aquí. Las funciones mediante las cuales se calculan las puntuaciones se eligieron de modo que sería beneficioso para una federación individual mostrar los mejores resultados posibles. Y dado que el tamaño de las asignaciones presupuestarias es un valor constante, la colusión entre federaciones no tiene sentido, lo cual es fácil de demostrar usando métodos de teoría de juegos. De hecho, en el caso de dos federaciones, obtenemos un juego de suma constante que es estratégicamente equivalente a un juego de suma cero, de modo que los intereses de los jugadores son mutuamente opuestos. En el caso general, podemos asumir que tratamos con un juego cooperativo insignificante, en el que el ingreso total máximo, el tamaño de las asignaciones presupuestarias, es igual a la suma del ingreso máximo posible de todos los jugadores (federaciones) combinados. En un juego así, unirse a jugadores en una coalición no tiene sentido, ya que esto no puede afectar de ninguna manera sus ingresos.

El segundo problema surge cuando la federación no puede utilizar plenamente la cantidad de fondos que las autoridades ejecutivas regionales están dispuestas a proporcionarle, es decir, puede resultar que la federación presente una solicitud que sea significativamente menor que el volumen de fondos

requeridos. En este caso, se trata del llamado problema de asignación de recursos, cuyos mecanismos de resolución son bien conocidos.

Significado práctico

La importancia práctica del estudio radica en la aclaración de las herramientas de cálculo y análisis para la clasificación de los deportes, evaluación su efectividad y eficiencia [3]. También el estudio puede ser útil para:

- el desarrollo de políticas públicas y planificación estratégica en el campo deportivo;
- autoridades estatales, autonómicas y locales, empresas privadas en el desarrollo y ejecución de proyectos de inversión en el ámbito del deporte;
- jefes de organizaciones deportivas de todo tipo cuando quieran resolver sus propias tareas específicas;
- especialistas en diseño de inversiones para evaluar la efectividad de proyectos de inversión existentes y prometedores en el ámbito social;
- desarrollar nuevas formas de informes sociales, documentación contable y analítica, manuales de formación, etc.

Además, el uso de aparatos matemáticos modernos permitirá no solo evaluar objetivamente un resultado deportivo específico, sino también hacer un pronóstico del desarrollo de un deporte en particular en la región.

Abstract

This paper targets the late stage of adolescence by observing decision-making styles among young adults-university students. The main research goal was to evaluate the late adolescent decision-making styles in terms of their academic achievement. The study comprises 77 final-year students on the Croatian Faculty of Economics, Business, and Tourism-University of Split. The results revealed that intuitive decision-making style is the dominant decision-making style among university students. Findings show a negative statistically significant association between dependent, avoidant, and spontaneous decision-making styles with objective and subjective academic achievement variables. However, results indicate that students prone to rational decision-making are positively associated with their academic achievement level. Further, female students are found to show a greater tendency toward intuitive and spontaneous decision-making than male students. Lastly, research results and limitations of the study regarding future research directions are provided.

Keywords: University Students, Decision-Making Style, Academic Achievement

Introduction

One of the most critical periods in an individual's life is adolescence (Dere Ciftci, 2015). It is a susceptible development stage of an individual. It is a crucial period for identity formation (Ericson, 1959) because adolescents face making many essential life decisions influencing their future (Bacanli, 2012). According to many researchers, the adolescence development stage is very relevant for studying decision – making competence (Baiocco et al., 2009) because the decision made in that phase can have significant consequences for the whole individual's life (Tuinstra et al., 2000). It is a crucial period in which decision-making skills are developed, and vital decisions need to be made (Cenkseven-Onder and Colakkadioglu, 2013).

The adolescent period can be roughly divided into three different phases. Each is different regarding individual characteristics that concern physical, intellectual, emotional, and social development; early adolescence (approximately 10-13 years of age), middle adolescence (14-17 years of age), and late adolescence (approximately 18-24 years of age). Final-year university students fall into the category of the late adolescent period. Among plenty of activities that university students in this period need to make on their own are activities that concern decision making processes. As Ericson (1959) stated, major development tasks involve the exploration of various dimensions of identity and the commitment to identity during the late adolescent stage. University students in this stage of life need to make plenty of decisions related to their personal development, which will reflect on their social life (social relations) and their professional areas - on their career pathways.

University education is an upgrade stage in one's education process. Knowledge, skills, values, and beliefs are enriched through many different activities like learning, researching, training, reading, etc.

Cite this Article as: Ivana BULOG And Luka DADIC "Late Adolescent Decision-Making Style concerning Academic Achivement" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Consequently, they shape attitudes and behaviors concerning many decisions they need/must make. Logically, these decisions have an impact on their academic achievement. In this stage of life, youth have been consolidated their mental life, crystallized their attitudes and opinions, and reached rational mental maturation. They have developed self-esteem, confidence, independence, and personality and can make vital real-life decisions. Decision-making engages many cognitive processes, such as information gathering and processing, problem-solving, judgment, memory, and learning (Baiocco et al., 2009). Piaget (1972), at the forefront of cognitive development, pointed out that decision-making forms part of the adolescent phase of an individual's development process.

Ozturk et al. (2011) believe that during adolescence, the independent decision-making style develops. Individual decision-making style is influential in his/her well-being. Decision-making styles differ from person to person, and the same decision-making style cannot be suitable for every decision-making scenario. However, not all decisions are made in the same manner. In accordance to the situation, type of the decision-making problem, characteristics of identification and problem-solving, and interaction with others in the realization of certain activities, decision-makers use different decision-making styles (Bulog, Matić, Dadić, 2018).

Although adolescence is a crucial stage in one's life, relatively few studies investigated the relevance of decision making in this development stage (Crone et al., 2003; Tuinstra et al., 2000 in: Baiocco et al., 2009). Most empirical research has examined the relationship between decision-making style and career development variables (Mau, 1995; 2000; Payne, Bettmen and Johnson, 1993; Phillips, Friedlander, Pazienza and Kost, 1985 in: Bacanli, 2012), but the rare are the ones that focused on the relationship between decision making and academic achievement. Namely, some studies analyzed secondary school students' decision-making styles and academic achievement (Bala, Kaur and Singh, 2017), targeting middle adolescence.

However, according to the authors' knowledge, these analyses were not done among university students, targeting the late adolescent stage, especially in the European context. Thus, this paper targets the late adolescence stage, aiming to analyze decision-making styles in terms of academic achievement among young adults; final-year university students in Croatia. This research can help students and higher institutions recognize the importance of decision-making in this development stage of life.

Literature Review

Decision-Making Style

Decision-making is a part of every, big or small, private or business, individual, or group activity. As a term, it is defined from several different perspectives, mainly depending on the researcher's primary discipline and his point of view. Decision-making is a reasonably complex process that characterizes every human being because without making decisions, we cannot live, develop ourselves or make achievements. It is an essential aspect of every individual's daily activity (Bulog, Matić, Dadić, 2017).

We all differ in the way we make decisions. The processes or approaches that individuals follow in making decisions are known as decision-making styles (Janis and Mann, 1997; Scott and Bruce, 1995; Davids, Roman and Leach, 2016). According to Scott and Bruce (1995) decision-making style can be understood as (1) a habitual pattern that individuals use in decision-making, and (2) as individuals' characteristic mode of perceiving and responding to decision-making tasks. Decision-making style has been defined as an individual's typical model of interpreting and responding to decision-making tasks (Harren, 1979). Namely, through decision-making style, we have a way to understand why a person, while facing, apparently identical situations, uses such different decision-making processes (Nutt, 1990). Although most persons tend to use a specific decision-making style more often than the others and possess a preferred, dominant style, individuals may adopt their decision-making style according to a given situation (Pennino, 2002 in: Bulog, Matić, Dadić, 2017).

Decision-making style is called a situation that includes the approach, reaction, and action of the individual who is about to make a decision (Philips, Pazienza, and Ferrin in, 1984 in Deniz, 2011, p. 106). The decision-making style refers to the unique manner in which individual approaches, responds to, and acts in decision-making situations (Arroba, 1977; Payne, Bettmen and Johnson, 1993 in: Bacanli, 2012).

Several researchers have proposed different decision-making styles, starting with Janis and Mann (1977), who proposed a decision-making style that ranges from vigilant to defensive avoidant. Johnson (1978) proposed decision-making styles regarding the manner individuals gather information and how they understand it. Harren (1979) identified three styles that are researched the most and studied the most in the literature: rational, intuitive and dependent. Pazienza and Ferrin (1984) added the avoidant style, while Scott and Bruce (1995) added a spontaneous decision-making style. These decision-making styles ranged from processes in which there was a thorough evaluation of the available decision making alternatives to those based purely on intuition and feelings (Davids, Roman and Leach (2016). Further, Leykin and DeRubeis (2010) identified nine decision-making styles that range from a methodological and systematic approach to dependent, spontaneous, avoidant and anxious forms of decision-making.

In their systematic review, Davids, Roman, and Leach (2016) provided a precise categorization of the plethora of different decision-making styles in the literature and often overlapped one another. They underwent them under one common denominator and divided them into two categories: adaptive and maladaptive decision-making style. As seen in their review paper, an adaptive decision-making style concerns processes that could yield the best course of action. In contrast, maladaptive concerns decision-making processes that would hinder or interrupt an attempt to achieve the best course of action.

For this paper's purpose, the most accepted and commonly used in decision-making styles research - Scott and Bruce's (1995) definition and classification of decision-making styles will be followed. Namely, they define decision-making style as a habitual pattern individuals use in decision-making or individuals' characteristic mode of perceiving and responding to decision-making tasks, and they distinguish the following decision-making styles:

- Rational decision-making style (RDMS), characterized by thorough research for and logical evaluation of alternatives.
- Intuitive decision-making style (IDMS) relies on hunches and feelings.
- A dependent decision-making style (DDMS) is characterized by a search for advice and direction from others.
- Avoidant decision-making style (ADMS) is specific to individuals who attempt to avoid or postpone decision-making.
- Spontaneous decision-making style (SDMD) is determined by a feeling of emergency and by trying to finalize the decision-making process as soon as possible.

Academic Achievement

Academic achievement represents performance outcomes that indicate the extent to which a person has accomplished specific goals that were the focus of activities in instructional environments, specifically in school, college, and university (Steinmayr et al., 2014). Academic achievement can also be seen as the aftereffect of education, best determined by continuous assessments and examination throughout students' education period. This approach would define academic

achievement as the level of schooling one has completed and the ability to attain success in their self-studies (Kaloiya et al., 2017).

Among the many criteria that indicate academic achievement, some indicators are rather general, such as procedural and declarative knowledge acquired in an educational system, while grades or performance on an educational achievement test represent more curricular-based criteria. Educational degrees and certificates are seen as cumulative indicators of academic achievement (Steinmayr et al., 2014). Academic achievement greatly influences a person's life, as it defines whether one can take part in higher education, determining their vocational career. Besides the utmost importance for an individual, academic achievement reflects a nation's wealth and prosperity (Steinmayr et al., 2014).

Endya Stewart (2008) differentiates two characteristics that significantly influence student achievement: individual-level and school-level characteristics. The first includes student effort (characterized by the level of school attachment, involvement, and displayed commitment), peer associations (an essential factor in adolescent socialization and motivation influencing the outlook students to adopt toward achievement), and parental school involvement (presence of parents through attendance at teacher conferences and taking part in school activities such as open houses and social activities). School structural characteristics comprise a school's structure, staffing, organization, resources, and climate.

Decision-Making Style and Academic Achievement

Decision-making is an activity taking part in everyday business and individual situations. Decision-making is incredibly complex during adolescence, which is a critical period of transition, as the adolescent has to undergo the evolution task of making the best choices for his future independently (Filippello et al., 2013).

Decision-making style, as a potential predictor of academic achievement, has been subject to thorough research with various outcomes and conclusions. Filippello et al. (2013) found no significant differences in how students with high and low academic performances make their decisions. However, significant differences in self-efficacy suggested that students with high academic performance are more efficient in making decisions in daily life than individuals with low decision-making self-efficacy, whose academic performance was also lower. In research on secondary school students, Bala et al. (2017) found a significant relationship between decision-making styles and academic achievement. Furthermore, they suggest a significant relationship between academic achievements and rational, avoidant, and spontaneous components of decision-making style. In contrast, such a relationship does not exist between an intuitive component and academic achievement.

In a study among university students, Aly et al. (2017) determined a significant effect of career decision-making self-efficacy (a student's belief about the achievement of tasks necessarily required for making career decisions) on academic achievement. Also, they found no significant gender differences in both career decision-making self-efficacy and academic achievement. Although the mentioned studies do not come to a joint conclusion, indicative is that a particular characteristic linked to decision making has always been determined as significantly influential on the students' academic achievement.

Methodology

Research Goal

Considering that decision making styles influence human behaviors in many aspects, this paper targets final-year university students in Croatia, examining their decision-making styles in terms of academic achievement. Thus, the main research goals are:

- to evaluate decision –making styles in the late adolescence stage, and
- to evaluate the association between decision –making styles and academic achievement among late adolescents.

Measures

Due to its wide application and confirmed validation, the General Decision - Making Style (GDMS) instrument (Scott and Bruce, 1995) was applied. It encloses 25 items that measure five different decision-making styles: rational (RDMS), intuitive (IDMS), dependent (DDMS), avoiding (ADMS), and spontaneous (ADMS) – five items per each style. The scale uses Liker's responding, with items ranging from 1 to 5 (1 indicates strong disagreement and 5 strongly agree with the statement). High scores represent the high tendency of respondents to use a particular decision-making style when making decisions. Cronbach¨s Alpha coefficient for the whole instrument was .74.

To measure academic achievement level, two variables were concerned: objective academic achievement (OAA) variable, and subjective academic achievement (SAA) variable. OAA includes a question about grade point average, while SAA refers to the item that rates satisfaction with the overall academic achievement level on a 5-point scale.

Data Analysis

An online questionnaire was used as the primary research instrument. The statistical processing of gathered data was made using SPSS software. Correlation analyses were performed to evaluate the relationships among decision-making styles variable and variables of academic achievement. Group differences were analyzed using multivariate analysis of variance (MANOVA). The internal consistency of the overall GDSM scale was measured by Cronbachs alpha.

Sample

The sample comprises 77 final year students at the Faculty of Economics, Business, and Tourism at the University of Split. As Table 1 shows, the research sample was dominated by female students (64.9%), and the age range was between 23-25 years representing the late adolescent stage. Further, 88% of students had some work experience during studies indicating their proactivity and motivation for practice knowledge.

Table 1: Research samples' main characteristics (n=77)

Variable		Mean	SD	Percentage
Gender	*M*	1.65	.480	*35.1*
	F			*64.9*
Age	*21*	*23.31*	*1.029*	*3.9*
	22			*19.5*
	23			*28.6*
	24			*37.7*
	25			*10.4*
Working experience	*Yes*	1.12	.323	*88.8*
	No			*11.7*

Results and Discussion

In order to answer the research questions, the statistical analysis is presented in this chapter. Table 2 displays means, standard deviations, and associations between all measured variables: five decision making styles and two academic achievement variables. Results show that the intuitive decision-making style (IDMS) is the dominant decision-making style among university students. It is prevalent in the research sample (M=3.10). It is followed by RDMS, which relates to the decision-making forms of a thorough investigation of possible options (M=2.73). Next is DDMS that refers to the assistance of others in advice and directions when making decisions (M=2.61), then style that refers to the avoidance of taking action (M=2.34), and the last one is SDMS (M=2.19). It can be concluded that students are prone to use intuitive and rational style when making their decisions. The low mean value of dependent, avoidant, and spontaneous style indicated that students avoid these styles when making important decisions related to their academic achievement.

As data presents, an intuitive decision-making style can be considered a primary and dominant style among late adolescents. Considering that the research sample is dominating by females, these results are not surprising. Namely, women are much more prone to rely on emotion, feelings, and details when making decisions than men. The most substantial relationship is found between avoidant and dependent decision-making style (r=0.817) and spontaneous decision-making style (r=0.716), while there is no correlation between rational and dependent, avoidant, and spontaneous styles.

Considering the association between decision –making styles and academic achievement among late adolescents, Table 2 reveals that there is a negative statistical significant relation ($p<.05$) between three decision-making styles (DDMS, ADMS, and SDMS) and the objective academic achievement variable (OAA) as well as with subjective academic achievement level (SAA). As decision-makers' tendency toward DDMS, ADMS, and SDMS increases, academic achievement level decreases, and vice versa, meaning that when academic achievement level increases, students will show a lower tendency to use DDM, ADM, and SDM styles. Thus, the dependent, avoidant, and spontaneous component of the decision-making style is negatively associated with young adults' academic achievement. Since these decision-making styles are characterized by an absence of self-control over the decision-making process (search for advice and directions from others, attempts to avoid decisions, fast decision-making process), it is quite understandable why these styles lead to the decrease in academic achievement. Among plenty of factors that affect adolescents decision-making behaviors; poor indecisiveness, self-control, low self-esteem, loss of self-confidence, emotional arousal, sensitivity, sudden emotional reaction (Cifti, 2015) are factors that can result in making poor decisions affecting his/her academic, private or business achievements.

Table 2: Summary of means, SDs, and correlations between measured variables (n=77)

	OAA	SAA	RDMS	IDMS	DDMS	ADMS	SDMS
OAA	1						
SAA	*.701***	1					
RDMS	.123	.208	1				
IDMS	-.143	-.185	*.396***	1			
DDMS	*-.284**	*-.387***	-.008	*.457***	1		
ADMS	*-.432***	*-.493***	-.091	*.468***	*.817***	1	
SDMS	*-.366***	*-.412***	-.096	*.433***	*.545***	*.716***	1
Mean			2.73	3.10	2.61	2.34	2.19
SD			.689	.478	.760	.820	.595

**. Correlation is significant at the 0.05 level (2-tailed).*
***. Correlation is significant at the 0.01 level (2-tailed).*

It could be stated that a positively active decision-making style concerning academic achievement in the late adolescence period among university students is a rational decision-making style. As shown from the table, RDMS does not show a significant relationship with academic achievement level variables (p>.05), but the associations are positive.

Further, to test whether or not final-year university students' tendency toward decision-making styles differ concerning the gender variable, a multivariate analysis of variance (MANOVA test) is performed. RDMS was excluded from the model because the dependent variable must correlate well to use this test. These differences are presented in Table 3. The MANOVA analysis indicates that F value in the test of gender is significant at the .000 alpha level. Two differences (IDMS and SDMS) are significant at the .05 alpha level, and two are not significant (DDSM and ADSM), where the alpha level is above .05.

Table 3: Results of MANOVA test for gender (n=77)

Source	Dependent Variable	Female Mean	Male Mean	F	Sig.
Gender	IDMS	3.21	2.90	7.980	.006
	DDMS	2.61	2.60	.008	.930
	ADMS	2.39	2.24	.591	.444
	SDMS	2.35	1.89	11.732	.001
Hotellings Test value=.362, F=6.519 Error df=72.000 Sig. .000					

The female students are found to show a greater tendency toward the use of intuitive and spontaneous decision-making style than male students do. These differences regarding intuitive and spontaneous decision-making style may be dominant because of the general differences between man and woman. The idea that men and women differ in their emotional responses has been present in the literature for years. However, the model's insignificant differences indicate that students, regardless of their gender, are prone to rely on dependent and avoidant decision-making styles when making decisions.

Conclusion

The study's primary research goals were oriented to the evaluation of decision–making styles, as well as the association between decision–making styles and academic achievement among late adolescents. The target population was final year university students. The findings suggested that most students tend to use intuitive decision-making styles when making their own decisions. Hence, intuitive decision-making style is the prevailing decision-making style among late adolescents in our sample. Female students are found to show a greater tendency toward intuitive and spontaneous decision-making than male students.

Further, results revealed a statistically significant negative association between dependent, avoidant, and spontaneous decision-making styles with objective and subjective academic achievement variables. It is conditional that decision-making styles impact, but negatively on the students' academic achievement and vice versa. It seems that with an increase in academic achievement, students' orientation toward dependent, avoidant, and spontaneous decision-making styles will decrease. However, rational decision-making is positively associated with academic achievement, but this relationship is not significant.

Such finding highlights the importance of recognizing students' decision-making styles. University teachers also should be aware of the usefulness of decision-making styles for learning and overall achievement level, because a specific characteristic linked to decision-making style can be significantly influential on the students' academic achievement.

Decision-making style is just one of the plenty variable that influences academic achievement, and there are so many contexts in which decision-making style can be studied. So, considering these two variables, in this kind of context, can be a limitation of this study, meaning that future research could consider some other contexts and some other variables - contextual factors. The research sample has its limitations also, and the broader sample could upgrade insights and knowledge of the analyzed issue. In that line of taught, a more significant number of observations could be accomplished, observing not just one university in the country. Nevertheless, data were collected using self-report questionnaires with subjective opinions of respondents. Some other report instruments could suit better for this topic.

Nevertheless, even with these and many other limitations one can find for this study, the findings of this study will be useful for late adolescents - current and future university students and teachers. Namely, it can help students better understand how they are making decisions and how it can help them improve their achievements. This study represents the only first step in understanding the relations among decision making styles and academic achievement in a late adolescent sample. These results extend the previous knowledge related to the decision-making process.

Abstract

One of the basic objectives of implementing the lean management concept in companies is to achieve adequate operational efficiency, eliminate waste and reduce operating costs. Lean Management is the concept that focuses on the long-term perspective in its approach. One of the most frequently implemented methods of this concept is 5S. 5S is an easy to implement set of rules for eliminating waste, organizing the workplace or increasing employee involvement. The implementation itself is quite simple, however, the problem is to maintain the benefits resulting from the implementation activities in the long term. 5S comes from 5 Japanese words - Seiri (Sort), Seiton (Set in order), Seiso (Shine), Seiketsu (Stadardize) and Shitsuke (Sustain). The aim of the article is to present the results of a survey conducted in a production company regarding the effects of implementing this method in a factory in Wroclaw, Poland. The article discusses issues such as the evaluation of the method implementation, employee involvement, benefits of implementation processes

Keywords: lean management, 5S, process optimization, employee involvement

Introduction

Ghodrati et al (2012) claims that 5S is a method used to ensure that the quality of the working environment is maintained in order to reduce the area used, enhance employee involvement, reduce errors, create a proper and well-organised workplace, maintain discipline and cleanliness. Osada (1991) claims that the first step in the process of taking care of production quality should involve the implementation of 5S. The 5S method is a practical way of visual control which consists in creating, maintaining appropriate organization and continuous improvement of the workplace. It does not matter what the nature of the work is. 5S concerns not only production workers - physical work, but also administration workers - office work. Gapp et al (2008) emphasize that the 5S method was first applied in the automotive industry and later extended to other industries and sectors. 5S is a key element of TPS (The Toyota Production System) and is known to have been implemented for the first time in this factory.

Silveira (2006) states that the practical 5S approach is beneficial to every organisation as it helps to increase the quality of "life" for all the links in the company, i.e. employees, customers, suppliers, etc. In his article, Hubbard (1999) highligts that the implementation of 5S also contributes to the identification of problems arising in everyday operational activity. Singh et al (2014) mentioned that the implementation of 5S makes it possible to increase the involvement not only of operational employees but also of managers in making good decisions.

Masaaki Imai (2006) a guru and a forerunner of continuous improvement of kaizen, points out the benefits of implementing 5S from the point of view of the employee as well as management. Employees should know that with 5S their work environment will be clean, hygienic, pleasant and safe, and that all kinds of waste will be eliminated by minimizing the need to look for equipment, making the work

of operators easier, reducing workload and freeing up space. Whereas the management should be aware of the fact that the successful implementation of 5S at the position:

- helps employees to learn self-discipline so that the employees involved will strive for standardisation;
- allows to pay more attention to the emerging waste, and recognizing the problem is the first step to eliminate waste and strengthen 5S;
- easily regulates malfunctions in different areas of operation;
- makes quality deficiencies visible;
- improves work efficiency and reduces operating costs;
- reduces unnecessary movements, unnecessary transports, unnecessary inventory;
- allows you to identify and solve problems with storage processes such as receiving, storing, sorting or picking and delivering materials;
- identifies and resolves problems related to production imbalances, machine breakdowns, forklift trucks or delayed deliveries;
- reduces the number of accidents at work.

The 5S method is widely known and accepted in many industries - in particular in manufacturing and services. Due to the limited number of pages of the study, the authors of the paper have decided to present only its abbreviated description from theoretical perspective. The table below presents the theoretical approach to the 5S steps including its definitions.

Table 1: Particular 5S steps

Japanese term	Definition	English term	Typical definition
Seiri	Organized: Distinguish between the less essential and necessary	Separate	Get rid of everything not needed.
Seiton	Neat: Put things where they best meet their functional purposes.	Straighten	Put things away
Seiso	Clean: Inspect for and eliminate waste, dirt and damage.	Scrub	Clean and paint.
Seiketsu	Standardized: Maintain known, agreed upon conditions.	Standardize	Develop rules to keep everything clean and organized.
Shitsuke	Disciplined: Practice the habit of doing what is required even if it is difficult	Systematize	Audit the workplace to ensure the rules are being followed.

Source: Patten, 2006

The aim of the article is to present the results of a survey conducted in a production company regarding the effects of implementing this method in a factory in Wroclaw, Poland.

Survey Results

The subject of the survey involved a production company from the paper industry employing over 350 people in Poland. It is one of 10 factories operating in Europe, belonging to an international concern - a leading supplier of products for European customers, as well as the world's leading manufacturer providing top quality selected paper products for all individual and institutional customers. The company, including the Polish one, is constantly developing its activities so that the products and services are the best for all target customers. It puts emphasis on the high quality of its products with

absolute observance of the rules of occupational health and safety. The company is aware of the fact that in order to improve the effectiveness of the implemented processes it is necessary to minimize or even eliminate activities that do not add value. Aiming to gain a competitive advantage, better quality of products, increase efficiency, improve working conditions, safety at given positions, but also to enhance the efficiency of employees, machines and equipment, the company has decided to use the concept of lean management starting with numerous training and then introducing the 5S method in selected pilot areas. According to the managers, success depends to a large extent on the employees and above all on teamwork. Every employee plays an important role in the production process and their involvement in improvement processes has a significant impact on the efficiency of the entire company.

Test Methods and Survey Group

The aim of the research was to assess the use of 5S method on two production lines in the company as well as to identify the involvement of employees in its practical implementation. Based on the obtained results, the analysis and evaluation of the implemented 5S method will be carried out to enable better implementation of 5S in other areas of the company. The article will present the answers of the employees concerning, inter alia, their evaluation in terms of the implementation of the 5S method, training, involvement in 5S actions, benefits.

The survey was conducted in July, August 2019 with the use of a survey questionnaire among production-related, administration and direct production employees working at workstations. The questionnaire was anonymous and, considering the way the survey questionnaire was delivered, the method of distribution and in-depth face-to-face interviews were mainly used. Another tool used included observation sheets. An Excel spreadsheet was used to analyse the survey data.

The information obtained by the authors was not only quantitative (measurements of results), but also qualitative (direct interview, direct observation, possible statement of an employee). The respondents were supposed to answer 20 questions, including two from particulars. The questions were mainly closed questions, but also open questions, where the respondents had the opportunity to indicate their own answer, express their opinions. This article will present the answers to 12 questions including 2 regarding the particulars.

The production company has more than 10 production lines. An average of 20 people work on each of them in 3 shifts. A few years ago there were attempts to implement the 5S method in many areas simultaneously, but unfortunately it ended up being a failure. The first step was taken then - the 5S method was introduced, but unfortunately it turned out to be more difficult to sustain and continue it. There was less commitment on the part of employees, there was no standardization, self-control and above all self-discipline. This time a decision was made not to implement it everywhere, only 2 pilot production lines were selected where 5S audits are being carried out at the moment. Therefore, the target research sample included 43 employees of only these two production lines. The respondents included managers, area engineers and operational employees. All respondents were employed on a permanent basis. 36 employees responded to the survey which constituted about 83.72% of all classified employees. Such a percentage of completed questionnaires was mainly due to the involvement of area engineers and people cooperating with them, who were willing to help and support them in achieving the survey results.

The largest group in terms of age was made up of employees aged between 30-40 i.e. 12 employees, and later successively up to 29 year-olds in the number of 11 employees, 41-50 year-olds i.e. 7 respondents and the last age groups 51 year-olds and above with the total number of 6 employees (Figure 1).

Figure 1: Age of employees in the analysed enterprise
Source: Elaboration based on the surveys carried out.

As far as seniority is concerned, 35 respondents replied, 1 person did not respond (Figure 2). The largest group were employees who worked less than 1 year, i.e. 11 people. The second group differing only in one employee were employed for 1 to 3 years. The third and fourth group consisted of employees with experience from 11 to over 20 years in the total number of 11 people. These employees are very experienced and have a lot of interesting ideas. At the very beginning of the implementation of the 5S method, this group was resistant to changes, saying very frequently "that they have more important things to do at work, that it is unnecessary, just a waste of time", knowing that previously there were attempts to implement 5S and unfortunately it ended in failure. Nevertheless, this group has a big impact on other employees and now most of them know the benefits of introducing 5S in the company. The least numerous group included workers employed for 6-10 years, i.e. 2 people and for 4-5 years, i.e. only 1 person.

Figure 2: Seniority of employees in the surveyed enterprise.

Detailed analysis of research results concerning the implementation of the 5S method in the analysed company

The first question concerned the employees' assessment of the implementation of the 5S method in the company (Figure 3). The authors wanted to check how the respondents perceive the introduction methodology, what attitude they have, what is their assessment of the implementation method. It is therefore noteworthy that the answer "very badly" was indicated by only 1 person, although three employees had no opinion at all on this subject. Based on the data obtained from the survey, it turned out that out of all the respondents, four people, i.e. 11.76%, do not know what 5S is at all. On the basis of other subsequent questions asked in the survey, it turned out that these 4 people have not participated in previous training on the 5S method, so they are not entitled to make assessments. According to the direct interview, the author concluded that people who did not have training do not know all the benefits of using the 5S method, but they see its effects and notice the problems that arise. Out of 34 answers given, almost 62% evaluated well and probably well. 5.88% rated it very well. The result achieved in this way indicates that the employees of these two selected production lines are aware of the possibilities and benefits that can be obtained from the implementation of the 5S method.

Figure 3: The structure of answers to the questions about the evaluation of 5S implementation in the enterprise

Source: Elaboration based on the surveys carried out.

When asked about their training in the 5S method (Figure 4), almost 70% took part in it and they understood it. 13.89% of respondents do not remember if they had any training at all. This result is related to the employees with longer work experience who seem to have already had training, but are not entirely sure. Considering the failure of the first approach to the implementation of the 5S method, this time they did not participate in it. Ex aequo 8.33% of the respondents did not undergo training at all and did not know what the method was. They were mainly newly hired employees. It is important that after the survey and the results were presented, the company's managers made a quick decision to internally train the staff and display on board 5S method's characteristics of the benefits and types of waste for better understanding and recognition.

Figure 4: The structure of answers to the questions about the training in 5S method in the enterprise

Source: Elaboration based on the surveys carried out.

In response to the question about understanding the 5S method training in terms of changes in the company (Figure 5) there were over 83% of positive answers (yes and a little). Only 11.11% did not know what these changes are and why which was obviously due to lack of previous training. To 5.56%, i.e. 2 employees, it did not matter at all.

Figure 5: The structure of answers to the questions about understanding the training in the 5S method as regards changes carries out in the enterprise.

Source: Elaboration based on the surveys carried out.

The next question concerned the employee's assessment of his department/line's involvement in 5S operations (Figure 6). The results can be considered satisfactory, as 70.59% indicated a good, very good and even excellent answer. 2 people did not give an answer. Only one person marked terribly, and 5 employees assessed it poorly. In this question, the respondents had the opportunity to write down

why they assessed this way. Not many of them gave the reasons for such a situation, but those who did, probably know about the hardships and are aware that the 5S implementation is a long-term process and may be subject to various fluctuations, which are related to the involvement of employees or the dynamics of company development. Not all employees observe the introduced changes, they do not want to adapt, they resist because they do not see the need for changes. While conducting interviews with employees or 5S audits, not all employees seemed to know and understand exactly the essence of 5S. Most often, they identify it only with cleaning, tools arrangement, or marking out the put-down boxes, forgetting that 5S brings also other benefits. Other reasons for the lack of involvement in 5S actions mentioned by the employees also include: the lack of discipline, no self-discipline of the staff, no time or just "no, because I don't - because I have to".

Figure 6: The structure of answers to the questions about the evaluation of involvement of a department/line in 5S operation

Source: Elaboration based on the surveys carried out.

After the introduction of 5S, do you see an improvement in your job? - This is another question asked to the respondents. 61.76% of employees answered yes (Figure 7). They have the potential and they share the whole burden of implementing 5S, they can see that they can work more effectively than before. They think 5S means easier work, better ergonomics, a friendlier work environment, the possibility of doing something more, realizing one's own improvement at the workplace, but also safer work. 5.88% respondents do not think that 5S improves work because the most important thing - as they say - is production, not "some sort of cleaning" or tidying up the tools in the cabinet and documentation. The fact that you use, for example, 5 tapes or films on one shift, and the supply is for the whole week or month, does not matter. According to the employees: "there has always been a supply and unfortunately will be, and you shouldn't worry about it," because "it will be used anyway." According to some employees, it does not matter whether it happens in one month, two or six months - the company will still have to pay the costs. It is regardless of the fact that this is frozen money, which could be used for other purposes, such as new investments or dissemination of an employee suggestions system . Moreover, there are cases when an employee looks for tools - no problem, after all - "always has and will always look for them". For 26.47% of the respondents it does not matter whether there is a visible improvement of work at the workplace. 5.88% of respondents consider it only a bother, a new idea, which, as with the earlier implementation of 5S in the factory, may not succeed. The latter workers claim that they know where to look for tools, or they openly say: "why should we make a selection, after all, it may be useful" in the near future.

Figure 7: The structure of answers to the questions about a visible improvement in the job after implementing the 5S method.

Source: Elaboration based on the surveys carried out.

In response to the question about the greatest influence of particular 5S on the good organization of the workplace (department, warehouse, production area), so that it is clean, ordered and properly organized, the respondents had to choose one of six indicated answers, such as: selection, systematics, cleaning, standardization, self-discipline, all of them are important (Figure 8). 66.67% of employees indicated that all of them are important. This means that most are aware of the effects that can be achieved in the short and long term. Knowledge of individual 5S, implementation and control should become a natural action and a habit of every employee in their daily work. At the beginning of the implementation path most employees associated 5S only with cleaning and even said "I'm not here to clean", "this cleaning has to be done by someone else, I have more important things to do", "there is an outside company to clean" or "we can clean, but only when the machine is stopped" etc. Many people were against it, and now they know that 5S is not just about cleaning, they take all the steps.

23.33% of the respondents answered that systematics. Searching for tools, tapes, documents, forklift trucks was everyday life. At the beginning of the 5S implementation in the company, employees often expressed their negative opinions such as: "I know where it is, there is no need to create a special place", "why do it, on the second shift and they will do it their own way", "only I use these tools", "it can all come in handy". And now employees realize that all the things they need should be in the right amount and in the right place because only this approach will make work easier, use resources properly, reduce unnecessary employee movements, reduce time, increase job efficiency and give more opportunities for optimization. The third place was taken by cleaning. This is a very important element noticed by the respondents. The employee should know that by keeping the workplace clean, he/she has an impact on reducing breakdowns, prolonging the time of use of a machine or a given device. Cleaning is also a prevention, preventing damage, destruction. Selection, standardization and self-discipline have obtained the same number of indications each 6.67%.

Figure 8: The structure of answers to the questions about the impact of particular 5S on good work organization to make it clean, ordered and properly organized

Source: Elaboration based on the surveys carried out.

The growth in labour efficiency is a very important indicator for each company allowing to identify the products produced by one employee in a given unit of time. Thanks to higher efficiency, a company can produce more with a constant effort and thus improve its competitive position in the market. Factors influencing the increase of work efficiency include proper work organization, condition of machines and equipment used at work, competence, involvement or experience of employees. In response to the question whether the implementation of 5S is associated with an increase in work efficiency - 47.06% answered “rather yes” and “definitely yes” (Figure 9). This is a satisfactory result and indicates a high level of employees' awareness of the effects of the 5S method. In total, 32.35% of respondents indicated answers "rather not" and "definitely not". 20.59% of the respondents do not know or have no idea about it at all. Analysing this result, the management should carry out a 5S method reminder training, explain the impact of 5S on work efficiency and at the same time explain what work efficiency is, how it is calculated and what benefits it can bring to the company.

Figure 9: The structure of answers to the questions about the impact of 5S implementation on the growth of work efficiency

Source: Elaboration based on the surveys carried out.

The next question concerned the employees' knowledge of the benefits of using the 5S method (Figure 10). The result is really very good. 80% of the employees have answered that they know. 16.67% i.e. 5 respondents do not know what the 5S method is at all and what the benefits may be. Only 1 person does not know the benefits at all. It is very important to note also the fact that nobody indicated the answer that they know what the benefits are, but do not want to apply them. 6 people did not give an answer at all. During an in-depth interview with the employees it turned out that most of the employees know the benefits of using the 5S method, they can list them. As mentioned earlier, employees know about the waste on their production lines, their areas. They were very much involved in the training and were not afraid to talk about waste in their jobs, as demonstrated by the losses they noticed and written down. Respondents know that if 5S is not implemented in a given area, they may be more or less exposed to the occurrence of losses resulting from e.g.:

- waiting for needed raw materials, materials for production,
- waiting for the truck,
- the inability to find the right tools on time, because they can be put away anywhere, or only some employees know where certain tools or materials are,
- too much stock,
- overdue products,
- misused space due to over storage of things in particular areas,
- defects caused by the lack of order and damage to components,
- unnecessary movements by employees,
- dirty machine and equipment surfaces, or
- lack of standardization and others not mentioned.

Figure 10: The Structure of answers about the knowledge of applying 5S method

Source: Elaboration based on the surveys carried out.

Benefits from the use of 5S observed by employees - this is another question asked to the respondents (Figure 11). Employees could indicate more than one of the 8 different benefits contained in the survey on the basis of the author's knowledge and experience, they could also write down the benefits they noticed that were not mentioned in the survey form. The employees added only one benefit - a faster access to materials, tools - which ranked last. In total 69 different benefits were marked. The biggest benefit the employees observed was the facilitation of work, i.e. 23.19% of the marked answers. The result is the best, but it is a pity that not greater. Unfortunately, still many employees perceive 5S as an additional job, an additional duty rather than a facilitation of everyday, routine activities. The second

advantage noted by the respondents with 23.19%, i.e. a higher level of health and safety at work is worth noting. This is a very good result and very important as it contributes to avoiding hazards, dangers, accidents at the workplace in the future. Through its systematic approach 5S allows staff to work in an orderly place. Cleaning, as mentioned earlier is prevention against unexpected failures. A failure to clean machines on an ongoing basis, according to the adopted schedule, may contribute to sudden unplanned downtime - breakdowns and repairs. A mess after a sudden, quick repair can lead to accidents, reduced productivity, a limited use of machines and equipment. Standardization simply requires working in compliance with health and safety regulations. Self-discipline allows workers to keep a particular workplace safe, and self-improvement contributes to even better improvement and elimination of waste, paying attention to even better standards while respecting the applicable health and safety rules. The third place, with a share of 17.39%, was occupied by improved well-being of employees resulting, among other things, from better ergonomics of work, possibilities of self-improvement, possibilities of improvement and better communication with the management. The fourth benefit consists in the reduction of pollution with a share of 8.7%. The fifth place, i.e. 7.25%, is the reduction of problems from the machine park, as mentioned earlier. There are fewer breakdowns, less downtime because the machine is not left on its own, it is systematically cleaned. The sixth place is the cost reduction with 5.8%. The seventh position with a 4.35% share was occupied by quality improvements and increased production capacity ex aequo.

Figure 11: The structure of responses regarding the benefits observed by the employees resulting from the application of 5S method in an enterprise

Source: Elaboration based on the surveys carried out.

Only about 53% of the respondents answered the open question about the greatest benefits of implementing 5S. 21% of the respondents wrote that there are no benefits, whereas the remaining employees indicated the four most important ones in their opinion. These are: everything in its place - it is easier to find the desired item, greater efficiency, cleanliness and shorter introduction period of a new employee. The latter advantage allowed the production lines to save time through the creation of fixed put-down places, and the introduced instructions, OPL (one point lesson) significantly improved work and contributed to the elimination of frequently made mistakes.

Figure 12: The structure of responses regarding the greatest benefits of 5S implementation in an enterprise

Conclusion

The 5S method is a natural step towards continuous improvement, the beginning of future changes, obtaining greater productivity, a method that also allows the introduction and successful implementation of other lean management tools, methods such as TPM, Just in Time, SMED and others. Many small improvements at workstations can contribute to a better result in the future. A similar opinion on the benefits of implementing 5S in the enterprise can be found in Falkowski et al (2013).

The 5S method often seems to be simple to implement, but unfortunately it is more difficult to maintain the introduced changes. From the very beginning you can see both enthusiasts and opponents. Resistance to change, fear of additional duties or something new - these are often barriers that appear during implementation. Not everyone is ready to change the culture of work to more productive than before.

5S requires the involvement of all employees, management in the implementation of tasks, improved communication. It requires a change in the attitude of employees to eliminate waste at workstations and therefore in processes. It is important that employees are aware of the appearance of various waste in their actions leading to errors and defects, and consequently to costs. The 5S method can prevent their occurrence. However, in order for the 5S method to function as a method of continuous improvement, the whole company should know what benefits it can bring to the employee, management and organization. Every employee from the lowest to the highest level should be aware of the implementation, know the basic rules and undergo appropriate training. The benefit for the company will then include identification of the employee with the company and customer satisfaction. Conducted surveys have shown that employees of two production lines know the main benefits of 5S. At present, they are open to implementing changes and willing to introduce improvements. All they need is: knowledge, resources and support of the management. Employees know waste, they know the benefits of implementing the 5S method, but it is difficult with self-discipline. And now the role of the management and the person responsible for 5S implementation is important. Every day employees

should be made aware of the goals, benefits, until 5S becomes a habit of everyone in everyday work. Employees can see the changes, they work more smoothly, but still have to be motivated to follow and watch 5S every day. Compliance with the 5S method in the workplace guarantees among other things: cost reduction, inter alia, eliminating all waste, unnecessary activities, unnecessary movements, prevents losses and defects, makes work easier, shortens the time of performing individual tasks, clarifies work instructions, reduces delays, ensures better, constant and even high quality, higher efficiency of both workers and machines, higher level of health and safety at work by eliminating failures and accidents at work (e.g. the inspection of machines when cleaning), improves well-being of employees, promotes good contacts between employees of different departments and, most importantly, provides the necessary basis for further improvement of work and product quality. The results of the research carried out are consistent with the results of other researchers, e.g. Gupta et al (2014) in his article, authors stated "that introducing the 5S and kaizen rules brings great changes in the organisation, for example, increasing of effectiveness and efficiency in the processes, improved visibility of the process, improved morale and safety of the employees, reduced delays, searching time and dangerous conditions." Other authors Singh et al (2014) emphasize that "5S is an effective tool for improvement of organizational performance, regardless of organization type, size, its production or its service. Consequently, 5S technique would strongly support the objectives of organization to achieve continuous improvement in performance and productivity." Other authors Patel et al (2014) emphasize another aspect (corresponding to the research results presented in the article) that very essential is training of workers about the 5S rules.

Abstract

This paper aims to demonstrate the dualistic model of strategic planning with reference to Russian experience. There are two mainstreams of strategic planning. First is the social-economic strategies and the Federal law on strategic planning in Russian Federation. Second is formed by strategic presidential orders known as "may executive orders". We try to provide the systematic view on the institutionalization of strategic planning in the dualistic model. The model turns to be acceptable for the public management practice. However, it shows controversies and there are difficulties in implementation of the model. Inductive and deductive reasoning combined with critical analysis are employed in this paper. The contextual approach is used in this study as well.
By now the dualistic model of strategic planning was not identified. This paper will contribute greatly to the understanding of strategic management practices. The critical analysis of the strategic planning in a specific country helps to compare and improve the public governance in different countries around the world.

Keywords: Strategic Planning; Strategic Management; Public Management; Russian Federation; Legal Regulation.

Introduction

The planning as an inherent part of public management passed in Russia a complicated way from the predominant role in soviet times to the disuse in the post-Soviet first decades and back to the new start as strategic planning in 2000. The priority national projects were the first experiments in the goal-setting in 2000. Later the strategic planning started to institutionalize. Russia started to develop strategies of different kinds. Russia even has adopted a special federal law on strategic planning announcing that there will be a system of strategic planning. Quite a rare example of the legal regulation of strategic planning.

The topic of strategic planning in different countries with comparative elements became popular recently (Joyce, Bryson &Holzer (eds), 2014; Drumaux & Joyce, 2018). There were studies of the approaches to strategic planning in public sector (Joyce, 2015;). Some elements of strategic planning in Russia are discussed in academic publications in Russian academic circles (Vilisov 2016) and in international studies (Kudryashova E., 2014). However, the problem of the dualism in strategic planning shaping a special model was not in the focus of the academic publications. This paper is focused on this issue and to certain extent fills the gap in the current academic discussion.

Due to the complex and interdisciplinary nature of this research it requires the mixed-methods to be applied. The study shall cover both the content of the strategic documents and the practice of their application. We shall refer to the inductive and deductive reasoning as well as the critical analysis of the political trends. The contextual approach shall help us to identify the patterns and prospective of strategic management.

The paper aims to show the specific model of strategic planning elaborated during the recent decade in Russia. This model can be characterized as the dualistic model and can be identified not only in Russia. In the dualistic model the presidential strategic planning and other strategic documents form two parallel streams. The dualism has its implication for the political process and strategy implementation. This study contributes to the understanding of contemporary practices of strategic planning and gives a basis for further comparison and improvement of the public governance.

The main Features of Strategic Planning in the Russian Federation

The contemporary long-term strategic vision in Russia started from the national projects in 2002-2003. The national project of the 2000 were experiments and were presented in political statements.

By the 2008-2009 strategic planning started to institutionalize in two mainstreams. The first mainstream of strategic vision is the set of executive orders issued by the President of Russian Federation in 2009, in 2012 and in 2018. The executive orders of 2012 and of 2018, issued in May shortly after the inauguration. Together they are known in mass media under the term “May executive orders”.

The starting point of May executive orders was in 2009 - the Executive order of the President of Russian Federation N 536 of 12 May 2009 “On the basis of the strategic planning in Russian Federation”. Paragraph 12 of this document vested the general ruling of strategic planning in the President of Russian Federation as the head of Security Council. Following this on the 7th of May 2012 just after the beginning of the presidential term President Putin signed a bunch of 11 executive orders:

Executive order N 596 “On long-term state economic policy”;
Executive order N 597 “On the measures for implementation of state social policy”;
Executive order N 598 “On the advance of state health service policy”;
Executive order N 599 “On the implementation of state policy in the education and science”;
Executive order N 600 “On the measures aimed at provision for Russian citizens with affordable and comfort housing and at advancing the quality of utility services ”

Executive order N 601 “On the main directions of development of public management system”
Executive order N 602 “On the provision of inter-ethnic harmony”;

Executive order N 603 “On the implementation of the plans (programs) of building and development of the Russian Army, military forces and authorities and modernization of defense industry”;
Executive order N 604 “On the further development of the military services in Russian Federation”;
Executive order N 605 “On the measures for realization of foreign policy of Russian Federation”
Executive order N 606 “On the measures for realization of demographic policy in Russian Federation”

These executive orders outlined the main goals of development and articulated 218 tasks for the Government of Russia during the period of 2012-2020. The meaning of the May executive orders as the mainstream of strategic planning in Russia was not so clear at the beginning. With the time more and more attention was paid to those executive orders. It was steadily repeated that the failure to perform the tasks of May executive orders 2012 would be followed by personal public political liability of every member of the Government and of every head of the region.

154 of the tasks were accomplished and withdrawn from the special presidential control by May 2016. So, performance of the May executive orders 2012 was 88%. The information on the May executive orders is presented in a special section of the Russian Government web site http://government.ru/orders/selection/406/ .

In 2018 tradition of the May executive orders as strategic planning framework was affirmed by the only one new executive order. On the 7th of May 2018 the President issued the Executive order N 204 "On the national purposes and strategic tasks of development of Russian Federation for the period till 2024". This Executive order presented the following goals to be achieved by 2024: the provision of sustainable growth of population; increase of the expectancy of life till 78, increase of the effective revenues of the citizens and growth of pension benefits overhead inflation rate; double decrease of the poverty; improvement of the housing conditions for more than 5 millions families; speed up of the technological development and 50 % increase of the technological entities; accelerated implementation of digital technologies in economy and social sphere; Russia's entry in five major economies of the world and the speed of economic growth higher than average in the world keeping the macroeconomic stability including inflation rate not higher than 4%. One of the goals is formation of the high productive export oriented manufacturing and agriculture sector within the main sectors of economy. This sector is expected to develop on the basis of contemporary technologies and highly qualified personnel.12 national projects became key instrument of its implementation. National projects have no legal status and rather political instruments and means of accountability. The Government intended to introduce 91 indicators of the national projects into the statistic accounts in order to provide accountability and transparency.

The may executive orders tradition was interfered by the presidential order issued in July 2020. This order followed the constitutional reform 2020 in Russia (Verlaine M., Shashkova A.V. and Kudryashova E.V., 2020) and reflected the deep crisis in economy. The new Executive order N 474 "On the national goals of Russian Federation development for the period till 2030". The strategic goals were tailored for the reality and the crisis context.

The second mainstream of strategic planning initialization in Russia origins from programs of social-economic development issued according to the Federal law of Russian Federation of 20.04.1995 № 115-FZ "On the state prognosis and programs of social-economic development of Russian Federation". Programs of social-economic development were issued in 2001, 2003, 2006 non-systematically following the political needs (Smirnova, 2011). In 2008 the Concept of long-term social-economic development of Russian Federation for the period till 2020 was adopted. Finally, in 2014 the Federal law № 172-FZ of 28 June 2014 "On strategic planning in the Russian Federation" (further The Federal law on strategic planning) was adopted as a culmination of this second mainstream.

The Federal law gave the formal definition of strategic planning. According to the law of 2014 planning is elaborating and implementing the main guidelines of the Government of Russian Federation, plans of the federal state bodies and other plans. Planning focuses on the goals and priorities of the social-economic development and the goals of the national security articulated in the strategic documents. Goal setting is defined as the directions, purposes and priorities of the social-economic development setting and ensuring the Russian Federation's national security.

The mismatches in strategic documents

The Federal law on strategic planning aimed to streamline the strategic process in Russia. The system of strategic planning understood as the mechanism of cooperative interaction of the participants within drafting and implementing the strategic planning documents as well as their monitoring and controlling. The legislator meant to create a system of strategic planning including certain level of coordination of strategic documents.

However, it did not succeed in building a coherent system. The rhetoric question could be heard in publications if the Federal law on strategic planning is a "technocratic utopia" or a "sleeping institution"? (Vilisov, 2016). Strategic documents of the same level are in conflict with each other and the hierarchy is not clear.

The Law on strategic planning said nothing about the strategic documents issued before it's coming into force. The massive of strategic documents before the 2014 was not abolished. For example, the

status of the concept of long-term social-economic development of Russian Federation on the period till 2020 is unclear.
There are certain mismatches in the strategic documents. The strategic goal set in the concept of social-economic development in Russia till 2020 was to achieve the level of economic and social development corresponding to the status of Russia as the world leading state in XXI century, having the advanced position in the global economic competition with guaranteed national security and promotion of it's citizens' constitutional rights.

According to the Executive order N 536 of 2009 the goal of strategic planning was to create institutional, organizational and other measures to ensure the constitutional rights and freedoms, high standard of living for citizens and the sustainable development, defense and security for Russia on the basis of its resources' efficient use and capacities of civil society involvement.

It follows from the May executive order of 2018 that the strategic goal till 2024 is to facilitate breaking scientific, technological and social-economic development, increase of population, enhanced standard of living and comfortable living environment, opportunities for every person to develop.

The mentioned strategic goals are not completely different, but still the different emphasis is obvious. The goals of strategic planning are not unified and this causes further problem of communicating and delivering the goals for implementation (Kudryashova, 2019; Sattarova, Shokhin, 2018).

In 2016 the High school of economics issued the Report on monitoring of the implementation of Federal law on strategic planning. The Report stated that the system of strategic planning was not fully developed (High School of Economics 2016). Although the law always wish to impose order on chaos that was not the case for the Federal law on strategic planning and the strategic documents which keep on conflicting with each other.

The Report was focused only on strategic planning documents without general assessment of the strategic management after the Federal law on strategic planning. It gives general assessment and conclusions without case studies of the particular documents and mismatches in the specific goals. For example, it is stated that the goal-setting documents in the field of security were adopted on different levels from 1996 till 2015, cover different spheres related to the security issues and the list of those documents is provided. According to the Report all the security goal-setting documents are completely different in terms of general approaches. They include policies, concepts, doctrines. The methodologies of those documents have nothing in common.

The Report especially points to the whole array of sectoral or industry-oriented goal-setting documents. The Energy strategy of Russia till 2030 adopted by the Federal Ministry of energy and approved by the Government resolution of 13 November 2009 No 1715-p can be mentioned as an example of the industry-oriented document. The scopes of industry-oriented strategies were voluntary. The Rules on elaborating, drafting and adjusting the industry-oriented (sectoral) strategic documents (adopted by the Government decree of 29 October 2015 No. 1162) allow to define the scope of industry or sector quite discretionary. By the same way the coordination and the methodic are left to the ministry drafting the strategy, although the strategy has to be approved by the Government. This regulation opens to each ministry the way to work on its own agenda and contribute to the chaos in the industry-oriented strategic documents.

The industry-oriented strategies were adopted without coordination and consistency both before the Federal law on strategic planning and after it's coming into force. Those documents are found by analysts to be very difficult to interlink between each other and to match them against the main goal-setting social-economic documents of Russia. The bulk of the sectoral and industry-oriented documents are overlapping, conflicting or leaving the gaps.

The cross-cutting idea of the Report is the lack of unified comprehensive methodology for the strategic documents in Russia. Although the Federal law on strategic planning provided that there shall be a methodic support for strategic planning. The methodic support includes the adoption of guide-lines and

directives on the drafting and adjusting the strategic documents (part 12 of the article 3, Federal law on strategic planning).
The lack of comprehensive methodic support for strategic documents is considered to be the main reason for the chaos in strategic documents. In this respect we should spot one debatable assumption made in the Report. The analysts of Hight School of Economics assume that the strategic planning system is intended to be not a "centrally-organized" and "centrally-maintained", but a "distributed" system of strategic planning (High School of Economics, 2016). This assumption is not supported by facts or argumentation in the Report. In the historic retrospective and in the first decade of 2000s before the Federal law on strategic planning it was a top-down public strategic management.

The strategic planning which is not based on the presidential orders is heavily criticized and even not very well understood as we could see from the Report of High School of Economics. The presidential part of strategic planning is considered to be better organized and in fact it is better delivered to the public. Still both streams are developing as parallel or as complimentary.

Discussion and Findings

Two mainstreams of strategic planning were developed in Russia during recent decades. First is the Federal law on strategic planning in Russian Federation, the social-economic strategies and other related strategic documents. Second is formed by strategic presidential orders known as "may executive orders". These two mainstreams could not be considered just a long term and medium-term strategies within one system. At least the actors of strategic planning do not consider these two main streams to be parts of one strategy. The balance of two parallel strategic planning streams has been functioning already nearly a decade and it can be admitted that here we have a specific dualistic model of strategic planning. Although this model is far from being ideal.

In 2018 the Ministry of Finance proposed to scale down the strategic documents massive. The May executive order 2018 was considered by The Russian Government and the federal ministries to be de-facto the main strategic document. Therefore, it was suggested by the Ministry of Finance to establish it de-jure. The May executive order could be the "root document" of the strategic planning along with the Presidential Addressing to the Federal assembly. The May executive order according to the initiative of Ministry of finance could be on top of the hierarchy of strategic documents with the key role. It may be adjusted by annual Presidential Address to the Federal Assembly if necessary. This approach was presented by Ministry of Finance as a solution for the chaotic strategies and the spontaneous non-public interactions between different public bodies.

The Ministry of finance has given an example of conflicting strategies. The Energy strategy sets as a goal of the coal mining the increase up to 245M tons per year and another overlapping document - the State program of energy production development - requires 365-410M tons per year. The sectorial strategic documents as a category the most difficult for systematization. In 2018 the industry-oriented strategies give the best illustration for the overlapping and conflicting provisions.

The main political reason of the Ministry of Finance scale down proposal was that the numerous strategic documents make possible the non-public political processes at the interface of government, presidential administration, regions, State Council and Security Council (Dyachkov, 2019; Davydov, 2020). The communication between political and administrative sector has certain level of ambiguity. The vertical and horizontal communication between different actors within the strategic planning organized properly.

The initiative of the Ministry of Finance could destroy the diversity envisaged by the Federal law on strategic planning. The sophisticated set of strategic documents with levels, short, medium and long-term horizon could be simplified and diminished to only one or two documents. However, it never happened. The initiative to zoom in the strategic planning was not implemented. There was a wide discussion, but no substantial changes were made. Finally, the solution of the issue was referred to the technological field. The problem of the strategic planning documents systematization was considered later in the framework of the digitalization of official documents. The digital platform for the public

management shall include among others the concise compilation of strategic documents showing their scopes and links.
Therefore, it looks like the dualistic system is accepted by the actors of strategic planning process and even supported by them. There is a need both in concise presidential documents and sophisticated regulation with levels, terms and scopes even with the lack of unified methodological approach to the strategic documents. It is unlikely that one of the two strategic streams will be eliminated. This study is focused on Russian experience, however, within the Eurasian economic integration there is an intensive interchange of political practices and public management experience. It should be mentioned here that according to the survey on the systems of strategic planning the Eurasian Common Economic Space member-states (Eurasian Economic Commission 2014) the approaches to strategic management still have much in common on the post-soviet space. We can expect that the same dualistic model may appear in the countries -members of the Eurasian economic integration.

The dualistic model of strategic planning in Russia has its disadvantages but it has withstood the political and social tests. The problems of dualism have not been solved yet, but both streams of strategic planning are developing and compliment each other.

The Impact of Big Data on Financial Management: Labor Market Perspective

Olga PILIPCZUK

University of Szczecin, Szczecin, Poland
olga.pilipczuk@usz.edu.pl

Abstract

The paper examines the impact of big data technologies on financial management. The main contribution is the model of perspectives of big data impact on financial management supplemented with skills influenced the finance manager profession. The paper fulfills the research gap about the impact of big data technologies on the financial management considering both the literature analysis and labor market research. The purpose of the literature study was to identify the dimensions which drive the big data technologies in financial management. The labor market study was conducted to analyze the current core skills for finance managers influenced by big data. The common skills model with main perspectives of big data impact and core skills related was created.

Keywords: Financial Management, Big Data, Skill Model, Labor Market

Introduction

"In the past years, big data in finance has led to significant technological innovations that have enabled convenient, personalized, and secure solutions for the industry" (Talend 2020). As a result, big data (BD) analytics has managed to transform not only individual enterprises but also the entire financial services sector (Talend 2020). It also contributes to the sustainable development goals (Alvarez 2019).

Data volumes from unstructured and structured sources have been growing exponentially in recent years. Large complex data create business value for organizations, especially in finance domain, although almost all the industries are under the impact of big data.

The traditional analytical tools are not yet such efficient as big data technologies. Big data is based on advanced technologies and fast algorithms. Big data technologies help to complete the predictable tasks. Therefore, the finance managers will have more time to focus on complex, higher-risk, strategic work, instead of making routine operations. This will result in a link to the new skills of data management and IT technology skills and will bring new challenges to the labor market (CPA 2019).

According to Deloitte company "firms in the financial sector are under coming pressure to exploit big data to enhance service differentiation, reduce risks and improve performance" (Deloitte 2012).

Moreover, big data combined with Analytics 3.0, creates a substantial value by offering new business models which could help in better understanding of financial market needs (Ke, Shi 2014). Through processing transactional data and mining financial information using big data and

Cite this Article as: Olga PILIPCZUK "The Impact of Big Data on Financial Management: Labor Market Perspective" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Analytics 3.0 algorithms, the enterprise could improve the financial management, lower cost of capital, and generate the gross profit (Ke, Shi 2014).

The experts noticed that nowadays there is also a growing need for students to learn financial data analysis and reporting (Houser 2018). This drive the labor market's need to recruit the new generation of managers in sphere of finance. The universities should be prepared, offering education courses that meet market needs for new specialists.

The 2016 survey revealed that 59 percent of employers say data science and analytics skills will be necessary for accounting managers by 2020 (Forbes 2019). The number of companies deploying Big Data will double in the near future (Lawson et al. 2019). Big data, machine learning, AI, and the cloud computing are fueling the finance industry toward digitalization (Hasan et al 2020).

However, the current situation with COVID-19 has generated great uncertainty, that could have impact on finance labor market. The uncertainty powered by COVID-19 leads to fear and extreme volatility in financial markets (Chang et al. 2020).

Moreover, COVID-19 has not only caused uncertainty and volatility across global financial markets and economies but has also disrupted the college experience for many and has impact on the job market for finance students (FMA 2020). European Commission estimates that the most vulnerable segments of the working population will be impacted, such as low-wage workers, women, and young professionals (European Commission 2020).

The labor market impact of COVID-19 related confinement measures is expected to be higher in some Southern European Member States and Ireland. These are the countries in which the share of sectors forcefully closed are higher (European Commission 2020). The countries which noticed the high impact of COVID (contracts loosed) are Greece, Bulgaria, Romania, Spain, Slovenia, Ireland, Italy.

Despite of uncertain situation the enterprises still looking for experienced finance managers. The main directions of the finance manager profession's transformation are related to cloud computing, sustainability, big data, artificial intelligence, and cognitive analytics.

The main contributions of this paper are the research using the hybrid approach based on the literature study and the labor market research to check the impact of big data technologies on financial management. As the result the model of perspectives of big data impact on financial management with skills related was created. The literature study was focused on scientific papers and non-scientific literature sources, such as market reports and experts' opinions. Therefore, the results of the present study could have meaningful practical implications.

The paper is structured as follows. First, a literature study is provided, outlining the issues raised by the research on the dimensions of the impact of big data technologies on financial management. This is followed by a survey conducted on selected labor markets and the discussion of the results of that survey. Finally, conclusions and future perspectives are described. The complete research framework is shown in Figure 1.

Fig. 1 : The research framework

Literature study

Big data has not only influenced many fields of science and society, but has had an important impact on the finance industry (Begenau et al. 2018, Choi, Lambert 2017, Schiff, Cafferey 2017, Shen, Chen 2018, Sun et al. 201913, Hasan et al. 2020, Pilipczuk et al. 2019).

Many papers describe the impact of big data on financial management. The paper of Ke and Shi (2014) makes an analysis about the changes "that big data brings to accounting data processing, comprehensive budget management, and management accounting through affecting the idea, function, mode, and method of financial management" (Ke, Shi, 2014). The authors of the paper "Big Data: Implications for Financial Managers" take a close look at what big data means for financial managers (Fanning, Grant 2013). The paper of Sophie Cockcroft examines the literature on "potential research opportunities for the use of big data in the cross disciplinary space of information systems, accounting and finance area and identify the current research approaches" (Cockroft 2016). In paper of Sun, Shi and Zhang (2019) authors states that "finance big data is becoming one of the most promising areas of management and governance in the financial sector. It is significantly changing business models in financial companies" (Sun et al. 2019). The paper of Yang et al. (2017) explore the current landscape of big data in financial services. The authors propose a framework, which facilitate the way how big data influence on finance (Yang et al. 2017).

The preliminary literature analysis revealed that big data could be concerned from several perspectives (Weinberg et al. 2013). It is caused by different definitions of big data what could be found in the literature, as well by different opinions as among practitioners.

The paper of Demchenco et al. (2014) contributes to the emerging big data research by analyzing current definitions of big data from different perspectives, suggesting enhancement to the terminology as well as describe new research opportunities (Demchenko et al., 2014). The authors point out the importance of delivering the results to consumers (Demchenko et al., 2014; Baro et al., 2015).

In work of Ekbia et al. (2015) several definitions with different perspectives available in literature, namely the product-oriented perspective, the process-oriented perspective, the cognition-oriented perspective and the social movement perspective are presented (Ekbia et al. 2015).

The further literature review was based on works described the definition of big data and related conceptions which were grouped according to appropriate perspectives (Chang 2018).

As the result, the following eight perspectives were created:

Value Perspective

The analysis made by authors in work (Ylijoki, Porras 2016) shows that the evolution of the definition started with data to infrastructure topics and followed by the business value of data.

Becker and others (2016) provide the following definition: ”Big Data technologies are a new generation of technologies and architectures designed to extract value economically from very large volumes of a wide variety of data by enabling high-velocity capture, discovery, and/or analysis” IDC (Becker et al, 2016).

The Capgemini company argues that success of big data projects lies in realizing business value (Capgemini 2016). On the other hand, in work OECD (2015) authors argue that creating value from big data relies on supporting decisions with new knowledge generated from data analysis (OECD 2015).

The study of Olszak and Zurada (2020) investigates an issue of big data and elements shaping big data based on business value creation (Olszak, Zurada 2020).

“Value creation from big data occurs through the process of data management, where managers are able to democratize, contextualize, experiment and execute data insights in a timely manner” (Zeng, Glaister 2018).

Process Perspective

The literature review made it possible to select several definitions connected with process perspective. According to Networked European Software and Services Initiative” Big Data is a term encompassing the use of techniques to capture, process, analyze and visualize potentially large datasets in a reasonable timeframe not accessible to standard IT technologies” (NESSI 2012). ”Big data is high volume, high velocity, and/or high variety information assets that require new forms of processing to enable enhanced decision making, insight discovery and process optimization” (Laney 2001). Big data is also ”growing technological ability to capture, aggregate, and process an ever-greater volume, velocity, and variety of data” (Podesta et al., 2014).

In work by Sakr et al. (2018) the situation when massive amounts of event data generated as business processes are executed and stored in transaction logs, databases, e-mail correspondences, social media is described (Sakr et al. 2018). The business process analysis and big data connection can play an effective role in improving the efficiency and the quality of various data-intensive business operations using a wide spectrum of emerging big data systems (Sakr et al. 2018). Big data analytics can help in business processes management by providing actionable data to all stakeholders throughout the policy lifecycle (Van Grondelle 2013).

Similarly, the purpose of the Fosso Wamba and Mishra's paper (2017) was to improve the understanding of the integration of business process management, business process re-engineering and business process innovation with big data.

The purpose of the Battisti et al. (2019) paper was to improve understanding of the integration between big data and risk management in business processes, with special reference to corporate real estate.

Moreover, in 2017 the framework for business process data management based on big data approach was created (Sonia 2017).

Cognitive Perspective

Appel, Candello and Gandour (2017) from IBM Research state that "the era of big data is the bases for innovative cognitive solutions that cannot rely on traditional systems" (Appel et al. 2017). Likewise, Hurwitz and Bowles (2015) highlight that emerging solutions for cognitive computing must gather huge amounts of data about a specific topic, interact with subject matter experts, and learn the context and language of that subject (Hurwitz et al. 2015). They also emphasize the significance of this technologies in high-risk situations. Moreover, the authors underline the importance of ability to predict outcomes with the high degree of accuracy in abovementioned situations, especially the automated trading algorithms for stock market (Hurwitz et al. 2015).

In work 'Cognitive Big Data. Introduction of Cognitive Big Data as concept and framework" authors proposed a 5-Trait Framework (Lugmayr et al. 2017). They also provide the definition for cognitive big data: "human understandable data supporting mental capabilities as socio-technical system, in the right application context, right granularity with knowledge and wisdom processing in the foreground" (Lugmayr et al. 2017).

In work of Han and Du (2018) the different aspects of interaction between big data and cognitive science are discussed (Han, Du 2018).

Several papers are focused on interrelations between AI and financial functions: analytics, accounting management, auditing, management, and more others (Garrido et al. 2010, Myers et al. 2007, Li, Vasarhelyi 2018, Greenman 2017, Lee 2016). Cognitive assistants are useful for business situations when users need information retrieval support from a large number of financial sources (Li and Vasarhelyi, 2018, Garrido et al., 2010; Myers et al., 2007).

Sustainability Perspective

In paper "Big data and open data as sustainability tools" authors describe the main aspects of connection between big data and sustainability (Vijay, Farkas 2018).

In work of Etzion and Aragon-Correa (2016) authors contend that "big data are naturally aligned with sustainability concerns (e.g. multidimensional nature, collective actions, smart allocation of resources, efficiency priority)". Additionally, they point out that "sustainability reporting will become increasingly data driven, employing a wider array of real time, data-rich entryways into exploring organizational sustainability performance" (Etzion, Aragon-Correa 2016).

Several works described the spectrum of issues of connection of big data and sustainability concepts also appears (Perez, Barreiro Quintans 2019, Serban 2017).

Data and Knowledge perspective

In literature several definitions related to data perspective are provided. According to Wang et al. (2016) ”Big Data exceed the reach of commonly used hardware environments and software tools to capture, manage, and process it within a tolerable elapsed time for its user population (Wang et al., 2016).” Another definition “data sets whose size is beyond the ability of typical database software tools to capture, store, manage and analyze” provide the McKinsey Global Institute (Manyika et al. 2011).

The paper of Sam Hijazi describes the attempts to combine knowledge management and big data fields together (Hijazi, 2017).

The study in work of Michael Kaufmann (2019) proposes a knowledge-based and value-oriented approach to big data management, focusing on knowledge processes and value chains when designing technical information systems for coping with big data (Kaufmann, 2019).

Change Perspective

The big data phenomenon involves the global changes in social sphere. The change perspective within the enterprise usually interrelated with management, particularly with change management.

Domański and Jędrzejczak (2015) argue that big data is changing not just the nature of the evidence, but also the ways in which it is presented, and the skills needed for its analysis and interpretation (Domański, Jędrzejczak 2015). From the other hand, Polese et al. in 2019 define the big data as “the potential to quantify and change various aspects of contemporary lift, to revolutionize the art of management” (Polese et al. 2019).

Change management is becoming increasingly data driven (Tushman et al. 2017). That brings new challenges for the enterprises. It also brings changes from analysis based on result to mining based on process (Ke, Shi 2014).

In addition to changes within organizations themselves, there are also implications for other stakeholders, such as education providers (Pugna et al. 2019).

Product Perspective

The product perspective the most extensive one. It interrelated with many other concepts such as process, sustainability, data, and knowledge perspective.

To integrate the business processes of an organization and more effectively manage and utilize volumes of data generated during product lifecycle need a more advanced analysis approach to develop a solution on a strategic level (NSF 2011). In more narrow context the big data could be defined as ”large, diverse, complex, longitudinal, and/or distributed data sets generated from instruments, sensors, internet transactions, emails, videos, click streams, and/or all other digital sources available today and in the future” (NSF 2011).

Quality Perspective

The literature analysis reveals connection of big data and quality management (Ge, Dohnal 2018). Several papers were concentrated on the big data quality (Ge, Dohnal 2018, Loshin 2020, TIP

2020). The paper of Ramasamy and Chowdbury (2020) discuss the main aspects of the big data quality and analyses the quality dimensions (Ramsamy, Chowdbury 2020).

All the changes related to abovementioned perspectives have influence on financial labor markets and the transformation of the finance managers profession.

Finance (financial) manager (FM) - a person responsible for the supervision and handling of the financial affairs of an organization (Collins Dictionary 2020).

Finance manager skills are those that help individuals in this role oversee all aspects of a company's financial transactions, including budget analysis and calculation of return on investment as well as purchasing and staffing decisions. Finance managers provide accurate data analysis and strategic propositions to create profit and reduce loss. A finance manager's skills are built from a wide array of roles and responsibilities (Indded 2020).

Finance managers skills are in continuous transformation. It involves the need to enlarge the skills models with new conceptions.

It has been found that the needed skills for next decade are (Wang and Wang 2016; Chua, 2013, Indeed 2020): value management, business process management, sustainable management, cognitive analytics, knowledge management; project management; change management skills; sustainability management, product management, IT skills.

Information technology (IT) skills requirements for finance managers are very extensive. They cover the following areas:

- Knowledge of data extraction tools in the mining of business intelligence.
- Use of tools that support data modelling and analysis.
- Knowledge of emerging payment platforms.
- Better working knowledge of connectivity and IT security.
- Knowledge on how IT applications integrate.

The next part of the paper focuses on checking the requirement on technical skills in selected labor markets.

Labor Market Research

The research was conducted in July – August 2020. The data were collected at the beginning of July, and after that the study was repeated two times. The empirical research was conducted according to the framework presented in Figure 1.

The selection of labor markets was made according to following criteria: differentiation in GDP level, IT development level, geographical position (different regions: two from American continent with high GDP level, one from EU, one outside the EU with high GDP, and one from region outside the EU with low level of GDP), population differentiation. The language factor also has had influence on selection. The 5 following countries were taken into consideration: the United States of America, Canada, Poland, the United Kingdom, and Ukraine.

At the beginning, the most popular job search websites were compared. The following selection criteria were used: 1) the largest number of current finance managers posts, 2) ability to provide “advanced search” with the finding options, which allowed to search for specific key words within the job posts’ textual content, 3) popularity in studied countries. Consequently, the “Indeed” job

search website, britishjobs.co.uk, pracuj.pl, rabota.ua were chosen. The study was associated with following indeed job group category: Finance & Accounting > Finance Management Occupations > Finance Managers & Directors.

The website searching engines were used to filter the job positions. The following key words were studied: “finance manager”, “finance director”, “big data”, “sustainability”, “sustainable”, “cognitive”, “cognition”, “business process”, “business process management”, “ value management”, “product management”, “value management”, “IT management”, “data management”, “knowledge management”, “change management”, “quality management”, “project management”, “customer management” etc.

The total number of jobs offers for finance manager profession and the number of offers finance managers (FM) with big data skills requirements were calculated during the July-August period. After removing the duplicate job posts, and that obviously did not meet the eligibility criteria the extracted job posts were analyzed. After that, the average number of offers for the research period was calculated and the share of the job offers related to perspectives studied. Table 1 presents the results of these calculations.

Table 1: The number of jobs offers for finance managers and core big data perspectives share.

Perspective/Country	USA	Canada	UK	Poland	Ukraine
The average number of job offers	11524,67	2709	3808	756	657
Big data	22%	2,2%	1%	2,7%	0,5%
Sustainability	10%	6,1%	15,6%	3,8%	0%
Cognition	8%	1,5%	0,4%	0%	0%
BPM	17,7%	5,2%	26%	2,9%	2,7%
Value management	3,2%	0,3%	11%	0%	0%
Knowledge and Data management	5%	5%	5,5%	1,3%	2,7%
Change management	22%	8,7%	9,1%	2%	0,5%

The research reveals differences in big data skills demand among the studied countries (fig. 2). The highest impact of big data on finance managers positions was noticed in USA labor market. 22% of analyzed job posts here contain the big data experience requirements. The demand on big data skills in rest of the countries vary from 0,5 to 2%. The number of offers with big data skills requirements for finance managers was at the comparatively similar level in Poland and Ukraine.

Fig. 2 : The total number of jobs offers for finance managers and the number of jobs offers with BD skills requirement.

The graphical interpretations of size of the demand on skills related to big data (Table 1) in different counties are presented on Fig. 3-7. The less significant dimensions were product and quality perspective. These skills were required more for positions related to financial operations in production management.

Fig.3 : The tree map of demand on FM skills related to BD impact dimensions in United States

Fig.4: The tree map of demand on FM skills related to BD impact dimensions in Canada

Fig.5: The tree map of demand on FM skills related to BD impact dimensions in United Kingdom

Fig.6 : The tree map of demand on FM skills related to BD impact dimensions in Poland

Fig. 7: The tree map of demand on FM skills related to BD impact dimensions in Ukraine

Moreover, the analysis of IT skills requirements reveals that IT experience was related mostly to following tools: ERP systems (for example SAP software, MS Dynamics and Navision, Oracle software, Sage software, QuickBooks); analytic platforms (for example Cognos, Tableau) and MS Excel calculations.

Likewise, successful finance managers are adept at several of the following social and behavioral skills: leadership, problem solving, communication, analysis, interpersonal skills, attention to detail, organization, ability to work independently, cognitive abilities (indeed.com 2020).

Results and Discussion

The analysis of the big data impact shows that sustainability management, business process management, change management, data and knowledge management and value management are currently the most required dimensions in analyzed countries.

The labor market research reveals that financial managers core skills related to perspectives currently needed in labor market are:

- Forecasting, planning, maintain financial models, budgeting and accurate reporting required mathematical and statistical skills.
- Data and Knowledge Management skills.
- Business Processes Management.
- Change management.
- Quality management.
- IT knowledge.
- Supply chain management.
- Project management.
- Product management.
- Value management.
- Sustainability management
- Customer relationship management (CRM).
- Cognitive analytics.

Finally, the perspectives were grouped in pairs and connected with the core skills (Fig. 8). The figure 8 presents the details of this connection.

Fig. 8 : The model of big data (BD) impact on finance managers skills - perspectives and skills related

The research has several limitations. First, the study was based on the jobs offers which usually contain the unprecise formulations of skills and job posts. It was necessary to remove the

duplicates and fuzzy wording. Furthermore, many offers contain requirements related to the several perspectives. Product perspective was often associated by searching engine with the product managers job posts rather than finance manager posts, so it was hard to define the "borderline". The quality perspective also was associated with production management, so it has the less significant impact on finance managers competencies.

Conclusions

Today big data technologies have a significant impact on financial management. This impact increases the meaning of sustainable development and cognitive analytics for financial managers as well as several other modern conceptions.

The developed model underlines the core drive streams influenced the finance managers profession. The further research will be based on enlarging this model with social, behavioral, and cognitive skills.

There is a wide range of practical applications for the developed holistic model. First, it can serve as the basis for developing a finance manager competency models in enterprises. In addition, the model can be used in universities as a starting point for the development of up-to-date curricula and training courses.

Funding

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00.

Abstract

The article considers the theoretical and methodological tools for the development of the business platform technology design for further education in a modern university in the context of the tourism and economic forum, which objective is to form the project skills of innovative brand project products, improving the skills of communicative interaction in an unconventional, artificially created market realities. The forum is defined as one of the educational technologies for the implementation of topic-centered interaction between educational entities in the format of a tourism and economic profile. The main components of the forum such as mission, main task, opportunity are described in the topic. The situation analysis is carried out, the project is presented, its main structural and thematic sections are indicated, and the technology for its implementation is described in detail. The main training profiles can be regional and international. Related types of educational tourism can be carried out within each module: linguistic, sports, communicational, business-oriented. The final part of the article contains the main business platform problem field, which includes the use of the following factors: cultural, psychological, and pedagogical. The article describes the forum thematic module in detail: "Market participants' brand communicative cooperation skills construction". There are other modules topics, which can be the basis for any project content for the forum. Article presents the results of the forum elements approbation.

Keywords: Educational Process, Commercial Education, Development of Business Platform Technology, Forum Building Technologies, Forum Content.

Introduction

The development of project business platform technology for further education in a modern university in the context of the tourism and economic forum is rather new direction, which is evoked by the crisis in the interaction between science and practice (Ndou, Mele, Vecchio, 2019). Today it is proposed for consideration by many authors, in various scientific areas, for example, as an "inductive empirical generalization scheme in the context of intersubject communication" (Pugacheva, 2014;

Cite this Article as: Anastasiya KOPYTOVA, Olga LOYKO, Valerii SIZOV, Olga SANFIROVA And Oksana NESTEROVA " Development of Business platform Technology for Further Education in Modern University in the Tourism and Economic Forum Context" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Sizov, Irkutskaia, 2014; Yamaguchi, 2020). In this case, the intersubject communication is mainly emphasized.

The development of project business platform technology allows not only engaging in the above aspect, but also restoring the disturbed balance of the scientific and practical approach in the announced profile formation. This direction is also updated by the methodological contradiction: young generation is ready and wants to receive new knowledge in their free time from studies, participate in projects of interest to them, and choose eventful forms of leisure. On the other hand, there is no such practice in higher educational systems. Therefore, the relevance of creating business platforms is obvious today. Tourism and economic regional projects of any profile are extremely popular at all units' administrational layer of the university. Developed as part of a business platform, student's projects may be products of international exchange. Experience has proven that Chinas, Mongolias, Koreas surrounding countries are interested in joint project activities. The most popular international technology in this format is the “forum”. In the system of this direction, it is very possible to carry out educational constant content, using interactive international exchange in the school-university system. In this case, it is advisable to take into account the importance of interdisciplinary approaches of any profile, which determine competitiveness and complexity (Chervonnii, A. A. Vlasova, T. V. Shvaleva, E. I. Tsvenger, 2013, P 14).

For example, a successful combination of interchanged specialties, such as economics, law, geography, tourism that function at the Faculty of Economics and Management can be an excellent basic start to the development of an entire educational movement, a new relevant direction - the organization of project activities in the forums' context. It is such a scientific combination that allows the faculty acting as a moderator for any scientific profile, because the education's goals today are to prepare the education's subjects to create a cost-effective business product of any configuration. Such experience already exists in the Russian Federation, for example, the Seliger All-Russian Youth Forum which is an active discussion platform in the system of recreation, science, education and leisure. These areas pose serious competence tasks both for the organizing teachers and students participating in the forums (Artemenko, 2013, P 14). Teachers need to take into account market requirements and introduce into additional education system the formation of precisely this knowledge, skills and abilities of students.

In the situation of fierce competition and information oversaturation, a broad specialist who can manage information resources, create new innovative projects on the basis of interdisciplinary research, be able to interact in a team, be flexible and adaptive to changing realities, have strategic vision and adequately evaluate the current situation is required (Artemenko, 2013, P 9-14; The future of education). All this skills set can be successfully developed in the declared activity.

In the context of fast-evolving socio-cultural dynamic it is impossible to base only on economic aspects while business products development and implementation. Economics more than any other science tends to behavioral domain. Modern marketplace had long ago drifted away from accustomed economic indicators. It increasingly includes in social and psychological dimensions, where emotions became a product. To develop and implement this aspect the wider range of different knowledge of sciences are needed. In this case the issue of the forum's technological development arises. This development based, first of all, on the dominant of cultural personality values and its interaction with important economic indicators. In this connection forum's theoretical, methodical, technical objectives would be:

1. To master fundamental psychological, cultural, philosophical concepts and the ability to apply them in economic practice, in connection with its transition into an emotional, behavioral field. The basic concept for the entire model is the logical triad: activity, behavior, perception.

2. To form the axiological foundations of economic education as a basic category of behavioral economics. It is solved basing on the studies of the major philosophers, culturologists, artists, writers, theologians, etc., who have works on economic topics, by analyzing the economic material from a cultural point of view, using the basic concepts of the forum model. At this stage, it is important that

students master the basics of reflexive analysis, can critically assess the targets, value attitudes, tools and methodological arsenal necessary for behavioral economics.

Now as the relevance and the main research questions have been posed we can dwell on the definitions of the article.

In this case, "forum" will be the main definition. The encyclopedic meaning of the “forum” has Latin origin (lat. Forum). In ancient Rome, it is a square, a market that has become the center of political life, while the modern, adapted definition has the meaning of a mass representative assembly, congress. For example, the World Youth Forum (Big Encyclopedic Dictionary).

In our case, the forum is an educational technology for the implementation of a theme-centered interaction between educational entities in tourism and economic profile's format with a selected market segment in a system of constant interdisciplinary approach using non-standard conditions. The tourist profile allows implementing the forum as an educational product in the context of educational tourism.

The main components of the “forum” concept: mission, main task, technology, goal, place, content.

1. ***The mission of the forum*** in educational tourism context is the creation of a business platform where any young person and team can demonstrate their talent, enrich human capital, find like-minded people, get professional training on issues of interest, build a system of business relations, relax, etc.

2. ***The main objective of the forum*** within the business platform framework is to provide further education for the participants' projects presentation and international targeted exchange. it is the opportunity to show your project, your program or idea to all interested structures. This is a direct access to investments, grants, funds of the largest private companies and state corporations, to state programs; obtaining new knowledge, skills in an interactive interaction system. Ensuring a high level of quality in terms of the educational programs tension should be comparable, at least, with a semester training course on the theme.

3. ***General technology of holding a forum*** within a business platform: the main macro component is a forum which context made micro-components to be possible: information lectures, quests, quiz, master classes, brainstorming, interactive project “case studies”.

4. ***The objectives of the forum*** business platform are:

- To form an interest to research activities.
- General and specific knowledge consolidation and deepening in the declared area.
- To form the design skills, their use in tourism and economic multidisciplinary research.
- Creation of scientific ideas about the forms and structures of the cultural, religious and spatial organization of society.
- Formation of skills to use the historical and cultural approaches in solving economic and tourist profile's theoretical problems.
- Practical skills formation.

5. ***The venue of the forum program*** is the university, its assets.

6. ***The forum program's place in the educational modules' system***. Students can consider the forum's thematic format in many disciplines of the economic and advertising module, and can also take it as an independent section of the variable part of the disciplines.

Materials and Methods

Let us give an example of a possible educational tourism and economic forum, which, with a basic concepts' detailed study, can be included in the work of the university.

***Topic**:* "Formation of brand communicative interaction skills among market participants."

Objectives: Development of brand communication skills created by innovative, joint service projects, PR - promotion of branded tourism products; introducing innovative technologies for creating territories' tourist brands and tourism products' brands.

Tasks:

Training the skills of a business approach to innovative products and services (teams, workshops, laboratories, etc.),
Introducing the cultural and ethnic diversity of the Russian Federation,
Establishment of cultural relevance presented in brands.

Program content

Program summary

The program includes theoretical and practical blocks, reveals the modern brands component value, contains experimental creative tasks.

Content component

"Value as the main component of brand communication." A small information block is being hold:

- "Values in modern society."
- "Socio and cultural systems on the political map of the world."
- "The concept, essence and tasks of branding".
- "Reasons for branding".
- "Economic product-history". Later teams are invited to find certain correspondences in the author's model of the societies' subjects value hierarchy, presented in the form of a figure. Then they are given a set of cards illustrating the value preferences in the tourism and economic sphere of the market interaction's subjects. It is necessary to find correspondence between the level of values and the tourist product-service. Based on the selected criteria, it is supposed to develop in teams an assessment of the existing personality types as the main subjects of society, to determine the level of their preferences in choosing tourist products and services on the value model basis.
- "Global brands assessment." The team should give an expert assessment of the world's leading brands in value criteria terms studied in the previous assignment.
- "Symbols and meanings of culture as the main value components in creating a brand." Work with existing world cultural symbols, search for their correspondence to modern market brands. In this section it is necessary to understand the brands' language, to decipher the information of the proposed brands, to evaluate the professionalism of creating such brands.

Practice-oriented block

Staging as the main technological element of branding. Design types:

- staging through the word;
- staging through visualization.
- staging through action.

All staging types are some way or another involved in this module:
- Work with the world philosophers' sayings on this issue.
- Solving problems associated with changes in brand attractiveness in connection with changes in social values, social events, market conditions, etc.
- Staging the fairy tale “How a man sold a cow” (staging is a show-off based on drawing the main actions of the tale through recognizable characters in society. Fulfillment technology: each team is given extract, the other team guesses it, then the storyline is built fairy tales by drawings. Winners are evaluated according to developed criteria, such as: accuracy of the storyline, speed, symbolism, originality).

- Drawing of paroemia.

- Capture the brand market. Creating a planned situation. At the beginning, the market situation in a particular product segment is declared, then tasks for capturing the market are offered. Products for sale on the market are selected.

- Presentation of your brand.

Theoretical sections may include:

1. Monitoring the target audience, competitors and market conditions. The current state of the existing brand in the market is assessed.
2. Formation of the idea, development strategy and staging and brand positioning conception.
3. The value tools use discussed above. Promotion of brand values, not products.
4. Creation of brand elements: brand name (naming), legend, slogan, logo type, brand book, guide book, label design and packaging.
5. Definition of promotion's tools and methods, the choice of interaction with the target audience methods.
6. Monitoring the state of the brand, evaluating the effectiveness of its development, corrective measures creating.

The time of the forum can vary from a week to two, depending on many factors: the degree of employment, organizational issues, etc.

Due to the requirements to the article wordage, we were able to provide only a brief summary of one forum example. In this regard, the remaining thematic forums will be presented only in the title.

1. Emotional intelligence, psychological maze.
2. The motivation for building a value pyramid.
3. Team work forms. Formation of a systematic approach to the development of own team. The principles of creating an "anti-fragile" team and key processes of its activities. Command Options. Work with patterns.
4. Change management.
5. Product technologies: building a pyramidal system of goods' consumption by various types of people.
6. Development of business thinking: flexibility and adaptability, a systematic approach, customer focus. The solution of situational economic problems.
7. Technologies for creating service products.
8. Digital city, the design of the digital city. My place is in the digital city. My business is in a digital system. My society in a digital city. Digitalization - myth or reality, ways of survival. Basic information and communication technologies and Digital tools.
9. The concept and essence of interactive innovative business technologies for travel catering.
10. Interactivity as a psychological category.
11. Modern interactive techniques.

12. The concept of innovation and tradition in building a business.
13. Tourist services ethics and culture. Sorts and types of interactive business technologies. Interactive innovative business technology for tourism services. The philosophical aspect. Social and cultural problems of interactive business technologies.
14. Symbols and meanings embedded in the objects of the world heritage presentation and retelling.
15. Values in social and cultural systems as the basis of modern interactive business-related projects.
16. Prerequisites for the development of an innovative business environment in the tourism sector.
17. Management of interactive innovative business technologies typical variety.

Given the continuity of education, which was announced above, we turn to the thematic sections for kids.

1. Economics for kids. Analyze emotions and types of people, work on their preferences' recognition, both business and security skills.

2. Game "The adviser" - "What will we advise to people from the picture to buy on the market considering their gender, age, nationality, religion, values)?".

3. Game "The store". Testing concepts: how much does it cost, what kind of products and goods are there in the store. Work with banknotes, search for genuine one. Playing "The store" we train memory and attention. The buyer points to the goods, and the seller must give it without asking again.

4. Home, nature, man. The interaction of the three systems, a game quest. A game of association.

5. The game "Agent 007": the development of multifunctional tasks aimed at developing skills such as prioritization, a short way to complete tasks, and another way to complete the order of tasks.

Formation of the value-semantic foundations is based on the stages, factors and criteria presented in Table 1. The main problem field of a business platform is identified when using cultural, psychological, and pedagogical factors.

Table 1: Model of value-semantic foundations formation on the forum

Stages of the value-semantic foundations formation			
First stage. Theoretical	Second stage. Theoretical-experimental	Third stage. Practical	Fourth stage. Monitoring
Understanding the peculiarities of countries' and regions' development; identification of the role of economic and geographic, cultural, religious, psychological factors. Search for the system-building idea that can only rely on value attitudes of respect for national individuality	Teaching the core of cultural analysis of countries and regions, their in-house urban space	Formation of a sustainable value-semantic attitude in an understanding of the man and the world unity. The person acquires new operational means to realize his relationship to the world.	Study the abilities of a holistic characteristic of any economic object or phenomenon with the involvement of all previously acquired knowledge.

Factors	
Psychological	Expressed in the evaluation of informational orderliness on personal experience and the proposed information basis.
Cultural	Expressed on the basis of ideas about the social and cultural tradition associated with the use of one or another element in this context. In more detail, this factor is reflected in the knowledge of national-specific realities features considering the forum's international format.
Pedagogical	Expressed in the search for the most effective pedagogical tools. The use of the classic practices of the “Pedagogical Management” considering the possible levels of training, mood, self-confidence of the subjects of training while this material perception.
Criteria	
Scientific and educational	Search for ways to solve economic problems using a systematic various sciences data analysis. The main objective of this block is to understand the development patterns of the value component of objects, social systems and the person himself, as a key figure capable of performing a cognitive function.
Emotionally-resilient	Includes the education of emotional and associative thinking. Emotional perception of the surrounding world is an integral part of the existing dynamic "human" system balance.
Transformative through the action	Includes not only active, but also distinct knowledge, understanding and confidence in the value of cultures and geo-subjects.

The forum program effectiveness is assessed on the basis of systematizing the data from written questionnaires and verbal surveys among forum participants, building a systematic observation of each forum participant, according to the following indicators: knowledge of basic economic laws, orientation in the geopolitical and value-semantic world space, analysis of personal value and the semantic field of the forum participants, etc. These aspects are carried out through pedagogical guidance based on coaching and nudging (soft, guiding influence), which constitute pedagogical tools.

Results and Discussion

Preparations for the international forum is in prolonged nature, fragments of the forum have been implemented by the teachers of TSPU since 2016. There were held weekly events: ecological marathon "Die Naturwelle" with economic aspects for pupils of Tomsk gymnasium № 6 (2017), excursion "Little Motherland: Northern Way" for students of the "Boarding School for Students with Hearing Disabilities" within the framework of inclusive education, for school № 51, and also Japanese and Chinese students (2018), financial training "Soft and Hard-skills in financial literacy" for domestic and foreign students of economic and non-economic specialties of TPU, TSPU, TUSUR, pupils of Tomsk lyceum № 51 (2019), regional competition on financial literacy in TSPU for pupils of Tomsk and the Tomsk region (2019), quest "I am in the financial world" for students of

TSPU (2020), economic and pedagogical online forum on the topic "Audit in education" with the preschool practicing specialists involvement, school and additional education (2020) and others. The total number of participants is 100 people. To assess the event effectiveness the forum participants were interviewed before and after the event implementation on the basis of verbal and written questionnaires. Thus, the declared base demonstrates a fragmentary study of all forum aspects: cross-cultural, pedagogical, psychological, economic.

During the forums' idea implementation, it was found that one or another picture of the world prevails among the participants:

1. Contemplative and domestic picture of the world. It corresponds to the subjective human perception. There is an obvious cultural limitation of the subjects in it, which affects the entire creative process of life.

2. The formal picture of the world is used by the natural sciences. This picture of the world presents our world not from a subjective point of view, but in the form of descriptive models. The study revealed that these students can easily create layouts of economic products, draw brand elements on a specific topic, but in this case, there is a big problem with the internal ideological content.

3. Value-semantic, reflecting the sum of knowledge and ideas that connect, first of all, to the issues of origin, meaning and purpose of our world. In terms of behavioral economics, this aspect is the most important, and as the experience has shown, it is the most effective.

The picture of the world leaves its imprint both on its further economic behavior and on the creative component of this behavior associated with the economically efficient product development.

Analysis of the survey conducted before the implementation of the forum program showed that the participants did not understand the significance and importance of the cultural, psychological, philosophical component in the economy (Table 1 and Table 2). All attention was paid to assessing the economic efficiency of one or another process or phenomenon, perceiving them exclusively as economic objects.

There is opposite picture after the forum's implementation in the survey: it was confirmed that the participants realized the importance and significance of this approach to the economy, showed great interest in the proposed activities (Table 2).

Table 2: The results of the survey on the formation of a picture of the world among the forum participants

Title of the picture of the world	The prevalence of the picture of the world among the forum participants, %	
	before the forum	after the forum
Contemplative and domestic -50%	50	27
Formal picture of the world -29%	29	29
Value-semantic - -21%	21	21

The conductions of forums allowed forming new values among the participants and setting priorities (Table 3). The survey results led to the conclusion that the participants realized the importance of the above aspects in behavioral economics, understood their practical application.

Table 3: Values formation among forum participants

Title of the picture of the world	Formation of values among forum participants, %	
	before the forum	after the forum
Material values	32	11
People around	24	14
Nature	4	7
Government	13	14
Morality	7	22
Science and art	4	32

The results of the student survey system helped to clarify some gaps in the formation of value attitudes in the teaching economic disciplines cycle:

1. Weak capacity to integrate acquired knowledge into various subjects (75%).
2. Lack of knowledge about the value components that have developed in different cultures (90%).
3. Negative attitude to their native country, ignorance of its "comparative advantage" over other countries, and, accordingly, a complete lack of citizenship (50%).
4. There are no general concepts in economics, lack of information about modern technologies of many production processes (40%).
5. Little understanding of their future profession, lack of systematized knowledge about its prospects at the present stage, its connection with real life (70%).

Evaluation of psychological, cultural and pedagogical factors formation revealed a good tendency in the educational orientation of the forums (Table 4 and Table 5). The survey expanded the understanding of the digital series, it was found that the participants paid the great attention to the emotional component, which was embedded in the first psychological series, and also showed interest in cultural values, sought to expand their ideas on them (the second range - cultural). But most importantly, the participants reconsidered the modern economic knowledge, realized the importance of transcendental interaction in this knowledge, saw their undeniable capabilities and their comparative advantage in developing their own business products, thereby increasing their economic activity. Individual participants were ready to create their own forum.

Table 4: Psychological and cultural factors formation

Title of the picture of the world	**Formation of factors among forum participants, %**	
	before the forum	**after the forum**
Psychological	35	65
Cultural	30	70

Table 5: Formation of the pedagogical factor among the forum participants

Index	Forum participants self-assessment, %	
	before the forum	after the forum
Ready and configured	50	90
Ready and confident	12	90
Don't ready and configured	7	9
Don't ready and confident	47	15

These indicators were supported by a conversation, during which conclusions were formed, supported by an analysis of the self-assessment of the participants in the forum of the pedagogical factor (Table 5). Before the beginning of the events, the indicator of general readiness and interest showed that participants were interested and actively motivated to participate; after the event, this indicator was increased, which indicates the expressed interest in the event and the desire for further cooperation. The Confidence and Readiness Indicator, which demonstrates attitudes towards the innovative nature of the event, showed typical results: uncertainty among participants before the forum. The indicator of motivation (not ready and not configured was not high, both before and after the event. As we found out, it could change depending on the professionalism of the forum organizers. The fourth indicator, reflecting the participants' willingness to act independently, turned out to be a floating indicator and was in direct proportion to the professionalism of the organizers.

In general, the forum participants, regardless of the age and gender structure, are positively disposed towards the continuation of scientific and educational economic activities in various inter-subject areas.

Conclusion

The task of the business platform is to create the new knowledge through the project activities of the interaction subjects. A new pedagogical communication system in the social and cultural services and tourism field should become the final components of the forms, methods and technologies of the business platform's project activities. This system involves the knowledge and management skills development, on the one hand, in a paradox of information saturation, and on the other - in a paradox of uncertainty, which involves in processing a large amount of information and understanding its purpose for making a decision. Future specialists training for scientific, innovative, market-oriented activities in any field is substantially the basic final component. (Konstantinov, Filonovich, 2005).

Thus, during research process the authors worked out the concept of a forum as a social and cultural, innovative, pedagogical phenomenon, the approved forum technology was developed and presented in detail, examples of new topics for further development in the system of lifelong education was provided, the data of testing the forum technology was analyzed. It can be concluded that certain elements of the forum have been implemented in practice. The business platform technology model described and proposed by the authors was maximally implemented in the "Die Naturwelle" project. As a result of four years of testing the forum fragments, the participants developed the skills of an interdisciplinary approach, project activity, self-assessment, economic analysis of environmental problems, expert activity, tutoring and mentoring. A pilot study may qualify for organizing an event with international participation. For the future, it is planned to hold an interuniversity event in Tomsk on the issue "Post-crisis economic thinking. Generation Z in the multicultural world" on the basic tools for the forum implementation described in this article and its adaptation to digital realities, as

well as the implementation of the partnership idea based on the creation of joint projects with SI TPU, the Tomsk Region Branch of the Siberian Main Directorate of the Central Bank of the Russian Federation and other organizations interested in cooperation.

The Impact of Subsidised Employment on Exiting Unemployment in Poland: An Analysis Based on Unconditional Competing Risks Models

Beata BIESZK-STOLORZ

Abstract

The main objectives of employment programmes implemented in Poland by labour offices are professional activisation of the unemployed and reduction of structural mismatches in the labour market. Demand-oriented instruments include intervention works, public works, socially useful works and funds for undertaking business activity and for equipping the workplace. They constitute the so-called subsidised employment. Costly implementation of the programmes forces evaluation studies and research on the effectiveness of these instruments. The aim of the article is to use unconditional risk models of competing events (*Unconditional Competing Risks – UCR*) to analyse the impact of subsidised employment on the probability and intensity of exiting unemployment. The study used individual data of persons registered in the Poviat Labour Office in Szczecin. The analysis showed that the impact of subsidised employment on the probability and intensity of exiting unemployment was marginal. the resignation from mediation of labour office was a very strong cause for de-registering the unemployed. This may indicate that the willingness to take up employment was not the main cause for the unemployed to register with the office and that the unemployed were not always interested in the proposed forms of activisation.

Keywords: Cumulative Incidence Function, Hazard Model, Competing Risks, Subsided Works, Unemployment

Introduction

After 2004, since joining the European Union, the Polish labour market has undergone major changes. There was a significant increase in activities related to professional activisation of the unemployed. Poland is implementing the objectives of the European Employment Strategy, i.e. it aims at full employment, improvement of the quality and productivity of work and strengthening social cohesion and integration. An important role is played by active employment programmes implemented in Poland. Their aim is economic activisation of the unemployed, reduction of structural mismatches on the labour market, improvement of the productivity of the labour force and verification of readiness of the unemployed to work. To this end, the following labour market policy instruments have been established in Polish legislation: trainings, intervention works, public works, professional preparation in the workplace, internships, funds for job creation and socially useful works. The implementation of active employment programmes is connected with large expenditures from the Labour Fund, hence research on the effectiveness of these instruments is undertaken and evaluation studies are conducted. The main task of the labour offices is to activate the unemployed and help them find work. It is important for work to be permanent, but in a particularly difficult situation on the labour market, the offices also offer subsidised work.

The aim of the article is to use risk models of competing events to analyse the impact of subsidised employment on the probability and intensity of exiting unemployment in a particularly difficult situation on the labour market. The observation of the unemployed started in 2013, when the unemployment rate in Poland reached its maximum. The study used individual data of persons registered in the Poviat Labour Office (Polish abbreviation PUP) in Szczecin.

Literature Review

In many countries, activisation programmes for the unemployed are widely implemented to promote employment among disadvantaged groups in the labour market, for example young people, older people or people with disabilities. These programmes are often implemented as temporary measures in response to unexpected major recessions. Economic theory shows that subsidies can increase employment. However, individual actions should also be considered in the context of the cost effectiveness of such policies. However, such programmes do not always produce the expected results.

Kim and Lee (2019) evaluated the Special Employment Promotion Zone programme implemented by the South Korean government in 2013 and 2014. It was implemented in a medium-sized city, which experienced a long-term breakdown after the global crisis of 2008 affected its main industry, the shipbuilding industry. Under this programme, employers were able to receive subsidies to cover a substantial part of their wages for maintaining employees or creating new jobs for their residents. The evaluation study showed that this scheme was not fully used in its first year of implementation and had little impact on employment. In the second year the programme increased the level of employment, mainly in the non-productive sector. The magnitude of the effect was small, but the effect continued after the programme was completed. The city and its industrial structure required greater structural adjustments, not temporary assistance. The temporary aid granted under the programme distorted the incentive for companies to take certain long-term corrective measures.

The employment crises accompanying the economic crises, which were observed in most European countries, were less noticeable in Norway. Before the economic crisis in 2008/2009, Norway had a period of strong economic expansion, high growth rates, falling unemployment and increasing employment. In the years preceding the crisis there was a lack of labour supply, which was partly solved by offering employment to immigrants from European countries, particularly Poland and Sweden. The employment subsidies applied are primarily targeted at groups of people with limited ability to work. Employers who employ such a person will receive compensation from the Labour and Welfare Administration (NAV). Employment grants in combination with other forms of action seem to promote the employment of people from vulnerable groups. The EEPO report (2014) points to the lack of long-term effects of these measures.

Gupta, Larsen and Thomsen (2015) evaluated the effectiveness of the subsidy programmes of wages of the disabled persons. These programmes were implemented as part of the reform of the Danish Flexjob system, aimed at employing people with long-term (partial) disabilities. Companies were reimbursed for all employees who were granted Flexjob. It has been shown that after the reform the employment structure has changed significantly in favour of permanently employed. However, the reduction in subsidies led to a reduction in the employment of disabled people.

Göbel (2007) studied the impact of Belgian programmes on the employment of young, long-term unemployed workers. He showed that participation in subsidised employment significantly shortened the time to take up regular employment, had a significantly positive impact on the duration of the first period of employment, but had no significant impact on the duration of unemployment after participation in programmes. The investigation showed that subsidised employment had a greater impact on the unemployed in a disadvantageous situation in the labour market.

Forslund, Johansson and Lindqvist (2004) analysed the impact of grants on the employment of the long-term unemployed in Sweden since the beginning of 1998. They showed that this programme had a positive impact on the employment of participants. The probability of taking up employment after the end of the programme increased and the time of unemployment shortened. However, these results were in contradiction with the results of most other Swedish programmes applied in the analysed period, which showed a negative or insignificant impact on the employment of the long-term unemployed.

Subsidised Employment in Poland

The level of the registered unemployment rate in Poland in the years 2004-2018 was changing. In 2004 (the year of Poland's accession to the European Union) it was 19% and in the following years it decreased to 9.5% (2008). Then, as a result of the global financial crisis it increased to 13.4% (2012). It remained at the same level in 2013, followed by a period of recovery from the crisis, which was reflected in a decreasing unemployment rate. In 2018 it was 5.8%. According to the Statistics Poland (the Local Data Bank; https://bdl.stat.gov.pl/BDL/start) the number of registered unemployed people changed similarly (Figure 1).

2018	12.6	15.8	8.0	47.5	11.0	5.1	-	-

Source: Own study based on data from MRPIPS.

The instruments most frequently used by labour offices in Poland are: job placement and vocational counselling, trainings, internships, professional preparation of the workplace, grants for starting up a business, public works and intervention and socially useful works. They affect two sides of the labour market: supply and demand. Training, internships and vocational preparation at the workplace are supply-oriented instruments. Demand-oriented instruments, i.e. the so-called subsidised employment, are: intervention works, public works, socially useful works and funds for the unemployed to take up economic activity and to equip the workplace for the referred unemployed. The latter two instruments are defined as measures to create jobs. Subsidised employment is a form of financial aid for the employer which provides an incentive to employ, assuming the reduction of costs (also full coverage of costs) incurred by him/her for employing employees. Subsidised employment is envisaged mainly for unemployed people in a special situation on the labour market. They are to enable them to enter the labour market and prevent the effects of long-term unemployment. The catalogue of basic forms of activisation of the unemployed in the years 2005-2018 was changing. Ministry of Family, Labour and Social Policy (MRPIPS) in Poland serves on its website every year, which forms are in given year the basic ones (https://www.gov.pl/web/rodzina/efektywnosc-form-promocji-zatrudnienia). Table 1 presents the structure of the unemployed starting to participate in basic forms of activisation in Poland in the years 2005-2018. Registered unemployed persons were most often offered internships. In the second place, there were trainings.

Fig. 2: Total cost and employment effectiveness of activisation programmes in Poland in the years 2005-2018

Source: Own study based on data from MRPiPS.

In order to assess the effectiveness of the implemented programmes, employment and cost effectiveness coefficients of basic forms of professional activisation are determined. Both forms of effectiveness are published in the MRPiPS elaborations (https://www.gov.pl/web/rodzina/efektywnosc-form-promocji-zatrudnienia). Employment effectiveness is an indicator allowing to determine the chances of finding employment after the end of participation in the programme. The assessment of the cost of getting an unemployed person into employment is assessed by means of cost effectiveness. Figure 2 shows the values of both indicators in the years 2005-2018. In the years 2006-2010, a large increase in cost effectiveness (from about 6.5 thousand PLN to about 13 thousand PLN) was accompanied by a relatively constant employment effectiveness at the level of about 55%. In 2011, there was a significant decrease in cost effectiveness compared to the previous year from about 13 thousand PLN to about 9 thousand PLN. Then, by 2015, both effectiveness showed upward trends, and after 2015, the employment effectiveness continued to increase with a decreasing value of cost effectiveness. All this indicates better use of funds for economic activisation of the unemployed in the years 2015-2018. In general, it can be concluded that over the years there has been an improvement in the effectiveness of basic forms of economic activisation – this is visible in the growing values of employment effectiveness, which at the end of the analysed period increased significantly compared to its beginning (Bieszk-Stolorz, Dmytrów 2019, 2020). From the point of view of social policy, it is important to bring the unemployed into employment (high value of employment effectiveness). On the other hand, from the point of view of state finances, it is important that this employment should have the lowest possible financial cost (low value of cost effectiveness). Analysing both of these efficiencies for subsidised

employment, it can be observed that the highest employment efficiency is characterised by co-financing of starting a business, followed by intervention works and refunding the costs of equipping or retrofitting workstations, while the smallest socially useful works. For this reason, the latter form was removed from the catalogue of basic forms of activisation in 2014-2018, despite the fact that in 2006-2013 it was the most frequently proposed form of subsidised employment. The costliest form (the highest cost effectiveness) of subsidised employment was the subsidised employment, which was followed by the refunding of the costs of equipping or retrofitting workstations.

Research Methodology

Selected methods of survival analysis were used in the study. It is a set of methods that investigate processes in which the time that passes to the occurrence of a certain event is analysed. The duration in a given state of units belonging to a certain cohort is observed. The duration that elapses from the beginning to the end of an event is a random variable T. Since the observation period is limited, certain units belonging to the cohort under consideration may not experience the final event before it has occurred. Such observations are considered to be right censored. Situations where the unit under investigation disappears from the field of view or another end-of-entry event occurs that excludes the occurrence of a specific event are also considered as such observations (Pepe, 1991). The latter type of event is called a competing event. Competing risk is defined as an event that excludes or fundamentally changes the probability of occurrence of another event (Gooley, Leisenring, Crowley, Storer, 1999). It is assumed that different types of events occur independently of each other (Crowder, 1994, 1996, 1997). The entity under investigation is exposed to different risks at the same time, but the possible event is due to only one of these factors, which is called the "cause of failure". (Aly, Kochar, McKeague, 1994). In addition to *unconditional competing risks, conditional competing risk models* are also considered. In the case of the first type of events their independence is assumed. For the latter, the probabilities of transition between states depend on explanatory variables and the time and type of being in the previous state. In the analysis of unemployment, the time of registration in the labour office may be observed, and the methods of survival analysis enable the assessment of the probability and intensity of exiting unemployment (Bieszk-Stolorz, 2017a, 2017b; Bieszk-Stolorz, Markowicz, 2015, 2019).

The survival analysis is based on two functions: survival and hazard (intensity) ones. The survival function is defined as follows:

$$S(t) = P(t > T) = 1 - F(t) \tag{1}$$

where: t is the duration of the phenomenon, $F(t)$ is the cumulative distribution function of the random variable T.

The survival function can be said to be a complement to the unity of the cumulative distribution function. In a situation where the distribution of the duration of the analysed process is not known, the Kaplan-Meier estimator (Kaplan, Meier, 1958) can be used to estimate the survival function:

$$\hat{S}(t) = \prod_{j:t_j \le t} \left(1 - \frac{d_j}{n_j}\right) \tag{2}$$

where: d_j – number of events in time t_j, n_j – number of units exposed to risk in time t_j.

The hazard function describes the intensity of the event at time t provided that it survives to time t and is defined as follows (Kleinbaum, Klein, 2005):

$$h(t) = \lim_{\Delta t \to 0} \frac{P(t \le T < t + \Delta t | T \ge t)}{\Delta t} \tag{3}$$

The cumulative hazard function, on the other hand, is the sum of hazard up to time t and for discrete time is determined by a formula:

$$H(t) = \sum_{j:t_j \le t} h(t_j) \tag{4}$$

The cumulative incidence function ($CIF_k(t)$) is used to assess the probability of an event occurring due to k before time t. This function is defined as follows (Klein, Moeschberger, 2003, p. 52):

$$CIF_k(t) = P(t \le T, \delta = k) = \int_0^t S(u)\, h_k(u) du = \int_0^t S(u)\, dH_k(u) \text{ for } k = 1,2,3,\ldots,K \tag{5}$$

where: $H_k(t)$ – cumulative hazard function; $S(t)$ – survival function; $\delta = 0$ for censored observations; $\delta = 1,2,\ldots,K$ for observations ending with an event of k-th type (one of the K competing events).

CIF_k is a function of the cumulative probability of an event of k-th type occurring before or at time t (Bryant, Dignam, 2004). This function is often called a subdistribution. The estimator of cumulative frequency due to the occurrence of k-th cause is given by the following formula (Marubini, Valsecchi, 1995):

$$C\hat{I}F_k(t) = \sum_{j:t_j \le t} \hat{S}(t_{j-1}) \frac{d_{kj}}{n_j} \text{ for } k = 1, 2, 3, \ldots, K \tag{6}$$

where: t_j - time j of the event; d_{kj} – number of events due to the occurrence of cause k in time t_j; n_j – number of units exposed to risk in time t_j.

Because $\sum_{k=1}^{K} d_{kj} = d_j$, it is true that:

$$\sum_{k=1}^{K} C\hat{I}F_k(t) = 1 - \hat{S}(t) \tag{7}$$

For the different types of competing risks ($k \ge 1$), the hazard function is described by the formula (Klein, Moeschberger, 2003, p. 50):

$$h_k(t) = \lim_{\Delta t \to 0} \frac{P(t \le T < t + \Delta t, \delta = k | T \ge t)}{\Delta t} \text{ for } k = 1, 2, 3, \ldots, K \tag{8}$$

The estimator of the $h_k(t)$ gambling function for cause k at the moment t_j is as follows:

$$\hat{h}_k(t_j) = \frac{d_{kj}}{n_j} \text{ for } k = 1, 2, 3, \ldots, K \tag{9}$$

where d_{kj} and n_j have the same meaning as in the formula (6). This model is also called the empirical hazard model.

Data Used in the Study

Methods of survival analysis require access to individual data. In the case of analysis of registered unemployment, their sources are the poviat labour offices. The Syriusz IT system implemented in them allowed to create a rich database for this type of analysis. In the study, anonymous individual data of 22,078 unemployed people, registered in 2013 in the PUP in Szczecin, were used. The time from the moment of registration to the moment of de-registration from the office due to a specific cause was analysed. The end of the observation was assumed to be the end of 2014. Numerous causes for de-registration were grouped (Table 2). The study was conducted in two stages. In the first stage, the causes were divided into four groups: non-subsidized work, subsidized employment, removal and other causes. In the second stage, the first two groups were combined into one – work. Since some of the observed units did not experience an event before the end of the observation, the study included right-censored observations (Table 3).

Table 2: Groups of causes for de-registration from the labour office

Stage I of the study	Cause for de-registration	Stage II of the study
Unsubsidised work	taking up job, other employment or non-agricultural business activity	Work
Subsidised employment	undertaking public works, intervention works or socially useful works, working within the framework of an additional job created by virtue of a granted loan or subsidy, granting one-off funds for undertaking business activity,	
Removal	refusal to accept an offer of employment or any other form of assistance; failure to appear in the labour office within the prescribed period,	Removal
Other	the right to a retirement pension, rehabilitation benefit, disability pension, permanent benefit, pre-retirement benefit/assistance allowance, nursing benefit, supplement to family allowance for single parenting of a child, receiving a guardian's benefit, being subject to pension insurance for permanent work as a household member in an agricultural holding, residence abroad longer than 30 days, change of residence/stay outside the area of operation of the labour office, illness or staying in a closed detoxification centre, participation in training organised by an entity other than the labour office, death, military service, taking up full time education	Other

Analysis of the Impact of Subsidised Employment on Exiting Unemployment

In the first stage of the study, cumulative incidence function (CIF_k) and hazard functions were determined for four different events ending the observation process ($k = 1,2,3,4$). Figure 3 shows the values of cumulative incidence function estimators for the following causes: unsubsidised work, subsidized employment, removal and other causes. In this way, the probability of de-registration for various causes up to time t or at time t was determined. The probability of de-registration due to taking up non-subsidised employment and being removed from the register was similar, but from 10th month onwards the probability of removal was slightly higher. The probabilities of de-registration for subsidised employment and other causes were marginal and did not exceed 5% and 8% respectively. Noteworthy is the fact that the survival curves for non-subsidized work and subsidised employment are regular. The probability curves for removal and other causes do not have this property. In their course, one can notice short value jumps. For the group, the remaining small value spikes occurred in the seventh month after registration. The analysis of data indicated that it was caused by an increased number of de-registrations in that period due to granting the registered unemployed person the right to receive a pre-retirement allowance/benefit. However for the removal a significant jump in the first month was connected with an increased number of de-registrations due to the fact that the unemployed person did not appear in the PUP within the prescribed period.

Fig. 3. Values of the CIF_k estimators determined in stage I of the research

Source: own study.

The intensity of exiting unemployment was then examined for the four identified causes (Figure 4). It was the highest for de-registrations due to the removal and taking up unsubsidised work. The intensity of removal and taking up subsidised employment was marginal. The high value and rapid decrease in the intensity of removal and subsidised employment in the first two months after registration is characteristic.

Fig. 4. Values of the hazard function determined in stage 1 of the research
Source: own study.

For an unemployed person it is important to take up a job in general, that is why in the second stage of the study the events of taking up a non-subsidised job and subsidised employment were combined into one group – work. CIF_k estimates and hazard functions were determined for three events ending the observation: work, removal and other. With this classification, the probability of de-registration due to taking up any job was higher than the probability of removal starting at the second month after registration. The other causes had a marginal impact (Figure 5).

Fig. 5. Values of the CIF_k estimators determined in stage II of the research
Source: own study.

Fig. 6. Values of the hazard function as determined in stage II of the research
Source: own study.

Figure 6 shows the hazard functions for the three types of events. The intensity of de-registrations due to taking up a job still does not exceed the value of hazard for removal; however, it is now clearly decreasing and reaches its highest value in the first months after registration.

Conclusions

Public provision of vocational training, wage subsidies and job search assistance are features of the modern welfare state. These measures are primarily the basis for a European "active labour market policy". They have also been present in the USA for several decades (Heckman, Lalonde, Smith 1999). This policy is also postulated as a way to alleviate the shocks in labour markets in the economies of the former Eastern Bloc and the countries of Latin America, which are currently moving to market systems.

The main characteristic of a modern welfare state is the need for "objective" knowledge of the effects of various government tax and transfer programmes. Different entities derive benefits and losses from such programmes. The assessment of these benefits and losses often plays a key role in policy decisions. Recently, interest in evaluation has increased as the number of countries with modern welfare states and the costs of running a welfare state have increased.

The methods of survival analysis used in the study: cumulative incidence function and empirical hazard model allowed to assess the impact of subsidised employment on the probability and intensity of exiting unemployment in Poland. The analysis showed that it was of marginal importance, which results from the limited resources available to the office. The probability of taking up subsidised employment within 24 months of registration did not exceed 0.05, and its intensity was highest within the first two months of registration. However, this had the effect of increasing the probability and intensity of employment in general. In addition, the study showed that the removal of an unemployed person or, in fact, the resignation from mediation of labour office was a very strong cause for de-registering the unemployed. The probability of de-registration for this cause was higher than in the case of taking up unsubsidised employment. This may indicate that the willingness to take up employment was not the main cause for the unemployed to register with the office and that the unemployed were not always interested in the proposed forms of activisation. It should be noted that the period covering the highest unemployment rate in Poland and the subsequent period of improvement in the labour market situation was analysed. The emerging greater employment opportunities may have induced the registered unemployed to look for a job without the mediation of the office and less interest in subsidised employment.

Abstract

Analysis of the phenomenon of unemployment is an important issue in socio-economic research. According to the literature on the subject, analyses concerning the labour market are focused on reducing the resources of the unemployed by taking up employment. However, there are more reasons for the outflow of the unemployed from labour office registers. The proposed job offers often do not suit the unemployed. They refuse to take up the offered employment, do not show up at the office within the set deadlines, interrupt participation in activisation programmes for no reason. As a result, they are removed from the register. In order to pursue an effective labour market policy, it is important to identify such groups of people. The aim of the study is to compare the duration in unemployment of three groups of de-registered people. These are de-registrations due to taking up work, removal and other causes (resignation from the mediation of the labour office). In the empirical example, a cohort of the unemployed, de-registered persons in 2017 from the Poviat Labour Office in Szczecin was used. As a research tool, a non-parametric model of the duration of a specific phenomenon was used – duration tables. Cohort tables for particular types of exiting unemployment were built on the basis of individual data of 19,931 people (SYRIUSZ IT system). In the construction of the tables the following features of the unemployed were taken into account: gender, age, education, seniority and number of subsequent registrations.

Keywords: Survival Analysis, Duration Tables, Registered Unemployment

Introduction

In 2004, in connection with Poland's accession to the European Union, labour market regulations were changed. The scope of activities related to counteracting unemployment was extended. The Act of 20 April 2004 on employment promotion and labour market institutions-imposed tasks related to employment promotion and activisation of the local labour market on poviat labour offices. One of the main tasks is to help the unemployed to find work.

It should be noted that the measurement of unemployment is defined differently. In Poland, usually registered unemployment or a panel survey are taken into account (Labour Force Survey; LFS). For international comparisons, a harmonised unemployment rate is usually used. Harmonised unemployment rate is calculated by Eurostat for the needs of monthly statistics. For Poland, the data are calculated by Eurostat on the basis of quarterly results of the Labour Force Survey (LFS), in accordance with the definition of the International Labour Organization (ILO) and the monthly results from the registered unemployment. This indicator in January 2020 in the European Union was 6.6% (Eurostat, 2020). Poland was ranked second among countries with the lowest unemployment rate (2.9%) after Czechia (2.0%). The highest unemployment rate was recorded in the following countries: Greece (16.5%), Spain (13.7%) and Italy (9.8%).

In Poland, statistical data on registered unemployment is collected in poviat labour offices. They provide rich information on all causes for de-registration. There are several dozen of them. In addition to taking up employment, the unemployed take a pension, retirement pension, pre-retirement allowance, go abroad, change their place of residence, and start education on a daily basis. Very often, registered people refuse to take up employment or participate in the forms of activisation proposed to them, and they do not appear at the office within the prescribed period. They are then removed from the register and lose their unemployment status.

The aim of the study was to compare the duration in unemployment of people who had been de-registered due to taking up work, removal and other causes. The non-parametric model of unemployment duration – duration tables – was used as a research method. The probability of remaining in the register and the intensity of de-registration were analysed depending on selected characteristics of unemployed people. In the study, individual data of 19931 people registered in the Poviat Labour Office in Szczecin (Poland) from the SYRIUSZ IT system were used.

Outflow of Unemployed from Labour Offices

Starting from 2013, the registered unemployment rate in Poland decreased from 13.4% (XII.2013) to 5.2% (XII.2019). In June 2020, the unemployment rate increased to 6.1%, which may be a result of the COVID-19 pandemic. At the same time, the number of people inflowing into and outflowing from unemployment was decreasing, while the number of de-registered people was higher. The structure of people was also changing due to the cause for de-registration. All variants of exiting unemployment from the office's records can be grouped into three groups: taking up work, removal and other causes. Taking up work should be understood as employment, taking up business activity and taking up subsidised work (e.g. public works, intervention works, refunding part of wage costs). Removal takes place due to failure to appear in the office within the prescribed period, rejection without reason of a job offer or discontinuation of participation in activisation forms or at the request of registered person. These are the reasons that prove a lack of interest in cooperating with the office. In the years 2008-2018, they accounted for between 19% and 32% of all de-registrations in Poland and in the years 2008-2013, they were slightly lower than taking up work (Fig. 1). Other causes include acquisition of the right to a pension, retirement pension, retirement benefit, receiving benefits, obtaining income, going abroad, death of the registered person or change of residence.

Fig. 1. Inflow into and outflow from unemployment from labour offices in Poland in 2008-2019 (in thousands)

Source: own study on the basis of the study: Statistical Yearbook of Labour 2010, 2012, 2015, 2017; CSO 2020, Registered unemployment I quarter 2020.

People registered in labour offices can be divided into two groups: real and seeming, i.e. people who are not interested in work (they are not looking for it or are not ready to take it up) and those working in the black economy or otherwise earning not less than 1200 PLN per month (Kotowska, 2014, p. 197). The seemingly unemployed constitute a large percentage of people registered – 43% in 2015

(Czapiński, Panek 2015). Analyses of the labour market indicate that not all registered unemployed people are interested in taking up work. They give various reasons for not looking for work. In 2015, women most often indicated childcare (36.1%), the belief that they will not find a job (18.4%) and activities related to housekeeping (13.9%). Men, on the other hand, expressed the belief that they would not find a job (30.3%) or indicated their poor health (19.3%) (Czapiński, Panek 2015, p. 415).

Data Used in the Study

Most methods used in the survival analysis require the use of individual data for each analysed unit. This is certainly a major difficulty due to the lack of access to such information. In the case of registered unemployment, such data are collected in Poland by poviat labour offices thanks to the SYRIUSZ IT system. In the presented study, individual data on 19,931 unemployed de-registered in 2017, obtained from the Poviat Labour Office in Szczecin, were used. These data included the date of registration, the date and cause for de-registration, thanks to which the duration of registration was determined. In addition, it included the age of the unemployed person, their gender, education, seniority and information on whether it was the first or subsequent registration with the office. Six age groups and five education levels were designated. Due to seniority, the persons were divided into those without and those with seniority. The study took into account the number of subsequent registrations. This feature has two categories: first and subsequent registration. The causes for de-registration were divided into three options: taking up work, removal and other causes. The structure of the unemployed, together with the designations of particular groups, is presented in Table 1.

Table 1: Structure of unemployed persons de-registered from PUP in Szczecin in 2017

Group		Total		Work	Removal	Other causes
		Number	%	Number	Number	Number
Total		19,931	100	8,120	10,582	1,229

Research Methodology

In the study, the duration tables were used, i.e. the non-parametric model. It is one of the oldest statistical methods used in medical and actuarial statistics (Merrell, 1947; Greville 1948; Kaplan, Meier, 1958; Cox, 1972; Namboodiri, Suchindran, 1987). Unlike parametric models, assumption of theoretical distribution of analysed variable is not required (Namboodiri, Suchindran, 1987). When the subject of research is the registered unemployment duration, it is difficult to assume a specific distribution. In such situation the non-parametric models are used, examples of which are duration tables (Balicki, 2006; Markowicz, 2012) or semiparametric ones (Bieszk-Stolorz, Markowicz, 2012; Bieszk-Stolorz, 2013; Bieszk-Stolorz, Markowicz, 2015, 2017; Markowicz, 2019). Durations tables are a tabular model, most often used in demography, as life expectancy tables. However, it is used in many other fields of science to study the duration of phenomena (Gołata, 1994; Gazińska, Mojsiewicz, 2004; Markowicz, Stolorz, 2006; Landmesser, 2013; Matuszyk, 2015; Wycinka, 2017; Markowicz, 2017, Mikulec, 2018).

In life expectancy tables, the annual age groups (full tables) are the most commonly adopted. In this study, for duration in unemployment, a 3-month range is used. The cohort in this case is the unemployed de-registered in 2017 for various causes (three options). The observation duration was maximum 7 years, so the last range in the tables was 81-84 months. The tables of unemployment duration present the process of changes in the composition of the cohort over time (Bieszk-Stolorz, Markowicz, 2016). The analysis used two basic functions: survival $\hat{S}_t^*$ (survival) and hazard $\hat{h}_t^*$ ones (Markowicz, 2018):

$$\hat{S}_t^* = \prod_{k=1}^{t} \hat{p}_k^* \tag{1}$$

$$\hat{h}_t^* = \frac{z_t}{\left(n_t^* - \frac{z_t}{2}\right) a_t} \tag{2}$$

where:
t – beginning of the duration interval $\langle t, t+1)$,
$\hat{p}_t^* = \frac{n_t^* - z_t}{n_t^*}$ – the probability of survival in the particular time intervals,
$n_t^* = n_t - \frac{c_t}{2}$ – number of units exposed in the interval,
z_t – number of units affected in the interval,
c_t – number of censored units in the interval,
a_t – interval of duration (3 months).

The survival function determines the probability that a unit will not experience a particular event until the end of a given period. The hazard function determines the risk of a specific event occurring in a short period $(t; t + \Delta t)$, provided that it has not occurred by time t.

Empirical Results

The main study was preceded by the determination of the median time to de-registration. It was determined separately for each of the three causes (Table 2). This preliminary analysis indicated that the fastest de-registration was observed in the case of removed persons, especially men under 24 years of age. The median time to start of working was slightly higher. Men up to 24 years of age were also the fastest to take up work. People that were de-registered due to other causes had the longest registered unemployment duration.

Table 2: Median time to de-registration by characteristics of unemployed persons

The survival function of unemployment duration, as one of the functions in the durations tables, informs about the probability of exit from unemployment for each group of causes (Figures 2-6: 1 – taking up work, 2 – removal, 3 – other causes).

(a) Total unemployed

(b) Women (K) and men

(c) First-time registration (1) and subsequent registration

(d) Lack of seniority (0) and seniority held

1 - taking up work, 2 - removal, 3 - other causes

Fig. 2. Function of survival in unemployment (in months) – total and by gender, number of registrations and seniority

Source: own study.

Unfortunately, it turns out that the state of unemployment is most quickly exited by people that are removed (Fig. 2a), especially men (Fig. 2c). For example, 80% of the cohort left the register up to 33rd month due to removal (women to 45th and men to 30th) and to 69th month due to taking up work (women to 66th and men to 72th). The unemployed registered for the first time than for the next time (Fig. 2c) and those with seniority than those without (Fig. 2d) take up work faster. Taking into account the age of the unemployed, one should note the equalisation of functions for taking up work and removal for the first two years in the case of young people (25-34 years, Fig. 3b). Taking into account education of the unemployed, the following observations are worth noting: much slower leaving the cohort due to taking up employment than due to removal for people with the lowest education (Fig. 4a), equalisation of both functions during the first year of unemployment for people with vocational secondary education (Fig. 4d) and faster leaving for work than by removal for people with higher education (Fig. 4e).

Fig. 3 Function of survival in unemployment (time in months) – by age (years)

Source: own study.

Fig. 4. Function of survival in unemployment (time in months) – by education

Source: own study.

The second of the presented functions, the hazard function, indicates the intensity of de-registrations in subsequent time intervals. The highest intensity was observed in the first half of the year of unemployment (taking up work and removal, Fig. 5a). A larger jump of the function in the final period of observation results from a small number of people remaining in the cohort. After 24-25 months from the registration, more people were removed due to failure to appear in the office within the prescribed period (higher value of hazard function). However, a jump of values of the function for the remaining causes at about 6-7 months results from granting the right to pre-retirement benefit to a larger number of people.

Figure 5: Hazard function (time in months) – total unemployed and by gender

Source: own study.

Fig. 6. Hazard function (time in months) – unemployed by education

Source: own study.

When analysing the course of the hazard function for the unemployed by gender (Fig. 5b-c) and by education (Fig. 6), attention should be put on the following: higher intensity of men's removals than women's removals in the initial period since registration (fictitious registration) and higher intensity of exits to work than removals in the initial period of unemployment for persons with higher education.

Conclusions

In order to lead an effective labour market policy, it is necessary to identify people at risk of unemployment. The unemployment rate is the basic indicator used in such analyses. The second, but no less important, is the time of seeking work. Methods of survival analysis allow to assess the probability of staying unemployed and to determine the intensity of exiting unemployment in relation to its duration. The tools useful for this type of research are the survival and hazard functions. Their undoubted advantage is the possibility of using incomplete data when the observed unit disappears from observation. Its presence in the cohort until censorship affects the results of the analysis. A barrier to using such methods may be the lack of access to individual data. A very good source of such data in Poland is the SYRIUSZ IT system implemented in poviat labour offices. It provides information about registered unemployment. The analysis of exiting unemployment should focus not only on people taking up employment, but also on people who resigned from mediation of the labour office for unknown reasons. The presented study showed that the people who were removed from the labour office, left the cohort most quickly. The course of the survival curves informs about the fact that during the analysed period, women took up work faster and men were removed from the cohort faster. Also, people registered for the first time, with seniority, young people, with higher education, took up work faster. The course of the hazard function indicated that the intensity of de-registrations due to taking up work and being removed was high in the initial period of unemployment. The course of this function was different for other causes. A detailed analysis makes it possible to identify the moments in which unusual changes occurred. In the case of the conducted study, these were described earlier: 6-7 months for de-registration for other causes and 24-25 months for removal.

The conducted research indicates a lack of willingness on the part of the unemployed to cooperate with the labour office. They are not determined to accept job offers, training or internships. These are people who expect different proposals to earn money than those made ex officio. They often work in the black economy or expect only to receive social benefits. In order to prevent such practices, it is essential to change the legal conditions.

The analysis presented in the article was based on data for the year 2017. It should be noted that these data are reliable. Information for subsequent reporting periods is still being verified, and once it has been verified and corrected, the authors will have access to it (they have permanent cooperation with the office) and will continue their research. Certainly, the analysis of data for 2020 will be interesting due to the impact of the COVID-19 pandemic on the phenomenon of unemployment in general, and especially on the change in the number of unemployed people (in particular subgroups) and on job search time. These data are not yet available. Due to the methods used, they require observation for a certain period of time – at least one year. Signals coming from the economy indicate that not only the unemployment rate but also the unemployment duration will increase. There may also be a decrease in the intensity of de-registration to work.

Abstract

Choosing the right design, architecture and technologies for an application can be difficult for architects and engineers, especially when dealing with big and fast data. Indeed, these platforms need to deal with the data growth and variety, while generating insights in a timely fashion. These constraints, combined with the wide range of available storage and processing technologies, are hard to satisfy. On the other hand, and with the lack of clear methodologies, best practices and validation tools, testers struggle to perform end-to-end evaluations for the developed Big Data solutions. The need for a generic benchmarking solution, able to integrate with any multi-layered Big Data architecture, is manifest. In this paper, we present and evaluate BABEL, a generic, scalable, distributed and end-to-end Benchmarking Platform for Big Data architectures.

Keywords: Benchmark testing, Big data applications, Distributed management, Software architecture, Performance analysis

Introduction

The need for Big Data platforms in modern companies is increasingly pressing, as the value extraction is the main source of competitiveness. Handling such "big and fast data" is essential not only for automated decisional needs but also for a wide range of operational activities such as transactional systems, machine learning, and Internet of Things (Chen, Chiang and Storey, 2012). However, these platforms need varied types of expertise and a consequent investment in terms of hardware, human resources and implementation time. On the other hand, with the lack of standard architectures and predefined platforms (Braun, 2015), it is difficult to choose the right design for a complex Big Data system.

In fact, Big Data architects can pick nowadays from an expanding array of technologies (Azarmi, 2016) which makes the choice of the adequate architecture very complicated, especially while taking into consideration all the functional and non-functional parameters, such as business requirements, technology, tuning, integration between layers, costs, etc. (Malik, Rafatirad and Homayoun, 2018)

Cite this Article as: Mohamed Mehdi BEN AISSA, Lilia SFAXI And Riadh ROBBANA "Benchmarking Big Data Architectures with BABEL" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

We propose in this article an evaluation framework to help infrastructure engineers, architects and developers decide which architecture suits best their needs. We use in our case benchmarking as an evaluation tool. Benchmarking (Anand and Kodali, 2008) helps to compare the performance and efficiency of a set of systems regarding certain predefined metrics.

Defining a generic benchmarking framework to compare the adequacy of an architecture to the needs of the client can be rather tedious, as each architecture can have different characteristics: distribution and parallelism degree, used technologies and patterns, relation and integration between layers, supported workloads, generated data and events, etc.

On the other hand, existing benchmarks like YCSB (Cooper *et al.*, 2010), TeraSort (O'Malley, 2008) and BigBench (Ghazal *et al.*, 2013) are technology-oriented, and don't support multi-layered architectures. This is due to the fact that Big Data systems follow different patterns and constraints depending on the application and the technical and physical architecture, in addition to other constraints, such as processing type, data schema, and distribution policy.

This is why we introduce in this article a new benchmarking framework called **BABEL** (the name is inspired from the myth of the Tower of BABEL, used to justify the origin of the presence of multiple spoken languages), the **B**ig d**A**ta **BE**nchmarking p**L**atform. It is a generic tool, defined by a set of interconnected components that are destined to work for any Big Data architecture. In the following, a literature review study was addressed in order to identify the existing Benchmarking solutions, their benefits and limits. Then, we introduce BABEL by detailing its features, architecture and design. Finally, we explain in the experimentation part how to get started with the tool, accompanied by performance and overhead tests.

Literature Review

Many research papers tackled the problem of Big Data Benchmarking, each one of them using a different approach and targeting a different system. Some review works performed a classification of the existing benchmarks following several characteristics, such as the solution type (micro-benchmark, end-to-end benchmarks or benchmarking suites). We choose to classify them according to the type of targeted benchmarked systems. We noticed that the overwhelming majority of these benchmarking solutions target either a specific technology, or a specific type of application.

Technology-Specific Benchmarking Solutions These solutions are created to study the performance of a specific technology when varying the platform, the workloads or the testing environment. Most of the technology-specific Big Data benchmarking solutions are targeting the Hadoop framework. The ALOJA benchmarking platform (Poggi *et al.*, 2014), for instance, a set of open-source configuration management tools, coupled with a data analytics web application, is used to benchmark the Hadoop environment when varying the system's architecture. MRBench (Kim *et al.*, 2008), HiBench (Huang, Huang and Dai, 2010) and MRBS (Sangroya, Serrano and Bouchenak, 2012) are benchmarking suites destined to test MapReduce workloads while TPCx-HS (Nambiar, 2014) defines a standard produced by the Transaction Processing Performance Council (TPC) for benchmarking Hadoop runtime, API and MapReduce layers. PigMix (Ouaknine, Carey and Kirkpatrick, 2015) tracks the performance of the Pig query processor and SparkBench (Li *et al.*, 2015) targets all layers of the Spark framework.

Application-Specific Benchmarking Solutions Each one of these solutions targets a specific type of Big Data applications. We can distinguish for example solutions dedicated to storage systems, going from relational to NoSQL databases and distributed file systems such as HDFS. We cite in this category BigBench (Ghazal *et al.*, 2013) an application-level Big Data analytics benchmarking suite that captures

operations via SQL queries and data-mining operations to be analyzed via Batch-oriented processing; BigDataBench (Wang *et al.*, 2014), which is an open source benchmarking solution coupled with a data generation tool, that uses an iterative and incremental approach for its design, rather than a top-down one; and XBench (Yao, Özsu and Khandelwal, 2004), a benchmark that targets XML databases. Other solutions focus on streaming applications, like Chronos (Gu *et al.*, 2015), a framework for generating and simulating streaming data; the benchmarking platform for streaming computation engines proposed by Chintapelli et al. (Chintapalli *et al.*, 2016), which constructs a data pipeline to generate and process realistic streaming data to be computed by the three most popular streaming engines: Flink, Storm and Spark Streaming; and StreamBench (Qian *et al.*, 2016), which proposes a middleware between the data generator and the data processors. Several works, such as those of (Armstrong *et al.*, 2013; Capotă *et al.*, 2015; Nai *et al.*, 2015; Ngomo and Röder, 2016), focus on graph processing and storage, while others such as those of (Cooper *et al.*, 2010; Luo *et al.*, 2012; Ferrarons *et al.*, 2014), specifically tackle Big Data solutions in the cloud.

All the solutions cited above fail to offer a generic design that can be applied to any Big Data system and architecture. On the other hand, most of these benchmarks evaluate individual system components (either hardware components like the CPU or Networking, or software components like HDFS), specific systems or operations (Han, John and Zhan, 2018), and must be combined or modified to be applied to Big Data applications with complex architectures. To the best of our knowledge, very few existing solutions are architecture-level, such as the one presented by Persico et al. (Persico *et al.*, 2018), which provides several analyses to compare the performances of Lambda and Kappa architectures for Online Social Networks. Even though this work focuses on the impact of the used architecture on the performance of the system, it does not provide a general design for benchmarking Big Data architectures, that is dynamic, agile and adaptable to any architecture with any number of layers.

BABEL: Design and Implementation

Features

Our objective is to design a solution able to provide a set of custom and standard end-to-end performance metrics such as throughput, latency, power efficiency, and client CPU/memory consumption, under custom test cases. It must be agnostic to the System Under Test (SUT) and its architecture, and applicable to any multi-layered system using Big Data technologies.

Our focus is to present a conceptual design and a concrete implementation of a generic benchmarking framework, whose main features are:

Genericity It should be technology-, application- and architecture-agnostic.

Dynamicity It should run in parallel with the system, without interfering with its behavior, and with negligible overhead.

Adaptability It must adapt to any number of layers in the Big Data application, as well as to any type of data and workloads.

Multi-Paradigm It should be able to benchmark streaming and batch processing systems, as well as operational and decisional platforms.

End-to-End Solution It needs to evaluate the behavior of the whole system, by measuring application- and system-level metrics.

Real-time Reporting It must offer a real-time reporting layer, illustrating the system's metrics on the fly.

Distribution and Scalability It must be configurable, and offer a scalable collection, processing engines and storage, in order to enable the continuous archiving of metrics for a better analysis.

Agility The platform should be flexible: during the different integration phases and also at run-time, new layers, metrics, and processing jobs can be added on the fly.

In this solution, a great importance is given to *usability*. In fact, in addition to a user-friendly reporting, the tester should have little code to write, thanks to an easy extension of the connectors.

Architecture and Components

As shown in Figure 1, two main layers are defined in this platform: the *Benchmark Core Layer*, destined for the orchestration of the evaluation process, and the *Benchmark Integration Layer*, in charge of the communication with the SUT.

System Under Test (SUT) The SUT is the physical implementation of the architecture that we want to benchmark. It can include an unlimited number of layers and technologies with different levels of dependency, distribution and service agreements. BABEL is compatible with different types of workloads: transactional, decisional or mixed, easily customizable by the tester. BABEL can also support other advanced and complex multi-layered architectures, such as Business Intelligence, Complex Event Processing, Data Science, or Internet of Things systems. In addition to that, it ensures a full support of cloud native applications and platforms.

Benchmark Integration Layer This layer's goal is to inject generated data to the SUT and to collect the performance metrics from its endpoints.

Fig. 1: Architecture of BABEL

Data Generator According to Han et al. (Han *et al.*, 2015), using real data in benchmarking is not always recommended, from a security point of view. On the other hand, it can be really hard to replay these data in the right chronological order with a realistic frequency. This is why, most benchmarks such as those presented by (Kim *et al.*, 2008; Cooper *et al.*, 2010; Capotă *et al.*, 2015; Qian *et al.*, 2016), use data generators for performance monitoring, which guarantees the respect of Big Data constraints: high data volume, velocity and variety.

The data generator is in charge of generating test data for the benchmark. The tester can manage the generated data flow by defining several configuration parameters for the generated data (number of fields, field length, etc.), producers (parallelism level, number of threads per producer, etc.) and SUT (connection parameters, hosts, ports, etc.)

The data generation module is an extension of the Yahoo! Cloud Serving Benchmark YCSB (Cooper *et al.*, 2010). It includes several Big Data connectors and gives a very high flexibility level, while integrating real use cases and a functional data generation. The data generation logic is managed by the orchestration layer and executed by the producers.

Benchmark Producers and Consumers The benchmark includes a set of scalable and distributed Producers and Consumers, in charge of connecting to the SUT. The producers are agents that help to disseminate streams to the entry points of the system. On the other hand, the consumers are in charge of collecting the metrics at the output of each one of the SUT's layers.

The producer and consumer's API can be enriched in order to respect the target business and technical logic. The API is generic and can be configurable to have a specific Producer's or Consumer's personality.

Each producer is identified by a unique *injectorId* in order to guarantee the consistency of the reports. However, as a unique producer is multi-threaded, we have to manage two levels of parallelism: a parallelism between different producers managed by the orchestrator, and a multi-threaded parallelism for a specific producer managed in the producer's configuration.

Consumers have also the same flexibility level and can be deployed using multiple approaches:

- **Agent mode**: the default mode. Just like the producers, consumers are deployed via agent processes that listen to specific layers and send metrics to the benchmark store.
- **Embedded mode**: in this mode, the consumer is deployed in the SUT layer via the API or using other techniques, such as the Aspect-Oriented Programming (AOP).
- **Plugin mode**: this mode is used when existing metrics are available in the SUT by default and can be integrated in the benchmark store via specific plugins.

Benchmark Core Layer The benchmark core layer includes its main components, in charge of configuring the integration layer. It doesn't depend on the SUT and target workload that we want to execute, as all its components are generic and extensible.

Benchmark orchestrator The orchestrator is the bandmaster of the system, in charge of triggering all the benchmark components with the adequate configuration. The orchestrator is in charge of the data generation distribution between the producers and their consistency with the metrics sent by the consumers. In order to be efficiently managed by the orchestrator, all benchmark components are listed and classified in configuration files, along with the SUT, the consumers and producers. This approach decouples the configuration from the implementation of the benchmark, and facilitates its portability and maintainability.

Benchmark Store This component is a scalable storage system, in charge of storing all the events and metrics reported by the producers and collected by the consumers of the integration layer. The metrics sent by the producers and consumers are stored as independent events with the real timestamp referring to the source system and the network time protocol server. We use asynchronous communications, in order to avoid the possible performance impact that can be caused by the integration of the consumers in the SUT, especially when using the embedded mode.

Benchmark Validator This component consumes the events from the store and transforms them into significant metrics and KPIs in order to prepare the next phase and simplify the reporting process.

Benchmark Reporter The reporter generates convivial graphs and reports for the tester, to help the decision-making process and enable a user-friendly display of the performance metrics. The generated reports can include independent metrics and KPIs for a specific layer or combined graphs representing performance lags between successive layers. It is also possible to compare workload results for the same or for different SUTs. The reporter component is in charge of the metrics indexing and visualization with the same scalability level as the previous layers.

BABEL Internal Execution Scenario

The main component and the entry point for the benchmark is the *orchestrator*, which has the responsibility to orchestrate all the other framework's components and to initialize the workflow with the appropriate configuration parameters. It first triggers the integration layer by sending the parameters to the *Data Generator*. This component has the responsibility to load the configuration from the orchestrator and to delegate to each *Producer* a test dataset based on time series as metadata for metrics traceability. Producers are distributed components in charge of the injection of data to the SUT. In parallel and for each layer of the architecture under test, the *Consumers* are managed by the benchmark orchestrator to consume results from the appropriate layer.

All integration components send asynchronous events to the distributed *Benchmark Store*. The *Benchmark Validator* pulls the new stored events, and performs a real-time validation of the performance metrics (throughput, latency ...), to be able to send the results to the *Benchmark Reporter*. The latter will start by indexing all the KPIs and metrics, to finally generate real-time and dynamic reports.

Implementation

We used Big Data technologies (Figure 2) for the implementation of BABEL in order to handle the complexity of the SUT, the volume of the generated data and the need of real-time processing in the validation and reports generation. Indeed, the Benchmark Store needs to be horizontally scalable and sustain a high throughput and a low latency. The Benchmark Validator needs to perform real-time validation of the event flow received from the store.

Fig. 2: Technical Architecture of BABEL

BABEL has a modular architecture and is composed of generic modules that can be adapted to different use cases independently of the SUTs, thanks to the use of interfaces and abstract classes.

You may find the open-source code of BABEL in the following GitHub repository: **https://github.com/mehdibn/BABEL**.

BABEL is developed in Java and uses the following technologies:

- The Data Generator extends YCSB APIs. The tester can keep the default data generation configuration, if random generated data are enough for the testing process. If not, he can easily develop his own data generation logic by overloading the **lastValue()** and **nextValue()** methods of the **Generator<V>** abstract class. He then just needs to specify it in the orchestrator configuration.
- We use the configuration and deployment management tool Ansible as an orchestrator. It supports a distributed execution and deployment, has a declarative approach, is idem-potent, and easily integrates with Big Data technologies. It centralizes all the definitions of the variables and parameters in two configuration files: the *inventory*, which defines the node groups, and *group_vars* which lists the producers and consumers with their installation and workload parameters.
- The benchmark store is implemented with Apache Kafka, a distributed ingestion tool, for a high performance, resilience and scalability. Kafka topics are automatically generated by the orchestrator when deploying the benchmark.
- For the benchmark validator, Logstash is used, because of its scalable and high-performance capacity for event collecting, cleansing and enrichment. The most important feature of this layer consists in transforming metrics to a unique BABEL schema to combine them in reports and dashboards. In case an advanced stateful processing is needed, as a perspective, Apache Flink can be used to implement more complex metrics' validations, requiring an event processing engine for advanced SUT architectures.
- For the reporter, Elasticsearch is used as an indexing system with time series design, plugged with Kibana for the visualization features. Indexes are automatically created by the orchestrator including a generic template of different metrics with pre-configured Kibana Dashboards.
- Basic Consumers and Producers are already developed and can be enriched by implementing the **GenericConsumer** and **GenericProducer** abstract classes. We consider that the effort is minimal as

only few methods will be overloaded by the tester: one to four methods from the specific CRUD operations of the SUT's first layers. Once specific producers and consumers are developed, they must be referenced in the configuration files by specifying their class names and binaries repository after compilation. For Java Management Extensions (JMX) consumers -one of the most used monitoring agents-, automatic on-demand deployment and integration are possible just by defining the SUT parameters in the *group_vars* configuration files.

Data generation BABEL supports customized data generation that testers can enrich easily in order to simulate their specific business logic.

The default benchmark generator can be used for performance testing when random data processing is supported by the SUT. Many parameters can be configured in the BABEL configuration file, such as the number of records to generate, the number of fields per record, the length of field, etc.

Supported Workloads Han et al. (Han *et al.*, 2015) argued that the workloads must be *relevant*, which means that they have to cover the typical behaviors of the evaluated system, *portable*, able to execute on different software systems and architecture, and *scalable*, adaptable to systems of different loads and scales. In order to respect these constraints, we offer the following workloads:

- **Write only [DEFAULT]**: can be used in order to simulate ETL systems, transaction systems, data collection, etc.
- **Read only**: can be used for user profile caching, when they are constructed elsewhere.
- **Update heavy workload**: a mix of 50% reads and 50% writes, and can be used for example for session storage and recording recent actions.
- **Read-modify-write**: in this workload, the client will read a record, modify it, and write back the changes. It can be used for example in user databases, where the records are read and modified by the user, or to record his activity.
- **Customized workloads**: Customized workloads can be configured by defining the proportion of each operation's type. In case of very specific workloads, testers can extend the **Workload** abstract class.

Both batch and streaming workloads are supported and can be configured by adjusting the number of records to generate, as well as the generation rate, that can be unbounded in order to simulate streams.

Getting started with BABEL

In order to use this framework to benchmark a Big Data architecture, we recommend the following approach:

1. Install Ansible on a separate node dedicated to the benchmark core and deploy its *ssh key* on the SUT nodes.
2. Clone the BABEL project from GitHub: https://github.com/mehdibn/BABEL
3. Check if the default data generator, producers and consumers are enough for your needs, or develop your own adapters.
4. Create your inventory describing the SUT and BABEL nodes.
5. Specify the configuration and architecture parameters in the *group vars* files by defining:
   a) Workload: parallelism level, number of fields and records, etc.
   b) Data Generator, consumers and producers' configuration
   c) SUT environment: servers addresses, number of layers, resources name like tables, topics, queues, etc.
   d) BABEL installation parameters

6. White-test the framework by running the various components without actually calling a real SUT, and simulating its behavior using dummy events. This will measure the cost of basic benchmark communications.
7. The reporting dashboards will be automatically generated based on the SUT parameters defined by the tester in the configuration files.
8. Deploy and start the different benchmark components by using the existing Ansible playbooks that will use the defined variables.
9. Real time automatically-generated reports and dashboards will be refreshed in order to show the pre-defined metrics.

SUT Evaluation Methodology

In order to evaluate the performance of the SUT, you first need to answer the following question: do we need to perform a load test (with a predefined reasonable workload) or a stress test (with an unbounded workload)? BABEL is configurable at runtime to support both approaches, depending on the needs of the tester.

Once this objective is fixed, testers need to answer the second question: what type of performance measures and metrics do we need to collect? In this perspective, different test scenarios can be considered:

- For a *performance tuning* purpose, it is advisable to maintain the same system and application configurations and to change one SUT parameter at a time to test its impact, such as: consistency level, partitioning, availability, memory, etc.
- For a *scalability or resilience testing* purpose, we can scale up and down the SUT by adding and removing nodes to its clusters.
- To test the *deployment environment*, we recommend maintaining the same architecture, while deploying it to various environments, that can be cloud based or on premise.
- To test the *performance of the chosen technologies*, we can keep the same architecture while switching from one technology to another.
- To evaluate and compare *multi-layered architectures*, we can keep the same technology stack but change the way they are composed and how they communicate.

BABEL is developed in a way that makes the benchmarking environment almost oblivious to the changes in the SUT. In fact, you just need to adapt the necessary producers and consumers by extending the existing APIs.

Benchmark Overhead and Processing Time

Inherently, the design of BABEL aims to minimize its overhead, by using asynchronous operations in the benchmark integration layer, when interacting with the benchmark core. In order to validate and measure the overhead, different tests were designed and implemented. Every operation is sent to the Benchmark Store, along with its timestamp, in real-time. For the test purpose, a Hadoop Cluster was deployed, including 10 Unix workers with 512GB of RAM, 64 cores and 10 SSD disks for each node. At this stage, a basic Big Data architecture is used including Apache Hadoop and Apache Spark. Producers inject generated data into HDFS, then a Spark batch job consumes it, executes a sort algorithm using each time a new consumer type.

Producers' Performance We compare BABEL with two standard Hadoop benchmarks: TeraGen (O'Malley, 2008) and HiBench (Huang, Huang and Dai, 2010). In Table 1, the results of three test

scenarios are presented. The workloads consist in injecting 500GB then 1TB and finally 100TB of data into HDFS, via the benchmark tools, and by keeping the same configuration: number of files, file format, parallelism level, basic SUT environment, etc. The values displayed below represent the average value obtained after executing the benchmark three consecutive times for every scenario.

During the BABEL and HiBench tests, we observed in the monitoring tools that the SUT was maximally stressed. This behavior was also confirmed by the execution times that were approximately the same. Comparatively, TeraGen is clearly less efficient.

After these tests, we can consider that the producer and data generation layer give acceptable performance results compared to their competitors and are able to stress the SUT by generating a lot of data via a distributed and scalable architecture.

Table 1: Comparative matrix between producers (Unit: second)

Workload	HiBench	TeraGen	BABEL Producer
500 GB	406,05	413,05	405,63
1TB	810,58	831,38	811,75
100TB	4081,76	4188,62	4078,81

Producers' Overhead Once we validated the producers' performance, the goal now is to measure their overhead. The first test scenario is executed without the integration of BABEL, only the producer was submitted by executing the same workloads. Then, in the second scenario, we re-execute the tests by integrating the producer with the BABEL core.

As presented in Table 2, the tests results show a very light overhead with values between 0,03% and 0,04% thanks to the asynchronous calls between the producers and the benchmark store. We consider that the producer's overhead is close to zero, which is only relevant when dealing with very precise SUT benchmark tests.

Table 2: Producer Overhead with Benchmark core integration (Unit: second)

Workload	Producer without core integration	Producer with core integration	Overhead
500 GB	405,63	405,75	0,0305%
1TB	811,75	812,04	0,0355%
100TB	4078,81	4080,31	0,0367%

Consumers' Overhead Following the same approach, we integrated several BABEL consumers with a Spark sort job using different modes. For every data load (500 GB, 1 TB and 100 TB), we compute the processing time of the spark job, without any consumer integration, then with an agent-based, embedded and plugin consumers. Table 3 shows the obtained results.

Table 4 summarizes the overhead of each consumer type compared to the execution time of the spark job without any consumer integration.

As expected, the lowest overhead belongs to the agent mode with values between 0,019% and 0,023%. This mode is based on independent processes deployed in the same SUT nodes with an indirect impact. We also note that the plugin mode's overhead has values between 0,038% and 0,041%, and, finally, that the embedded mode has the highest values between 0,049% and 0,053% as that it's the most intrusive one.

To conclude, even though all the overhead values are acceptable, we recommend the usage of the consumer agent mode when possible.

Table 3: Consumers Overhead (Unit: second)

Workload	SUT without consumers	Agent Consumer		Embedded Consumer	Plugin Consumer
500 GB	81,62	81,64		81,66	81,65
1TB	159,13	159,16		159,21	159,19
100TB	8050,43	8051,96		8054,70	8053,57

Table 4: Consumers Overhead compared to SUT tests without consumers

Workload	Agent Consumer	Embedded Consumer	Plugin Consumer
500 GB	0,021%	0,049%	0,038%
1TB	0,023%	0,052%	0,041%
100TB	0,019%	0,053%	0,039%

Conclusion

We present in this paper BABEL, a generic and scalable benchmarking platform for Big Data architectures. The idea behind BABEL is to offer a robust platform that collects the performance metrics from the system under test, stores and analyses them, to display real-time evaluations. BABEL is developed in a way that makes the effort to integrate it minimal, and the overhead to execute it close to null. Thanks to the scalable storage of BABEL, we are able today to keep a historical repository of the different test scenarios, an excellent use case for a machine learning application, helpful for automatic recommendations about the right behavior, configurations and load management of the system.

On the other hand, in order to facilitate the usage of Big Data architectures and technologies, we intend to integrate BABEL as a benchmarking platform in a flexible and adaptable methodology for governing, managing and applying data throughout the enterprise. BABEL is a project in progress. With the support of the open source community, the tool can be extended and adapted to communicate with various technologies by developing adequate consumers and producers.

Abstract

Decisional systems are dedicated to support the decision-making activities, based on the available data in the organization. Decision-makers nowadays are more demanding in terms of accuracy, speed and availability of the analytics. This induces the need for complex platforms, managed by big teams and integrating data from various sources. Implementing these platforms requires a meticulous organization and a well-honed process that takes into consideration the team workforce, governance issues and agility requirements. In this context, we present a design methodology called DECIDE, intended for large-scale decisional Big Data projects.

Keywords: Data management, Design methodology, Distributed decision-making, Quality assurance, Big data applications.

Introduction

Managing big data projects is a great challenge for many organizations (Katal, Wazid and Goudar, 2013). Indeed, one of the most stringent aspects is to find the right approach to use for a complex and large-scale project. These characteristics apply strongly to decisional projects, as they unify data from various sources, and involve heterogeneous and numerous actors. Decisional projects are meant to be complementary to operational platforms by adding a decision-making layer to the main business process (Popovič *et al.*, 2012). In some contexts, they even have their place at the core of the business, for platforms such as trading, fraud detection, etc. A decisional project can follow one of two approaches (Golfarelli, Rizzi and Cella, 2004): (1) descending (**top-down**), that starts by defining the KPIs from the business needs, then proceeding with the collection and analysis of data, or (2) ascending (**bottom-up**), that consists on first understanding data in an exploratory approach that will define the analysis to be performed.

According to Vidgen *et al.* (Vidgen, Shaw and Grant, 2017), the main three management challenges that big companies face in creating value for decision-making are: defining a clear data strategy, finding the right people to conduct a data-driven cultural change, and following information ethics. It is therefore

Cite this Article as: Mohamed Mehdi BEN AISSA, Lilia SFAXI And Riadh ROBBANA "Towards a Better Management of Decisional Big Data Systems: A Design Methodology" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

necessary to define the right methodology, that helps organizations address these challenges and determine the desired business and analytics goals (Saltz, 2015). A study conducted by Pricewaterhouse Coopers (PwC) and Iron Mountain (Reid *et al.*, 2015) on 1.800 businesses, shows that, even though most of the organizations are confident that they can extract value from their data, very few are actually getting full advantage from it. In fact, three out of four enterprises extract very little business value from their information.

According to Gartner (Moore, 2015), in addition to the lack of technical skills, the reasons for these failures are mainly the lack of organization and strategy. And this is where design methodologies provide value. Pahl *et al.* (Pahl *et al.*, 2007), define a design methodology as *"a concrete plan of action for the design of technical systems (...). It includes plans of action that link working steps and design phases according to content and organisation"*. In other terms, it is a process that formalizes and standardizes the rationale for system development decisions. Failing to use a consistent and documented methodology in a project, especially one involving new and fast-changing technologies, will most certainly reduce the likelihood of success and make it more difficult to continuously evolve by applying lessons learned across initiatives. PWC (Reid *et al.*, 2015) states that the good practices that should be applied by businesses to get the most out of their data, are mainly a well-established data governance, robust controls and data protection, the usage of fit-for-purpose data analysis and taking into consideration the business needs and goals.

The diversity of possible approaches and the fast-evolving ecosystem make it an imperative to define a more comprehensive and adaptable methodology. We refer to this methodology as **DECIDE**, which stands for **DEC**isional B**I**g **D**ata M**E**thodology.

Literature Review

Several decisional methodologies are defined in the literature (Romero and Abelló, 2009; Selma *et al.*, 2012; Abai, Yahaya and Deraman, 2013). These methodologies are mainly (but not exclusively) categorized into three types: **requirement-driven** approaches (Kimball *et al.*, 1998; Hüsemann, Lechtenbörger and Vossen, 2000; Winter and Strauch, 2003), that focus on the business users requirements, which should be collected beforehand, documented and formally defined to ease automation; **data-driven** approaches (Moody and Kortink, 2000; Jensen, Holmgren and Pedersen, 2004; Song, Khare and Dai, 2007), that focus on the underlying data sources to establish the Data Warehouse design, and **hybrid** approaches (Cabibbo and Torlone, 1998; Golfarelli and Rizzi, 1998; Boehnlein and Ulbrich-vom Ende, 1999; Bonifati *et al.*, 2001; Romero and Abelló, 2006), that combine the advantages of both data- and requirements- driven approaches, by designing the Data Warehouse according to available data sources, while taking into consideration the requirements of the business users.

The methodologies cited above apply specifically to classical Business Intelligence applications, where data is provisioned from stable and static sources, the data warehouse is centralized and structured, and ETL jobs are complex and periodic. But these constraints do not always apply to decisional Big Data projects, where data sources can be unstructured or/and generate data flows with a high velocity. Our approach is more exploratory, where the design of the storage systems and global architecture depend strongly on the data sources that include all sorts of real-time and near-real-time events. This is why we qualify our approach as **Event and Data-driven Approach**, as we are adapting to fast-moving and large-scale data sources.

For decisional projects, some teams, such as D2D CRC (D2D-CRC, 2019), tend to use Agile principles to organize their work, considering these architectural issues like any other development project. However, agility is difficult to implement in decisional systems, mainly because of the dimensional modeling's rigidity. In fact, the lack of planning and clear architecture can be a hindrance when designing the system,

especially when it comes to defining conformed dimensions. Dimensional modeling requires a global view of the users' needs to define the right model for the Data Warehouse, and it can be problematic to consider the KPIs from a limited set of users. But for Big Data decisional projects, we are not constrained by a frozen structure of the storage system. Agile methods can be very adequate, as the sources change and evolve constantly, and the user's needs can also vary depending on the type and content of these sources. This is why we opt for **agility** as a basis for our methodology.

On another perspective, Data Mining methods, such as SEMMA, KDD (Fayyad and Stolorz, 1997) and CRISP-DM (Shearer *et al.*, 2000), can be considered as alternatives for Big Data projects. Contrary to classical BI methodologies, Data Mining methodologies can easily adapt to Big Data projects, thanks to their bottom-up approach helping to apply data discovery to make complex analytics (Provost and Fawcett, 2013). In fact, their main goal is to understand and discover data, in order to deploy adequate data mining models that will help prediction and decision-making.

Some works (Angée *et al.*, 2018) tried to adapt these Data Mining methodologies to Big Data constraints. However, these solutions are still very strongly related to the specific case of data mining projects, contrary to our more global solution. On the other hand, pure Data Mining solutions do not take into account all transversal but crucial requirements of Big Data systems, such as the choice of the architecture, technologies, tools and roles. In addition, data governance, DevOps and team workforce considerations are neglected.

DECIDE: Design and Implementation

Features

The **DEC**isional B**I**g **D**ata M**E**thodology respects five fundamentals:

- **Agility**: it follows the Agile principles (Beck *et al.*, 2001).
- **Bottom-up Approach**: it is designed independently of specific KPIs.
- **Data and Event Driven**: it relies on the type and structure of the data sources, and on the various events generated by the environment, to design the data storage.
- **Multi-architectures**: it supports all decisional architectures that respect Big Data constraints.
- **Multi-technologies**: it is designed for any technology or stack.

DECIDE defines three main phases (Figure 1): (1) Data Preparation, (2) Data Collection & Storage, (3) Data Analysis & Presentation. Each of these phases is composed of a set of steps, with iterations in the same phase and between phases, showcasing the agility of the methodology. Every step defines data governance rules, as well as a data team-force distribution of roles and privileges, and a list of deliverables to be maintained all over the project.

Fig. 1. DECIDE Steps

Preparation Phase

The preparation phase helps to prepare the building blocks of the project. A successful and solid Big Data project should start by defining the initial requirements, considering the target business impact and putting the deployment and automation infrastructure into place.

Initial Requirements Definition The initial requirements' definition is the result of the first encounters between the developing team and the clients. It is done at the beginning of the project to identify the needs that triggered the implementation of such a system. There are two types of initial requirements:

- **Business Requirements**: Where the client states the global needs of the application, and the necessary Business Success Indicators (BSI), to be extracted and represented.
- **Quality Requirements**: The definition of the quality requirements justifies many choices, such as the architecture, required tests, or technologies. Several quality attributes can be taken into consideration, such as availability, consistency, security, monitoring, etc.

Agile Approach Once the requirements and success criteria are defined, the team should produce a first project plan. This first version will be split into different sprints with equal duration, going from one to four weeks. A sprint can include one or many DECIDE steps depending on the context: number of data sources, complexity of the implementation, ecosystem, complexity of the analysis, etc. This part of DECIDE was mainly inspired from the SCRUM methodology. A sprint is considered validated only if all transverse steps are respected and the BSI evaluation confirmed by more than one team member. The sprints' definition is different from one team and context to another. The idea is to optimize the delivery process using tasks tracking, while keeping a high delivery frequency and a proximity between business and IT teams.

DevOps Approach Big Data and DevOps are becoming a very close team in big projects. While agility is about adaptation to change and communication, DevOps makes sure that the operations constraints (hardware and deployment environment) are taken into consideration from the beginning at the same level as the functional requirements. It is even more crucial in Big Data systems, as the technology choice and even the programming paradigms are related to the way your storage system will be deployed. DevOps considerations imply the use of the CI/CD practices (Continuous Integration/Continuous Deployment), which induce the use of tools and frameworks to automate the testing, release generation and deployment processes. It also goes hand in hand with the use of virtualization and containerization to help with the easy deployment on different production environments and the lessening of the dependencies between the implemented services and the underlying system and hardware.

Transversal Phase

The transversal phase represents recurring actions and operations that occur throughout the execution of the project.

Data Governance Data governance is a set of rules, processes, roles, policies and standards used to ensure the overall management of the availability, usability, understandability and correctness of the data in the company. It helps the organization in several aspects: to create a shared understanding of the data, to improve data quality in an efficient and cost effective manner, to represent a clear data map to locate needed data and have a single version of the truth for business entities, to ensure that the data strategy is compliant with government and corporate regulations, and finally, to continuously improve data management policies by defining proper codes of conduct and best practices.

The DECIDE methodology defines the necessary governance activities throughout the entire data life-cycle. Every operation in a decisional project (extraction, transformation, storage or linkage) should be recorded and monitored. This enables the construction of the data lineage and the verification of its integrity and confidentiality. A data governance tool should be set up, and used regularly at every step.

Architecture Choice Choosing the right architecture helps to ensure that the quality requirements defined in the beginning of the project are respected. It depends on several metrics, such as the data and processing characteristics, the quality attributes and the restitution type. The choice of the architecture is not a one-step operation. It is done all over the development phases, as every step of the methodology will contribute in refining your idea of the adequate architecture.

Team Workforce Distribution The distribution of the team workforce throughout the different phases and steps of the methodology is represented in Figure 2. A scaling system from 0 to 10 is defined, representing the implication of every role in each step of the process. 0 means *absent*, while 10 says *essential*.

Fig. 2. Team Workforce

Tests and Optimization Testing is a critical operation that should occur not only at the end of the project, but also at the end of every step of the methodology. It will determine whether this step needs another iteration, or if we can proceed to the next one. Iterations can be used to optimize code, architectural choices or performance. DECIDE stands out compared to other bottom-up methodologies such as CRISP-DM, where the evaluation takes place at the end of the cycle, instead of at each step, which impacts the agility of the solution and the early detection of faults and design problems.

Data Collection and Storage Phase

This first phase's purpose is to prepare the environment for the data analysis. This preparation helps mainly in designing the storage system depending on the data to be collected.

Data Identification The design of a system following a bottom-up approach always starts with a data identification step, where various data sources are defined, for immediate use or in anticipation of a future need.

Data Sources Identification Data can come from many varied physical sources (mainframes, database servers, distributed systems, etc.) that can be of various types (production bases, logs, archived data, etc.). We first need to identify these sources, define their type (streaming, batch or mixed), and reliability. For the latter, a source reliability rating can be used, like for example the *Intelligence source and information reliability rating system*, which rates sources from A "completely *reliable*" to E "*unreliable*".

Datasets Identification From each data source identified in the previous steps, we list the datasets to be collected by describing their characteristics, such as structuring, type, data sensitivity, frequency and throughput, etc.

Data Models Identification This step is designed to prepare and simplify the dimensional representation of the data storage system that will store the final aggregated data. The idea is to represent each source dataset individually in an abstract way, by extracting its multi-dimensional view. This representation

must respect the standard OLAP naming convention, by tagging each attribute or entity in the dataset with one of the following types: identifier, measure, dimension, timestamp or non-decisional attribute. Once all datasets attributes and entities are tagged, you can now design or auto-generate the Data Models Graph including all the data sources, datasets and their attributes. Such a graph can be either drawn by hand or generated from a data source using a tool such as Collibra. For a starter, a graph is created for each dataset. Then, a set of tags can be added to the attributes in order to create dependency relations between the attributes of different datasets. Once all the graphs put together, we can use them to design the destination storage system, as well as the architecture and features of this system.

Data Cleansing and Enrichment Cleansing and/or enrichment of datasets improves their quality score and prepares the analytics steps. This is a first data scrubbing phase, done individually for each dataset, and can contain operations like identifying and removing duplicate records.

In a Big Data approach, as the cost of storage is very low, it's recommended to keep the different versions of the datasets before and after every data cleansing operation.

Deliverables The Data Identification step should produce, as an end result, the following deliverables:

- **SID** - *Source Inventory Document*: describes the data sources and datasets used in the system and the overall characteristics of each one.
- **DMD** - *Data Model Document*: contains a graphical representation of each data source using DMGs (Data Model Graphs).
- **TPD** - *Transformation Pipeline Document*: illustrates with diagrams the transformation workflow that every source dataset went through in order to be cleaned and enriched.
- **IED** - *Identification Evaluation Document*: lists the evaluation actions undertaken in this step.

Data Storage We identify the data stores to be implemented for persisting the data, their relationships and the data routing process between them.

Data Stores The data stores used in order to keep the archived and time-variant data are decomposed into four main logical layers, as described in Figure 3.

- **Integrated Raw Data Lake**: where the data is stored from the sources as it is, conserving their structure, relations and possible redundancies. The main objective of this store is to keep a repository containing all the company's data, without alteration.
- **Integrated Refined Data Lake**: where a denormalized and integrated version of the data is created, after an extraction phase, from the raw data lake.
- **Big Data Marts**: which represent a set of dedicated, single subject, schema-on-read, structured and decisional stores, where data destined to the same users are consolidated.
- **Serving Stores**: which are used to persist the results of the analysis phase. These stores are the only ones made accessible to the decision makers via visualization tools.

Data denormalization The architecture of the refined data lake is composed of a set of entities (tables or collections). These entities must be independent and completely non-correlated, respecting the principles of Big Databases: replication of attributes is thus favored over any dependency relation. The usual normal forms are no longer respected, which makes our refined database *denormalized*.

The advantage of this design is that the transformations can be executed via the ELT (*Extract-Load-Transform*) pattern thanks to the Big Data technologies and their high locality level (data storage and processing are localized on the same nodes) independently of the data sources.

Fig. 3. Big Data Stores

It is important to underline that the raw and refined data lakes are two logical structures of the same global data lake, and should be located in the same physical infrastructure. The DMG (Data Models Graph), generated in the preceding step, can be used to generate a new physical data model (**PDM**), that unifies the different data sources in the same physical data structure, driven by the measures and based on the identified tags.

Data Storage Modes We need to deal with a multi-temperature decisional architecture, that can be composed of three types of data: *Hot Data*, which is frequently used, and must be persisted on a fast storage system, *Warm Data*, a less-frequently accessed data, that must be persisted on a slightly slower storage system, and *Cold Data*, which is rarely used, but that is generally the most voluminous. This type can be stored in the slowest storage system, but also the most scalable.

Implementation and Deployment In order to choose the adequate storage technologies, it is recommended to establish a comparative matrix based on benchmarking solutions.

Once your storage systems chosen, you can transform your **PDM** into technical structures or deployment resources like topics in Kafka, namespaces and tables in Hive, etc. In this step, the Data Governance rules must be respected by defining private and public spaces. The Private Space is a technical group of resources reserved to a specific application or module, distinguished by naming rules. The Public Space represents data that can be shared by more than one application or module.

For each resource and structure, and before the deployment in a Big Data context, the replication factor and distribution policy must be defined, as being either Round Robin, by request, by relationship or by order.

Deliverables We can define here three main deliverables:

- **PDM**: The *Physical Data Model* describes the physical model of the stored data, as well as the governance aspects, such as the public and private spaces.
- **TDS**: The *Technical Data Sheet* describes the technical properties of the storage systems.
- **SED**: The *Storage Evaluation Document* keeps the pros and cons of each store with a specific evaluation, especially since the stores can be complementary to respond to different needs.

Data Collection

Definition of the Collection Processes In a modern decisional architecture and especially for streaming analytics, fresh data must be collected fast and with a high frequency without impacting the data

sources. For each data source and its adequate storage, you have to define the collection processes while taking into consideration the transformation type (pre-load or post-load), the pattern (distributed or centralized) and the execution engine (streaming, batch processes or Change Data Capture paradigm).

Estimation of the denormalization cost The cost of denormalization must be defined for batch and streaming resources, to choose whether denormalization is done in real time along with the collection process, or later after the data storage. In order to keep the initial datasets intact and avoid data loss, the second choice is, most of the time, recommended.

Choice of the right technology(ies) and deployment mode Before choosing the right technology to use for each process, performing a comparative matrix is recommended in order to benchmark two or three technologies. As data collection technologies and stacks, we identified the following families: Classical ETL (e.g, Talend Data Integration, Pentaho), Big ETL (e.g, Talend Big Data, Pentaho Big Data), Change Data Capture CDC (e.g, Attunity CDC, IBM Infosphere CDC), and DataFlow Management (e.g, Apache Nifi, Streamsets).

Deliverables In this phase, the **TPD** defined in the identification phase, must be enriched with information about the technical choices, processes and the pipeline for the transformation and refinement of the data. This file can be automatically generated by the governance tool. Like every other phase, an evaluation document, called **CED** - *Collection Evaluation Document* is created, in order to evaluate the data collection phase and identify the different postponed or potential actions and steps in an iterative approach. Team members give a score for each process by taking into account the different tests described in the transversal step.

Data Analysis and Presentation Phase

This phase aims to design, implement, test, automate, optimize, present and manage the required analysis. The data collected during the first phase is raw, with a low-density level. This means that it is difficult to exploit it directly or extract information from it natively. In this direction, the next steps allow the end users to explore existing data by building KPIs, graphs and dashboards via analytic processes. In fact, the Integrated & Refined Raw Data Lakes and the Big Data Marts should never be directly accessed by decision makers. Data users, such as Data & Business Analysts and Data Scientists should be the ones that make the information more accessible to them.

Data Analysis Identification and design of the analysis jobs Data users must collect the needs of the end users and decision makers. Each needed analysis is described, along with its attributes, pipeline, the frequency and latency of its operations, its type (OLAP, complex non-linear analysis, machine learning or customized), distribution and scalability, and application pattern (mono- or multi-threading, map-reduce, multi-agent paradigm, etc.).

Implementation and Deployment As usual for every implementation step, a benchmark of potential technologies is needed in order to choose the right one. The implementation of the analysis jobs has to consider the Big Data constraints, patterns and best practices, such as data locality, partitioning, design by query, minimization of disk usage, reduction of shuffle operations and nodes' exchanges, etc.

Deliverables In this step, we identify two deliverables:

- **APD**: The *Analytic Pipeline Document* describes the pipeline of each analytical job including the input, output, intermediate results and the characteristics of each operation.
- **AED**: The *Analysis Evaluation Document* describes the quality of each processing job depending on the used data, resilience, consistency, scalability and performance.

Data Visualization The aim of data visualization is to restore the results of the processing layer via reports, graphs, dashboards, etc. Data restoration tools and technologies need to use ergonomic and modern features, such as auto-refresh, maps and geo-data, in order to improve as much as possible the user experience. Several choices need to be made, such as the visualization types (reports, graphs, dashboards, etc.), their refresh frequency, whether it is on-demand or pre-built, and other specifications such as their security constraints or multi-tenancy.

Choice of the right technology(ies) and deployment mode Before the deployment, it is important to check the integration of the visualization technology with the other layers of the architecture. Beware that performance issues can be identified in this step, but not necessarily related to the chosen visualization tool, rather to its integration with the previous layers.

Deliverables In this step, we identified two deliverables:

- **DVD**: The *Data Visualization Document* describes the visualizations and reports with the following details: analytic job, serving layer, visualization type and its characteristics.
- **VED**: The *Visualization Evaluation Document* describes the quality of each visualization and the potential optimizations that will be treated in the next iterations.

Evaluation: Global Optimization and Testing End-to-end testing and optimization is the step where a complete use case is automatically run on the system, and where KPIs' compliance is evaluated. The key indicators that are considered are: performance, scalability, charge and resilience.

This phase will ensure the integration of the different layers, look for the optimization issues and perform the integration, consistency and global performance tests. There is also a possibility to add other data sources and other analysis thanks to the layers' independence. This phase is essential in order to validate the global functional and technical specifications, while taking into consideration other constraints, like: cost, pooling resources, global configuration tuning, etc. By contrast with the local tests done during each of the previous steps, the global test phase goes through all the architecture layers and ensures the correct integration between them by the implementation of end-to-end:

- **Integration Tests**: determine if independently developed units of architecture are correctly integrated when they are connected to each other and respond to the expected functional and technical needs.
- **Performance, Scalability and Charge Tests**: verify if the system, as is, satisfies the performance expectations of the end users.
- **Resilience Tests**: check the way the system reacts to real-life events, by verifying its compliance to the expected behavior, its ability to recover when any part of the infrastructure or application is failing, etc.

Deliverables The expected deliverable is **3ED**: The *End-to-End Evaluation Document* describes the evaluation of the entire platform based on the global architecture and integration constraints. All the potential architecture and configuration optimizations should be traced.

DECIDE Overhead Estimation

We discuss the cost of different DECIDE phases and their overhead compared to classical decisional methodologies. Before giving more details, let's recall that DECIDE was designed for Big Data decisional projects that usually have to deal with a large-scale, multi-tenant business deployment, with the ability to serve different departments. It is when we deal with these sorts of projects and platforms

that DECIDE shows its benefits. We already stated that most of the classical decisional methodologies have a top-down approach. It consists of designing the platform from an initial need without taking into account the business evolution and new opportunities. From a technical point of view, these approaches aim to collect and transform only the data that will be used for actual decisional needs, neglecting crucial considerations such as the data governance or the team workforce.

In order to measure the cost of each DECIDE phase and its overhead, we compare it to traditional decisional methodologies, when applied to an e-commerce use case. This platform aims mainly to improve the decision-making process in order to optimize stock, provider and customer relationship management. A classical approach can perfectly help to deploy an OLAP platform based on production databases using a centralized data-warehouse with adequate data visualization tools.

Let's imagine now new business opportunities that can be implemented via new decisional features, such as customer behavior analytics based on navigation logs and metrics. The problem with classical methodologies is that: (1) unstructured data like logs can't be managed and designed using a multi-dimensional approach, (2) once the data is collected, it is difficult to dynamically add new data sources, such as logs in this example, and (3) even if (1) and (2) were possible, the data schema must be modified, in order to implement new analytics related to new business needs, which is very costly and can cause a non-negligible down-time of the system.

We reckon that DECIDE's data collection and storage phase is more expensive when we have to deal with small projects. However, the medium- and long-term benefits fully cover this overhead thanks to the gain in terms of time to market and refactoring costs in the case of rapidly evolving needs. We notice the same cost impact of the governance, DevOps and documentation operations that help to maintain a solid link between the different team members. Governance, in particular, shows its benefits with data mining and exploration, as all lineage and metadata can be accessible for all team members from any place. Indeed, DECIDE enforces a collaborative approach and helps data reuse and analysis.

We thus recommend to use DECIDE for Big Data projects with at least six team members or more than one team in order to benefit from its advantages. It is also recommended for enterprise decisional platforms that require the management of different heterogeneous data sources and datasets in multi-department organizations.

From an infrastructure point of view, avoiding useless data duplication by reusing and tracking it helps to reduce the overall costs. The other advantage of Big Data technologies is that infrastructure is horizontally scalable with cheap scalability units. We consider that the cost of the data analysis and presentation phase is optimized in DECIDE thanks to the data collection and storage phase coverage. Indeed, if the data is collected with high quality scores and if the governance rules are respected, the analysis and presentation will be much easier in DECIDE compared to classical methodologies.

Conclusion

We present in this paper a new design methodology called DECIDE, dedicated for decisional Big Data projects. This methodology is agile, data and event driven, and places a strong focus on data governance and team management. Communication is crucial via shared deliverables and collaborative tools. DECIDE is intended for large scale projects involving big and heterogeneous teams. It is not a theoretical methodology designed for academic needs, as it was successfully applied on two financial use cases for a French corporate and investment bank: a cash management and a risk management platform. Thanks to DECIDE, both projects observed a noticeable increase in the quality scores of their data sources, and the improvement of the business success indicators of the company. Our methodology

relies strongly on automation and DevOps principles, where continuous integration, testing and deployment are appreciated and recommended. These constraints give rise to the need of Big Data Test frameworks and benchmarking systems, adaptable to any Big Data design, along with a strong ability to capture and process all events generated by the system. In this perspective, we propose in a future work, a new benchmarking framework, designed for Big Data systems with Big Data technologies.

Abstract

Modern companies strive to achieve a competitive advantage in their industry, while streamlining logistics processes in such a way as to minimize costs, effort, and time. It is no different in the construction industry, the developer industry. While conducting business activity, entities make decisions in conditions of risk. This phenomenon is complex and does not have one universal definition. The risk can be considered from the point of view of both the effects and the degree of achievement of the assumed target. The authors distinguish different classifications of risk according to the area in which it arises or the factors that cause it. The type of risk, around which the article focuses, is environmental risk. The bibliometric analysis shows that environmental risk is a concept that has been present in the literature for several decades, and the trend of publications in this area is constantly growing (Web of Science - WoS). The situation is different in the case of narrowing the search to environmental risk in construction, the Web of Science database contains a small number of publications on this subject - although here too the trend is growing. This situation indicates a gap in the area under study. It should also be noted that it is the bibliometric analysis that is helpful in areas not yet recognized.

Keywords: Environmental Risk, Construction, Bibliometric Analysis, Management.

Introduction

Modern companies strive to achieve a competitive advantage in their industry, while at the same time streamlining logistics processes in such a way as to minimize costs, effort and working time. It is no different in the construction industry, the development industry, which is presented in the article. While conducting business activity, entities make decisions in conditions of risk. This phenomenon is complex and does not have one universal definition. The risk can be considered from the point of view of both the effects and the degree of achievement of the assumed goal. The type of risk around which the article focuses is environmental risk. Risk is the objective uncertainty of an undesirable event. A risk changes with the uncertainty, not with the degree of probability. Environmental risk has a negative dimension and refers to threats of environmental pollution by economic operators. Environmental problems in construction are not new but are still rarely considered in terms of risk management. The area under study is also important from a scientific point of view, and authors of scientific publications point out that construction has a high environmental impact[1,2,3,4,5] Construction, together with energy and transport, are the three largest sectors that contribute to greenhouse gas emissions and consequently pose a threat to the climate [6]. Construction has a negative impact on the environment through factors such as pollution, climate change, carbon emissions, dwindling natural resources, waste generation and land use change [7,8]. The article presents the results of a bibliometric analysis of environmental risk management in the construction industry. As it turns out, it is helpful in case of analysis of areas so far poorly recognized, unknown to analysts or when organizations operating in each area do not provide information [9]. The aim of the

study is to try to determine which areas of knowledge are the main ones in research on environmental risk, as well as how the research trend is shaped.

The main objective, together with the specific objectives, is the scope of the research, so that environmental risks are considered in the context of logistical processes in construction, while taking into account the impact of innovation.

Further research has established the following hypothesis:

H1. Innovation is the main factor reducing environmental risk.

The subject of the research in the theoretical part is environmental risk, which is the starting point for further considerations. In the empirical part, the subject is the developer companies.

the bibliometric analysis carried out is intended to determine the further steps of the research, taking into account the specific objectives:

to identify the barriers that businesses face in reducing environmental risks;
- to establish a link between a company's position in the construction industry and its commitment to minimise the negative environmental impact of its activities;
- to define the factors for selecting the supplier and assess to what extent environmental risk is an important criterion for making decisions;
- to identify the impact of innovation on the reduction of environmental risk.

The Characteristics of Bibliometric Analysis

Bibliometric analysis is a method of measuring scientific literature. It allows to assess the size of scientific output based on the assumption that the essence of scientific activity (research and development, R&D) is to create knowledge reflected in the scientific literature. The analysis of literature with the use of bibliometric tools allows to identify thematic areas, but it may also be helpful in establishing new areas of research. Moreover, on this basis it is possible to estimate the concentration of individual researchers on specific areas of science. Quantitative methods in science, used to study development trends, were applied as early as in the 19th century in libraries and publishing houses. Over the years, these statistics were used to assess the contribution of a researcher to a field of science. However, the dynamic development of bibliometrics took place when the citation index appeared [10]. The citation index was first published in the 1960s by Eugene Garfield, founder of the Institute for Scientific Information[9]. It has been noted that the term "bibliometrics" is used alternately with "scienceometry". Scienceometry, in turn, according to the definition, deals with "quantitative methods of researching the development of science as an information process". [11]. Bibliometrics is a frequent tool used worldwide by scientists, companies, and institutions of public use, however, in Poland it is still relatively rarely used [9]. Bibliometric analysis, as already mentioned, often practiced around the world, is used to organize knowledge, manage it, search for new directions and possibilities. Studies on green supply chains have been developed so far[12,13], green innovations [14], green production[15], sustainable logistics [16] and reverse logistics [17].

Research Methodology

The method adopted in this article is the Systematic Literature Network Analysis (SLNA) method introduced by Colicchio and Strozzi [18], which combines a systematic review of literature on the one hand, and allows for the analysis of the bibliographic network on the other. These are the two stages according to which the analysis will take place. The first stage consists of the following parts [19]:

a. determining the scope of the analysis,
b. defines keywords, type of documents, time range, databases,
c. selection and evaluation of scientific works in a selected database.

The result of this stage is a set of scientific papers which will be used for later quantitative research. Then you can proceed to the second stage, which is the analysis and visualization of the bibliographic network based on quotations and keywords. The analysis of the citation network is based on references to articles in journals and other publications. The network is created by the author's references to other researchers, and then he himself joins the network. The nodes of such a network are individual publications, and the connecting elements, "arrows", are the citations [20]. It is assumed that citations represent the influence of the cited work on the author's new research [21].It is acknowledged that citations can be a measure of the importance of a publication, even though scientific papers with high citations do not always make a significant scientific and qualitative contribution to the area under study[22]. Based on citations, trends, and areas of interest in science can be identified. The bibliometric analysis will be conducted using the Web of Science Core Collection (WoS). Clarivate Analytics, formerly Thomson Reuters, is responsible for its release. WoS is a collection of scientific journals, conference materials, books. It is characterized by the ability to search by a specific topic, a specific author, title, language, time, and place of publication. The database contains many indicators for bibliometric analysis. In the further part of the analysis, VosViewer software was used, which enables analysis of the network created from keywords. It is possible to determine the strength of links between individual areas of research or the direction of development of a given idea.

Preliminary Results

First, an analysis of scientific work on environmental risk was carried out. As shown in Figure 1, the number of publications in this area continues to grow. The year 2020 is much smaller, since the analysis was conducted in March 2020. Therefore, it is considered reasonable to conduct research on environmental risk in construction for selected entities.

Figure 1: Number of publications on environmental risk based on the Web of Science, March 2020

Table 1: Search results for keywords environmental risk

Keywords	Search results
Environmental risk	18 291

Bibliometric analysis for the slogan environmental risk

From the activities carried out so far, preliminary statistics have already emerged, which are presented in Table 2. 18 291 results were collected in the database, which are as follows. The total number of authors working on the area under study is 61,782 scientists, coming from 172 countries. The authors represent 11 331 scientific entities. Most of them are publications from scientific journals, and the source titles are 5 584.

Table 2: Bibliometric indicators for keywords environmental risk

Publication statistics	
Number of records	18 302
Number of authors	61 782
Number of countries of origin	172
Number of science centres	11 331
Number of source titles	5 584

Years of publication

The further part of the analysis will follow the next available data in the Web of Science database. First, the years in which the scientific papers available for the set of selected keywords were published will be analysed.

The beginnings of the discussion in the area in question date back to the mid-70s, but the chart includes data from 1990-2020 (chart 1). The first source comes from 1976. It can be seen that the initial phase of development of environmental risks lasts until about 2000. Each year the number of publications has been gradually increasing. Slight fluctuations are visible, but the trend is constantly increasing until the current year. It is not clear whether the current number of publications is reaching its peak and the trend will be downward in subsequent years. It can be speculated, however, that the growing public awareness and growing legal restrictions of sectors concerning the environment will result in a further increase in scientific publications in the field of searched keywords. However, it is difficult to determine how long the trend will be upward and at what point the saturation of this area of science will occur.

According to the Web of Science database, the first scientific publication is the article Urban ecological containers, environmental risk cells and use of medical services, published in the United States. According to the source, the paper concerns preliminary empirical research between the concepts of urban ecology, environmental risk cells and use of medical services. The article discusses the need for the development of urban ecology as it is crucial for the understanding of urban space as a framework in which health risks are structured [23]. The same year there was also a publication on environmental risk factors influencing mortality in Norway. However, this is closely related to smoking and medicine [24] The most recent publication of this year is Energy, ecosystem development and environmental risk, which mainly concerns the insurance industry. The article notes that society increases environmental risk and that natural disasters are increasingly caused by people. It was recognized that if people feel responsible for the increase in natural disasters, they can certainly correct their mistakes. The conclusion of the article is that the best thing for the insurance industry may be to focus on saving energy, and unnecessary confrontation with the forces of nature wastes energy.

Knowledge area and scientific centres

At this stage, the scientific areas where environmental risks most often arise and the scientific centres where researchers deal with this phenomenon will be discussed. From the Web of Science, it can be determined that environmental risk is a multidisciplinary phenomenon that cannot be attributed to one area of science alone. The issue is extraordinarily complex, as can be seen in the number of domains to which they are assigned, and their diversity. The number of areas of knowledge is 145 and concerns, among others, such sciences as medicine, engineering, environmental sciences and even religion (2 studies). The interpenetration of disciplines is a natural step in scientific progress. This gives rise to new directions of research which combine at least two areas of knowledge. A similar phenomenon occurs in this dissertation. On the one hand, a risk is being discussed which, it would

seem, is mainly focused on environmental sciences, while on the other hand, the construction industry is considered as an engineering and logistical process. The combination of different scientific disciplines makes the research become interdisciplinary in nature. Table 3 contains the main areas of knowledge in which environmental risks are addressed.

Table 3: Main areas of knowledge identified for keywords environmental risk

Area of study	Number of scientific publications	% of 18 302 scientific publications
Ecology, environmental sciences	5 811	31,75
Engineering	1 764	9,638
Toxicology	1 503	8,212
Environment and health and safety	1 477	8,070
Neurobiology and neurology	1 426	7,791
Psychiatry	1 172	6,404
Psychology	860	4,699
Scientific technology (other topics)	771	4,213
Agriculture	747	4,082
Chemistry	674	3,683

The WoS database also makes it possible to carry out an analysis of the centres that dealt with the area in question. The data shows that the first 5 centres, out of the total number of 11 331, can be considered the most important. The number of publications is presented in Table 4, and the percentage share of those institutions in the total number of publications is 12.23%, which gives the total number of 2238 studies. The origin of the centres confirms the share of individual countries around knowledge examined, which are at the forefront of research on environmental risk. Looking in detail at the studies of the institution in first place (University of London), it was noted that the number of publications on environmental risk is on an upward trend and the h-index is 93. The upward trend in publications means that the researchers at this centre still see a need to develop and study the problem. A review of publications has shown that the main research is in the field of medicine [25,26,27].

Table 4: Main scientific centres identified for keywords environmental risk

Scientific centre	Number of scientific publications	% of 18 302 scientific publications
University of London (UK)	574	3,136
University of California System (USA)	511	2,792
Chinese Academy of Sciences (China)	440	2,404
Kings College London (UK)	366	2,000
Harvard University (USA)	347	1,896
National Institutes of Health (USA)	276	1,508
Helmholtz Association (Germany)	237	1,295
Virginia Commonwealth University (USA)	235	1,284
Consejo Superior de Investigaciones Cientificas (Spain)	225	1,229
Centre National de la Recherche Scientifique (France)	213	1,164

Based on the data contained in the Web of Science database, a visualization of the connections of individual keywords was performed, which is shown in Figure 1. The map was created in VOSviewer. Keywords of all publications form clusters based on which it is possible to identify areas of knowledge in which scientific works are created and connections between them. For the keywords "environmental risk" five clusters can be specified, marked with different colours. The number of keywords in each area indicates the development of a given area.

Figure 1: Map of key word clusters

Literature review on environmental risks in the construction industry

The next step is to narrow down the keywords. The article focuses mainly on the environmental risk, occurring in logistics processes in the construction industry. Therefore, the basic concept of environmental risk was used to find the publication, and the second one was defined as the construction industry. In the first stage, the total number of publications obtained for the research area is 18 302 results. However, using the second keyword this number was limited to 9 publications only. Table 5 presents the search results. Filtered data were also saved on an external data carrier for further analysis.

Table 5: Search results narrowed down to keywords

Keywords	Research results
Environmental risk AND construction industry	9

There is little work on this area of knowledge, but this does not mean that the topic is irrelevant. To date, the topic is insufficiently researched, which is a research gap. For the h-index search results it is 4, while the average citation is 8.56 and the total sum of quotations is 77. The first publication was made in 2007. It shows that concrete is the second most used substance in the world after water. In the process of cement and concrete production, demolition of concrete structures, recycling, there are activities which are potential threats to the environment and at the same time cause financial losses. In order to create a sustainable industry, it is necessary to reduce environmental risk. The authors presented a simulation of a system that examines the optimal flow of concrete materials, a company

strategy to minimize this type of risk [28]. So far, this is not enough to determine the trend. From the Web of Science database, it can also be seen that there is no leading centre that specialises in publishing with these keywords. Also, it is not possible to list the leading authors, their total number is currently 40. The analysis shows that 9 publications come from several areas of knowledge, such as environmental science, construction technology, engineering, scientific technology covering other topics, materials science, chemistry, and polymer science. The division into individual categories is presented in Table 6.

Table 6: Main areas of knowledge identified for the keywords environmental risk and construction industry

Area of science	**Number of scientific publications**	**% of 18 302 scientific publications**
Ecology, environmental sciences	4	44,44
Construction technology	3	33,33
Engineering	3	33,33
Building technology	3	33,33
Materials Science	2	22,22
Chemistry	1	11,11
The science of polymers	1	11,11

The most frequently quoted article is Life cycle carbon dioxide emissions simulation and environmental cost analysis for building construction. From the point of view of article it is an important publication, because it confirms the rightness of addressing the topic. The article states that the building industry has a large impact on the environment, especially carbon dioxide emissions. The authors emphasized that the recent years in the construction industry have been mainly focused on economic costs, and not on the impact of activities on the environment. The change took place recently, when the dependencies between industry, product life cycle (in this case buildings) and environment were noticed. The study presents a carbon assessment system with a function of calculating environmental costs. The presented method can be used in economic practice and will be helpful for engineers, architects, who will have the ability to assess the environmental risks for the building's life cycle, resulting in the choice of an appropriate construction method [29].

An interesting item that concerns the area under consideration is the article that discusses how construction tasks expose workers to many ergonomic risk factors - including environmental risk, which causes the possibility of musculoskeletal disorders to varying degrees. The result is problems that cause costly delays[30]. In Malaysia, on the other hand, an industrialised construction system was implemented to focus on mass production and modular products. A study of the site selection criteria for new production facilities was conducted and one of the most important conclusions of the article was that environmental risk proved to be an important selection factor[31]. The fact that the criterion of environmental risk is gaining importance was also visible in the amendment to the Environmental Protection Act of 2001, as well as in the laws and regulations on environmental protection in construction[31].

Feedback logistics is an important process for building logistics. This is what the next article focuses on the substance hexabromocyclododecane (HBCD). This product is often used in the construction industry but has a negative impact on humans and animals. It was mainly used in polystyrene foams. Most of these products will soon become construction waste, partly resulting from demolition, when the objects finish their life cycle. Such waste usually goes to landfills or incinerators. However, recycling of HBCD represents a small share compared to landfill, and this poses a risk to the

environment. It has been noted that little attention has been paid to this topic, so the article draws attention to the global environmental risks associated with HBCD.

Another publication confirming the importance of environmental risk for the construction industry is a study on transaction costs. They are a common problem in the construction industry and pose a threat to project implementation. The researchers used the risk as a phenomenon influencing transaction costs, which translate into the success of the investment. The study was carried out in Pakistan with 475 respondents. The results considered the impact of environmental risk on transaction costs as a significant risk factor. The respondents described it as critical because the phases of the investment depend on external factors which are not directly affected, and the projects are exposed to uncertainties. At the same time, environmental risk was divided into subcategories: unforeseen working conditions (25.62%), unforeseen events (25.48%), adverse weather conditions (24.84%) and employee strikes (24.06%) (Ali et al., 2018).

Conclusions

The bibliometric analysis, which initially listed 18,302 publications, showed that the problem of environmental risk is discussed very broadly in many areas, which proves that it is an interdisciplinary phenomenon. The trend of publications is still growing, so there was no exhaustion or saturation of the topic. After narrowing the keywords to the construction industry, the number of publications decreased significantly, there were only 9. This can be considered a research gap to be filled. The publications published so far confirm the significance of environmental risk for the construction industry. In addition, there are publications in the literature that include research aimed at identifying construction materials that are rapidly renewable and have little environmental impact. So far, such materials have been, for example: bamboo [32] sugar cane and even, interestingly, rice husks [33] Construction, alongside energy and transport, is one of the three most important factors contributing to greenhouse gas emissions that pose a threat to the climate[34]. This has forced industry to take measures that are sustainable and have a positive impact on the environment [35]. In the past, reducing costs, increasing productivity and quality have been the main reasons for companies to make changes. However, the growing awareness of the public, entrepreneurs, and contractors of the environmental impact of construction is setting a new course of action[36]. It should be noted that bibliometric analysis is a flawless tool. Unfortunately, despite the vastness of the database, it does not include all available publications on the area of knowledge under study. Nevertheless, bibliometric analysis allows to systematize the existing literature, to show the trend. On this basis, it can be concluded that the study of environmental risk in the logistics processes of the construction industry is the right direction of research. In addition, as mentioned earlier, bibliometric analysis is helpful in areas not yet identified. The bibliometric analysis showed the interdisciplinary nature of the term. The multitude of sciences in which the studies have been produced shows the importance of environmental risk for the economy, but also for health and life. In addition to such recurring fields of knowledge as medicine, engineering and environmental sciences, there have also been far fewer - such as religion, for example. The interpenetration of areas is natural in the progress of science. It provides an opportunity to develop new areas of knowledge. This phenomenon is recognized in the article.

Comparative Analysis of The Logistic Capabilities of Seaports with The Use of Management and Applied Logistics Methods

Bohdan PAC

WSB University in Gdansk / Wyższa Szkola Bankowa w Gdańsku, Gdansk, Poland,
bpac@wsb.gda.pl

Abstract

The logistic capabilities of seaports is a factor which affects competitiveness in a particular water region and service quality in land-sea transport chains handled by seaport facilities. It is also a factor which defines the universality of seaports. Logistic capabilities can be measured by means of methods which are used in management and applied logistics. In this paper, such methods are presented as tools applied for the evaluation of the logistic capabilities of seaports, described with a hierarchical multi-criteria model. The result of the research comes as a classification of the Polish seaports which are of primary significance to the national economy. This classification makes it possible to define the advantages and disadvantages of the analysed facilities and their port performance profiles. The paper is of a conceptual nature and is part of an individual project implemented by the author at the Baltic Centre of Applied Logistics on the modelling of the strategic capabilities of the maritime economy on the example of Poland – in terms of its economic and defensive aspects.

Keywords: Seaports, Logistic Capabilities, Multi-Criteria Model, Management And Applied Logistics Methods.

Introduction

Maritime transport plays a key role in the handling of international trade. The positions taken by particular countries in this field depend on their access to a transport network, and seaports where cargo handling terminals and other transportation, forwarding and logistics companies are located.

Logistic capabilities come as a defined set of resources/possibilities for providing the supplies, services or products required to implement particular productive, commercial, service or public operations. Logistic capabilities significantly affect the efficiency and effectiveness of a logistic system, thanks to which logistic processes and operations are implemented. The operation of a seaport is based on the implementation of particular processes related to cargo and vessels, based on its logistic system (Fig. 1).

Logistic operations performed at seaports determine the efficiency and effectiveness of sea-land transport chains. Therefore, the logistic capabilities of a seaport influence its position and attractiveness for many potential and current customers. Seaports play a significant role in the integration of various transport modes. They provide a wide range of services involving both cargo and seagoing vessels. Seaport capabilities can be evaluated in a measurable way by means of the appropriate methods applied in management.

The aim of the paper is to present a method for evaluating the logistic capabilities of seaports which are of primary significance to the national economy. Based on this, a comparative analysis of the discussed port facilities will be provided. In this paper, the research objective is to provide an answer to the following problem: how to evaluate the logistic capabilities of a seaport, based on methods used in management and applied logistics, in order to provide a comparative analysis of the discussed port facilities in this field ? A working hypothesis which needs to be proved in order to solve the above-mentioned problem has been formulated as follows:

Cite this Article as: Bohdan PAC "Comparative Analysis of The Logistic Capabilities of Seaports with The Use of Management and Applied Logistics Methods" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

A multi-criteria model applied to measure the logistic capabilities of seaports can be an efficient tool to provide a classification of such facilities in terms of their operational and systemic competitiveness, service quality, and universality in particular sea areas, and in handling land-sea transport chains.

Fig. 1. Operation of a seaport logistic system.
Source: Author's own elaboration

In the research process, the following limitations have been assumed:

- the research area is limited to Polish seaports, in view of the availability of indispensable statistical data;
- the statistical data refer to 2016.

In order to achieve the aim, to solve the research problem and to prove the working hypothesis, a number of research tasks have been performed:

- a review of specialist literature on seaports and their logistic capabilities;
- the development of a hierarchical multi-criteria model of seaport logistic capabilities, based on the available data on the logistic capabilities of the analysed port facilities;
- the selection of a method to evaluate the logistic capabilities of the analysed seaports;
- an evaluation of the logistic capabilities in accordance with the accepted method;
- a comparative analysis of the logistic capabilities of seaports – conclusions and recommendations.

Research Process

The research process, during which the above-mentioned research tasks have been implemented, is divided into eight stages (Fig. 2):

Stage 1 – A review and selection of sources: monographs and specialist periodicals on the operation of seaports and their logistic capabilities, with consideration of the assumed limitations;

Stage 2 – An identification of modules of seaport logistic capabilities. Based on the review of selected specialist literature (Link, 2016 and Winkelmans, 2003), seaport logistic capabilities have been defined in the following way:

$$\Pi_{log} = \{M_i; i = \overline{1,5}\} \quad (1)$$

where:

Π_{log} – seaport logistic capabilities,

M_i – the subsequent module of seaport logistic capabilities, i=5 – the number of modules of seaport logistic capabilities.

The following modules of seaport logistic capabilities have been defined:

- seaport efficiency (M_1), which refers to the general capabilities of a seaport in the field of passengers and cargo handling;
- cargo-type interoperability (M_2), which refers to the capabilities of an analysed seaport facility in terms of handling particular cargo categories and passengers (Cf.: NATO, 1997);
- handling seagoing vessels (M_3), where the types of seagoing vessels handled at a seaport are identified;
- operational scope of a seaport (M_4), which defines the sea-land area handled by a seaport;
- infrastructure of a seaport (M_5), which comes as a significant resource, indispensable for handling seagoing vessels.

Stage 3 – Identification of the components of seaport logistic capabilities (C_{ij}) and their allocation to the particular modules (M_i). Based on the specialist literature review (see: Link, 2016, Central Statistical Office, 2017 and Winkelmans, 2003), the identified modules have been attributed with the following components of logistic capabilities:

- the M_1 module has been attributed with: the maximal annual cargo handling capacity, given in thousands of tonnes (C_{11}), the actual turnover of a seaport in terms of cargo handling during the analysed period, given in thousands of tonnes (C_{12}), the total dead weight tonnage (DWT) of seagoing vessels handled during the analysed period, given in thousands of metric tonnes (C_{13}), the number of maritime specialist (C_{14}) and universal/multi-purpose (C_{15}) cargo handling terminals;

Fig. 2. The course of the research process.

Source: Author's own elaboration.

- the M_2 module has been attributed with: the actual volume of seaport turnover during the analysed period, given in thousands of tonnes of liquid bulk cargo (C_{21}), dry bulk cargo (C_{22}), container cargo (C_{23}), self-propelled ro-ro and non-self-propelled ro-ro cargo (C_{24}), other general cargo (C_{25}) and passengers, given in thousands of passengers (C_{26});

- the M_3 module has been attributed with: the total value of the dead weight tonnage (DWT) of the types of seagoing vessels handled at a particular seaport, given in metric tonnes for tankers (C_{31}), bulk carriers (C_{32}), container vessels (C_{33}), general cargo vessels (C_{34}), special vessels

(C_{35}), passenger vessels (C_{36}), barges and other vessels (C_{37}). DWT is the basic parameter which defines the size of a vessel and its loading capacity; it defines the total mass of the cargo, crew, supplies of fuel, supplies of drinking water and water for technical purposes, supplies of food, spare parts, etc., which can be taken on board without exceeding the maximum draft (for the draft up to the Plimsoll/load line)(Cf.: Hayler W., 2003);

- the M_4 module has been attributed with: seaport foreland (C_{41}), seaport hinterland (C_{42}), the integration scope of transport modes in the area of a seaport (C_{43}). A seaport foreland is formed by overseas areas and markets linked by regular shipping services to the seaport. A seaport hinterland is considered to be a land space over which a port has the dominant market share; the great majority of activities thus use that port for imports or exports (Cf.: Rodrigue J-P, 2020*)*. Integration of transport modes refers to the transport modes which are related to maritime transport in the seaport area;

- the M_5 module has been attributed with the following components: length of operational wharfs (C_{51}), length of operational wharfs of the depth ≥ 11 m (C_{52}), length of new and modernised wharfs (C_{53}), maximal draft of seagoing vessels handled at the seaport (C_{54}), area of warehouses (C_{55}), area of storage yards (C_{56}).

As a result, a multi-criteria model has been developed for evaluating seaport logistic capabilities (see: Belton V., Stewart T, 2002), as presented in Figure 3.

Stage 4 – Selection of seaport facilities for the analysis. In view of the assumed limitations, the analysis refers to the Polish seaports of primary significance for the national economy, namely: the Port of Gdańsk, the Port of Gdynia, and the Szczecin and Świnoujście Seaports, which are treated as one entity considering their complementary nature and one authority body managing the operation of both entities.

Stage 5 – Selection of a method for evaluating seaport logistic capabilities, in accordance with the model presented in Fig. 3. To evaluate the logistic capabilities, a rate-score-based method has been selected from those, which are used in management and applied logistics (CF.: Stabryła, 2006). This is an aggregation method which is applied to design and diagnose various facilities or phenomena. It allows interested parties to evaluate the value of a particular facility after the particular evaluation criteria are taken into consideration altogether. Using this method, makes it possible to provide a multi-criteria qualification of a seaport in terms of its logistic capabilities, presenting its actual status in a more comprehensive way. Combining the particular criteria allows us to answer the question of what the value of the facility really is in terms of the analysed aspect.

Fig. 3. A multi-criteria model of seaport logistic capabilities.
Source: Author's own elaboration, based on Belton V., Stewart T, 2002 and Link, 2016.

The solution based on this method refers to seaport logistic capabilities within the scope of the five defined modules, which are the evaluation criteria. The components attributed to the modules come as the evaluation sub-criteria. Based on the applied method, the benchmark status, the actual status and the rating evaluation have been determined for the analysed facilities, in accordance with the defined components of logistic capabilities, as presented in Table 1.

Table 1. List of the benchmark status, actual status and rating evaluation.

Stage 6 – Evaluating the logistic capabilities of the analysed seaports with the use of the rate-score-based method, as follows (CF.: Stabryła, 2006):

1) The values of rating evaluations which refer to the identified components of logistic capabilities have been calculated, based on the following equation:

$$W_{ij} = \frac{PC_{ij}^{AS}}{PC_{ij}^{BS}} \quad (2)$$

where:

$W_{ij} -$ rating evaluation for the subsequent component of the logistic capabilities of the analysed seaport;

$PC_{ij}^{AS} -$ actual status for the analysed component of the logistic capabilities of the analysed seaport, given in the respective measurement units;

$PC_{ij}^{BS} -$benchmark status (to which the actual status is compared) for the analysed component of the logistic capabilities of the analysed seaport, given in the respective measurement units.

2) Weight coefficients (($\overline{WC_{ij}^{V}}$), which refer to the significance of the components of logistic capabilities, have been defined, based on the opinions given by 10 experts, as presented in Table 2. The scale adopted for the expert evaluations is from 1 to 10;

$$\overline{WC_{ij}} = \frac{\sum_{y=1}^{10} WC_{ijy}}{10} \quad (3)$$

where:

WC_{ijY} – evaluation presented by the subsequent expert, where y=10 – the number of experts selected to provide the evaluation. The members of the expert panel were recruited from academic representatives who conduct scientific research on seaports, and practitioners from the field of the maritime economy;

Table 2. List of weight coefficients ($\overline{WC_{ij}^{V}}$) for the significance of the particular components of logistic capabilities.

Source: Author's own elaboration.

$\overline{WC_{ij}}$ – is the arithmetic mean of the experts evaluation for each component.

Next, the expert evaluations referring to particular components were verified in terms of consistency based on the classical coefficient of variation (Everit B., 1998) (see: equation 4 and Table 3)

$$v_{ij} = \frac{\sigma_{ij}}{\overline{WC_{ij}}} \tag{4}$$

where:

v_{ij} – the classical variation coefficient (calculated for the particular components);

σ_{ij} – average standard variation of the expert opinion at the component level.

Table 3. The preference scale of classical variation coefficients.

v_{ij}	**Preference scale**
$v_{ij} \leq 0.1$	Weak differentiation of the coefficient (a satisfactory level)
$0.1 < v_{ij} \leq 0.3$	Moderate differentiation of the coefficient (an acceptable level)
$0.3 < v_{ij} \leq 0.5$	Strong differentiation of the coefficient (an unacceptable level)
$v_{ij} > 0.5$	Very strong differentiation of the coefficient (an unacceptable level)

Source: Author's own elaboration

$\overline{WC_{ij}^{V}}$- the weight coefficient provided to each component on the basis of the expert evaluations, where the $v_{ij} = \frac{\sigma_{ij}}{\overline{WC_{ij}}} \leq 0{,}3$ (see: Table 2).

3) The weighted values of logistic capabilities at the component level have been calculated in accordance with the following equation:

$$WW_{ij}^{Log} = \overline{WC_{ij}^{V}} x W_{ij} \quad (5)$$

where:

WW_{ij}^{Log} - the weighted value of logistic capabilities at the component level.

4) The values of the logistic capabilities of the analysed seaports at the levels of the defined modules have been calculated in accordance with the following equation:

$$PWW_{i}^{Log} = \sum WW_{ij}^{Log} \quad (6)$$

where:

PWW_{i}^{Log} – logistic capabilities of a seaport at the level of the subsequent module.

5) The total values of the logistic capabilities of the analysed seaports have been calculated in accordance with the following equation:

$$\Pi_{log} = \sum PWW_{i}^{Log} \quad (7)$$

where:

Π_{log} – the total value of seaport logistic capabilities.

Stage 7 – Analysis and interpretation of the results. The analysis and interpretation of the results includes the following:

1) A comparison of the values of the logistic capabilities of the analysed seaports has been presented.

2) The share of logistic capabilities in the total logistic capabilities of each analysed seaport has been calculated at the module level, in accordance with the following equation:

$$MR_i = \frac{PWW_i^{Log}}{\Pi_{log}} \quad (8)$$

where:

MR_i – the share of logistic capabilities presented by a particular seaport at the level of the subsequent module within the total logistic capabilities of that particular seaport.

3) The port performance profile in the discussed group of port facilities has been analysed.

Stage 8 – Conclusions and recommendations. Based on the results obtained during the research on the status of the seaports in the discussed field, some possible areas for development of the analysed port facilities have been discussed, along with the utility of the applied qualitative method.

Results of the research

Based on the calculated values and verified weight coefficients, which define the significance of the subsequent components in the identified modules of seaport logistic capabilities, and based on the values of the rating evaluations of the particular components for the analysed seaports, the following parameters have been calculated, as presented in Table 4:

- the weighted values of logistic capabilities at the level of the components (WW_{ij}^{Log}) for the analysed seaports;
- the values of logistic capabilities according to the defined modules (PWW_i^{Log}) for the analysed seaports;
- the total values of logistic capabilities for the particular analysed seaports (Π_{Log});
- the shares of logistic capabilities. according to the identified modules (MR_i), within the total logistic capabilities of the analysed seaport.

Based on Table 4, a graphic interpretation of the following parameters has been provided:

- the values of logistic capabilities of the analysed seaports (Fig. 4), both: the total values (Π_{Log}) and the values referring to the particular modules (PWW_i^{Log});
- the shares of logistic capabilities, according to the identified modules for the particular seaport, within the total logistic capabilities of this seaport (Fig. 5) - $MR_i = \frac{PWW_i^{Log}}{\Pi_{log}}$;
- the port performance profiles of the analysed seaports (Fig. 6).

Source: Author's own elaboration.

Fig. 6. The port performance profiles of the analysed seaports.
Source: Author's own elaboration.

Based on the results obtained during the research, it is possible to state the following:

- the dominating seaport is the Port of Gdańsk in terms of the total value of logistic capabilities and its logistic capabilities at most of the module levels (with exception of the M_2 module where some slight dominance of Szczecin - Świnoujście seaports can be observed). This fact results from the volume of investments which have been undertaken over the years, such as the Northern Port, Gdańsk Refinery (now LOTOS) and the Deepwater Container Terminal (see: LINK, 2016);
- the levels of the total logistic capabilities of the Port of Gdynia and the Szczecin-Świnoujście Seaports are similar;
- compared to the Szczecin-Świnoujście Seaports, a strong asset regarding logistic capabilities presented by the Port of Gdynia is its operational scope (M_4) and its seaport infrastructure (M_5);
- during the analysed time period, the performance of the Szczecin-Świnoujście Seaports is better than the performance of the Port of Gdynia in terms of seaport efficiency (M_1) and cargo-type interoperability (M_2);
- a disadvantage observed for the Szczecin-Świnoujście Seaports is the current limitation referring to the draft of vessels handled at the Port of Szczecin (max. 9.15m), in view of the depth of the port basins (see: LINK, 2016);

Considering the port performance profiles during the analysed time period, it is possible to observe the following:

- the Port of Gdańsk takes the leading position among the seaports of primary significance to the national economy in terms of container cargo and liquid bulk cargo turnover;
- the Port of Gdynia presents high levels of container cargo and ro-ro cargo turnover. and it takes the second position among the analysed seaports in terms of passenger transport;
- the Szczecin-Świnoujście Seaports take the first position in terms of ro-ro cargo handling; the seaports also present a high level of liquid and dry bulk cargo turnover. and they take the leading position in passenger transport.

Conclusions and Recommendations

Summing up the research presented in the paper, it should be noted that the Port of Gdańsk presents significant prospects for further development, in view of the possibilities of further development of the

outer port and possible development of the Eastern Port in the future. The construction of a floating LNG terminal is also planned. However, placing such a facility in the Bay of Gdańsk may generate some negative implications in terms of safety, considering the fact that this small area is already characterised by a high concentration of port and logistics installations. The economic justification of such a facility should also be taken into consideration, not only in terms of costs, but also in terms of the capability volume indicated by such an installation on the Polish coast in relation to supply chains handled in the area.

A major disadvantage of the Port of Gdynia is its limited seaport area (see: LINK, 2016) and hence restrained opportunities for spatial development. Considering the above-mentioned facts, the idea of constructing a deep-water outer port has been presented (for vessels of a maximal draft up to 16m), and the operation of a dry dock at the hinterland of the Port of Gdynia (outside the port area) in order to provide most logistics services.

It should also be noted that almost all the operations which involve handling container cargo shipped by sea take place at both above mentioned ports. Considering the aspect related to the rationality of distribution port and logistics resources, there is the threat of overinvestment in seaport infrastructure in the Bay of Gdańsk area. An additional problem is also the question of security related to the close vicinity of Kaliningrad Oblast.

A major disadvantage observed at the Szczecin-Świnoujście Seaports refers to the insufficient depth of port basins at the Port of Szczecin.

As a result, some dredging work has already begun in order to deepen the waterway between Świnoujście and Szczecin to improve the access to Szczecin from the sea for vessels of a maximal draft up to 12 m and dead weights of 50 000 DWT and 2 500 TEU. The Port of Świnoujście handles vessels of a maximal draft of 13.5 m. The strong points of the Szczecin-Świnoujście Seaports include an LNG terminal (located at the Port of Świnoujście), and a plan for the construction and operation of a container terminal of a maximal annual cargo handling capacity up to 1.5 million TEU.

It should be noted that the implemented strategy of developing seaports in Poland does not include the development of port infrastructure in the coastal area between the Bay of Gdańsk and the Bay of Pomerania (a distance of over 400 km) at all, leaving it underinvested and undeveloped in terms of the maritime economy and the distribution of port and logistics resources. The last element which should be noted in the strategy for the development of Polish seaports is the modernisation or even reconstruction, for navigability purposes, of rivers which connect seaports and the national economic hinterland - up to, at least, the 4th navigability level along the entire length of rivers, i.e. the Vistula River for the Port of Gdańsk and the Oder River for the Szczecin-Świnoujście Seaports. Such an investment would definitely improve the accessibility of these facilities from the land and it would contribute to the reduction of transport costs in the supply chains handled there.

Considering the method and the multi-criteria model applied to evaluate seaport logistic capabilities, it is possible to state that they allow us to provide a relatively precise evaluation of the logistic capabilities presented by the selected seaports. The results of the research can be used to provide an evaluation of the operational and systemic competitiveness levels of the analysed seaports, which can be observed in terms of their logistic capabilities.

The application of the solution presented in the paper depends on the availability of data. The evaluation of the shares of logistic capabilities, according to the identified modules within the total logistic capabilities of a particular seaport, makes it possible to identify its advantages and disadvantages referring to the specific facilities. Moreover, it is possible to identify a port performance profile in a measurable way. Subsequently, comparing the geographical location of the seaports and the hinterlands they handle, it is possible to define some possible areas for the development of land-sea supply chains. Summing up, it should be stated that the solution presented in this paper allows us to provide a comprehensive evaluation of the logistic capabilities presented by a particular seaport, along with its capabilities in performing numerous port operations.

Abstract

The subject of the paper is the analysis and assessment of Poland's GDP growth and dynamics of economic convergence within the EU. Results of economic growth were evaluated in comparison with the EU28 averages and the other Visegrad countries (Czechia, Hungary, Slovakia). The aim of the assessment in the paper is to verify a hypothesis, constructed by theorists of international economics, that regional integration is an opportunity for the caching-up countries to accelerate growth as well as diminish the economic and technological gap. Results of the empirical analysis, which encompassed both the pre-accession period and the European Union membership period of the V4 countries, confirmed that they had higher GDP growth rates compared with the EU-28 averages, however, the rates varied within the analysed group. The largest economic gap pertained to Poland and the dynamics of closing it was the highest in 2008-2019. The opportunities for Poland's economic growth in the first half of the 1990s and in 2002-2007 were not fully exploited. Nevertheless, Poland had the highest capacity for economic growth during the recession - stagnation years (2008-2013) out of all EU members and was able to maintain high growth rates in 2014-2019. Even though economic convergence measured by the GDP growth and per capita GDP can be considered Poland's impressive achievement, the assessment of the GDP growth supply and demand sources points to only slight technological changes in the economy. The major factors of Poland's economic growth in the entire period of 2002-2019 included non-ICT capital contribution and increase in consumption demand. Only in Czechia a higher contribution of ICT capital to GDP growth allowed for a decrease in the technological gap. In the remaining V4 countries non-ICT capital contribution to the GDP growth was also not conducive towards a significant technological modernisation of the economies.

Keywords: benefits from economic integration, GDP growth, supply and demand factors of economic growth, economic convergence

Introduction

The Visegrad Group (Visegrád Four or simply V4) consists of Czechia, Poland, Slovakia and Hungary. During the post-war development of Central and Eastern Europe dominated by the Soviet Union these four countries had the strongest economic ties. At the turn of the 1980s and 1990s, the institutional base of the system controlled by the USSR fell apart and the CEE countries turned towards closer cooperation with the Western European countries, which were undergoing final stages of liberalising the flow of merchandise, services, and factors of production. As a consequence a disintegrated space was created in Europe which became in the centre of political interest of both the European Union and the United States. They expected that Western Europe would undertake steps

KAKOL " Poland's Economic Growth at the Pre-accession Stage and in the Conditions of Membership in the European Union against the Background of Other Visegrad Countries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

encouraging closer economic ties with the CEE countries, which were already undergoing reforms leading to democratisation of their political systems and pro-market changes in the functioning of their economies.

The European Union authorities were uncertain about formulating a strategy that would define the rules and timeframe of integrating the post-socialist countries with the EU economy that reached an advanced stage of regional interdependence. For the first time, the Community was faced with a need to prepare a model of integration with a large group of countries (12) with a clear development gap even towards the economically weakest members (Spain, Portugal, Greece). There were more factors against another territorial enlargement of the European Communities.

Firstly, there was a considerable acceleration of the integration process within the 12 members of the European Community as a result of the Delors plan adoption (1989) and initiation of its realisation (introduction of the Economic and Monetary Union). The basis for the next, higher stage of integration was The Maastricht Treaty (1992). Coincidence in time between the introduction of the EMU and preparation of the EU for another enlargement was particularly difficult to reconcile even more since in the late 1980s the EFTA countries (European Free Trade Agreement)[i] started negotiations to join the European Communities. Since 1990s, leaders of the EU were focused on overcoming challenges connected to the adoption of the common currency and were not ready to discuss institutional reforms required to significantly increase the number of member countries - by a dozen of new CEE members.

Secondly, intensification of globalization processes began in the 1990s, followed by a new wave of technological progress known as the ICT revolution. These phenomena impacted the acceleration of structural changes both in domestic economies as well as the world economy and led to the new international distribution of economic potential enhancing the global competition. Therefore, the European Union began tightening economic cooperation with CEE countries with extreme caution, focusing on trade liberalisation within the framework of association agreements known as Europe Agreements. First deals of this kind were signed with Czechoslovakia, Poland and Hungary on the 15th December 1991[ii].

Aim and Research Method

The aim of the paper is to indicate the formal grounds and decisions of the European Union leading to Poland's accession, to assess the effectiveness of the adjustment process determining the fulfillment of membership criteria, and to evaluate the process of reducing the development gap at the pre-accession stage and under the conditions of functioning in the EU in 2004-2019. Poland's macroeconomic outcomes in terms of the dynamics of convergence were assessed on the basis of quantitative and efficiency indicators, such as: GDP growth rate, GDP per capita, changes in the level of labor productivity (in relation to the EU average), as well as on the basis of supply and demand factors contributing to GDP growth. The method of separate appraisal of supply and demand sources of GDP growth becomes increasingly useful in the conditions of low and declining economic growth in the EU. It is designed to better understand the reasons behind the diversity of countries in terms of their capacity to economic growth and tendency to weaken the convergence process.

The assessment of Poland's economic dynamics in 2002-2019 was carried out with the distinction of three 6-year periods in order to obtain an answer regarding the diversity of Poland and other V4 countries (Czechia, Hungary, Slovakia) in terms of economic dynamics depending on the phase of business cycle and the results of economic convergence. In the long-term analysis, the following years were distinguished: 2002-2007 (relatively good economic conditions), 2008-2013 (recessive-stagnant), 2014-2019 (post-crisis recovery). Contribution of supply factors to the GDP growth includes: quantity of working hours, quality of labour, non-ICT capital, capital in the ICT sector and TFP growth. Demand factors illustrate the contribution of private and public consumption, investment and net exports. The aim of the empirical analysis is to answer the question: Does Poland properly use the opportunities of more dynamic growth arising from the accession to the EU and are

the effects in reducing the economic gap satisfactory? The answer to this research question is formulated by confronting Poland's economic growth and its sources with the results of other V4 countries. The analysis was based on the use of primary statistical data obtained from the databases of the European Commission (Ameco, Eurostat) and The Conference Board, as well as the results of research by other authors.

Benefits from Regional Economic Integration - Theoretical Introduction

Countries are interested in creating regional integration blocs in order to dynamise economic development and improve the efficiency of allocation and use of production factors. Various approaches and criteria are applied to assess the potential and real benefits that can be derived from integration. One can consider short-term, long-term, macroeconomic, sectoral, structural, microeconomic, social, civilization, political, cultural benefits etc. From the economic point of view, the most important are the sources of benefits leading to higher economic growth and improved efficiency of the use of production factors.

Contemporary theorists of international economic integration take advantage of the vast achievements, that were created in this field in the second half of the 20th century, and still remain the basis for assessing the effects of integration depending on the degree of its advancement. The starting point is the concept of B. Balassa (1961), who adopted - as the determining criterion - the following stages of integration: free trade zone, customs union, common market, economic union and full economic integration. The theoretical foundations of international integration developed in close connection with the advancement of economic ties within groups of countries. The greatest influence on the growing importance of the theory of regional integration in international economics resulted from reaching higher stages and pioneering experience in the field of integration in Europe.

In the beginning, theorists focused on the benefits of market integration, inter alia: J. Pekmans (2001), R. Baldwin and Ch. Wyplosz (2009), W. Molle (2006), B. Rosamond (2000), D. Swann (2000), P. Bożyk and J. Misala (2003), J. Ładyka (2001). The benefits of market integration are primarily analysed and assessed in two aspects: 1) sources of origin, 2) the effects of liberalisation of trade (goods and services) and flows of production factors (capital and labor). In the first case, the benefits are derived from the market size and the scale of production, the deepening division of labor, including the fragmentation of technological processes and specialization in economic activity, but also the increase in competition, its effects and competition protection policy. In the second case, the assessment encompasses: the effects of trade liberalisation, and liberalisation of capital and labor flows. The greatest threat to the participants of the internal market of integrated group of countries is the low competitive ability of economic entities from catching-up countries.

Protection of competition is an essential condition for achieving the goals of market integration, it is intended to eliminate less efficient producers and limit the expansion of national monopolies. Research in this area is focused on (Mucha-Leszko 2017, p. 77): 1) the functioning of market mechanism, with particular emphasis on changes in its structure, the behavior of market participants and the impact of market situation on economic efficiency at the micro- and macroeconomic levels, 2) the analysis of market-state relations justifying the desired scope of interference and state activity in order to remove the imperfections of the market mechanism and optimise the competition policy aimed at increasing economic efficiency. An advocate of controlling the "invisible hand of the market" was the influential Italian professor of economics T. Padoa-Schioppa, who participated in the preparation and implementation of integration plans (Ross 1995, p. 42).

The acceleration of market integration in the second half of the 1980s resulted in an increased interest and discussion on the benefits of monetary integration. This was justified by the desire to obtain greater benefits of the common market due to the introduction of the common currency. Liberalisation of capital flow contributed to the growth of its mobility. Sudden outflows and inflows of capital and changes in demand for currencies led to an increase in the frequency and extent of fluctuations in exchange rates. The destabilisation of the global foreign exchange market was an

important argument for the supporters of the monetary union in convincing that the benefits of introducing the single currency would be even greater than those predicted by the authors of the optimum currency area theory (Commission of the European Communities 1990).

Representatives of neoclassical economics believe that a diversified economic development and income per capita result from differentiation of the accumulation rates of production factors and their declining productivity. An important addition to their method of proof stemmed from breaking down investment into real capital and human capital. Previously, the analysis was limited to investment in physical capital (Ben-David and Loewy 2003; Lucas Jr. 1988, p. 39). The usefulness of analyses of economic growth increased as a consequence of adding another important element, which is the productivity of production factors resulting from knowledge (human capital) and research and development activities accelerating technological progress (Romer 1990; Grossman and Helpman 1991; Siwiński 2005, p. 734–738). The works of R. Barro and X. Sala-i-Martin published in 1990–1992 constituted a breakthrough in the development of research on the processes of economic convergence, which inspired the introduction of new research methods based on econometric models and the development of concepts to better assess the results of convergence (Barro and Sala-i-Martin 1990, 1991, 1992). There were also proposals to measure different types of convergence. The most common subjects of research are *beta* and *sigma* convergence. The first (*beta*) is defined as the ability of countries at lower stages of development to achieve a higher rate of economic growth than highly developed countries. The dynamics of reducing the economic gap (catching-up) in relation to the more developed countries depends on the GDP growth rates. *Sigma* convergence is the result of *beta* convergence and occurs when the variation in GDP per capita between countries decreases and is measured by the standard deviation (Mucha-Leszko 2014, p. 18–19).

Diminishing the development gap depends on the strength of the influence of economic growth factors - labor input and labor productivity. Capital expenditure and the Total Factor Productivity (TFP) contribute to the increase in labor productivity. Potential abilities of achieving and maintaining a high pace of economic growth depend to a large extent on the economic policy of a country which influences shaping of more or less favorable conditions for the inflow and use of foreign capital and technology in order to increase economic activity, create new demand and structural changes. The impact of foreign direct investment on GDP growth is multilateral and therefore their economic effects may accumulate as a result of a higher investment rate, economies of scale of production, the use of modern technologies and methods of work organisation and management, through spill-over effects derived from developing cooperation with local companies which under the pressure of competition become more innovative, and employees improve their qualifications (Mucha-Leszko 2014, p. 20).

The Polish "road" to the European Union - the Formal Grounds

Analysis of the contractual relations between Poland and the European Union points to the following documents and facts:

1. Europe Agreement establishing an association between the European Economic Communities and their Member States, of the one part, and Poland of the other part signed on the 16th of December 1991. The document entered into force in two stages. In order to accelerate the liberalisation of trade the part pertaining to that (Interim Agreement) entered into force on the 1st of March 1992, and the full application commenced on the 1st of February 1994.

2. Poland made a formal request for membership in the European Union on the 8th of April 1994.

3. European Council Summit in Copenhagen (June 1993) - for the first time the European Union officially confirmed that membership was the common goal for the countries that signed the association agreements as well as the EU. However, the statement in Copenhagen was much too general to satisfy the association countries which expected much more binding declaration from the EU.

4. European Commission began working on an integration strategy for the associated CEE countries in 1994. The first part was presented in July 1994 and contained details on the Copenhagen Summit final conclusions, and the second, in September, pertained to the institutional cooperation, harmonisation of law, competition policy and trade, macroeconomic and structural policy, policy in the major areas of the economy, regional and social policy including EU aid for integration and reforms (URM 1995, p. 34-48). Looking back, the European Council meeting in Essen in 1994 had the crucial impact on the process of Poland's integration with the EU. The Council issued a report describing the strategy of preparations for the CEE countries to become members of the EU. The report was accepted by the European Council and included in the final documents of the Summit as Annex IV.

5. Other documents containing tasks for Poland and the other CEE countries in order to adjust their economies to the fulfillment of the EU membership criteria were created in 1995. During the Cannes European Council meeting in June, the EU leaders adopted the European Commission's White Paper on the preparation of the associated CEE countries to integration with the Single Market of the European Union. In December 1995, during the Madrid Summit, the European Council tasked the European Commission with issuing an opinion on the membership applications. Thus, the formal process of the CEE countries accession to the EU was initiated.

6. In July 1995, the European Commission presented a positive assessment of Poland's membership application (avis) and recommended initiation of the accession negotiations to the EU Ministerial Council. Apart from Poland, the first group qualified by the Commission for EU membership, meaning the most ready to fulfill EU membership criteria, included Cyprus, Czechia, Estonia, Hungary and Slovenia. In the Conclusion, Commission recommended initiating negotiations with Poland and the other countries in order to accept them as members of the Union (Komitet Integracji Europejskiej 1997a, p.102).

7. As a result of undertaking political and economic reforms as well as the process of negotiations, Czechia, Hungary, Poland and Slovakia together with Estonia, Latvia, Lithuania, Slovenia, Cyprus and Malta became members of the EU on the 1st of May 2004.

Assessment of The Adjustment Process and Economic Growth of Poland, Czechia, Hungary And Slovakia In the Pre-Accession Period

Fulfillment of membership criteria by Poland and the other CEE countries required economic adjustments in three areas: 1) in respect of economic indicators, 2) structure of the economy, 3) rules of macroeconomic policy. Nevertheless, from the point of view of closing the development gap towards the EU countries and getting a positive evaluation of the economic adjustments, rather than the level of GDP, the more important factor was an upward trend in GDP growth, including GDP per capita. Hence, the National Strategy of Integration emphasised that "one of the most important factors contributing to the appraisal of Poland's readiness for membership will be economic trends (capacity to balanced growth in the conditions of declining inflation and simultaneous liberalisation of access to the domestic market)" (Komitet Integracji Europejskiej 1997a, p.13).

Analyses of growth trends pointed to the losses in development suffered by Poland in 1978-1994, when the average annual per capita GDP growth was negative (-0.97%), while the rate in Western Europe ranged from 0.79% in Sweden to 2.06% in Spain. In Denmark per capita GDP growth was 1.99% and in other European countries it ranged from 1.56% to 1.84% (in Belgium, Italy, Austria, Portugal, Germany and the UK), (Felbur 1996, p. 429). Hence, Poland's economic gap towards the more developed European Union countries increased significantly.

Improvement of economic conditions in Poland followed suit with the systemic transformation and increasing role of the market mechanism as a regulator of economic activity. However, in the early 1990s, Polish economy did not regain the full capacity for economic growth after the shock therapy reforms of Balcerowicz, production capacity was not fully used. According to the calculations of P.

Białowolski (2005, p. 46) the highest negative deviation of real to potential product occurred in October 1993 and equaled 4%, but during the period of 1993-1994 it gradually declined from 2% to 0. A more profound change happened in 1995 when the degree of production power utilisation increased noticeably and real product was higher than potential product by 1% to 2% until October 1998 (Białowolski 2005, p. 46). In the late 1990s, the negative factors affecting economic activity in Poland sourced from the Asian crisis (1997) and the Russian crisis (1998), but the latter one had a bigger impact due to stronger economic ties. Once again, the real product was below the potential product in January 1999, and the most extreme deviation occurred in the second quarter of 2002 and equaled 4% (Białowolski 2005, p. 47).

Figure 1: GDP per capita in PPS as percentage of EU-28 average in selected CEE countries in 2000 and 2019

Source: Own elaboration based on: Eurostat (2020).

In the early 2000s, Poland's GDP per capita was only 47% of the EU-28 average, and significantly lower than in Czechia (71.6%) and Slovenia (79.5%). On the other hand, worse results pertained to Romania, Bulgaria and the Baltics. In the Visergad Group, Poland was last (in 2000). Nevertheless, the difference from Hungary and Slovakia was slight - respectively 5.3 pp and 3.1 pp (fig. 1).

During the pre-accession period, after the signature of the Europe Agreements, the GDP growth rate rose in the Visegrad countries as a result of increased trade and inflow of foreign direct investment. In 1995-1999 the annual averages of GDP growth were: in Czechia 2.3%, Poland 5.9%, Slovakia 4.3% and Hungary 2.7% (European Commission 2014, p. 145). During the period directly before accession (2000-2004), economic growth in Poland decreased noticeably to 3.2% (annual average), only slightly in Slovakia - to 4.0%, while Hungary and Czechia had growth rates of 4.5% and 3.7% respectively (European Commission 2014, p. 145).

According to research by R. Dobrinsky and P. Havlik (2014, p. 4), in 1995-2000, the average annual GDP growth in the EU-27 was 2.84% and in CEE-10 3.38% so the convergence factor was 0.54 pp, that included 2.57 pp in Poland, 0.56 pp in Slovakia and 0.10 pp in Hungary. In Czechia the economic gap towards the EU-27 continued to increase by an average of 1.00 pp per year. According to these calculations, in the second half of 1990s, Poland had the highest GDP growth among the Visegrad countries thus having achieved a high dynamism of the convergence process. During the final years before the EU accession, the average annual growth rate in Poland decreased to 3.08% (2000-2005), whereas in Czechia and Hungary it was above 4.0% and in Slovakia it reached 4.91%. As a consequence, the Visegrad Group significantly improved its economic position in the EU - by 2.51 pp, and the convergence indicator for Poland was 1.28 pp (per annum) (Dobrinsky and Havlik 2014, p. 4).

In total, in 1995 - 2005, after the coming into force of the Europe Agreements, the adjustment process which encompassed the decrease of the economic gap measured by the level of GDP per capita and GDP growth rates was effective in Poland, Slovakia and Hungary. While Czechia was not up to par with the three mentioned countries, its economic gap was still significantly lower since Poland, Slovakia and Hungary reached Czech GDP per capita from the year 2000 as late as 2019 (fig. 1). Basically Poland's economic gap, just as Hungary's and Slovakia's towards Czechia slightly declined. Much better results in the convergence process pertained to the Baltics (fig. 1).

Economic growth and contribution to the increase in GDP of supply and demand factors in 2002-2019

Table 1 contains the real GDP dynamics in 2002-2019 divided into three 6-year cyclically differentiated periods. The period of 2002-2007 includes the economic slowdown of 2002-2003 following the demand shock in 2001 in the United States and the economic prosperity of 2004-2007. The years 2008-2013 are considered as recessive-stagnant while in 2014-2019 the post-crisis recovery pertained to all the European Union member countries. The distinguished periods allow for the evaluation of the capacity for economic growth of individual countries during economic prosperity, crisis or revival and ability to regain lasting recovery after a deep recession.

GDP growth indicators in the years directly preceding accession as well as post-accession (2002-2007) reveal that all the Visegrad countries had growth rates almost double or more than the EU-28 average (2.4%). A clear leader in terms of GDP growth was Slovakia (annual average of 6.6%). GDP growth in Poland and Czechia ranged from 4.5% to 4.7%. Hungary was a "catching-up" country with the lowest growth rates (3.6%) which, nevertheless, still allowed to continue closing the economic gap towards EU-15 (tab. 1). In 2008-2013, Poland, Czechia, Slovakia and Hungary were characterised by more varied GDP growth rates. Poland had an exceptional capacity for economic growth during the two recessions and a period of stagnation - annual average GDP growth rate was 3.1%. Slovakia also achieved good results in terms of economic growth with the average of 1.8%. Czechia diminished the economic gap only slightly with the convergence factor of 0.1 pp. The only Visegrad Group country where the divergence process took place (the average annual decline in GDP of 0.5%) was Hungary. This result was worse than the average growth rate for EU-28 (0.0%) (tab. 1).

Table 1: Growth of real GDP in the EU-28 and V4 countries in 2002-2019 (percentage change, periodic averages)

Countries	2002-2007 Annual Average	2008-2013 Annual Average	2014-2019 Annual Average
European Union - 28	2.4	0.0	2.1
Czechia	4.7	0.1	3.3
Hungary	3.6	-0.5	4.0
Poland	4.5	3.1	4.0
Slovakia	6.6	1.8	3.1

Source: Own calculations based on: The Conference Board (2020).

After the 2008-2009 crisis, Hungary dropped from third to sixth rank in the analysed group of CEE countries in terms of per capita GDP (fig. 1). Sizeable losses to Hungarian GDP were caused by deep recessions in 2009 and 2012. A decline in economic activity was a consequence of a large domestic demand shock (in the case of both investment and consumption). In 2008-2012, average annual decrease in investment in Hungary was 4.3% and private consumption 2.4% (European Commission 2018, p. 7; Mucha-Leszko 2019). Post-crisis recovery in 2014-2019 was the strongest in Poland (4.0% per year) and Hungary (4.0%) with growth rates double of those for EU-28. The weakest results in the Visegrad Group pertained to Slovakia - by 0.9 pp lower growth rates than in Poland and Hungary (tab. 1).

The process of convergence as well as comparative advantage in trade depend on the increase in labour productivity. Table 2 contains an increase in the level of labour productivity per hour worked in relation to the EU28=100. According to the data, in 2002-2007 Poland had the lowest labour productivity which was below 50% of the EU-28 levels. On the other side of the spectrum were Czechia and Slovakia with productivity around 2/3 of the EU level (tab. 2).

Table 2: Labour Productivity per hour worked in the EU-28 and V4 countries in 2002-2019 (EU28 = 100, periodic averages)

Countries	2002-2007 Annual Average	2008-2013 Annual Average	2014-2019 Annual Average
European Union - 28	100.0	100.0	100.0
Czechia	68.4	72.1	75.6
Hungary	60.6	68.8	65.1
Poland	48.8	56.2	60.8
Slovakia	65.5	75.8	74.5

Note: Percentage of EU28 total (based on million purchasing power standards), current prices.

Source: Own calculations based on: Eurostat (2020).

During the recession and stagnation years, all the analysed countries increased their levels of labour productivity, but the highest increase pertained to Slovakia - by 10.3 pp, Hungary - by 8.2 pp , Poland - 7.4 pp and Czechia - 3.7 pp. During the economic downturn all the countries improved their economic effectiveness indicators measured by the level of labour productivity in relation to the EU average. Nevertheless, these positive tendencies occurring in all the Visegrad Group countries - which encompassed improvements of this basic measure of effectiveness which is labour productivity - reversed during the post-crisis recovery. In Slovakia and Hungary the indicators of labour productivity declined (in relation to EU-28). An increase persisted in Poland and Czechia (4.6 pp and 3.5 pp) (tab. 2).

Concluding, changes in the levels of labour productivity in Czechia, Poland, Slovakia and Hungary point to a significant advancement in the convergence of effectiveness. The most improvement in relation to the average labour productivity in 2000-2007 pertained to Poland (in 2014-2019) - by 12.0 pp, which was followed by Slovakia (9.0 pp), Czechia (7.2 pp), Hungary (4.5 pp) (tab. 2). Despite a sizeable increase in labour productivity in Poland, it still remains the lowest within the Visegrad Group, and in particular in comparison with Czechia and Slovakia (by about 15.0 pp).

Table 3: Contribution of labour, capital and TFP to GDP growth in Czechia, Hungary, Poland and Slovakia in 2002–2019 (in percentage points, periodic averages)

Countries	2002-2007 Annual Average	2008-2013 Annual Average	2014-2019 Annual Average
Labour Quantity Contribution			
Czechia	0.3	-0.1	0.7
Hungary	-0.6	-0.5	1.4
Poland	0.6	0.0	0.5
Slovakia	0.5	0.0	0.6

Source: Own elaboration and calculations based on: The Conference Board (2020).

Table 3 contains data on the input to the GDP growth of various factors of production in the analysed countries. As emphasised, high economic growth in 2002-2007 occurred in Czechia, Poland and Slovakia. The lowest dynamics pertained to Hungary, where a slowdown in economic activity started sooner. By 2007, its growth rate was close to zero which affected the annual average for the entire period of 2002-2007. Considering the impact on the decline in economic growth of the supply factors it appears that, different from the other countries, a decrease in the contribution of labour quantity occurred (-0.6 pp). On the other hand, contribution of labour quality was comparable to Poland and higher than in Czechia or Slovakia. Capital contribution to the GDP growth in Slovakia, Hungary and Poland was focused mainly on the non-ICT areas of the economy. Czechia was exceptional in this respect with lower contribution of non-ICT capital compared with the ICT sectors. The structure of supply sources of economic growth in Slovakia is also worth mentioning. The basis for a high GDP growth in Slovakia (6.6% per year) stemmed from non-ICT capital, ICT capital and increase in TFP. Similarly to Slovakia, Czechia had a favourable structure of supply growth factors in 2002-2007 - the highest contribution of ICT capital, the lowest in terms of non-ICT capital and a high input of TFP growth. ICT capital contribution created technological progress, and high growth of TFP contribution impacted the increase in labour productivity. Czechia and Slovakia's structure of supply sources of

economic growth in 2002-2007 proves that they achieved good results in closing the technological gap. Within the Visegrad Group, Poland did not stand out in terms of economic growth and had the lowest contributions to GDP growth of both ICT capital and TFP growth as well as generally low capital contribution (non-ICT and ICT). To sum up, in 2002-2007 Polish economic growth was mainly based on labour contribution and the opportunities of technological adjustment to the EU levels were not seized (tab. 3; Kąkol 2018).

A phenomenon of Poland's economic growth during the EU membership was a relatively high economic growth during the recession and stagnation of 2008-2013. Poland was the only European Union member that did not experience recession in 2009, only an economic slowdown. Polish macroeconomic results were also impressive within the Visegrad group during the entire period of 2008-2013. Average annual GDP growth was at a high 3.1%. During the same time in Slovakia it was 1.8%, in Czechia 0.1% and Hungary suffered from a decrease of 0.5% per year. It is worth noticing that despite unchanged labour input (no deterioration in the labour market), an increase in the contribution of the quality of labour occurred in Poland. The major change, compared to 2002-2007, was a sizeable increase in the contribution of capital and TFP to GDP growth. However, capital was mostly invested in the non-ICT sector which was not conducive to the creation of technological progress in Poland. ICT capital contribution remained low (0.4 pp). Capacity to economic growth during the two waves of recession in the EU and lack of sustained recovery until 2014 in the other Visegrad countries was lower compared to Poland and in particular in Hungary and Czechia.

Assessing the supply factors contribution to economic growth in the post-crisis period of 2014-2019, it is worth noticing the increase in labour contribution in all four countries, particularly Hungary, since in 2008-2013 it experienced a sizeable decrease in employment (Białowąs et al. 2019, p. 17-18). Return to work resulted in the decrease in the contribution of the quality of labour to GDP growth in all the V4 countries, since workers with lower qualifications which lost their jobs during recession were rehired. The most important factor of economic growth in 2014-2019 in all the analysed countries was non-ICT capital contribution, with the exception of Czechia where the contributions of both ICT and non-ICT capital were proportionate what allowed Czechia to speed up the technological adjustment of the economy to the EU level.

In conclusion, one needs to answer a question - whether supply sources of high economic growth in 2002-2019 were favourable for technological progress, increase in labour productivity and TFP. Within the Visegrad Group, Poland had the highest economic dynamics, but the supply sources of economic growth did not ensure creation of technological progress. Capital contribution to GDP growth was relatively high, but it was not concentrated in the ICT sector, which affects increase in labour productivity and allows for a higher growth of labour productivity in services developed due to the utilisation of ICT technologies which are carriers of technological progress. In the Visegrad Four, capital contribution led to the decline of technological gap only in Czechia. In Poland, Slovakia and Hungary non-ICT capital contribution to GDP growth was not conducive towards significant changes in technological bases of the economy and structural changes.

In table 4 the indicators of contribution to economic growth in terms of demand factors have been compiled. Domestic demand includes private and public consumption and investment, while external demand represents net exports of goods and services. In general, consumption has been an important factor in maintaining economic activity in the EU countries for many years.

At the beginning of the period 2002-2007, there was a slowdown in GDP growth and influencing the increase in demand became an essential condition for economic recovery. The indicators illustrating the contribution of private consumption to GDP growth in Slovakia, Poland and Hungary in 2002-2007 prove its great importance in achieving high economic dynamics of the analysed countries. Public consumption was a significant source of economic growth in Poland, but also in Slovakia, Czechia and Hungary. In total, private and public consumption in Poland accounted for 2.99 pp contribution to GDP growth, which was 4.5%.

Table 4: Contribution to the GDP growth of demand factors in Czechia, Hungary, Poland and Slovakia in 2002–2019 (in percentage points, periodic averages)

Country	2002-2007 Annual Average	2008-2013 Annual Average	2014-2019 Annual Average
Private Consumption			
European Union - 28	1.02	-0.06	0.96
Czechia	1.83	0.22	1.55

Slovakia	1.62	1.79	-0.33

Note: GDP at constant prices.
Source: Own elaboration and calculations based on: Ameco, 2020.

The level of private consumption depends on employment and wages, tax policy, social transfers and access to cheap loans. In Poland, the main sources of private consumption growth were (Mucha-Leszko 2020, p. 19): 1) high (with the exception of 2002) growth of GDP and population income, 2) increase in propensity to consume resulting from improved living conditions and well-assessed economic growth prospects, 3) easy access to credit, especially housing loans. The increase in the level and quality of consumption of the Polish society led to a decline in the propensity to save. This process proceeded very quickly and from January 2002 to January 2006 the savings rate in Poland dropped from 10% to 0% (NBP 2016, p. 43).

The most sustainable demand sources of GDP growth occurred in Czechia in 2002-2007, and their contribution was as follows: private consumption 1.83 pp, investment 1.59 pp, net exports 0.63 pp and public consumption 0.49 pp. The demand sources of GDP growth in Slovakia and Poland were dominated by consumption (private and public). Consumer demand was significantly supported by investment, which constitutes the basis for long-term economic growth (Mucha-Leszko and Twarowska 2016). Czechia, Poland and Slovakia had a comparable contribution of investment to GDP growth, and Hungary had a lower contribution.

In the case of Slovakia, there was a large contribution of external demand to GDP growth as an effect of export competitiveness (tab. 4). Czechia was second in this respect. In 2002-2007, Poland imported more than it exported, so external demand was not a source of economic growth. During the recession-stagnation period (2008-2013), the most considerable factor of economic growth in all Visegrad countries was foreign demand, and its largest contribution to GDP growth pertained to Slovakia and Hungary. It was also of great importance in Poland and Czechia. Private consumption was the major source of economic growth in Poland. Slovakia and Czechia stood out with low rates of private consumption contribution to GDP growth, and its significant decline was recorded in Hungary. Public consumption played a minor role as a factor of GDP growth in all four countries. However, the decline in investment had the most regressive impact on the economic situation in 2008-2013. Its largest fall was recorded in Czechia and Hungary, slightly lower in Slovakia. Only in Poland the contribution of investment to economic growth was moderately positive. In conclusion, it is worth recalling that in the period of two recessions and post-crisis economic stagnation in the EU, Poland achieved an average annual growth rate of 3.1%, and the most important demand sources of GDP growth were: private consumption, investment and net exports.

After two waves of recession (2009, 2012), the economies of the EU countries could not achieve a stable recovery for a long time. It was only in 2014 that they recorded an increase in GDP, which in 2014-2019 amounted to an average of 2.1% (EU-28). The economic dynamics of Poland and Hungary was almost twice as high as the EU average (4.0%), and the growth rate of Czechia and Slovakia was 3.3% and 3.1% respectively. The lower average annual GDP growth rate (2014-2019) in Slovakia as compared to Poland was the result of the deep recession in 2009 (-5.5%) as well as the stronger, and longer than in Poland, economic downturn after 2010, which persisted in the period of 2011-2014 (Mucha-Leszko 2017, p. 84-85). In Czechia, the lower periodic average of GDP growth rate in 2014-2019 was a consequence of the two-fold slowdown in economic activity in 2016 and 2018 (Mucha-Leszko 2019, p. 70).

Concentrating on the demand factors of economic growth in the Visegrad countries, it should be emphasised that private consumption, supported by public consumption, had the greatest share in GDP growth in all of them. The contribution of investment was comparable in Czechia, Poland and Slovakia, but relatively low after their large decline in 2008-2013. While investments in Hungary played a significant role in reviving the economy. The impact of external demand on the strength of economic recovery in the surveyed countries varied, from moderately positive in Poland and Czechia to negative in Slovakia and Hungary (tab. 4). It should be pointed out, however, that the decline in foreign demand was a consequence of regressive trends in international trade (Wojtas 2017).

Conclusion

When assessing the results of Poland's economic growth and the pace of the convergence process against the background of the V4 countries, it should be emphasised that Poland suffered significant development losses, measured by the negative GDP growth rate in 1978-1994 (-0.97% annual average). The fundamental change in development trends took place in 1995. The exceptionally high economic growth was maintained in 1995-1999 - an annual average of 5.9%, while in Slovakia it was 4.3%, Hungary 2.7%, and Czechia 2.3%. In 2000-2004, Poland's economic growth rate decreased to 3.2% per year, and in the remaining V4 countries it increased and amounted to: 3.7% in Czechia, 4.0% in Slovakia and 4.5% in Hungary. To sum up, in the pre-accession period, the possibilities of reducing the economic gap were not fully used, especially in the first half of the 1990s and in the years 2000-2004.

Poland's economic growth under the conditions of EU membership was more dynamic and stable. In 2002-2007, Poland's convergence coefficient with the EU-28 amounted to 2.1 pp, in Czechia 2.3 pp, Slovakia 4.2 pp and Hungary 1.2 pp, i.e. in the V4 group at a level close to the average. Poland's success was the high dynamics of reducing the economic gap in 2008-2013 and 2014-2019. In the recessive-stagnant period, the convergence ratio in relation to the average EU-28 GDP growth reached the level of 3.1 pp in Poland, in Slovakia 1.8 pp, Czechia 0.1 pp, and Hungary increased the

economic gap by 0.5 pp annually. During the post-crisis recovery period, all the V4 countries achieved a higher growth rate than the EU-28 and the convergence coefficients were varied, Poland 1.9 pp, Slovakia 1.9 pp, Czechia 1.2 pp, and Hungary 1.0 pp. The highest dynamics of economic growth and convergence under the conditions of EU membership was achieved by Slovakia and Poland.

As emphasised, an important aspect of the analysis of economic growth results is the appraisal of the contribution of supply and demand factors. When assessing the contribution of supply factors to GDP growth, it is necessary to answer the question whether the structure of supply sources of growth was favorable from the point of view of influencing technological progress, increase in labor productivity and TFP. The contribution of capital to GDP growth was relatively high, but it was invested outside the ICT sector, while the contribution of ICT capital remained low, and it is the carrier of technological progress. Only Czechia had a proportional contribution of ICT and non-ICT capital. Thus, the structure of supply sources of GDP growth did not ensure Poland, Slovakia and Hungary reducing the technological gap, but ensured achievement of this goal for Czechia. The structure of demand sources of GDP growth was also unfavorable for Poland. Consumption was the dominant factor throughout the period considered. In summary, the weakness of economic growth in all the V4 countries were low investment and concentration of capital expenditures outside the ICT sector (in the latter case, with the exception of the Czechia).

To conclude the evaluation of Poland's economic dynamics during the EU membership, it is worth pointing to the forecasts of Poland's diminishing the economic gap published in the 1995 report "The Polish Economy in 1995" (1996, p. 3). The authors of the report predicted that Poland would have achieved a GDP per capita level of 75% in relation to the EU by the year 2022 or 2025 (the second scenario). The analysis carried out in the paper confirmed the nearly 100% accuracy of these forecasts (fig. 1).

---

[i] Austria, Finland, Norway and Sweden. They became members in January 1995 (with the exception of Norway where the accession treaty was rejected in a national referendum).

[ii] Czechoslovakia was divided into two sovereign states - Czechia and Slovakia in 1993.

Abstract

Faced with a new set of challenges ranging from international cash and risk management, to Open Banking and various types of regulations, the financial services sector is undergoing a phase of digital transformation thanks to the adoption of the latest Big Data technologies. This transformation is enabling banks and financial institutions, as a whole, to modernize their information systems whilst maintaining the highest levels of compliance and security. With raw data seen as the main asset to address key business requirements, financial institutions embarked on a mission to innovate their core services. Their main aim is to exploit the data to better serve customers, meet increasingly stringent financial regulations and compliance, as well as growing the business as a whole. Empowered by in-depth coverage of security, data governance, storage and processing, new financial platforms must be able to respond to the business needs and support a variety of mission-critical requirements. Such needs can vary from critical regulatory frameworks to the highest security requirements set out across the industry. Thanks to new Big Data platforms, financial institutions are now able to reduce time-to-market for new applications as well as the costs of maintaining a rather expensive legacy infrastructure. We show in this article how Big Data concepts and technologies were applied to two financial use cases: a Risk Management and Cash Management Platforms.

Keywords: Finance, Risk Management, Cash Management, Regulation, Business Intelligence, Data Warehousing, Big Data.

Introduction

In the financial domain, information represents the main source of competitiveness and income for businesses (Yu and Guo, 2016). Having the most reliable information as soon as it's available means you are ahead of your competitors. Also, mutualizing data from several sources in a unified storage, purifying it and performing parallel computing on massive amounts on historical data is a huge advantage for financial companies. Indeed, modern financial companies are using data characterized by the 3Vs (Volume, Velocity and Variety) (Yu and Guo, 2016).

A study conducted on the US market (Zhang, Shi and Khan, 2018) shows that the number of financial transactions noted 50 times increase in only a decade. Even before the outbreak of the COVID-19 pandemic, and due to the noticeable increase of mobile payments and e-commence, the size of the payments market was predicted to reach 2 Trillion US$ by the end of 2025 (QYResearch, 2019). But volume is not the only issue for financial data. The need for a low latency when processing financial

Cite this Article as: Mohamed Mehdi BEN AISSA, Lilia SFAXI And Riadh ROBBANA "Big Data in Finance: Redesigning Risk and Cash Management Platforms by introducing Big Data Technologies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

requests is at its peak, as a constantly increasing amount of trades are executed online (Tian *et al.*, 2015). In fact, nowadays, financial markets can experience up to 500 quote changes and about 150 trades in 1ms. Aside from that, financial data is composed of structured data, mostly in the form of time series, such as those provided from global stock exchanges, and unstructured data, gathered from social media, web articles and videos, and that are becoming valuable sources in modern trading strategies (Zhang, Shi and Khan, 2018).

The characteristics cited above justify the need for Big Data tools, methods and best practices, in order to extract meaningful values from raw data in a timely fashion. However, and despite the awareness of the decision-makers about the importance of this technological shift, it is still a struggle for most of them (Goes, 2014). Indeed, financial companies have resorted for a long time to high performance computers to deal with intensive processing (Tian *et al.*, 2015). But the constant increase of data volume generated the need to scale out the system, and thus use new storage and processing paradigms. This shift comes with a whole set of challenges, and calls for the use of Big Data analytics as well as transactions' management.

Big Data platforms are beneficial for the financial market in many aspects (Tian *et al.*, 2015). They can help organizations add a layer of intelligence to their trades, by exploiting all available data in a reasonable time. They help to avoid indiscernible risks, give more accurate customer profiling and detect fraud in real-time. Enforcing a robust data governance to safely use the data while maintaining the usability is a key success factor for these types of applications. On the other hand, integrating accurate structured data with high-volume social networks insights can reveal hidden market opportunities, contrary to more classical means (Yu and Guo, 2016).

Due to the requirements of the CAP theorem (Brewer, 2012), that states that consistency, availability and partition tolerance cannot be applied simultaneously, developers and architects are faced with the difficult task of finding a reasonable tradeoff between the performance of the system and the correctness of the data. The 3V properties of Big Data encourage in general to favour availability over complete consistency. But in financial applications, and especially in the risk and cash management contexts, this can be problematic, as consistency is a crucial requirement. This justifies the need for an evaluation system that helps to extract valuable metrics for an appropriate decision-making.

In this paper, we detail the impact of Big Data on decisional platforms compared to classical Business Intelligence ones. We then show how Big Data technologies were integrated in two financial platforms: Risk and Cash Management, by taking into account the different financial constraints and requirements.

Decisional Platforms from Business Intelligence to Big Data

Business Intelligence and Big Data Business Intelligence applications use tools, techniques and technologies allowing the exploitation and the consolidation of the heterogeneous data, in order to facilitate decision making within the company and to allow the decision maker to have an overview of his activity. They are based on Online Analytical Processing (OLAP) that structures data as a set of facts and dimensions. They rely on a well-defined process: data extraction, transformation, loading into the data store, analysis and visualization.

On the other hand, Big Data technologies allow collecting, storing and analyzing massive data characterized by volume, variety and velocity via varied terminals, in real time and from any geographical zone. They represent, today, powerful tools for companies in the decisional world thanks to their distribution, scalability and modern architectures. The introduction of these technologies gives companies many opportunities to improve their information system and to make it more efficient by supporting new features and options that did not exist before. Big Data systems use distributed storage systems to benefit from their (theoretically) unlimited capacity, and the computation power they can offer thanks to the multiplication of resources. Technologies differ in

this area, from those that enable the processing of huge quantities of inputs in order to have a complete view of the existing data and extract value with a high throughput, to those that process high velocity data in real-time to render results at a low latency.

Big Data technologies can be integrated in every layer of the information system, and in all types of applications: transactional, analytical, or transverse, such as monitoring, business process management, and security. In this article, we are only dealing with OLAP architectures and the impact of Big Data technologies on them, which introduces a new concept known by **Big-OLAP**. In fact, Big Data systems can also be used in the decisional world, as they provide powerful and precise tools for extracting value and facilitating decision-making and prevision. Some even tend to declare that, now that Big Data is evolving and maturing, the classical Business Intelligence is about to disappear.

Architecture Contrary to BI solutions, Big Data systems don't follow a rigid and well-defined decisional chain, but are characterized by the flexibility and adaptability of their architectures. Moreover, Business Intelligence applications are always driven by Key Performance Indicators (KPIs), contrary to Big Data solutions that support a schema-less approach applicable to all decisional KPIs and requests (Herodotou, 2011). Decisional Big Data systems are known to be data-driven, which means that the business needs are extracted from the existing data, and can evolve with them. While BI systems work the other way around: the business needs (illustrated by KPIs) are defined first, and from these needs, the structure and type of the stored data are deduced.

Data Collection Data Collection in a BI architecture must go through a rather heavy and long transformation phase that must happen periodically, preferably at night or in the weekend when the source systems are at rest. But in Big Data systems, and due to the velocity property of the data to be stored, subjecting them to a long processing step before storage is impossible. This is why they need to be collected and stored in a real time fashion first, as they are. This important distinction drives the need to very different types of storage systems: for Business Intelligence applications, we are talking about Data Warehouses, versus Data Lakes for Big Data systems.

Data Storage: Data Warehouse and Data Lake The Data Warehouse is a structured store that respects either a star (Gopalkrishnan, Li and Karlapalem, 1999), snowflake (Levene and Loizou, 2003) or fact-constellation schema (Geetika Saxena1, 2014). It is a centralized, structured and KPI-driven storage system. On the other hand, a Data Lake is a data store designed for Big Data applications, characterized by its distribution and capacity to store and treat a high volume of data. In addition, the most important advantage of a Data Lake is its capacity to manage a schema-less data that is often denormalized, redundant and stored in bulk (Fang, 2015).

The choice of the terminologies "Data Warehouse" and "Data Lake" explains very clearly the main difference between these two notions. Being a warehouse, a Data Warehouse is there to store the data in an organized manner meant to facilitate searching and extracting valuable information. Whereas a lake is there just to engulf all the goods you intend to throw in it. It doesn't care about classifying it, filtering it or structuring it at first. It is just intended to store a huge amount of data, and it's up to the user later to go through all the mess and see what he can do with it.

In Data Warehouses, data needs to be shaped before it is stored, as it uses a *schema-on-write* processing type, while Data Lakes do not use any predefined structure while writing data, but defines the necessary structure for processing when reading it (*schema-on-read*). In Data Warehouses, data is generally read using multi-dimensional queries and transformed into in-memory hyper-cubes before being sent to the reporting tool, while with Data Lakes, treatment is co-localized with the data, supports distribution and parallelization, and can be pretty complex. Both data stores are historical, which means that data is not supposed to be deleted or modified, only added and read. All data are tagged along with timestamps, and any modification or new addition will just be appended to the old value, thus enabling archiving and applying a next-to-zero-data-loss strategy. As a summary, we present in the Table 1 a more exhaustive comparison between these storage systems.

Table 1. Data Warehouse VS Data Lake

	Data Warehouse	**Data Lake**
Data Structuring	Structured	Not (necessarily) structured (denormalized)
Subset	Data Mart	Lake Shore
Data Volume	Important	Very High (100*TB*)
Information Density	High	Low
Distribution	Centralized	Distributed
Co-localized Treatment	Not supported	Supported
Scalability	Vertical	Horizontal and Vertical
Users	Business Professionals and Decision Makers	Data Scientists and Data Engineers

Data Analytics Data Analytics in BI solutions are characterized by their centralized nature, and are mainly focused on the OLAP approach. Big Data technologies, on the other hand, are broader, and can benefit from the underlying infrastructures' scalability. Big Data technologies can also be used and integrated in the analytics phase of a decisional chain based on new compute patterns like map-reduce. Usually, these patterns rely on Big Data concepts like distribution and data locality, which are hindered by the centralization property of the Data Warehouse. Nevertheless, even without a real distribution of the data, these technologies support a massively parallel processing phase, that improves in a spectacular way the performance of machine learning algorithms, for example.

Decisional Big Data Architectures

In this section, we present different Big Data architectures for decisional projects based only on Big Data technologies, patterns and tools. These architectures are seen as a revolution in the decisional world thanks to their modern design, overall scalability and features such as real time stream processing.

There are two well-known Big Data architectures for decisional projects:

Lambda Architecture A generic architecture (Kreps, 2019) designed to store and process a massive amount of data while taking into account the volume, the velocity and the low latency constraints. This architecture solves complex problems that involve real-time stream processing as well as batch jobs. It aims to provide complete and dynamic views and satisfy the needs for a scalable, robust and fault-tolerant system (Persico *et al.*, 2018). It consists mainly of three layers: the first layer is called the Speed Layer, and aims to produce real-time views only on recent streaming data. The data is processed on the fly, without any access to the historic store and only resulting views are stored. The second layer is the Batch Layer, and its main goal is to perform on-demand historic analysis. Data is first stored in a distributed batch storage, as it is, without or with very little loss. Once stored, any analytical request can be performed, and its result will be stowed in batch views. Speed Views and Batch Views, resulting from the speed and batch processes, are managed by the Serving Layer, which is responsible of their creation, their maintenance and their eventual fusion and integration. This layer is also the only communication endpoint provided to the decision makers, that can perform batch low-latency analysis along with real-time visualization.

Fig. 1. Lambda Architecture

Kappa Architecture The Kappa architecture is designed in order to simplify the Lambda architecture by combining the speed and batch capabilities into one layer known as real-time layer. In fact, this layer is mainly used for real-time stream processing, while taking into consideration historical data. Since there is no batch processing layer, only one set of code needs to be maintained, which can decrease the complexity of the system, the biggest hindrance in the lambda architecture (Lin, 2017). Because the final user is no longer connected directly to the historical store, he cannot trigger any on-demand processing and all historic analysis must go through the streaming factory.

Other Big Architectures Lambda and Kappa architectures can be the most famous Big Data architectures, but they are not the only ones. In fact, some other less known greek-lettered-architectures exist, such as *i*ota (Apache Incubator, 2016) which is a lambda-inspired architecture specifically designed for internet of things applications. Other than that, a lot of companies choose to combine Kappa and Lambda characteristics into a customized architecture specifically adequate for their needs.

Fig. 2. Kappa Architecture

Benefits: The Big Data architectures for decisional projects are as advanced as they are today thanks to their support for real-time Big Data analytics, their overall distribution and scalability and their high availability. In addition, they support schema-less design for historical storage and analytics. On the other hand, these architectures enable us to consider and handle data differently, depending on their types and characteristics. In fact, data can be classified according to its access date, and access and change frequency. So, distinguishing a multi-temperature data management solution involves having **hot**, **warm** and **cold** data, the first being the most recent and frequently accessed data, and the last the oldest and rarely accessed ones. This data classification is very helpful to optimize data access and change operations particularly for Big Data architectures. For example, we can choose the type of storage depending on the type of the data it contains, putting the hot data on stores privileging access speed, while the cold data can be put on stores supporting enormous volumes, but not necessarily fast. In the Lambda architecture, the hot data is immediately processed by the stream layer, while the cold data is archived in the Data Lake and processed on demand for Analysis, Historical Lookup or Auditing.

Limits: Implementing Big Data systems in a decisional context faces several challenges. In fact, designing and setting up a Big Data architecture represent a major revolution in the company, that requires a broad and quite scarce expertise. In an existing and implemented decisional project, these architectures are not easy to integrate because they represent a major architecture revolution. Moreover, to implement them, a broad expertise in Big Data systems and technologies is required, as they are known to be less documented and less regulated than other technologies, in addition to the lack of any Big Data methodology for decisional projects. On the other hand, using Big Data technologies can be too complex and extreme for some simple and straightforward use cases where plain old BI solutions can do the job. If real-time processing is not needed, if KPIs are clear, fixed, and well-defined from the beginning, there is no need to go for a haphazard Big Data decisional architecture with less support and documentation.

Compatible technologies: Some of the well-known OLAP decisional technologies that respect the Lambda architecture is Druid (Yang *et al.*, 2014). Indeed, it is an open source, end-to-end solution meant to offer flexible, low-latency analytic queries on real-time data. The solution combines the low latency guarantees of stream processors and the correctness and flexibility guarantees of batch processors. It also introduces a serving layer specifically designed for interactive analytics. Another

technology, called Samoa (Bifet and Morales, 2015) implements the Kappa Architecture, by introducing machine learning models in the streaming context, combining both batch and streaming jobs into the same layer.

Big Data and Decisional Risk Platform

Context

At a French corporate and investment bank, the first Big Data need consists in building a new scalable decisional Risk Management Platform based on Big Data technologies.

The existing Risk Management solutions have already shown their benefits, by allowing to manage the significant complexity of market risks indicators. However, they had also some limitations when it comes to dealing with Big Data. In fact, the legacy infrastructure didn't scale well to data which volume increases steadily and continuously. This is due to the fact that only vertical scalability is supported, which makes its maximum capacity quite limited, and calls for very expensive infrastructure changes. In addition to that, new compliance and regulation requirements like the BCBS239 principles (ECB, 2018) (data dictionary, normalization, data lineage, audit trail, KPI, etc.) and the Fundamental Review of the Trading Book (FRTB) (BCBS, 2013) regulation, require advanced and complex analytics.

In this direction, a new scalable and international Big Data Risk Management Platform was designed and implemented, in order to reach a high level of data integrity and quality. This platform aims to ensure a rationalization of the entire ecosystem, deprecation of obsolete systems, harmonization of pricing libraries and optimization of operational and decisional processes. We have subsequently been able to optimize the generation of different regulatory reports and distribute each one to the various regulators, leading to better compliance across every department.

Specific training sessions were arranged for development, infrastructure and project management teams in order to present the Big Data fundamentals and prepare the kick-off of the first Big Data program of the company. On the other hand, the focus of the team on this particular project was on data governance, being the first priority of the program. Then, we accompanied the team in the different phases of this program from the proof of concept and prototyping to the production run. The project is still ongoing. Following the Agile and DevOps approach, the solution is already in Production, while the clients' needs are still changing and evolving.

Architecture and Implementation

The developed platform aims to store and process a massive amount of data while taking into account the volume, velocity and low latency constraints. The system respects the Lambda architecture as presented in figure 3. It aims to solve complex problems that involve real-time stream processing as well as batch jobs. It provides complete and dynamic views and satisfies the needs for a scalable, robust and fault-tolerant system. Data governance rules were applied from the beginning, in order to guarantee high data quality that will directly impact the analysis phase.

Fig. 3. Risk Management Platform Architecture

Data Sources Different data sources were identified from internal (pricing modules, real time order flows and ticks) and external systems (social media and partners' data). From a technical point of view, these sources were classified as batch (relational databases, Rest APIs) and stream sources (real time streams, logs and metrics). The data collection processes were designed and implemented via StreamSets, which is a Big Data integration tool facilitating the collection of these different datasets. Two different execution engines were used by StreamSets to distribute the collection processes: (1) Change Data Capture for relational databases (Ankorion, 2005), and (2) Apache Spark using micro-batch for the other sources. A big part of the data is collected from social media like Twitter, LinkedIn, etc., and injected into Apache Kafka without any transformation in order to keep their original content and ease the evolution of the platform for new needs.

Speed Layer Implementation Two sorts of streaming jobs were defined:

1. Transformation jobs that execute cleansing and enrichment operations to prepare data to be analyzed. As different sources were identified, an important homogenization phase was implemented by creating different streaming views traced in the data governance tool which is Colibra.
2. Analytics jobs that consume real time events from internal and external datasets in order to make the decision-making easier for traders by reducing the time to market. Real time streaming jobs consume transformed data and execute real time analytic algorithms using the structured streaming API of Apache Spark combined with other machine learning tools like Tensorflow and Scikit-learn. Thanks to this layer, traders can have a unified real time dashboard that reports several business indicators like trading activities combined to real life activities like news, weather, social media, public opinion, etc.

Batch Layer Implementation Apache Spark (mainly Spark SQL API) and Apache Hadoop were used in the batch layer. The analytics jobs aimed to execute three types of jobs:

1. Historical data exploration: these jobs produce on-demand and interactive reports with specific and temporary queries requested by regulators or traders and executed by Hive LLAP.
2. Daily trading activities summarizing: these jobs produce scheduled reports, and use Apache Spark to consume internal data, then send the analyzed data to regulators as required by the financial regulations like FRTB and MIFID II.
3. Data mining and discovery: these are machine learning jobs using Apache Spark ML, that help to understand the relation between datasets and create new business opportunities in a trading context that can be impacted by various internal and external factors.

Business Impact

From a functional point of view, the implementation of this platform was very beneficial for both regulation and trading activities.

As described in the context section of this use case, building daily regulator reports was not possible with the legacy technologies as we had to deal with high data volume. Without these big batch reports, trading activities could not be maintained, as it was required by the regulator for business continuity. Data quality and analysis precision were the biggest challenges in this part, as very important sanctions can be applied in case of inconsistent reports communicated to the regulator that can freeze bank activities.

In addition to that, the platform delivered real time analytic reports for trading activities by taking into account different sources from national and international financial markets, internal systems like pricing modules and other external sources like social media. Thanks to this module, more efficient predictive algorithms, based on new explored data like tweets, news and weather, gave better scores and helped the decision-making process. Real time reports based on an event-driven approach also helped traders to reduce time to market thanks to the low latency processing engines.

For this use case, the most important thing was to manage the datasets collected from the different intra- and inter-projects data sources, or from partners, customers and the internet. The data sources and datasets were well traced and defined in the governance tools, which helped the company to continue the enrichment of the Data Lake in order to improve existing modules and implement new needs.

Big Data and Decisional Cash Management Platform

Context

For several years, banks have been working on cash management solutions servicing both international trade and transactional banking product lines. In this context, a new decisional cash management platform was implemented by transforming its operational and decisional models using Big Data technologies. This platform enables decision makers to form an opinion in a timely fashion, while taking into consideration the financial context where the competition is increasingly harsh. In addition, it will make real time transactions' management possible thanks to real time fraud detection and transactional modules supporting high data volume with low latency. It also aims to modernize the decision-making with real time and streaming analytics for fraud detection and KYC (Know You Customer) modules.

Respecting Service Level Agreements requires real time validations of B2B important transactions. In parallel, KYC reports are generated on-demand, based on high data volume.

The team committed to deliver one minor and major release per month in order to accelerate the deployment with Agile best practices and by respecting the production service level agreements. The biggest challenge in this use case is the consistency, by insuring the *exactly once* semantics that will avoid transactions loss and their duplication. This feature is essential in a cash management context that requires high consistency and integrity levels, which directly impact the platform's performance.

Architecture and implementation

The cash management platform, presented in figure 4, is divided in two sub-platforms. The first one is fully operational and aims to manage the different B2B transactions with an event processing approach. The second one is decisional via two different layers:

1. *Fraud detection module*: respects the Kappa architecture and helps to validate the different transactions managed by the operational platform.
2. *KYC (Know Your Customer) module*: implements a Data Lake architecture and aims to store and analyze data collected in real-time from internal and external sources, using change data capture technologies.

Different types of data sources are identified: the operational and transactional internal system, social media and web crawling services that provide important information about different customers, internal accounting services, bank referential, internal CRMs, and various logs and metrics.

A big part of the legacy system is implemented using MQ-Series, representing operational transactions deployed all over the world. Real-time data collection jobs use Apache Storm, an event processing technology that helped to integrate real time transactions into the Kafka topics of the decisional platform. Thanks to these jobs, transactions can be consumed immediately by the fraud detection modules. Other in-house collection jobs were implemented with Apache Spark and Apache Storm in order to integrate the rest of the datasets form external and internal data sources.

Fig. 4. Cash Management Platform Architecture

Apache Kafka is used as a centralized message bus for event collection. It is also the point of contact between the different modules and sub-platforms. Once the data is collected into Kafka, Spark batch and streaming APIs are used for processing. In addition, Atlas was chosen as the governance tool for both data and analysis workflows.

In the fraud detection module, Apache HBase was used to persist different states of the Spark Streaming jobs and referential with a high consistency level. Fraud detection modules implemented with Spark Streaming checked the conformity of the B2B transactions by verifying if one of the actors is blacklisted or has any fraud proof from social media and official institutions. It was designed to have real time interactions with the operational platform with a high scalability level in order to respect the real time aspect of the transactional platform.

In the second module, raw data is stored into HDFS, then consumed by Spark jobs with a batch approach including: prediction algorithms, OLAP queries and customer behavior analytics.

Once the data is collected into the Data Lake, KYC analytic jobs consume it from different storage layers. In this module, data is prepared for OLAP queries via Spark then presented via other data visualization tools like Tableau and QlikView. Data from the Data Lake is collected and processed using machine learning algorithms for a better customer behavior understanding thanks to the combination of different datasets.

Business Impact

From a functional point of view, this use case is similar to the first one, when we compare the situation before and after Big Data integration. Indeed, it was not possible to implement a real time transactional platform with fraud detection due to the high data volume and the complexity of the fraud analytics. In addition, the real time specificity of these sorts of platforms requires an end-to-end low latency processing. Today, and thanks to Big Data, it's possible to maintain a real time cash management platform deployed in an international B2B context.

The decisional platform had to respect high service level agreements while making the right compromise between the availability and consistency levels. Data governance and security were also important in order to respect the compliance and regulations across the different countries. It also helped decision makers to have a global view of the different customers and partners. Prediction and data mining allow to explore new opportunities and create customized services and products.

Conclusion

In financial decisional use cases, the classical decisional platforms show some shortcomings. In fact, the traditional storage and processing models in Business Intelligence systems are not sufficient anymore when confronted with data that becomes more and more massive, varied and with a high velocity. This is where Big Data solutions can be of great use. In fact, these solutions have proven their efficiency when dealing with enormous constantly increasing amounts of data with a changing schema. On the other hand, Big Data technologies are evolving, day after day, by offering new features and capacity to deal with the demanding users. However, architects and developers find it increasingly hard to implement adequate solutions for their needs. They try to initiate internal Big Data and decisional projects, which tend to be very complex, with a high level of risk, and the need to involve a big number of actors with various skills. The lack of Big Data decisional methodology and tools with adequate governance rules and fundamentals make it an imperative to define new standards, especially in the finance domain.

Holiday Niches and their Impact on Mainstream Tourism – Future Trends

Corina Larisa BUNGHEZ

Bucharest University of Economic Studies, Bucharest, Romania
E-mail: corinabunghez@yahoo.com

Abstract

This research paper describes the emerging trend of niche tourism and focuses on some of the most important forms of this type of tourism activity, analyzing both current development and future evolution of these tourism trends, also being aware of the current global pandemic context. We assess the enormous versatility and potential of the selected niches, and we highlight the impact that these activities will have on mainstream tourism, both economically and socially, in the near future. The trends presented in this research paper will benefit both the tourism industry and the consumer and will fundamentally transform tourism in the near future.

Keywords: Niche Tourism, Future Trends, Economic Impact

Introduction

Mass tourism is by now an important part of our daily lives. But niche tourism is also growing at a rapid pace. Initially an expensive and elitist concept, targeting sophisticated travelers, who were enthusiastically interested in pursuing a diverse range of activities, niche tourism is now readily accessible to most people, being one of the fastest growing sectors within the domain of tourism.

The term *niche tourism* has been borrowed mostly from the term *niche marketing*, which has adopted the concept from a newer discipline, ecology. Hutchinson is considered to be the first who used the term niche, referring to a region in a vast area, region characterized by environmental factors which disturb the welfare of species. (Hutchinson, 1957) In this sense, niche tourism can be linked to the particular natural and anthropogenic resources of a region, to the characteristic lifestyle of the tourists that engage in this type of activity and to their social status and their financial resources, etc. The niche tourism market, which is characterized by its name, targets a small number of consumers when compared to mass tourism, but, at the same time, it is a constant tourism market. Niche tourism is more identified with what tourists are doing than their number in a particular destination, at a particular time.

Any discussion of niche tourism needs to be considered against the other extreme of mass tourism. The rise of mass tourism, fueled by the growth in the aviation sector in the 1950s and 1960s, also gave rise to the backpacker tourist who later became the highly specialized and sophisticated middle-class traveler of the developed world. (Lew, 2008)

Over time, the transition from mass tourism to niche tourism has been a slow and cumbersome process that necessitated a large amount of material and human resources in order to develop the much needed new and specialized infrastructure. The development of infrastructure in the past decades has allowed people to reach destinations all over the world in record time. Keeping with the accelerated technological advancement, tourism will continue to expand its digitalization process. There are more and more applications for niche services nowadays, that are extremely personalized. These special applications perfectly know their target consumers and make them suggestions based on their budget, their family

structure and their traveling and browsing habits. On the other hand, for destination managers and traveling planners, who want to use tourism as a mechanism for economic growth, focusing on niche tourism offers greater opportunities because this attracts consumers that are willing to spend more money.

In order to position niche tourism products, Novelli considers the notion of an increasingly experienced group of tourists demanding specialist holidays to meet their specific desires. (Novelli, 2005) The presence of activities, tourist attractions, settlements, food services and other facilities make up the fundamental components of niche tourism regarding mixed destinations, being aware of consumer needs and wants. The focal point of the niche tourism market is the focus on the demands and the expectations of the customers. The relation between supply and demand is well taken into consideration because tourists are in a never ending search for a more satisfying experience during theirs holidays. (C.T., 2010) In a world in which monotony is becoming more pronounced due to globalization, niche tourism is defined by its diversity and by new ways in which it can differentiate itself from the competition. Niche tourism doesn't have the negative implications that mass tourism has gotten along with its expansion, namely the negative impact on the environment and the degradation of socio-cultural relations.

If mass tourism is a standardized product aimed at a large segment of the market, niche tourism is situated at the opposite end of the tourism spectrum, being heterogeneous by nature and based on a larger demand for a more exclusive, unique and distinctive product.

The consumer is actively involved in the formation of a specific niche through its own consumerist practices. Because of this, in order to escape from the competition of mass tourism, the producer is no longer the sole identifier of adequate niche markets, because these niches are formed and developed by both producers and consumers, who act in a symbiotic mode in order to mutually benefit by it. (Richards, 2011)

Over time, the different types of niche tourism have been presented in specialty literature in a random fashion. There are, however, some authors that have categorized them based on different criteria.

In order to better analyze the impact that certain types of niche tourism have over mass tourism, we will utilize the classification made by Alex Papathanassis in his book, The Long Tail of Tourism. (Paapathanassis, 2011) Tourism niches are built on persisting social trends such:

- Sustainability (e.g. Eco-, Inclusive-, Agro-tourism)
- Experience-economy (e.g. Space-, Sport- & Extreme-, Military-, Film-, Dive-tourism)
- Self-development & individuality (e.g. Cultural-, Educational-tourism)
- Hedonism & voyeurism (e.g. Armchair-, Drug-, Sex-, Dark-tourism)
- Consumerism (e.g. Shopping-tourism)
- Conscious living (e.g. Health- & Medical, Religious-, Wellness-tourism)

Consumer experience in tourism is defined as a conglomerate of personal reactions and emotions associated with tourism activities. (Sugathan & Ranjan, 2019). The creation of memorable experiences is necessary in order to attract new consumers and to keep the ones you already have loyal. All of the aforementioned tourism forms satisfy this requirement.

Next, we wish to present and analyze the impact of these forms of tourism, focusing on one form of tourism in each of the categories presented.

Ecotourism

Ecotourism is considered to be a niche segment that targets a small category of tourists, when compared to mass tourism. Nevertheless, ecotourism is the sector with the biggest growth in all the niche tourism markets.

The consequence of broadly defining the borders of what constitutes to be ecotourism is the cause behind the difficulty of properly measuring and assessing the market share and the size of this segment. Even so, estimates tell us that ecotourism makes up for roughly 20% of the tourism global market.

The eco tourist is the individual who visits the less developed areas with an appreciative, participatory and selfless attitude. They interact in a noninvasive way with local flora and fauna and use natural resources in a conscious, reserved manner, while contributing through voluntary work or funds that are directed to the preservation of the area and the economic welfare of the local community. (Ziffer, 1989)

Ecotourism has two specific components: specialized operations and non-specialized operations. The non-specialized ones include all common elements characteristic to all forms of tourism: tourist guides, adequate clothing, tourism agencies, hotels and transportation. The specialized ones are those which refer to the specific activities of ecotourism: eco cabins and hotels in urban or more secluded areas (resorts), protected areas, eco thematic attractions, services in otherwise inaccessible areas by interesting means and local tour operators (natives).

There are independent groups successfully promoted as ecotourism products: aboriginal/indigenous tourism (related to cultural tourism), ornithology, celestial ecotourism (aurora borealis, astronomical observations, astrophotography), hiking and nature observation, landscapes photographing, outdoor education and research, etc. (Weaver, 2008)

Ecotourism attractions are primarily based on biodiversity and natural habitats that are, for the most part, unaffected by human activities. Thus, taking place in relatively isolated places, the current pandemic crisis will not impact this sector as severely as others. On the contrary, people will tend to visit more isolated places and ecotourism could benefit by this crisis. These zones require a specific conduct, in order to properly preserve and protect the tourism destinations so that they may keep their natural qualities and their sense of wilderness.

Ecotourism could indirectly compete with two tourist segments in terms of content and characteristics of the tourism product. These are cultural tourism and adventure tourism and they form, together with the ecotourism, what we call alternative tourism. (Papathanassis, 2011)

It is estimated that the future development of ecotourism in terms of application will depend on several factors. These are: revenue growth; increasing the education level; increased leisure time; population growth; easier, cheaper, faster and safer access to ecotourism destinations; greater care for the natural environment and people's feeling of alienation from it because of increasing urbanization and the development of technological elements.

Beyond all these elements, there is a necessity for properly trained people to educate the general tourist regarding the importance of nature conservation. Also, practicing ecotourism in these areas brings significant financial benefits that can be directed to further develop and maintain the natural parks and protected areas within the zone. Thus, ecotourism is a viable alternative for economic growth for these communities.

Space Tourism

Space tourism is an industry with extraordinary potential, but at present is limited by the conditions in which it can be done, because the prices are huge. Until the year 2019 the cost of a trip to the International Space Station aboard the Russian Soyuz spacecraft was 30 million dollars/flight. At present, the collaboration between NASA and SpaceX will inevitably lead to a commercial development. Axiom Space has already started the selling of tickets aboard the SpaceX capsule, at the price of 55 million dollars/ticket. The trip will last 10 days and will be directed to a privately funded orbital space station. Further technological advancement will massively lower the prices for space travel, starting with the amount of $200,000 that Virgin Galactic assigned in the beginning. Space travel will become more accessible to a greater number of people, especially in relation to the results of a market analysis, which has found that potential consumers are very price sensitive. (Goehlich, 2005) A study shows that at least 10 million people from around the world would be willing to spend a year's salary for space travel. (Smith, 2001)

It is expected that the number of space travelers will grow somewhere to a million per year when the price of a ticket will be under $ 10,000. According to research, rich and adventurous young people seem to form the most suitable target market due to their care-free rebellious component and the low level comfort that they will accept in return of the fact that they would be among the first passengers in space. (Crouch, et al., 2008) A study made by Futron Corporation in 2002 made the prediction that by 2021 the suborbital flight market will reach 15.000 passengers/annually, bringing in revenue of about 700 million dollars. (Futron, 2002) We are almost in 2021 and this approximation is totally unattainable in the current global context. But we can safely assume that the number is not unachievable and we may see this happen in a number of years. Another study made in 2006, in which 783 high income Australian respondents participated, showed that those who were mostly interested in space travel were thrill-seeking young men. (Devinney, et al., 2006)

The economic potential of the development of space tourism is extraordinary. This type of tourism will bring massive economic and social benefits in the future, because we can estimate that it will undoubtedly surpass aviation on Earth.

The progress of the space tourism sector would generate, alongside the indirect technological and scientific advancements, an important direct economic component that will lead to the exponential growth of this sector. Because space tourism has the potential of becoming its own branch in the tourism industry, the effects of this economic development will be significant, both for the companies and industries involved in the process, and for the evolution of society as a whole. In this type of endeavor, the investor's primary concern is the return of the investment and the generation of profit. In order to do so, every process involved will be thoroughly made as efficient as possible. Space activities will therefore become a massive economic generator and the launch costs will dramatically plummet, which will lead to an acceleration in the further development of this industry.

Space tourism will become an activity that will include a very large number of people (both operators, and beneficiaries) and will generate important commercial profits in the next few decades. It is imperative that we recognize this fact and that we realize that, in the near future, space tourism may become as common as other forms of tourism. But because the reality of space tourism is still quite far away, we may safely assume that the current Covid pandemic will not influence this branch of niche tourism. Because of the sensational experiences offered to the consumer, space tourism will become a major sector of the entire tourism industry, transforming this niche branch of tourism into one of the most important tourism activities of humanity.

Cultural Tourism

Cultural tourism is the most dynamic contemporary form of tourism, being interested in the lifestyle and traditions of particular communities or regions, built or natural heritage, artistic performances and products, cultural hubs and landscapes.

The first appearance of cultural tourism as a research topic has its origins at the beginnings of the 20th century, but only in 2002 did the International Council on Monuments and Sites publish a formal definition regarding this form of tourism: cultural and cognitive-cultural tourism is the form of tourism that is focused on the cultural environment and that includes historical and cultural landmarks within a destination, and the values, arts, crafts, traditions, habits and lifestyle of the local populace.

Cultural tourism is defined by the World Tourism Organization (WTO 2012 Report) as "journeys whose primary or secondary purpose is the visiting of sites and the participation in events that represent a cultural and historical component which is part of a communities' cultural heritage." There are serious cultural and heritage/historical tourists who are motivated by the inherent characteristics of cultural sites and, at the other end of the spectrum, there are people who accidentally visit such venues but are not truly interested in the sites' inherent cultural and heritage assets. (Morrison, 2013)

Cultural tourism includes, besides visiting historical sites, the opportunity to learn more about past human achievements. As a part of domestic tourism, these visits are a great source of admiration, national pride and learning about ancestors.

The complexity of cultural tourism is further generated by customer motivation diversity, induced by differences in education levels, tourism experience, quality of life and quality of the tourism products being offered. (Davidson, 1993) Also, cultural tourism has been identified as one of the most rapidly growing areas of global tourism demand. (Richards, 2005)

Cultural tourism is an instrument for economic growth, generated by attracting visitors from outside the local host destinations. These visitors are partially or generally motivated by an interest in historical, artistic and scientific components, or by information regarding the lifestyle, the realities and the traditions of a particular community, region, group or institution. This kind of voyage focuses on the study of the cultural landscape, and this includes visual and theatrical arts, values, traditions, events and lifestyle. Cultural tourism is especially interesting for suppliers because, as a rule of thumb, people that focus strongly on cultural attractions spend more money than regular tourists. Also, they show a tendency toward staying longer at the destinations, which, in turn, brings even more revenue. (Richards, 2007)

Because cultural tourism is primarily focused on the visiting of cultural venues or museums and experiencing artistic products and performances, the current global pandemic has affected, to some extent, this important tourism sector. But people will always be interested in the lifestyles and traditions of different cultures, and as soon as the Covid pandemic loses momentum, we will definitely see a resurgence in cultural tourism demand.

Armchair Tourism

The one thing that history has taught us is that people are most innovative in difficult times. This also applies to the travel industry, where professionals and brands are doing their best to keep the interest in traveling at a high level, despite the current global Covid pandemic situation. This has resulted in the surprisingly successful overnight growth of armchair tourism. This adaptation happened because tourism is going through one of its darkest periods in a long time, and tourism specialists find themselves in the impossibility to change this situation. Indeed, this isn't the greatest of times for classic travels, but, in the

meantime, we can opt for virtual travel. If until more recently the trend of virtual tourism was relatively ignored, because people preferred real experiences, more and more people are now glad that technology has advanced so much, in order to allow this type of tourism practice.

Because lately, due to the current global pandemic, tourism has been mostly relegated to rescheduling holiday plans or postponing them, the phenomena of armchair tourism is currently growing at a rapid pace, enabling us to travel all over the world, virtually.

If tourism is not seen as a physical change of the hereabouts but rather as a change of ones' psychological state of recreation, education, adventure, or other purposes associated with tourism, armchair-tourism can also be included. (Mazanec, et al., 2002)

Armchair-tourism has three main parts: books, television and the internet. Until the emergence of the internet, books were the armchair-tourism media because they were the best information source for life there. Nevertheless, new media has slowly overtaken the time spent on reading. Armchair-tourism such as travel magazines or cultural documentations are more focused on the market aged 40 and older. Nevertheless, the younger generation should not be neglected since new developments will enhance the experience of watching TV, increasingly attracting younger viewers. (Papathanassis, 2011)

Many tourist boards are nowadays using more and more virtual content in order to attract customers and to encourage future visits. These can come in the form of digital events, which provide enriching cultural content and livestreaming video talks using live content from experts, partners and notable individuals. Tourist boards will also use dedicated web pages on which they will promote virtual experiences. Museums, safaris, or other interesting venues can therefore be experienced from the comfort of your own home.

There are destinations and travel brands which can keep the magic and inspiration of travel alive for now – even if it is virtually, from the armchair. Many travel brands and destinations are working on the premise that if the travel consumer can't come to us, we will go to the travel consumer. There are digital platforms where a plethora of extraordinary destinations can be accessed and visited by virtual means. Over 2500 museums all over the world are providing virtual tours for those who are interested. During these tours they can enjoy rooms, shows and events, in which the tourist can participate virtually.

Also, the exponential evolution of technology has another benefit. Even if virtual reality is, at present, only capable of recreating to a limited degree the destination that is being visited, we now have another tool at our disposal: augmented reality. This changes the way in which a visitor can explore a destination in real time. Augmented reality is the technology that gives the visitor information that can be superimposed over the real time landscapes or streets, using a digital device. This technology is being used in order to animate history and to bring back life into exhibits found in the most important museums and venues of the world. Having all these means at our disposal, we can therefore travel anywhere, anytime and we are no longer dependent on the caprices of weather or the uncertainty found in difficult times, such as the one we are experiencing nowadays.

Shopping Tourism

As studies have shown, shopping is one of the most sought out activities no matter where tourists go. (Timothy, 2003) This activity gained traction with the development of theme parks, of malls and designer shops. Visiting a theme park or going shopping in another country and even inside the borders of your own country has become, for many tourists, a purpose in itself. Bill Bryson, an American travel and humor book author said that in the past he used to build civilizations, but now he builds shopping malls. Another American author, Erma Bombeck, affirms that the chances of entering into a store to buy a loaf of bread and exiting with just a loaf of bread are three billion to one. These aspects emphasize the worldwide consensus that, in our society, humans are unable to function without constantly going shopping.

When trying to define this special tourism sector only one facet can be defined clearly, namely that this kind of tourism includes the purchase of goods, the most typical being clothes, shoes, leather goods and luxury foodstuff. (Friedrich, 2006)

The main advantage a tour operator could enjoy is the fact that shopping tourism has a positive economic impact on the destinations as well as at least no negative environmental and socio-cultural effects. Meaning local life, natural environment and cultural sites are not going to be disturbed nor destroyed since many traditional malls, factory outlets, and markets do already exist. To be more precise, economically this implies: more secure jobs, as the malls will have a continuous number of visitors; tax income will increase due to the value-added tax (VAT) of more sales; shopping tourism does not seem as seasonal as other tourism products; in addition foreign tourists will increase the balance of payments. (Papathanassis, 2011) Also, the environmental impact is almost non-existent, this not being the usual norm with tourism activities. This happens because, neither accidentally nor by design, wildlife killing or vegetation being destroyed by tourists do not occur. There is also a socio-cultural impact: a shopping mall is visited by locals as well as national or international tourists and as such it is seen as a positive attraction since access is not limited to neither of the two groups. (Swarbrooke, 2002)

The Covid situation has temporarily shifted this type of tourism to a more domestic focused approach. People are now more inclined to go shopping in local tourism destinations. But shopping has become a life-dictating activity for many people. And even in the current difficult pandemic context, everybody goes shopping and we have become dependent on it.

Wellness Tourism

In our fast-paced society, we tend to often forget about ourselves. Because of this, health issues can arise due to stress, exhaustion and living a sedentary life. All these problems can be fixed by escaping into wellness centers. For more and more people, wellness is no longer a trend or a necessity, but has become a lifestyle.

The wellness industry has grown substantially in the last years, at a global level. The numbers are continually growing and the market value of the wellness industry has reached 580 billion Euros. Lots of hotels, airports and corporations have understood the importance of wellness and thus provide some kind of wellness services to both guests and staff.

The wellness world is a global economy made out of multiple components: beauty and care, fitness, nutrition and alternative medicine. Popular perception regarding the importance of healthy diets, fitness and other health practices has been developed into whole new business sectors. As the healthy lifestyle movement gains more and more traction, auxiliary markets, ranging from food and beverage to hospitality, start offering more products that reflect the values of the health-conscious consumers. This is another example of the multiplier effect of tourism. Additionally, the Covid situation is the perfect incentive for healthier lifestyle choices. Thus, people are becoming more aware of the importance of overall health management and are more readily willing to pay for these kinds of services.

Wellness tourism is defined in the specialty literature as traveling associated with the practice of maintaining or improving personal states of being.

From 2015 until 2017, the wellness tourism market has grown annually by a margin of 6,5 %. Until 2022, GWI anticipates that this market value will reach 919 billion dollars – representing 18% of global tourism – with over a billion wellness-oriented travels all over the globe. (GWI, 2018)

Today, wellness tourism is much more than just the destination or the activities – it is an extension of the traveler's lifestyle and values. The wellness tourism sector is a large spectrum one, and offers are divided

between many categories: fitness, healthy nutrition, therapeutic treatments (massages, beauty procedures). But every one of them is centered around enhancing the tourist state of being and state of mind.

Further opportunities are given to current trends, such as the alternative forms of medical therapies from Asia. However, these trends have to be recognized early enough and then must be implemented into serious, high-quality products. Besides from competitive criteria, such as price, or the kind and quality of services provided, the importance of attractiveness of the surrounding area as a choice criterion should not be underestimated. (Papathanassis, 2011)

Specialists estimate that, if the consumer appetite for wellness services maintains its rate of growth, the wellness global tourism industry will reach one trillion dollars in the shortest of time.

Conclusions

There is enormous potential with all of the emerging niche tourism products presented in this paper. All of them arguably represent what one may designate as a megatrend, either at present or in the near future. Additionally, each of the selected products have incredible versatility because they don't target a particular "special" group of consumers, but instead they appeal to a larger proportion of the population. In other words, the niches examined are not mutually exclusive in terms of target market. The phenomena of tourism globalization by developing infrastructure and thus new destinations, and the technological advances in human transportation, with the usage of the mega-ship or the implementation of large-scale commercial space travel, will transform these megatrends into tourism behemoths, and will result in the creation of new specialized holiday niches that will generate huge profits and further expansion. The examples we have presented show a promising outlook for each of the niches examined, as the current global pandemic cannot but temporarily slow the inevitable growth of these tourism sectors.

There are three main aspects of the tourism industry that we can synthesize from this paper. Firstly, the tourism sector is in a constant, ever-growing direction, with more and more people willing to spend money in tourism activities. Secondly, the mainstream holiday package isn't as stable as it used to be, and we can say that the current crisis in the world is a major influencing factor. Thirdly, there are some tourism niches that have great appeal and show incredible potential for the near future.

But there are three more tour operating aspects that we have to take into consideration when making assertions: the capacity risk, the consumers' perceived risk and the unknown reaction of the large tourism groups.

Higher profits can be generated when entering and developing niche markets. Because of this, there are many mainstream companies that have already entered into a number of niche markets. The technological advancement can thus be utilized by specialists in order to benefit in a sustainable way from each particular niche selected. And the tourists are more pleased because the holiday experiences are tailored to their needs and wants, making the product more individualized and consumer-oriented. For the tourism industry as a whole, the growing of niche markets can be seen as a "holiday" from the usual negative practices regularly associated with mainstream tourism, such as environmental irresponsibility and questionable ethics. This means that when niche tourism fully matures and inevitably integrates itself into mass tourism, becoming mainstream, it will carry its benefits into the new tourism industry.

Water Resources and Achieving a Comprehensive Balance of The Three Components of Sustainable Development

Vladimir A. CHERNOV

Nizhny Novgorod, Russia
E-mail address: Chernovva@rambler.ru

Abstract

Conservation of water resources is extremely important for achieving sustainable development in its three components: economic, social, and environmental. The author examines the existing environmental problems and identifies the most significant ones that require urgent solutions. A review of measures to preserve the environment, waste water sludge disposal technologies and individual production facilities in the field of ecology was conducted. Fundamental indicators of environmental efficiency and ecological and economic efficiency in the construction of a green economy have been introduced. A set of measures to combine the efforts of environmentalists, economists and the population in achieving sustainable development is proposed.. For this purpose, technical means of preserving and protecting the environment are studied, economic indicators for managing sustainable development are found, and measures are proposed to improve the culture of consumption of the population, leading to the transformation of irrational production in order to preserve natural resources and the biosphere. Increasing the culture of consumption is considered not only as a way to preserve the environment, but also as a natural phenomenon that contributes to the balance of supply and demand, reducing labor costs to ensure human life, reducing inflation, increasing the reliability and convertibility of the national currency, and strengthening the country's financial sovereignty.

Keywords: Waste water sediments, ecological economy, ecological efficiency, ecological-economic efficiency, recycling, thermal drying, waste treatment, waste-free technologies, integrated reporting, natural capital, consumption culture, balance, currency reliability, financial sovereignty.

Introduction

Every year, environmental problems become more complex, and their solution becomes more and more necessary for the survival of mankind. The problems are the need to preserve the biosphere, natural resources and achieve sustainable socio-economic development. Environmental issues are usually handled by ecologists, biologists, and specialists with technical education. However, economic solutions need to be increasingly linked to environmental concerns in order for any economic decisions to take into account environmental impacts. In order to solve environmental problems by economic means, it is necessary that environmental issues become an essential component of financial policy. The economic impact of new projects should be compared with the environmental damage of the project and the impact of conservation activities. The total elimination of adverse effects on environmental impacts in industrial production is impossible, but it is necessary that the damage caused can be replenished by natural processes and human involvement in environmental conservation, and nature can be restored. Therefore, economists need to join forces with ecologists and work more closely in this direction. This article is one form of such interaction.

For example, let's consider the problems of ecology of the Volga basin, which includes, first of all, the largest water bodies in The middle Volga basin. Among them: Gorky, Cheboksary and Kuibyshev reservoirs of the rivers Volga and Oka. The quality of water in them is determined by natural factors (landslide processes, erosion, etc.) and anthropogenic (waste water, storm water, surface runoff from territories, water transport, etc.)

No matter how much talk about the prevalence of domestic water consumption, From industrial consumption in Russia, but an increase in domestic water consumption, Wasteful consumption of water

Cite this Article as: Vladimir A. CHERNOV " Water Resources and Achieving a Comprehensive Balance of The Three Components of Sustainable Development" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

in apartments, increase water costs, but do not significantly increase waste water pollution, Since the water is then returned to the ground without industrial contamination, And the human body is the natural product of the earth, which contains the same elements that exist in the earth. Human consumption of water is a natural exchange process. Therefore, the presence of household meters for water consumption in Russia cannot become a significant factor of water purification, as the number of water resources and their provision to the population in Russia are not comparable to European, African and other countries, where due to the small number of fresh water bodies, water supply costs much more. And therefore in these countries household meters significantly increase savings, unlike Russia. The country 's water resources are contaminated primarily by industrial pollutants, transport, garbage, detergents, etc., washed away by precipitation and melting snow, and the sale of domestic water meters in Russia is more needed by business than by solving environmental problems.

According to Rosstat, 40% of contaminated wastewater in the Volga basin is discharged into the Cheboxary reservoir. In these effluents the content of harmful components is many times higher than the established norms. The bulk of harmful substances come from the industry of the Nizhny Novgorod region in the area of the inflow of Oki. Among the pollutants: heavy metals (copper, zinc, manganese), nitrogen-containing (nitrites, nitrates) and organic (easily and hardly oxidizable substances) and inorganic components. Many scientific publications are devoted to this problem.

According to research data from Moscow State University (MSU), Oka is most polluted by many industrial enterprises, including Dzerzhinsk chemical plants, discharges of large livestock complexes, and other pollutants. The problem is compounded by outdated treatment facilities, garbage dumping in water protection zones, pollution during snowmelt, etc.

From the river, the Cheboksary reservoir is filled with nutrients that cause blue-green algae to bloom in the summer. According to research, this flowering is accompanied by the release of toxic substances.

As noted in MSU research, in the Oka basin, in addition to the Nizhny Novgorod region, there is a Moscow region that pollutes the Oka riverbed with household sewage through the Moscow river .

Oka brings significant environmental damage to Gorkovsky and Cheboxary reservoirs, which are considered the most eutrophic bodies of water. In them, water quality, oxygen regime deteriorate, valuable fish breeds disappear, recreational conditions deteriorate.

A comprehensive solution to these problems has not yet been found, but the United Nations General Assembly Resolution sets out universal goals and objectives that cover the whole world, are comprehensive and indivisible and ensure a balance between the three pillars of sustainable development. Certain actions are also taken, technologies are being developed to reduce the negative impact on the environment in accordance with the standard (GOST R 56828.12-2016).

Goal 6 of the UN General Assembly Resolution aims to improve water quality by 2030 by reducing pollution, eliminating discharges and minimizing emissions of hazardous chemicals and materials, halving the proportion of untreated wastewater and significantly increasing recycling and safe reuse of wastewater worldwide.

AVAILABLE TECHNOLOGIES USED IN SOLVING THE PROBLEM

Storm water treatment facilities are used to treat wastewater generated during rains, snowmelt, and road irrigation from petroleum products and suspended solids. They are used to clean drains in shopping centers, gas stations, residential areas, warehouses, bridges and roads. When diverting industrial effluents, sorbing materials are used.

One of the advanced enterprises of Russia for the development, introduction and manufacture of equipment for water treatment and water disposal is Argel Group of Companies. In particular, it produces storm treatment facilities "Veksa" of different sizes and different productivity, depending on the customer 's needs.

The technology of treatment of more complex waste water, such as mine, quarry, sub-product, etc., provides for additional methods, including preliminary reagent treatment of effluents with coagulants and flocculants.

The waste water treatment carried out does not sufficiently contribute to solving environmental problems. During the biochemical treatment of 15 billion m3 of wastewater annually in Russia, about 1 billion m3 of wastewater precipitation with a humidity of 98% with a content of 70-90% organic and 30-10% mineral substances is formed. Sewage sludge from urban treatment facilities is classified as a hazard class IV. Such sediments contain heavy metals, sulfur-and chlorine-containing compounds, which prevents their disposal. Therefore, their processing is required.

As a result of the analysis of scientific and technical information of technologies for processing mechanically dehydrated sludge of waste water, thermal recycling technology - thermal drying - was recognized as the most appropriate. The use of such technology allows to disinfect and reduce the moisture content of sewage sludge from 83-86% to 10-20%, which facilitates the removal of sludge from the territory of treatment facilities and simplifies their further disposal.

Thermal (thermal drying, combustion, pyrolysis, thermolysis, etc.) and biothermal (composting, vermicompost, etc.) methods are used to treat dehydrated sediments.

The method of sediment recycling is selected individually for each enterprise taking into account the composition of precipitation and local conditions (availability of territories, ecological situation, interest of enterprises of the region in recycling products, etc.).

Application of advanced technologies of waste water sludge disposal contributes to reduction of payments for waste placement, increase of revenues from sale of product radiated as a result of thermal drying. This dried product may be used:

- As organomineral fertilizer;
- For filling mining sites;
- For construction of waste storage sites;
- In road construction;
- For soil reclamation purposes;
- For creation of fill slopes, greening of highways;
- In the production of cement, asphalt, ceramics;
- As additional fuel in power plants and incinerators;
- To produce combustible gas during pyrolysis (gasification).

Thus, the technologies of thermal treatment of waste water sludge allow to reduce environmental payments for waste placement, restore land areas for economic use, obtain commercial products for subsequent reception.

Modern waste water sludge thermal drying plants have a number of advantages, including simple design; Efficient drying at low temperatures; Does not require large investment investments; they are completely automated; Waste is used to generate heat required for drying; Complete disposal without generation of waste to be disposed of; Compliance with fire and environmental safety requirements.

New directions of waste-free technologies of waste water sludge utilization with their use as alternative fuel are developed for cement plants in Karlstadt (Bavaria). The main costs of such dryers are the cost of the energy needed to evaporate the water. Such technology is cost-effective. It allows the enterprise to free itself from fuel price volatility.

One example of corporate solutions for environmental protection in the Russian Federation is the investment project "Ensuring environmental safety" within the framework of the environmental strategy of Open Joint Stock Company "Russian Railways". The project provides for construction, reconstruction, modernization of treatment facilities, equipment for cleaning of polluting emissions to the

atmosphere, waste disposal, acquisition of equipment and installations for environmental protection purposes, equipment of environmental laboratories, purchase of analytical devices, equipment for elimination of emergency spills of oil products, etc.

In the Nizhny Novgorod region, in 2018, the largest automated waste sorting complex in Russia with an investment of 1.2 billion rubles was opened on the territory of the existing solid waste landfill "MAG-1" near Dzerzhinsk. At the same time, part of the sorted waste is subject to burial at the landfill, and the other part (plastic, paper, metal) is sorted, processed and sold as secondary raw materials. This project is one of the examples of public-private partnership in solving the problem of solid municipal waste processing.

In Nizhny Novgorod, a high-tech plastic processing plant with innovative polymer processing equipment has also been opened, which will mutually operate with the waste handling complex MAG-1. The plant produces polyethylene granules and flakes, which are raw materials in the production of plastic bottles, automotive products, pipes, furniture, cable insulation, etc.

This is a very important project, especially in the context of Russia 's acute shortage of polyethylene granule manufacturers and the underdevelopment of the secondary raw material market. Granules produced at the plant have high quality - said Sergey Halevsky, Director of the Fantastic Plastic Plant. Half of the plastic for processing at the plant will come from the largest waste handling complex "MAG-1" in Russia, located in the Nizhny Novgorod region, and the second half - from other regions of the country. Plastic recycling helps solve the problem of particular importance, as plastic waste accounts for a quarter of the world 's total waste.

The complex of equipment for solid plastic processing for the plant was delivered from the Russian manufacturer StankoPET. In terms of productivity and quality, the operation of this equipment is not inferior, and in certain parameters - exceeds European analogues, and in price - significantly lower than them. At the same time, the company "StankPet" is not limited to the production of high-quality equipment, but also offers ready-made solutions for opening business in this sphere.

Taking into account the construction of significant projects supported by the Government in the ecological sphere, experts still assess the Nizhny Novgorod region as one of the most disadvantaged in the level of purity and careful treatment of nature. According to the summer of 2019 in the ecological rating of the subjects of the Russian Federation it occupies 81 positions out of 85. Information sources - reports of mass media, organizations, authorities, appeals of citizens, documents, etc. - were used in the rating. Unfortunately, the rating of the region has not improved in recent years. Chairman of the Board of the All-Russian Public Organization Green Patrol, expert of the ONF Monitoring Center on Ecology and Forest Protection, member of the Public Council under the Russian Federation Andrei Nagibin notes problems with garbage disposal as the main negative factors of poor environmental situation in the regions.

In this regard, work is continuing to improve the environmental situation in the region. In particular, in the village of Ilino-Transborskoe Semisovsky district of Nizhny Novgorod region on 28.08.2019 began the construction of two sewerage treatment facilities within the framework of the federal project "Recovery of Volga" of the national project "Ecology." Financing of the project from the federal, regional and local budgets amounted to 71,368,000 rubles. The working capacity of the structures is 250 m3 per day. Terms of construction of facilities - 2020.

In order to preserve the environment, law enforcement agencies prosecute subjects of illegal business - organizers of landfills.

Comprehensive Solution to The Problem

The above-mentioned state of environmental pollution and the measures taken to clean and preserve it indicate that the actions of highly specialized environmental actors are insufficient to solve environmental problems, and the involvement of as many producers as possible is necessary. An im-

portant factor in solving environmental problems is the joint work of main production technologists, ecologists, economists and programmers at the beginning of the choice of technological solutions. One example of such cooperation is the production of efficient heat insulation materials from waste production. The main principle in solving environmental problems in production should be to minimize the ingress of pollution to treatment facilities, as it is more effective to prevent water pollution than subsequently to clean contaminated water.

The conservation of natural resources, the reduction of waste and harmful emissions will be facilitated by lean manufacturing technology («lean manufacturing» or «lean production») as part of the Total Toyota Production System (T-TPS), which was further supplemented by the methods of other corporations. The basis of the complex of lean production technologies is improvement of production quality and efficiency due to reduction of losses, reduction of actions that do not add value to the product of production.

The introduction of the Internet of Things (IoT) into information and communication technologies (ICT) in the digital economy will allow real-time tracking of the progress of raw materials throughout the production chain from supply to production, release of wastes of this raw materials and to their further use in production as recycled waste, processing, transfer, sale as raw materials for others, etc. The Internet of Things is able to provide, in an automated manner, the most accurate data on the level of waste in production, the proportion of its use in the production of other types of products, the extent to which production is waste-free and the extent to which waste is not subject to further use. The environmental purity of production will be assessed by the smallest proportion of waste not subject to further use, both direct and as a result of processing, by the lowest emission of dirty substances and by the degree of their purification in the automated mode of artificial intelligence.

In economic solutions the problem of ecology is connected with the international concept of sustainable development and integrated reporting - the main source of information for economic solutions in ecology. The UN General Assembly Declaration provides for sustainable development in its three pillars - economic, social and environmental - in a balanced and integrated manner.

Integrated reporting on natural capital, including indicators on the use of natural resources, their conservation and improvement in the environmental dimension of production, should be used more widely to reflect environmental performance data from enterprises. Such data are given in the section "Natural capital" of integrated reporting (Figure. 1).

Fig 1. Indicators of natural capital

Increasing environmental problems and the need to address them had led to the emergence of a new environmental economy. The economy involved in solving environmental problems has been called the Eco-friendly economy «Green Economy». Its main task is to ensure maximum people 's economic effect with minimal load on the environment. The efficiency of such an economy is achieved by measures that increase economic efficiency. The economic efficiency of waste water sludge utilization is estimated by the completeness of the use of resources from sediment processing in production, as well as the return of each resource in the growth of output volumes taking into account the use of the best technologies.

Existing environmental regulations are becoming an essential tool for competition among environmental technology and equipment producers. The competitive development of this industry has the main advantage over other sectors of the economy in that they lead not to pollution of the environment, but on the contrary - create products for cleaning and preservation of nature and at the same time become full competitive profitable production. Environmental technologies and their products are most in demand in all developed countries. Therefore, the advanced development of the environmental sector of the economy leads not only to the preservation of natural resources. Highly technological competitive development of the economy in this sphere is the most important component in achieving strategic sustainable development of the Russian Federation. Therefore, in this market segment it is necessary to achieve advantages at the international level. Leadership in this industry most ensures environmental cleanliness and strengthens the economy. It will be assisted in the development, transfer, diffusion and development of environmentally sound technologies, as provided for in paragraph 17.7 of the UN General Assembly Resolution.

In order to ensure the competitiveness of highly technological domestic production in the field of ecology, priority financing of research and development (R & D) in this field is necessary. This will

be facilitated by the UN Multilateral Forum on Science, Technology and Innovation, which will be convened once a year for a two-day meeting.

The Forum will provide a platform for facilitating interaction, networking and networking among relevant stakeholders and multi-stakeholder partnerships to identify and analyse technology needs and gaps, Including in the areas of scientific cooperation, innovation and development, Transfer and diffusion of relevant technologies to achieve sustainable development goals.

Environmental performance indicators are an important tool for monitoring sustainability of development, taking into account the environmental dimension. The degree of perfection of environmental interaction with the environment is typically measured by the following displays:

- Amount of raw material and energy used;
- Volume of emission into atmosphere;
- Quantity of waste per unit of output;
- Frequency of environmental incidents;
- Number of emergency incidents;
- Proportion of recycled waste;

Service mileage per unit;

- Quantity of emissions of individual pollutants;
- Investment in environmental protection;
- Number of legal actions in this area.

Detailed instructions on the selection and use of environmental performance indicators are given in ISO 14031 "Environmental Management. Assessment of ecological effectiveness. Guidelines "and ISO/TO 14032" Environmental Management".

In the agricultural industry, the economic assessment of the efficiency of any agricultural reception, together with energy and environmental assessments, is one of the main evaluation parameters. The economic factor encourages the use of waste and, in particular, sewage sludge in the production of various types of fertilizers. Sewage sludge is used, for example, as a fertilizer in wheat growing.

For economic assessment of consumption and measures for economy and safety of water resources it is necessary to use such indicators as:

- Dynamics and structure of consumed water resources;
- Water consumption per unit of production;
- Average daily water consumption;
- Return on average daily water consumption on revenue;
- Dynamics and structure of investments in environmental facilities, water protection investments;
- Environmental safety indicators: the amount of pollutants discharged into water bodies;
- rationality of water consumption;
- Cost of water resources, etc..

For example, the analysis of water consumption at enterprises is carried out by comparing the volume of production and the 1 of water consumption per ton of production. In addition, the return of water consumption in the form of the ratio of revenue to water consumption of the enterprise is considered (Table 1).

This indicator characterizes industrial and at the same time natural capital. According to the table, we see an increase in the volume of consumption of the organizations involved in economic activities of natural resources. The enterprise needs to decide whether the consumption of this amount of water is justified relative to the growth of production and sales. In the dynamics of change, there is a lag in the rate of sales growth from the rate of water consumption growth, that is, the yield of consumed water

resources is decreasing (Table 1). Thus, increased water consumption is not justified by a proportional increase in production and sales.

Table 1: Average daily water consumption and return as revenue from sales

№	Indicator	Year			Rate of gain, %	
		2016	2017	2018	2017	2018
A	Б	1	2	3	4	5
1	Revenue, thousand rubles.	285545215	344526645	361485474	120,66	104,92
2	Average daily water consumption, m^3/day.	750	900	1100	120	122,22
3	Return on average daily water consumption on revenue. 1 string/2 string	888,4	869,23	858,09	97,8	98,7

The average daily water consumption shows a negative impact on the sustainability of the organization, since in 2018 the company used more water than in the previous reporting period. 22,22% (122,22% – 100%) (table 1). Water resources are used less efficiently, which means that the intensity of waste for future generations is increasing. It is necessary to reduce the average daily consumption of water. In order to increase savings, increase the efficiency of water resources use and reduce harmful emissions to the environment, the Holding company is beginning to actively use a closed water supply system.

As a result of these measures, there have been positive changes: the return on water consumption in 2018 decreased by 0.9% compared to 2017 (98.7% - 97.8%). Such a small increase in efficiency nevertheless marks a commitment to rationalizing the still inefficient consumption of water resources.

It is important to compare the cost of saving water with the cost of preparing it for reuse in production. If the costs of preparing such production, attracting additional equipment, material costs and the resulting additional environmental pollution are higher than the savings from the re-production of water or from the closed water supply system, the project will not justify itself in terms of environmental preservation.

Our research and review of the methods used to preserve the environmental environment have shown that they are almost insufficient for an integrated environmental solution. A comparison of growing environmental problems and approaches to their resolution indicated that the planet was unable to withstand the unreasonable growth of human consumption of natural resources.

The resolution of the UN General Assembly adopted on 25.09.2015 is intended to protect the planet from degradation, including through the introduction of rational models of consumption and production, and the rational use of its natural resources. For this purpose, in accordance with goal 12 of the General Assembly Resolution, by 2030, it is envisaged to halve the global amount of food waste per capita and reduce the loss of food in supply chains. By 2030, it is planned to significantly reduce the volume of waste by taking measures to prevent its formation, reduce it, recycle it and reuse it. Paragraph 8.4 of the Resolution provides for a gradual increase in the global efficiency of resource use in consumption systems, so that economic growth is not accompanied by environmental degradation, as envisaged in the strategy for the transition to rational consumption and production models. From the author's point of view, these measures need to be developed and expanded.

Introduction of rational models of consumption and production, rational use of natural resources is directly related to the need to increase the culture of consumption. Attempts to discuss the problem of consumer culture are considered by some participants to be "utopian". But utopia does not consist in the attempts of mankind to strive for a culture of consumption, but in the opposite, that is, in the delusion that humanity can immensely and unreasonably consume to infinity, and nature and in particular – the planet will allow it to do so to infinity. This is utopia.

Pollution and the reduction of natural resources objectively challenge humanity to more rational and less wasteful consumption, which is becoming increasingly evident. The depletion of the planet in the form of irreparable losses already leads to an increase in the cost of natural resources and to forced significant restrictions in consumption, to an increase in diseases caused by environmental degradation. As V.D. Kalner notes:... "the natural environment cannot change at the same speed as the volume of innovations of the fourth technological revolution into world politics and economy". The most important task of humanity is to minimize the loss of natural resources and to prevent irreparable losses that nature cannot recover. And if consumption is not rationalized, the damage caused to nature and, as a result, to the conditions of human existence, health and life will be much greater.

In particular, the UN General Assembly calls for a radical change in the nature of production and consumption of goods and services. According to item 28 of the General Assembly Declaration, governments, international organizations, the business sector and other non-state actors and individuals should contribute to changing unsustainable patterns of consumption and production, including by mobilizing financial and technical assistance from all sources to strengthen the scientific, technical and innovative potential of States.

Thus, over the years, the contradiction between the growth of consumption and the need to preserve the environment as the most important condition for preserving the health and survival of mankind is growing and becoming more acute. The carriers of this contradiction are the producer of consumer goods and the consumer.

The interests of producers (business) are to increase the volume of production and sales. Following its interests, the business is engaged in artificial generation of demand for products where demand for it is insufficient to increase sales. With sophisticated ways of promoting products, the business industry creates models of goods, the demand for which is formed not by the utility and natural needs of buyers, but by the promotion of false values, false perceptions of prestige and priorities. For example, the prestige of a high price, or when a product is acquired not from natural needs and not for benefit, but because it is "prestigious," the desire for a rapid change of consumption items. The fashion business industry aims to change consumer goods as soon as possible by buyers in order to increase demand in pursuit of profits regardless of the degree of wear and tear of the goods being replaced.

Business often creates varieties of products in which people do not experience natural needs, and which are full of ingredients harmful to the human body. But at the same time the business industry by means of media, media spaces, sophisticated advertizing and PR-actions artificially forms demand for such products, in large quantities inspiring the prestigiousness of consumption contradicting common sense, advantage and human health. Well-being is often replaced by the imposition of unreasonable, unnecessarily wasteful consumption. All this increases the burden on the environment, increases its pollution, leads to depletion of the resources of the planet. His attitude to such processes was expressed by V.D. Kalner: "This increases the contradictions of the" zombie economy "and the global" post-truth "with the flora and fauna surrounding us, the billion-dollar world of living organisms of the Earth 's biosphere, expands the environmental risks and threats faced by our closest descendants".

In order to resolve the contradictions between the interests of the producer and the consumer in order to preserve the environment, it should be taken into account that the business is not able to abandon its interests noted earlier, since they are an important condition for its existence and development. So the business can work through his interests, then a change in demand, which the market will be more in demand products that meet the natural needs of man and bringing him benefit. In this regard, it is important to cultivate a more rational attitude to consumption, so that people get what they really need, first of all, for their benefit, satisfaction of natural needs, comfortable existence, and not for the profits of sellers obtained by any means that cause unjustified damage to natural resources and the environment, human health and life on the planet.

It is believed that more rational consumption will lead to a reduction in demand and, consequently, to recession and crisis. This is possible in tactical terms in terms of current narrow interests of business.

In strategic terms, reducing human consumption will only balance demand and supply. The relative reduction of purchase requests will lead to a relative reduction in the demand for income growth of the population in those areas that do not cause natural needs and do not benefit the consumer, but are artificially, sophisticated imposed by business through mass influence on the consciousness and sub-conscious of consumers, the formation of false values (manipulation of mass consciousness and sub-conscious). This is also one of the important problems of mankind, which will require relatively less human labour to provide life, thus reducing the relative need for jobs, thus contributing to a relative reduction in unemployment. And the relative reduction of business revenues and revenues to the state budget from reduced demand will be compensated by the relative reduction of demand for these revenues by the population.

Inertial formal adherence to the usual dogmas, limited to narrow business interests without taking into account changing conditions, without sufficient care to preserve the bio-sphere, has exhausted itself in the face of increasing contradictions between consumption and the preservation of the health of the planet. Formal (undialectic) adherence to outdated, self-sustaining dogmas creates new risks and threats to nature and the survival of mankind. A new complex, systematic approach to industrial management with integrated interaction in solving environmental problems is required. The time is passing when nature allowed society to follow certain laws of the market, removed from the context of the more General laws of existence. Individual market laws require their complex linkage and systemic interaction with the more General objective laws of nature, society, and thought development in order to achieve such a coordinated harmonious interaction between man and nature that would serve not only narrow short-sighted business interests, but also nature conservation, fundamental economic growth, and the strategic survival of mankind on the planet.

In this case, we are talking about the need to transform demand and then the structure of production in order to form useful consumption, preserve human health, the environment and life on the planet. At the same time, the stimulation of demand to increase business activity should be achieved on the basis of natural needs and benefits for the person through instruments of more equitable distribution and redistribution of income in financial, tax policy. Discussions on income redistribution have also been expressed in sources (Kim D.H., Lin S.C. 2018, pp. 825-848; Oechslin M., 2009, pp. 313-344).

This way is built on the basis of the fundamental principles and laws of the development of nature, society and thought, a dialectical approach that takes into account the place, time and circumstances. In this case, a relative economically justified reduction in demand will help reduce inflation, strengthen the purchasing power of the national currency, its stability, reliability, and therefore convertibility on the world market. This is a necessary condition for strengthening the state's finances and financial sovereignty.

The reverse approach - the desire not for well-being, health, meeting the natural needs of society, but for sophisticated manipulation of the consciousness and consciousness of the population in the narrow interests of business, is based not on the fundamental laws of economic development, but on speculative manipulation, deception of citizens to sell them what they do not need. Such disregard for the foundations of economic development with their substitution for speculative manipulations, formal (undialectical) follow-up to obsolete dogmas cannot lead to stable development of the economy, the State, improvement of the quality of life, well-being of citizens, preservation of the environment for present and future generations, but exacerbates social contradictions, causes political and economic crises, causes unjustified damage to the environment and natural resources. Similar processes in separate publications give names in the form of "zombie economy" and global "post-truth," creating... "threats dangerous to our closest descendants" (Kal'ner V, 2019, p. 50).

Increasing the culture of consumption is achieved, first of all, by common sense and awareness of one's own choice in consumption, which brings benefits; awareness that consumption is not an end, but a means in human life, which distinguishes it from the animal. Ethics and aesthetics are the most important components of consumer culture. A person makes a purchase choice based on aesthetic preferences. The widespread promotion of epatage under the guise of "creativity" destroys aesthetic education, harmony of tastes, and leads to subcultural aesthetic perversions in order to expand de-

mand that is not conditioned by the natural needs of a person and the utility of a consumer item. As a result, the consumer purchases a product based not on natural needs, but on false value orientations, perverse ideas artificially formed by business. Thus, the consumer spends the earned money not for their own benefit, but in the short-sighted interests of the business, which is subtly manipulating their consciousness.

Education, upbringing, and enlightenment lead to a culture of consumption. An uneducated, unenlightened person is more easily deceived, replaced by concepts-manipulating the mind and subconscious, accepting false values and following them. When such manipulation takes hold of the masses, there is a mass fanatical adherence to false values. The destruction of culture generates cynicism and indifference to the problems of humanity and nature.

On the other hand, an unspoiled, immoral person in business is more inclined to deceive consumers, manipulate their consciousness and subconscious in achieving narrow-minded short-sighted business interests to the detriment of the interests of society and the preservation of the environment. Therefore, the role and importance of education, culture, morality and spirituality is increasing in solving problems of ecology and sustainable economic development.

The Findings and Conclusions

Upbringing, education, and enlightenment should be achieved in the system of preschool, school, secondary, and higher education. In the system of higher education it possible in the formation of General cultural, General professional competences stipulated by the Federal state educational standards and universal competencies under the project of Moscow state University named M. V. Lomonosov, Ministry of Finance, world Bank to enhance economic culture and financial literacy of the population. To do this, it is necessary to strengthen the programs of basic disciplines with knowledge of ethical norms, moral values, culture of thinking based on dialectics, as well as to include courses in financial literacy and behavioral Economics in the curriculum of non-economic educational areas.

Thus, to solve the problem of preserving the biosphere, natural resources, and achieving sustainable socio-economic development, a comprehensive approach is needed that combines the capabilities and efforts of environmentalists, businesses, and citizens. Business is able to solve these problems based on corporate social responsibility by improving integrated indicators of sustainable development. Citizens are able to contribute to the solution of this problem by improving the moral level, culture of thinking, economic culture, financial literacy and consumer culture, which must supplement the system of education and upbringing.

Digital Economy and Social Capital On the Example of Selected EU Countries

Michal GOLINSKI

Warsaw School of Economics, Warsaw, Poland
mgol@sgh.waw.pl

Abstract

A new civilization revolution – commonly referred to as digital - is unfolding before our eyes. The changes it entails will affect the society, economy, culture and politics - virtually all areas of our reality. The world that is being created will be subject to constant change.
An analysis of the relationship between digitalization processes and social capital in EU countries, with special attention to Central and Eastern Europe (CEE), is the objective of this paper.
Its results reveal a low level of social capital (SC) in the countries of this region, which constitutes a development barrier that may exclude CEE countries from fully benefiting from civilization transformations and catch them in the middle-income trap.

Keywords: Information Economy, Digital Economy, Digital Multiverse, Social Capital, Online Social Capital, E-Metrics.

Introduction

In the last decades we have been observing sustained efforts aimed at bridging the development gap between the CEE region and the rest of Europe. The effects of these efforts are noteworthy, however, more needs to be done, also with regards to digitalization. Overcoming technological, financial and organizational barriers has been unproblematic as CEE countries have access to the same cutting-edge solutions, and in some areas – even more advanced. Having bypassed certain development stages and implemented the latest solutions immediately, CEE countries have benefitted from a rapid technological transformation. These are often social and cultural barriers – one of them being the low level of social capital – that pose a greater challenge.
The article endeavors to explore the relationship between the level of digitalization and the level of social capital in CEE countries.

Digital Economy or Digital Multiverse

We are beginning a new era of civilizational expansion, the magnitude and weight of which are comparable to the great civilizational revolutions known from history. Unquestionably, the exponential development of information and communication technologies (ICT) lies behind this transformation.

A plethora of terms is used to address the unfolding changes, digital society or digital economy being most popular recently. Regrettably, they fail to fully mirror the impact of ICT on our whole reality. The author proposes to use the phrase "digital multiverse" to do justice to the complexity and multidimensionality of the research area, and it is the author's own definition of this term that will be used in this elaboration.

Digital multiverse (DM) is a network of people, organizations, communities, devices, systems, applications and data and their relationships of a global nature, where the mainspring is the exponential

Cite this Article as: Michal GOLINSKI "Digital Economy and Social Capital on the Example of Selected EU Countries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

scientific and technological progress. The constitutive elements of DM are: intensive use of ICT, integration of physical and digital systems, hyperconnectivity forcing interdependence and cooperation, automation of information exchange and data analytics, unpredictability of development, disappearance of barriers and the arising new development opportunities. The motive forces determining the nature of DM are the processes of digital destruction and digital transformation. The described phenomena determine the characteristics of DM, such as: flexibility of structures and processes, high level of innovativeness, increasing efficiency, globalization, speed of reaction to signals generated by the environment, creation of new consumer needs, intensification of business interactions, creation of intelligent products and services, progressing servitisation of the economy and rise of new occurrences and phenomena. The rise of DM spawns new opportunities, but also threats in practically all areas of human existence.

Modern technological progress is exponential, digital, and combinatorial (Brynjolfsson and McAfee 2014). These generate the phenomenon of digital disruption, which is responsible for the collapse of the organizations, industries or societies unable to adapt to the changes taking place. Today, however, it affects not only the economy but the whole existence. This means a constant change of the existing rules and an unremitting necessity to adapt. Such a dynamically changing reality places new demands on both our skills and education and on our cultural and social competences. The latter are also determined by the level of social capital. For a long time now, social capital has played a significant role in economic and civilizational development, and it can be assumed that as the complexity of the reality around us increases, its role will grow.

The Issues Regarding Measuring Digital Multiverse

Traditional telecommunications statistics gave rise to quantitative DM studies. They focused on the development of infrastructure, neglecting social aspects. Such approach had significant drawbacks as analyses limited to technical infrastructure failed to describe DM. The use of ICT is inseparably linked to the skills and motives of those using them. Information in a society plays an economic, social, technological, political and cultural role, therefore, while pondering on DM, social and human factors cannot be overlooked. This increasing interdependence between ICT and the social sphere requires new tools for the evaluation of access to ICT, its use, influence and barriers to its adoption.

It seems appropriate to postulate that social and cultural factors – such as social capital - also be included in the research on the level of digitalization. The importance of SC is evidenced by the fact that in the Report by the Commission on the Measurement of Economic Performance and Social Progress (Stiglitz et al., 2009) the term *social capital* appears 41 times.

Social Capital

In traditional societies, the “prestige” of individuals and social groups depended on their physical capital - most often land, and later their financial status. Currently, the role of human capital has proliferated. Nowadays, the importance of social capital is increasingly emphasized. This obviously does not mean "replacing" these forms of capital as the most important factor of production or social diversification. On the contrary, one of the features of digital economy is the already growing economic inequalities. Numerous forecasts (MGI 2017, MGI 2019) predict the collapse or fundamental change of many professions as a result of an ongoing automation process. The growing complexity of the modern world will require greater and more diverse stock of capital.

We will all face the change in the nature of our professional activity, which will often require higher levels of education or new skills such as teamwork, creativity, emotional intelligence, social and other soft skills (MGI 2018). The role of social capital is therefore likely to grow.

Offline and Online Social Capital

For last two decades the concept of social capital has been popular among authors representing different scientific disciplines, and used in various, often distant contexts due to its ambiguous nature. Some sceptics - such as Solow (2000: 6-10) – question the validity of this term. According to the principle that too broad a term loses its meaning, the concept of social capital has become very vague. The development of ICT has reinforced these uncertainties. In addition to the traditional understanding of social capital (let us refer to it as offline social capital), a new phenomenon of online social capital has emerged, already omnipresent in scientific literature (see Spottswood and Wohn 2020).

In the introduction to his book, Faucher (2018: xiii) proposes a definition, which aids further deliberations over this phenomenon: "1) At the user-end, online social capital is a product of online exchanges that in many cases can be expressed in some numeric form, which may or may not be correlated with a perception of an online user's value in a digitally networked community. Online social capital becomes a kind of offering to the social marketplace when users attempt to leverage the quantifiable measures of friends, followers, views, and likes for some goal. 2) On the network owner's end, online social capital is the labour of users that can be mined as a data commodity and converted into profit, while also existing as a strategy to keep a digitally networked community active in providing their unpaid labour."

Digital per se and relatively new, online social capital is inextricably linked to the development of ICT, particularly social networks and platforms. Offline social capital arose from a long-lasting and culturally conditioned process of people's interaction in the real world. In their famous work, Putnam, Leonardi and Nonetti (1993) explain the differences in the level of social capital in Northern and Southern Italy through social phenomena occurring hundreds of years earlier.

The two types of social capital are therefore fundamentally different, but in today's digital world they are inseparable and interdependent. On Faucher's (2018: xiii) words: "This is not to say that the affordances of digital networks do not permit considerable overlap between the two types of social capital, but that these digital networks upon which ever more social interaction occurs, manifest a whole new host of opportunities and problems that are unique to the nature of online interaction".

The relationship between the two types of social capital is exceptionally complex and interesting. However, the subject matter goes far beyond this article. Therefore, in its further part, offline social capital, understood in a traditional way, will be analyzed according to the classics of this issue: Bourdieu 1986, Coleman 1988, Fukuyama 1995 or Putnam 2001. The term social capital (SC) will be used hereinafter. We can assume the simplest understanding of it: Putnam's (2001: 21): social resources that enable "cooperation for mutual benefit", or Fukuyama's (1995: 10): "the ability of people to work together for common purposes".

The Importance of Social Capital

Based on reciprocity and trust, social capital influences the willingness to cooperate and its effectiveness. A noteworthy feature of social capital is that it enables achieving objectives that would otherwise not be achieved at all or would require much more work.

Social capital boasts distinctive features that distinguish it from other forms of capital. Unlike human capital, it is not individual. Like human capital, but unlike physical capital, stocks of social capital do not

depreciate as a result of use, but grow, which is supported by Ostrom (2000, p. 179): "social capital does not wear out with use but rather with disuse."

Social capital significantly affects the development process. Its impact is stronger after reaching a certain level of economic development. In relatively less developed countries, human capital influences economic growth more potently than social capital (Czapiński and Panek 2009: 277). The role of social capital increases with economic development, which results in increasing complexity of social, economic, institutional and interpersonal structures.

Krishna (2002:16) emphasizes social connotation of SC: ”The level of social capital is thus a critical variable affecting overall societal achievement. Development, democracy, as well as community peace—all three social domains examined in this study—benefit, it is concluded, in situations of high social capital.”

More than two decades ago, Fukuyama envisaged the role of SC also in the development of DM: “Societies well supplied with social capital will be able to adopt new organizational forms more readily than those with less, as technology and markets change. (…). Such a society will be better able to innovate organizationally, since a high degree of sociability will permit a wide variety of social relationships to emerge” (Fukuyama 1995: 27, 30).

Digital multiverse and social capital

Previously, the attention of quantitative DM studies was put to the areas: ICT infrastructure, its use and indispensable skills. These elements exist in majority of DM research, irrespective of whether they employ numerous set of basic indicators (e.g. Eurostat) or composite indices (e.g. The Digital Economy and Society Index - DESI).

Interesting, yet less recognized are the social and cultural environments favorable to the creation of DM. It seems reasonable to claim that, at a certain level of digitalization development, such issues can be essential. Broad and multifaceted, the social and cultural contexts of DM may involve a wide spectrum of problems as a research object.

In modern economy, the importance of intangible forms of capital (human, social, institutional) is increasing. According to World Bank's estimates, intangible capital may constitute from 60% to 80% of the total wealth of developed countries (Scrivens and Smith 2013: 9).

Digital multiverse and social capital are interrelated. The development of ICT entails increased complexity of social and economic environment. Effective functioning in such complex conditions requires a high level of social capital, which boosts the formation of DM, characterized by growing information needs of its participants. Consequently, the growing information needs trigger a demand for new ICT solutions. Therefore, high level of social capital is conducive to the creation of DM, which amplifies the impact of social capital. Social capital in DM is of great significance as it leads to better economic outcomes, lowers transaction costs, and fosters innovation and dissemination of technology (Fidrmuc and Gerxhani 2007: 2). It is the author’s opinion that the impact of social capital on the development of DM justifies its incorporation into the quantitative analysis of DM.

Methodology

DESI - Digital Economy and Society Index (EU2020) will be applied as a measure of DM development level. The DESI is a composite measure created by Directorate-General for Communications Networks, Content and Technology (DG Connect) to assess the degree of the implementation of the Digital Single Market strategy (DSM 2020).

As already mentioned, the concept of social capital is ambiguous, multifaceted and difficult to measure. Many authors assume various proxies as numerical depictions of SC.

Scrivens and Smith (2013: 17-18) give several definitions of social capital that can be found in academic literature. For the purposes of this article, in which the idea of social capital is compliant with the understanding of the "founding fathers", Fukuyama's (1995:10) definition seems appropriate: "the ability of people to work together for common purposes in groups and organizations". The issue of measuring social capital is equally difficult. Various methods and approaches are described in the works of Van Deth (2003) or Scrivens and Smith (2013).

Since this article only attempts to incorporate SC into the concept of digitalization, a simplified approach will be used - with regards to the issues of definition and measurement. Paldam and Svendsen (2000: 339) state in the simplest words: "Social capital is defined as the density of trust". This approach may be restrictive, however, it mirrors the traditional understanding of SC. Trust reduces transaction costs, increases the efficiency of resource allocation and promotes social control. This approach allows for the selection of simple measures representing this phenomenon. Van Deth (2003: 83, 85), who, admittedly, defines social capital more broadly, distinguishes personal trust and social trust in the trust category. The author proposes specific measures of both categories: trust in other people and confidence in institutions. For the purposes of the deliberations presented here, such limitation seems justified and sufficient.

Data from the World Values Survey and European Values Study joint survey round (2017-2020) published in July 2020 (WVS 2020 and EVS 2020) will be used as measures of SC defined as above. Two questions from this study were used to quantify trust:

- Q57.- Generally speaking, would you say that most people can be trusted or that you need to be very careful in dealing with people? The prevalence (%) of the response *Most people can be trusted* serves as the level of trust in other people.

- Q73.- I am going to name a number of organizations. For each one, could you tell me how much confidence you have in them: is it a great deal of confidence, quite a lot of confidence, not very much confidence or none at all? Parliament.
The sum of the responses *A great deal* and *Quite a lot* serves as the level of confidence in institutions.

As the WVS and EVS were conducted in the period 2017-2020, and the replies for most countries relate to 2018, the article - for all characteristics, also DESI – adopts the 2018 values. The analysis included 22 EU countries for which data were available.

Chosen characteristics for trust and digitalization are shown in Table 1. The following figures show the interrelations between the aforementioned trust and DM characteristics. The following indicators were selected as relevant for further considerations:

- As a measure of DM, the DESI indicator (values and ranks) was chosen: Table 1 - column 4-5.
- Two indicators were chosen as measures characterizing trust:
- trust in other people - columns 6-7,
- confidence in institutions - columns 8-9.

Table 1: Values of characteristics describing the level of SC and DM

No. (1)	Country (2)	Code (3)	DESI Value (4)	DESI Rank (5)	Personal Trust value (6)	Pesonal Trust rank (7)	Social Trust value (8)	Social Trust rank (9)
1	Austria	AT	51.9	8	49.8	5	43.7	4

Data source: DESI (2018a), WVS(2020), EVS(2020)

Results

The charts below show a graphic representation of the relationship between digital multiverse and social capital. DM (Y-axis) is described by DESI, and issues regarding social capital (X-axis) are presented using the characteristics listed in Table 1. Each chart depicts two characteristics divided according to average values. This allowed for clustering countries into four groups:

- DM above the average value and the characteristics corresponding to trust above the average value - right, upper part of the chart – "digital-confident",
- DM below the average and trust above the average - right, lower part – "analog-confident",

- DM below the average and trust below the average - left, lower part – “analog-unconfident”,
- DM above the average and trust below the average - left, upper part – “digital-unconfident”.

Fig. 1: DM vs. the level of personal trust

Date source: DESI (2018a), WVS(2020), EVS(2020)

Sweden is the frontrunner in the field of digitalization. Only Estonia is well ahead in comparison to other CEE countries with respect to the EU average. Slightly below this reference point are Lithuania and Slovenia, ahead of France or Italy. Bulgaria, Romania and Greece come last in the race.

In the personal trust category the first three places are occupied by Denmark, Finland and Sweden. Only the countries of the "old Union", except for France, Italy and Greece, are above the average. All CEE countries are below it. Romania, Greece and Cyprus bring up the rear. The values representing trust, however, are drastically more varied than those representing DM. 77% of Danes, 24.7% of Poles and only 6.6% of Cypriots agree with the statement: Most people can be trusted. The least trusting are the

inhabitants of CEE and Southern Europe. Left top and right bottom parts of the chart are empty, which means that countries with a higher level of digitalization are also characterized by a higher level of personal trust. The low average is also noteworthy - only one in every three citizens of a surveyed group of countries trusts other people.

Fig. 2: DM vs. the level of social trust

Data source: DESI (2018a), WVS(2020), EVS(2020)

In the social trust category, Sweden, Denmark and Finland take the first three places. It should be emphasized that confidence in parliament representing social trust is the sum of two answers - affirmative and accepting. Three CEE countries - Slovakia, Hungary and Estonia – rank above the average. Interestingly, Hungarians have more than 4 percentage points more trust in their parliament than Estonians. Other CEE countries, as well as Italy, Cyprus and Greece, classify below the average. Greece, the Czech Republic and Croatia come last. Also in this case, individual countries are very different from each other. Trust in their parliament is declared by 63% of Swedes, 20.1% of Poles and only 6.55%

Croats. The average for the surveyed group of countries is also low, only 30.4% of citizens have any confidence in the legislative power. The left, upper part of the graph is empty - there is no "digital-unconfident". There is "analogue-confident", however, in the right lower part of the graph there is Hungary, Slovakia and France.

The findings presented above reveal a relatively low level of SC in CEE countries. For both characteristics studied, the values are usually lower than the average, and significantly lower than in the leading "old EU" countries. Therefore, CEE countries cannot benefit from economic and social opportunities offered by high level of SC. This may constitute a significant barrier to development in the future.

Poland can serve as an interesting example here. Over a decade ago, the authors of "Social Diagnosis" - one of the most important research, comprehensively analyzing the situation in the country, which ceased to be published in 2015 - stated: "We live in a country of ever more efficient individuals and an ever more inefficient community" (Czapiński and Panek 2009: 149).

A significant economic advancement of many individuals and the country as a whole has been, to a large degree, the result of rapidly growing human capital. Human capital allows for the promotion of individuals, social capital is essential for the implementation of community projects and the promotion of the whole country. To a large extent, the challenges related to DM concern joint tasks.

The existing sources of growth, such as cheap labour, are running out. Without a significant growth of SC, Poland is at risk of a slowdown and being caught in the middle-income trap. The level of wealth, above which human capital is no longer the decisive factor for development, has probably already been reached. There is little time left for building social capital.

Human capital is created by individual investments. A rapid increase in enrolment rates in Poland with respect to higher education over the last three decades can serve as the best example for this fact. Social capital cannot be built solely on the basis of individual investments. Its creation is a long-lasting, culturally and historically conditioned process, related to the formation of a civic community as a result of daily experiences of individual citizens in the public sphere. It seems that the above remarks apply not only to Poland but to most CEE countries.

Conclusion and Further Research

It emerges from many empirical studies regarding DM that success is linked to infrastructure and education. Although weighty and noteworthy, social and cultural aspects are still insufficiently documented. It is, however, only reasonable to claim that - at a certain stage of DM development - these aspects might become crucial. Being a complex area, the social and cultural context of DM – as a research object - may pose a plethora of questions. One of such surfacing issues is social capital, which - as arises from the case of CEE countries - calls for increased efforts aiming at its development.

It is the author's opinion that the importance of the issues connected with social capital for DM development justifies including them in the quantitative analysis of DM. It is supported by significant interdependence between DM level and personal trust (correlation coefficients 0.9) and social trust (0.76).

The considerations presented in this paper are of groundwork nature. However, the discussed topics seem to be quite thought-provoking and worthy of further research. Such studies will help determine which characteristics should be analyzed and which indicators should be used in order to better analyze the relationship between DM and social capital. The complexity of DM will increase exponentially. The answer to the question what tools to use to measure such a complex reality will become a great challenge for the researchers involved. The limitations of the analysis presented in the paper should be clearly

indicated. First of all, it is subjective and the views expressed in it are those of the author. SC characteristics have been selected arbitrarily by the author. It is an invitation to discussion, rather than a final assessment. The analysis carried out is rather simplified, as only one element of social capital – trust – is taken into consideration. The data available allowed for evaluating only 22 EU countries.

The following may serve as directions for further research:

- Applying a set of measures to define social capital more broadly.
- Possibly, applying an aggregate measure of SC for an analysis of relations with DM, quantifying social capital (although devising such a measure may pose problems).
- Extending the analysis to include developing countries, where the role of social capital is crucial for development.
- Including online social capital into the analysis - its importance is already visible and will only continue to grow.

Low level of SC in CEE countries results from the interaction of many cultural, social and historical factors. Their detailed analysis would go far beyond the scope of this article. The dominant factor appears to be the complex history of these countries. Starting from the feudal times, through the recovery of self-determination in the early twentieth century and ending with the heritage of communism and centrally planned economy. The situation is not improved by the wave of populism and the rule of political groups that are moving away from the principles of liberal democracy. These phenomena lead to deep social divisions, further reducing social capital.

It is to be hoped that the retreat from populist tendencies will lead to further gradual harmonization of formal rules and informal standards in "old" and "new" Europe. This will reduce the gap in social capital across Europe and enable CEE countries to achieve the vision of digital multiverse. This is one of the conditions for these countries to avoid the middle-income trap and continue their civilization development.

One can hope that the intra-European gaps in SC and also in formation of DM should gradually disappear as new member states catch up economically, institutionally and culturally with the old ones. The stakes are high because countries characterized by increased generalized trust tend to be more prosperous.

Extraordinary Events as A Consequence of Hazards

prof. dr hab. Bernard WIŚNIEWSKI

WSB University in Dąbrowa Górnicza, Poland
bfwiśniewski@o2.pl

Summary

Conclusions from research run in the field of security allow to distinguish many of its determinants. Among them are primarily: threat, uncertainty, risk, opportunity, challenge. Researchers are constantly trying to find cause and effect correlation between later. It seems indisputable that among the elements of safety exists a phenomenon known as an "extraordinary event", which is not granted its rightful place in the research fields of security specialists. No doubt it is, after all, a consequence of a peril, which results from a logical sequence of phenomena that may favor or compromise security. The problem situation outlined in this light was used to present considerations on the affinity between "threats" and "extraordinary events". The article is preceded by a synthetic introduction. In the view of assumptions made, the first part of the article focuses on presenting the criteria for threat identification, that was utilized in the further part of the paper to present issues related to extraordinary events. This presentation was based on a review of selected and adopted positions of recognized experts in security research field. The article concludes with a summary that addresses the main issues raised in this study.

Keywords: Security, System, Threat, Extraordinary Event, Cataclysm, Catastrophe, Accident, Incident

Introduction

Security and its determinants are challenging to define on account of the immense, overwhelming range of their categories, highly difficult, if not impossible to be described concisely [1].

Security is most frequently perceived as:

- a guarantee of the inviolable survival of the security entity and its free development [2];
- a state of certainty, calm, absence of danger and protection against it [3];
-the status obtained as a result of a duly organised defence and safeguarding against all hazards using powers and measures from the entity's various spheres of activity [4].

Security as a state attained through deliberate, complex and collective human action can also be regarded as a praxeologically understood, socially significant human creation [5].

The level of security is dependent, inter alia, on the adequate identification of and reaction to emergencies and the resulting extraordinary events.

For the aforementioned reasons, both safety and dangers and emergencies require scientific research that does not permit naivety and taking anything 'on the word'. Any content of a scientific task can be validated, verified, and if it is not checked, it is not a task of scientific theory and as such does not need to be researched at all. The scientific worldview (as long as this can of course be said) does not adopt any solutions to the reality around us if they are not the product of activities that are in line with the correctness of scientific research, does not mean at all that it is merely sceptical; on the contrary, it is precisely the awareness of scientific methods, the nature of scientific cognition, that makes it possible to identify facts that may be laudable as truth [6].

The multi-facetedness of security is related to the subjective evaluation of the phenomena occurring around or within a particular body. As long as in his opinion these developments have little negative impact on his existence, the entity then feels safe. Which concerns are considered unimportant depends primarily on ones assessment of his own abilities. In some circumstances, the same problems, of the same magnitude, will be hazards that violate the sense of security, while not in others. In view of the above, it must be stated that there is a wide range of intermediate states between insecurity and complete security, frequently classified as safety appropriate to the level of development of civilisation and socio - cultural conditions. Because it is an effect of the subject's perception of reality, and in it- oneself, in the perspective of further existence and development [7].

In thinking on security, one of the most desirable and appreciated assets of mankind, two fundamental approaches can be distinguished. The first concentrates on measures to be taken to prepare for protection against hazards, while the second focuses on shaping the environment in such a way as to distance and mitigate the possibility of their emergence. In both instances, although with a different approach, the threat is a key category [8].

Threats are becoming increasingly complex and hard to present. These problematic qualities make it particularly relevant while being dealt with, to acquire expertise, information, knowledge and the ability and readiness to recognize them. After all, it is more beneficial to detect a threat reliably and without any undue hesitation than to prevent or minimize the consequences of extraordinary events. The omnipresence of extraordinary occurrences, on the contrary, causes a great deal of attention and thus many attempts to define them. They may be classified on the basis of characteristics and criteria such as location of the source, nature, scale, duration, extent, occurrence, frequency, symptoms additionally propagation rate and effects [9].

The danger is only of a negative nature. It is a harbinger of qualitative changes in safety, both for the subject and the environment. It is frequently downplayed by a probe of knowledge, a skilfully organised system of information flow and a test of the ability to use conclusions from its analysis and evaluation.

An emergency event, on the other hand, is a rare occurrence in scientific studies, while in legislation it has become a permanent aspect of domestic security in particular. Must this be the case? It seems not to be, because an extraordinary event is a natural consequence of a threat which cannot be contained and is hard to control.

As a consequence, problems relating to safety determinants must be continuously investigated. Frequently, these studies focus on the issue of hazards, overlooking matters associated with emergencies. Perhaps not quite right?

Methodology

The research findings reflected in this study were derived from the research problem formulated in the form of a question: what is the relationship between 'threats' and 'emergencies'?

The rationale for launching research is to be found in a situation in respect of which the basic scientific and practical activities consist essentially of dealing with risks and mitigating the consequences of extreme incidents.

The above circumstances determined that the main objective of the research presented in this paper was to enrich knowledge of security and its key determinants, which are "threats" and "emergencies". [10]. Whereas the specific objectives were:

- to define the nature of "threats and "emergencies";
- determination of the boundaries between hazards and extraordinary occurrences.

In the research leading to this study, theoretical methods were used [11], which have been applied to research scientific literature on safety and legal provisions.

The subject-object scope of the hazards

The threat is a safety antonym. However, while security determines a specific state, the danger, in the fundamental sense of the word, is associated more with a phenomenon violating this state [12].

The term 'threat' is commonly associated with the verb 'threaten', which means as much as [13]:

- to threaten with something, to frighten, to announce something under threat;
- to face a state of danger, to become menacing, dangerous to someone;
- endanger health, safety, freedom.

It ought to be emphasised that to threaten - to intimidate someone, to announce something under threat, to create a state of danger, to become a menace to someone. Danger, on the contrary, means a state, condition, a situation, a grave danger, threatening something bad, jeopardizing somebody [14]. In the dictionary of national security terms, "threat" is defined as a situation in which there is an increased probability of creating a dangerous state for the environment [15]. A hazard also means something that may pose a threat to someone or something, cause harm or loss to anyone or anything [16]. A threat is also defined as any situation that may lead to damage. Normally, when thinking about damage, the harm includes primarily the damage consisting of loss of life, health or property, although in reality this is not the only damage that can occur in relation to the threat [17].

In common language, the term 'threat' is intuitively understood and related to a person's fear of losing values such as health, life, freedom, liberty or material goods [18].

There is a certain ambivalence in the perception of danger [19], which is, on the one hand, a purely subjective feeling resulting from the assessment of the phenomena occurring and, on the other, an objective factor causing uncertainty and concern [20]. Subjectivity in the reception of the external world is the result of the brain, which always provides a filtered vision of reality [21]. Objectivity in the perceiving of threats, on the contrary, is associated with the knowledge and experience and the application of adequate research techniques [22].

The threat can be viewed in two dimensions - narrower and wider [23]. In the first meaning, a hazard occurs when a person is anxious to lose highly cherished values, with his or her own life in the first place, which leads him or her to the belief that the hazard is understandable by the subject. In a broader sense, however, the threat will be regarded as a situation that is not consciously experienced by the individual [24].

In the context of what has been contemplated so far, it needs to be emphasised that threats can lead to conflict situations. A possible absence of goodwill of the parties involved to make concessions in their demands and mutual indictments may result in a security breach [25].

A characteristic feature of threats is their variability. It is possible to point out phenomena which in the past used to be threats, and no longer are, and also phenomena that, although previously not harmful, are currently a problem and pose a challenge. The strength of the existing hazards also evolves over time, i.e. the dangers diminish or intensify [26].

And let us also recall the position according to which „a threat is the set of events and processes that accompany human civilisation and that occur in different configurations, causing (or preventing) an imbalance. These concern not only entities that are permanently linked or temporarily correlated, but also all the components that create the material and spiritual environment of human life. These processes and events take specific forms - cataclysms, disasters, epidemics, wars, social pathologies and many other phenomena with destructive potential - creating significant impediments to the effective protection of values that underpin security" (life, health, freedom, quality of life, development prospects) [27].

The typology of risks is approximate to the one employed in the approach to safety. There are many attitudes to such a division. Nonetheless, allow us to recognise that the decomposition of risks can be achieved through the prism of subjectivity, objectivity and procedure.

In conclusion, let us assume that threats are circumstances brought about by random (natural) or non-random (intentional) causes, which have a negative impact on the functioning of a given system or cause adverse (dangerous) alterations to its internal or external environment [28] and result in the occurrence of an emergency event. While assuming that a security determinant should not be prioritised, it is necessary to emphasise that the vulnerability affects all other determinants and they remain all dependent on it.

An extraordinary event - what is it?

The dictionary meaning of an event is translated as what happened, occurred, took place; an accident, an episode [29].

The word "extraordinary", in turn, means something that stands out above average, very rarely occurs, uncommon, exceptional, unique [30]. But it also stands for an event caused by special circumstances which was not foreseen in a specific scheme or intended action plan and requires special measures to be undertaken. While it is quite common for an exceptional event to be regarded as negative due to its "unexpected" nature, an exceptional event may, in terms of its effects, have positive and negative significance, arising from the specific additional characteristics of the exceptional event in question.

By combining the terms, one would consider an extraordinary event to be above average. Does such a definition fully correspond to the consideration given to an exceptional occurrence regarded as a security determinant? Of course not. Then allow us to look at the concept that interests us in the context of other definitions.

An extraordinary event may also be understood as an undesirable event causing material damage or loss of health or life to people in or around the system [31].

An exceptional occurrence may be regarded as a foreseeable and spatially limited accident, caused by the impact of a natural, technical or technological disaster, damage to the operation or the deliberate action of a person, which compromises the stability of the system or of events and activities occurring therein, jeopardises human life and limb, material and cultural assets or the environment. It introduces a change in the quality of components of the system, and thereby changes in the quality of affiliation and relations amongst them [32].

An emergency event is a peculiar materialised phase of a growing hazardous situation, formed as a result of negative circumstances or conditions arising. An exceptional occurrence is the tangible consequence of a threat not eliminated in time. The event may be more or less extensive, it may have a different threshold, duration, but each time it terminates the existing state of affairs [33].

A slightly different attitude to the interpretation of the notion of an extraordinary event is included in the regulations governing the functioning of formations performing tasks in the area of general security and public safety.

Accordingly, in the first case, it is defined as an event in which the number of people at risk and affected, the extent and degree of environmental and property damage and destruction of infrastructure make it virtually impossible for public authorities to control the course of the event [34].
As far as public safety is concerned, an outstanding event is, according to the regulations in force in the Police, an exceptional situation brought about by an intentional or unintentional breach of the law [35].

Extraordinary events can be broken down into several categories:

−calamities, which are exceptional and violent events with a devastating impact arising in the course of human activity, as well as natural or technical conditions, covering an unlimited area and leading to serious danger to people and the creation of immense destruction that can be contained by the consolidation of efforts of one' own forces and support services;

−catastrophes seen as rare, tragic events resulting from human action, natural forces or the development of civilisation, extending over a vast area and causing grave danger to human beings and substantial loss of human life, which may be contained by the use of self-contained means with the possible participation of a support force;

−accidents considered to be exceptional occurrences resulting from human activity or from natural or technical conditions and resulting in hazards to human beings and causing injury of a limited magnitude, which can be dealt with by means of self-management;

−incidents which are above-average events which may compromise human health and/or result in minor losses that can be controlled by limited forces of one's own.

A solid evaluation of the consequences of potential extraordinary events and the likelihood of their occurrence appears to be possible only by incorporating a method of identifying the consequences. If the verification is performed from the perspective of the learning entity, the emergency event concerns only that party. On the contrary, if the identification is made from the point of view of the community, it only relates to accepted values considered important for the security of a community member and is bound to its culture [36].

Under the circumstances of an abnormal event, it is common for decisions to be made under time limits. In these situations, there may also be an element of surprise, not necessarily, for it is entirely predictable what impact the decisions taken and the solutions applied will have. Extraordinary events are very often accompanied by strong time and environmental pressure, which makes it extremely hard to pinpoint new threats and subsequent incidents. What is crucial is that an extraordinary event can take place under conditions of an action that is incompatible with the present one or a failure to act.

The basis for the interpretation of events and, above all, for predicting the consequences, are the pieces of information that get to us and the accumulated and structured facts from the past, partially interpreted by the cognitive entity and representing their knowledge base. The accuracy of assessment results from the reliability of the collected data [37].

The spectrum of the emergency comprises those situations which violate people's serenity and certainty of well-being - in purely physical terms. They can entail the loss of life, health or property - which are the basis of existence and allow the further development of the individual as well as the community in which he or she functions and is dependent on. There are a great many phenomena in line with the aforementioned term. The 'extraordinary' quantifier refers not only to the singularity and unpredictability, but also to the scale of those phenomena, which is manifested by the extent of the impact of a dangerous condition, evaluated by the number of people at risk [38].

In conclusion, it can be stated that an extraordinary event is an above-average situation resulting from a threat, undermining the sustainability of the system or the operations that take place in it, which harm the health and life of people and the needs for their daily existence.

Summary

The variability of the security environment directly affects the perception of security and thus also of threats and emergencies.

"Threats' and 'emergencies' are concepts with a strong affinity to the notion of "security". In short, if you are safe, you are not in danger. If you are at risk, you cannot be safe. This is an apparent dependence that results from subjective human perceptions. Even when a state of consciousness views a certain phenomenon as not posing a hazard, it has an unbiased effect on the subject, often invisible at first. It implies that we most commonly encounter a subjective sensation and an objective state of vulnerability [39]. It is definitely not the case with extraordinary events. They have nothing to do with subjective perception. They are simply an individual entity.

It transpires from the considerations presented that threats and emergencies are physical or social phenomena which are closely interconnected. They cause uncertainty and concern. Since this sense affects all areas of human life, therefore, hazards and emergencies cover a broad spectrum of phenomena. It can thus be said that 'threats' and 'emergencies' remain in such a close dialectic connection with each other as to make it pointless to consider them apart.

A synthesis of the definitions of "threats" and "extraordinary events" can be confined to the fact that a risk is a possibility of one of the negatively assessed phenomena [39] and an unusual event is not as much a possibility as the occurrence of the phenomenon.

Despite differences in interpretation of both threats and emergency events, the two have common traits. This mainly refers to the scope. Adopting this criterion, they can be divided into [40]:

- of limited scope, that is to say, occurring in a limited area or relating to a specific field of operation of the state and not giving rise to crisis situations, outside that area or fields;
- extending, i.e. gradually evolving from limited crisis situations to nationwide cases;
- nationwide, that is to say, those which, from the very beginning of their emergence, cover a significant part of the country or a major part of the domains of operation of the country.

In spite of the common qualities, one can also see discrepancies. They relate to the boundaries among these phenomena. For where a threat that was impossible to prevent expires, there is an extreme event.

Abstract

An organization can be successful when it is supported by various groups of its stakeholders. Therefore, it is especially important to identify stakeholders and apply an appropriate way to manage and communicate with them. The article presents the crowd as a strategic force influencing an organization. Various definitions and types of crowd have been described based on the literature review. In addition, it has developed its own model of crowd management and communication. Its structure is based on the grid of emotions and engagement. It allows to distinguish four types of crowds: crowder, seeker, spectator, actor. The proper process of communicating with the crowd enables the organization to manage it. The article is theoretical in nature and is the authors' contribution to the discussion on crowd management by contemporary organizations.

Keywords: Crowd, Types of Crowds, Communication, Management.

Introduction

A crowd is a collection of different people who have gathered by chance. G. Le Bon (2009: 15), who was considered a pioneer of crowd research in the 19th century, defined it as a collective subject governed by the law of unity of mind. This law is characterized by the individual's abandonment of himself in favor of the thoughts and actions of the crowd. The crowd can be impulsiveness, changeability, irritability, suggestiveness, credulity, exaggeration, intolerance, authoritarianism, conservatism, and cruelty (Le Bon, 2009: 15-32). In this perspective, the crowd is a nameless, random, impermanent, and irresponsible community that destroys. It does not have to be criminal destruction - there are cases, for example, of heroic deeds and the overthrow of criminal systems. But no matter what the result of the crowd's actions, the way to achieve them is always to destroy the system, not to build it. When exploring only the negative qualities of the crowd, it ignores the fact that its character gradually changed at the end of the 20th century and at the beginning of the 21st century. Today, the subject of scientific reflection has become to know not only the "angry crowd", but the crowd as a community of wisdom. The modern crowd is very diverse, it is both viewers of game shows, as well as corporations or crowds of people betting on sports, as well as clusters of drivers trapped in traffic jams. They are not subject to any formal order. The crowd also includes stock exchanges and organizational management teams. The latter have their own identity and are constantly influenced by changing information. Such an understanding of the crowd is the subject of research by J. Surowiecki (2010: 18). In his opinion, the crowd today is a collection of various interest groups, who share the ability to act together, influence decisions and solve problems in the organization, even if group members are not always aware that they are doing it. Such interest groups have purpose, are intelligent and even "collective wisdom" and are effective at problem solving. For this reason, the crowd may constitute an opportunity for the organization or a threat to the pursued economic and social goals and activities. It can therefore be assumed that the crowd is of strategic importance. For this reason, it is the subject of research by scientists representing various scientific disciplines (psychologists, sociologists, management theorists), as well as practitioners (innovators,

entrepreneurs, managers). The subjects of this research are behavior, attitudes, influence and power of the crowd on the organization, and ways of influencing and managing it.

The aim of the article is to diagnose the crowd as a strategic force in the market game and to discuss communication tools that may be useful for any organization conducting a dialogue with it. The study assumes that organizations should use the wisdom of the crowd to achieve their own goals. Such a change in management requires the organization to identify those interest groups in the crowd that will provide it with the necessary data, information and knowledge. For crowd management purposes, the Crowder-Seeker-Spectator-Actor model was developed to identify and transform crowd participants into an active market operator. The basis for building this concept is the communication process (screening, investigation, identification, cooperation, and management) of the organization with the crowd. The authors believe that effective communication and management with the crowd will enable the organization to build beneficial relations with them, which will enable building a competitive advantage as well as formulating and implementing effective strategies.

The Essence of The Crowd - Literature Review

In classical terms, a crowd is a collection of different individuals and groups. G. Le Bon (2009: 15), who studied the crowd in a psychological dimension, claims that it is organized and is governed by the law of mental unity. He distinguished heterogeneous and homogeneous crowds. Heterogeneous crowds are collections of individuals who are diverse in work and mental development. They can be nameless (street crowd, crowd of onlookers) and non-anonymous (parliament, jury). On the other hand, homogeneous crowds include sects (religious, military), castes (solders, priestly, workers) and strata (middle class and peasants).

In economics and sociology, the crowd is seen through the prism of collective behavior. His behavior may be different and contribute to creating market bubbles, developing panics with the large-scale financial effects, or leading the destruction of persons and prosperity. H. Blumer (1951: 167-222) developed his theory based on different behavior, there are four types of crowd: causal, conventional, expressive, and acting. In the causal crowd individuals interact very little, if at all, with one another. The conventional crowd results from deliberate planning and follow a clear set of norms. The expressive crowds are a typically form around an event packed with excitement. The acting crowd is motivated by an intense, single-minded purpose. This crowd are set in motion by powerful emotions.
More recent research on the management of mass victories of people has distinguished the following types (Zeitz, et al., 2009: 36): ambulatory - walking, usually calm; disability/limited movement - crowd has limited or restricted movement; requires additional planning; cohesive/spectator - watching specific activity; expressive/revelous - emotional release, for example, community fun runs; participatory - involved in actual event, for example, pickets, marches; aggressive/hostile - pickets, marches; escape/trampling - danger may be real or imaginary; dense/suffocating - reduction of individual physical movement; rushing/looting - attempt to acquire/obtain/steal something, for example, tickets; violent - attacking/terrorizing.

According to research study by L. Wang and T. Michoel (2019), the contemporary crowd is characterized by wisdom. The wisdom of the crowd is defined as the collective intelligence resulting from many people answering the same questions. The sum of the collective responses may be more accurate than the responses of each individual person. Through the wisdom of the crowd, the accuracy of prediction and decision making in organizations can be improved. Crowd wisdom estimates each individual's error level and minimizes the overall error in the crowd consensus.

Crowd wisdom research was conducted by S. de Oliveira and R.E. Nisbetta (2018: 2066-2071). Based on own research studies, they argue that demographically diverse crowds tend to be a bit wiser than homogeneous crowds. They suggest that in order to improve the quality of decisions made on the basis of crowd opinion, it is necessary to increase their variety, not just numbers.

V. L. Kendrick et al. (2012: 3223-3226) in a case study, examined the organization, coordination and security of crowds. The results of this study showed that the organizers lacked information about the

crowd, which made it difficult to plan and manage. Research findings challenge the availability, relevance, and placement of information on crowd satisfaction and comfort in event planning. In addition, researchers believe that inadequate communication and management systems existed to ensure compliance with internal procedures in the absence of any useful guidance to help with the organization of mass events.

In a research study by V. Fillingeri et al. (2018: 18-27), crowd is usually a meeting of people with different experiences. The aim of the study was to better understand how organizers approach the management and operational aspects of the crowd situation. They identified the following crowd influencing factors (V. Fillingeri et al., 2018: 20):

- Physical design of crowd spaces and facilities - organization of crowd, sectioning, one-way or contra flow system, exit routes, view, car parking (venue layout); sufficient personal space (space available); able to fulfil intended purpose, conflicting goals, barriers to goal achievement, competition between crowd member (goal achievement);
- Crowd movement - time considerations, presence of rushing/hurrying (time constraints); being in control of the situation; crowd participant confusion, choice, discretion (control); physical height, age, special needs (individual factors); trolleys, wheelchairs, pushchairs, bags, luggage (encumbrances);
- Communication of information - ability to find way around, disorientation, losing people (navigation); signage, information availability, language barriers (communication);
- welfare and wellbeing - seating, toilets, refreshments (welfare facilities); weather, heat, lighting, noise, pollution, odours, ventilation (environmental factors); presence of crowd participant anxiety, frustration, vulnerability, intimidation and claustrophobia (stress); participant desire to be in the crowd, enjoyable purpose, functional purpose (motivation);
crowd participant prior experience and expectations, familiarity with surroundings, cultural norms, and stereotypes (preconceptions).
- Public order - involvement at participants' discretion, unavoidable experience of a crowd (avoidance); presence of factors that distract from the crowd situation, positive and negative (distraction);groups of crowd participants, individuals isolated in crowd (company); feeling safe, fall risk, trampling risk, violence, other hazards (safety and security); appropriate, antisocial, pushing, jostling, competition (behavior); good mannered, boredom, hostility, excitement, anticipation, atmosphere (mood).

By analyzing the results of the researches, the authors found that the organizations need better understanding of the sociotechnical complexity of crowds and appreciation of the factors influencing crowd behavior.

Apart from the literature in the field of sociology, the problem of the crowd is discussed in the scientific works on strategic management. The crowd is defined as one of stakeholders that has an influence on the process of formulating and implementing the strategy. This impact can be positive or negative, may constitute an opportunity or a threat to the organization. For this reason, it is subject to strategic analysis. The relationship of crowd with strategy is described by R.P. Rumelt (2013: 319), who writes: "(...) The wrong strategy is to follow the crowd, replacing revealing visions with popular slogans". Such an approach to the problem, in his opinion, is related to the phenomenon original called "social herding". In his interpretation it notion means: “When we don’t know about something, it may be sensible to look at the behavior of others, assuming that at least some of them know things that we do not. But if everyone else is doing the same, then this process of mutual calibration can result in all the members of a group undertaking uniformed actions (…)” (Rumelt, 2013: 335).

K. Obłoj (2014: 187) presents the crowd as a public opinion. Describing and analyzing the company's environment, he draws attention to the importance of public opinion (crowd) as an important stakeholder influencing the organization's behavior. According to him, stakeholders are different groups, institutions and organizations that meet two conditions - they have their “stake” in the functioning of the organization, in its decisions and their effects, and are able to exert pressure on the

organization. As an example of positive behavior of the public opinion, he mentions forcing an international corporation to change its strategy taking into account environmental protection.
Although the concept of wisdom of the crowd is known in social sciences for over a hundred years (Galton, 1907: 450–451), his problem related to organization management has been little studied.

P. Wack (1985: 73-90) in the article on the development of scenarios about the future oil price, presents four types of stakeholders: players, subjects, referees (context settlers) and crowd. In his interpretation crowd is a type of stakeholders with the following features: unaffected (or low) interrest (stake) and low power. The success of an organization depends to a large extent on the support given by different groups of stakeholders. It is therefore very important to identify different groups of stakeholders and chose an appropriate way to manage them.

In the book by K. van der Heijden (2005: 260-263), the crowd is an actor whose influence the organization does not have to take into account when creating strategic scenarios compared to other stakeholders. The actor's strategic analysis reveals inconsistencies, confronting the internal logic of the scenarios with the organizational intuitive insight into the logic of the various key actors in the market game. Its purpose is to identify opportunities and threats related to various groups operating in the organization's environment. In the scientific study by A.M. Deren and J. Skonieczny (2016a: 7-15), the crowd is shown by the relationships with traditional market participants in the form of a model CMSA (crowd-movement-spectator-actor). In this model, the crowd is the force that creates the new market space, the crowd initially acts as an observer of market events. The development of such a chain in practice makes it possible to transform the crowd participants into an active participant in the market game. Their use by the organization enables the emergence of interactions leading to the transformation of the crowd into active actors (customers, competitors, regulators, and stakeholders).

In another scientific study by A.M. Deren and J. Skonieczny (2016b: 173-180) present the crowd as a force creating innovation in the organization. Without questioning the role of creative individuals in generating innovation, they point out to the increasing use of crowd wisdom by organizations in creating innovation and / or needs, which then feed into innovation.

To summarize above considerations, it should be stated that crowd is the subject of research by various authors, most often as a community of people who have a common goal and behave similarly towards other market participants. In the literature on management, crowd, as one of the stakeholders, is the subject of the market game. Having his awareness and wisdom can influence the behavior of the organization. For this reason, organizations should take into account the interests of the crowd in their strategies or activities. The condition for this is direct communication with him.

Crowd management using information technologies

Various methods of crowd management are discussed in the literature. The four most important ones that an organization can use in its decision-making process are presented below.

Crowdsourcing is a neologism created from the combination of the English words "crowd" and "outsourcing" (using external resources). This process derives from the free innovation sector and describes the outsourcing of tasks and creative processes to the masses of internet users. Within crowdsourcing, a number of categories are distinguished, such as: crowdfunding (joint financing of a project by the community), co-creation (co-creation - the joint performance of creative work by communities), microtasking (performing small tasks by the community included in a larger project, e.g. recognizing text) (Kasprzycki-Rosikon and Piatkowski, 2013: 15).

The crowdsourcing concept or method is coined by J. Howe (2006: 1-4) and defined as follows: "crowdsourcing represents the act of a company or institution taking a function once performed by employees and outsourcing it to an undefined (and generally large) network of people in the form of an open call". Crowdsourcing is an emerging topic and it has received great attention from scholars and practitioners. It overlaps with other contemporary concepts such as open innovation,

collaborative innovation, and user innovation. Some scholars believe that it falls under the umbrella concept of open innovation (Ebner et al, 2009: 342-356).

In the book by D.C. Brabham (2013) presented the following definition of crowdsourcing: "[it] is a type of participate online activity in which a individuals, an institution, a non-profit organization, or company proposes to a group of individuals of varying knowledge, heterogeneity, a number, via a flexible open call, the voluntary undertaking of a task". The participation of the crowd in such an endeavor consists in carrying out work, providing money, skills, knowledge and experience to the organization that needs them as resources necessary for the implementation of the adopted goals and activities related to them.

Similar method to crowdsourcing is crowdfunding. It is a form of financing various types of projects by crowd (community) that is or is organized around these projects. The project is then financed by a large number of small, one-off payments made by persons interested in the project. According to the definition presented by K. Krol (2013), crowdfunding is a type of accumulation and allocation of capital transferred to the development of a specific enterprise in exchange for a specific return, which involves a wide group of capital donors, is characterized by the use of ICT technologies, as well as a lower entry barrier and better transaction conditions, than generally available on the market.

In addition to traditional financing instruments, a new way of raising money via the Internet has recently established. This form of raising capital is called "crowdfunding" and allows companies and individuals to make a direct call to the public (the "crowd") via the Internet to raise money for their innovative and new ventures (Schwienbacher and Larralde, 2012: 369-391). The mechanisms of crowdfunding and the platforms that offer their users these specific online services vary greatly between the individual forms of crowdfunding. They differ on the one hand in how the financial resources are used and on the other hand in whether and in what form consideration is provided (Belleflamme et al., 2013: 313-333). Crowdfunding is an open call over the internet to acquire financial resources. Most project initiators use web-based platforms to launch their project or plan publicly. Most of those active in the market Crowdfunding platforms are within the last seven years originated and can be considered special understand forms of social media applications (Wu et al., 2013: 257-282).

Another method is crowdcasting. It is a problem-solving and idea-generating process in which an organization defines details of a specific problem or situation to a carefully chosen community of crowd for possible solutions. The process is often conducted as a contest. The results may be used to resolve difficult or complex development in technology or management. Sigismund et al. (2011: 101) argue that crowdcasting can be compared to a closed event that cannot be entered without invitation. They give an example of creating innovations for an international company. The players in this innovation event sign confidentiality agreements, and the solutions proposed by them become the property of the sponsoring company. Typically for crowdcasting is the selection of the target group in a crowdcast who is well-educated but not part of the culture of the company seeking the solution for technological and/ or organizational problems.

Relatively new, associated with the development of a democratic society and information technologies is crowdvoting. It is a method by which ideas for new products or services are voted on by the crowd (eg. Internet community). Internet users' voting does not generate such costs as experts' or consultants' fees. Additionally, voting by the crowd can bring tangible benefits to both the organization and other market participants. First of all, potential customers, feeling committed and appreciated, choose what they would like to use. In the case of a crowd vote, it becomes ratings, votes, opinions or recommendations (Lemeister, 2012: 388-392) that can be included in the decision-making processes in the organization regarding products, technology, quality of life, or the protection of natural resources in a smart and cost-effective way.

The common core for the distinguished methods of crowd management is social communication and cooperation. Social communication is a process where meaning is shared through information and knowledge exchange. M. Castells (2013: 65) writes that the course of this process is determined by

technology, features message senders and recipients, their cultural codes, references and communication protocols and the scope of the communication process. The tasks are fully completed with modern communication and information technologies, such as the Internet and social media.

On the other hand, cooperation is the ability to create bonds and cooperate with others, the ability to work in a group and with different groups (crowd) to achieve common goals, the ability to perform tasks in a team and solve problems together. This ability is one of the emotional competences that affect the quality of relationships between individuals, groups or organizations. Real cooperation is conducive to engagement and leads to the creation of internal bonds among members of the group to achieve common goals.

Crowd Classification – New Approach

The presented literature studies on crowd justify the conclusion that the crowd is a strategic force influencing the organization. The crowd can be a driving force both as a provider of information, knowledge, and other resources, and as a threat to the organization's goals and activities. In the first case, the crowd is an ally of the organization, while in the second, the crowd is hostile, which can significantly reduce the organization's operation on the market, and even destroy it. To counteract this, the organization should, to the best of its strength and capabilities, manage the background. It requires the use of analytical and management instruments that will enable the organization to recognize the crowd and determine those forces with which the organization can cooperate or reduce their negative impact. The understanding of collective behavior by different types of crowds as well as the social dynamics of crowd behavior as a strategic force allowed the authors to generate a new crowd management model. Due to the fact that collective behavior in a psychological and social perspective relates to an emotion - engagement grid, these own criteria were chosen for the crowd analysis in diversity management.

Figure 1: Diversity management's Crowds

Source: Provided by authors

Figure 1 shows four types of crowds:

- Crowder – group of people with low emotion and low engagement to organization.
- Seeker – group of people with high emotion and low engagement to organization.

- Spectator: group of people with low emotion and high engagement to organization.
- Actor: group of people with high emotion and high engagement to organization.

This model helps to identify the types of crowds and enables the establishment of basic communication strategies between the organization and the distinguished crowd types.

The process of Communicating with The Crowd

Communication with the crowd is critical to manage them. Communicating with the crowd is critical to managing it. This in turn means prioritizing the organization's communication systems. In connection with the developed typology and crowd, the process of communication of the organization with the crowd was developed and communication strategies were defined adequate to the selected types of crowds.

Figure 2 shows crowd communication management process elaborated by authors. The communication process consists of four steps to successfully communicate with crowd:

1. Monitoring/Screening: it is a routine activity of collecting information that can be used to make informed management decisions. Monitoring can take place at project or organizational level. Monitoring regularly provides managers and other stakeholders with information on progress towards goals and results (Project Management Institute, 2017: 105).
2. Investigation: it is an examination and research about specific topic and the goal is to determine the stakeholder in the organization.
3. Classification/Identification: In this activity, type of crowds will be identified and classified.
4. Communicating with crowds: Finally, different internal communication ways as will be categorized.

Figure 2: Crowd communication management process

Source: Provided by authors

The adjacency of the typologies presented on Figure 1 indicates communication strategies appropriate for each crowd group and the concept of crowd management was built, i.e.:

- to collaborate with actor: as the group of people with high engagement and emotion need to be engaged and organization must collaborate with them to change them as positive stakeholders.

- to empower the spectator: as a group of supporters with low emotion and high engagement, they should be empowered, and all the steps should be discussed.
- to involve the seeker: as they have high emotion and low engagement, they are potentially can be as actor, they need to be involved.
- to inform the crowder: an information exchange between organization and this type of people, whom have low emotion and low engagement, can help to increase their emotion and their engagement.

Conclusion

Crowd management can be considered as a strategic activity that is important to the organization. As shown in the article, the crowd is not a homogeneous group of people. Influencing the organization and engaging in its activities is a low-power stakeholder. The organization can use the crowd to achieve its own goals and objectives. Such action may contribute to strengthening the competitive position of the organization. Crowd management can be key to this. To this end, the organization should identify the crowd, defines its types and assigns an appropriate communication strategy. For this purpose, the crowd communication management process presented in the article may be a useful tool.

Quality of Life Monitoring: Opportunities for Digital Methods

Evgeny SHCHEKOTIN

Novosibirsk State University of Economics and Management, Novosibirsk, Russia
email: evgvik1978@mail.ru

Abstract

The article deals with the application of computer technologies in social sciences. Computer technologies have been actively used in the social sciences in recent years, especially in the applied and commercial sections. The digital world also opens up new data sources for researchers – all sorts of "digital footprint" that users leave in the digital environment. These digital methods in the social sciences are also applicable to the study of the quality of life of the population. The data source in this case is the subjective judgments of users in social networks about the state of quality of life in a particular region of Russia. A new method for assessing the quality of life of the population of regions based on data mining and big data technologies is proposed. The results of a study of the quality of life according to social networks in 83 regions of the Russian Federation are presented.

Keywords: Digital Methods, Digital Sociology, Quality of Life, Social Network

Introduction

All currently quality of life theories represents two large groups: objective and subjective methods (Nugaev and Nugaev 2003). Objective methods employ various statistic data sets, while subjective methods assess quality of life based on what people report and think of their lives themselves; such reports and opinions are collected by means of surveys or psychological and sociological experiments. In this research we analyze subjective quality of life as an individual's personal and subjective assessment of his or her own quality of life.

New information and communication technologies offer new opportunities to study subjective quality of life (Antenucci et al 2014; Appel et al 2016; Chen et al 2017; Sabatini and Sarracino 2017; Verduyn et al 2017; Yang and Srinivasan 2016). Thus, nowadays social media is the one of the principal information sources on mood, emotional experiences and behavior of people. Compared to surveys, social media as a source of information have both virtues and shortcomings (see Cody et al 2016; Dudina and Iudina 2017; Kryshtanovskaya 2018; Sanchez et al 2017; Schober et al 2016; Shchekotin et al 2020). We suppose that quantitative analysis of human behavior in social networks is a way to obtain sufficient information on the people's emotions and worries, as well as to assess their subjective quality of life. In this article we offer a way to study the subjective quality of life based on the information on online activities of social networks users.

Methodology

The methodology of our study consists of several subsequent stages:

1) development of a subjective quality of life model;
2) selection of VK communities;
3) classification of posts and messages in those communities;
4) automatic content analysis in the selected communities;
5) calculation of life quality index for different regions of Russia.

Quality of life model

There are lots of methods and models of quality of life and life quality available, with lots of common elements. Gavrilova (2004), for instance, distinguishes 17 most mentioned life quality parameters: standard of living; social infrastructure level; environmental condition; health condition; personal safety; education level; employment; quality of work life; quality of accommodation; quality of leisure and recreation; demographic situation; social confidence (social payments, various preferences); family; social connections; inequality; financial and economic condition in the area; nature and climate. In our model we have used several of these parameters; however, we have not included the others due to their complexity and the specific character of the selected communities. For example, such things as income level, family life, demographic situation and social connections are not widely discussed in the mass regional communities. We have also excluded quality of work life, quality of leisure and recreation and inequality as separate parameters, because studies of these indicators require a deeper analysis. However, we have included several additional parameters.

First of all, we have added the assessment of various administrative solutions and political situation in the region, because today the Russian authorities have direct and strong impact on the other parameters of quality of life and life quality. We have also included such parameters as general emotional state (psychological subjective life quality) and relationships between people to assess the emotional environment in the region. One more parameter of life quality, very important but frequently forgotten in the Russian studies, is the situation with political rights and freedom (Veenhoven 1996). Table 1 gives an overview of subjective quality of life parameters we have used in our study.

Table 1: Structure of life quality parameters

Categories	Indicators/Topics
Education	pre-school; secondary; secondary professional; higher; extended
Housing and utilities sector	housing and utilities services for population; administration (bureaucracy, work of employees, service quality, attitude towards people, rates)
Healthcare	service (conditions, technical equipment, bureaucracy, waiting time); treatment quality; work with certain population groups (elderly, children, disabled, pregnant)
Infrastructure	roads (quality); fuel; accessibility (between settlements and to housing, etc.); congestions; snow cleaning; storm water draining; affordability of housing, etc.
Safety (situation in cities)	special services work (Police, Ministry of Emergency, Road Police, Rosgvardiya); criminal situation (crimes, fraud, theft, administrative crime)
Environment	deforestation; ozone depletion; reduction of biodiversity; water and air pollution; overpopulation; soil degradation; biological waste; influence of politics and economics on environment; consequences of human impact on environment; measures of environmental disasters prevention, etc.
Relationships between people	friendliness/hostility of passerby, neighbors, strangers (co-travelers, passengers, etc.)
General emotional state	expression of feelings (happy/unhappy, satisfied/not satisfied, annoyed/inspired, sad/glad, etc.)
Work	unemployment level; salary; work conditions; official/unofficial employment; full/partial employment
Products	prices and inflation; competition between manufacturers
Taxes	bureaucracy; tax rate; tax burden; tax allocation
Lending and entrepreneurship	loans and mortgage; entrepreneurship (barriers, bureaucracy, etc.)

Social support on behalf of the state	subsidies; pensions; benefits; retirement age
Media freedom	censorship/freedom of speech; trustworthiness of information; objective character, etc.
Remonstrative potential (resentment of population)	political protest (protests addressed to the authorities) social protest (protests against social inequality, social problems); cultural protest (protests caused by some cultural event resulting in resentment)
Election freedom	election integrity; undue influence; transparency; information attack; attendance; competition during elections
Attitude towards authorities	attitude of population towards some personalities (president, prime minister, deputies, governors, mayors, members of the authorities) and their actions
Political resolutions	assessment of regional problems; managerial and staff decisions of the authorities; legislation (new laws and amendments); violation of the people's rights; attitude towards population; budget (generation and allocation); assessment of adopted decisions by the population
Domestic politics	assessment of functions of the regional authorities: - ability to set up and maintain regional economic activities - ability to maintain stability in the region and in the country - socially fair material wealth allocation - safe use of domestic - maintenance of lawfulness and order

Selection of VK communities

In our study we have included 83 out of 85 regions of the Russian Federation. We have not managed to collect data on two regions: Chechnya and Mordovia. In each of these 83 regions we have determined 3 largest cities and selected 10 VK communities discussing life there. We have defined them as 'urban communities'. We have filtered the communities according to several criteria:

1. They publish informative posts on social, economic and political life;
2. They publish posts of their subscribers with info on social, economic and political life;
3. The published posts contain sentiments on news and events;

We have excluded the following communities:

- online shops and other commercial groups;
- groups with information on sports and cultural events and personalities;
- communities of public places (restaurants, clubs, cinemas, etc.);
- food delivery services;
- communities on health, nutrition, fitness, etc.;
- communities on exchange of items and charity;
- communities with storytelling, stories and questions;
- dating communities;
- job offers communities.

In some regions (the Buryat Republic, Dagestan, Ingushetia, Tatarstan) we have included 10 regional groups not connected with any definite city. In these regions there are more than 3 large towns where the majority of the population is concentrated, so here we have included general regional groups to increase representativeness. In some regions with high population density in large towns we have selected only two or even one of them (like in Nenets Autonomous Area). We have searched for the communities manually and selected the largest ones corresponding to the above mentioned criteria. In doing so, we have built a cluster of 2410 communities.

Classification of messages and posts in communities

At the next stage of our study we have used the social media data collection and analysis platform of the University consortium of big data researchers (www.opendata.university), developed by the team of the Laboratory of Big Data in Social Sciences of Tomsk state University to download the materials from the selected communities. We have downloaded all messages, posts and comments for the period between January 1 and December 31, 2018. After that we have deleted all 'junk' like advertising, as well as the information beyond the scope of this study (job offers, sports and cultural events, free exchange, contests and campaigns, recipes, delivery and food, astrological predictions, sales of items, dating offers, discussions of private life of participants, etc.). We have deleted the 'junk' in two stages: 1) manual cleanup of approximately 60 thousand messages; 2) automatic cleanup based on the specially designed algorithm trained during manual cleanup. We have left only the messages of 20 words and longer and we have deleted all repeated messages. After cleanup we have left only approximately 3 300 000 messages. At the same time we have categorized the messages according to topics (given in Table 1) and style (positive, negative, neutral).

Automatic content analysis in selected communities

The database set includes posts from the walls of the regional VK communities retrieved through its public API (Application Programming Interface). Each post had to be categorized into one of the 19 categories or as 'junk'. The method is based on machine learning technologies of retrieval of unknown patterns from these texts. To create an automatic algorithm of texts classification we have used the following conventional libraries of machine learning: Scikit Learn (https://scikit-learn.org/stable/), Pandas (https://pandas.pydata.org/), Numpy (https://www.numpy.org/), as well as a set of tools known as NLTK (Natural Language Toolkit, https://www.nltk.org/) for the natural language analysis. The algorithm is based on Python 3 programming language.

At the data preprocessing stage we have deleted symbols belonging to neither English nor Russian alphabet. We have used stemming to bring all words to their basic forms. We have deleted all rare terms, which could have been typos. To be able to use different classification methods we had to present the texts in the vector form. To transform the texts into the terms significance vector we have applied TF-IDF (TF – term frequency, IDF – inverse document frequency), where the word weight is used in proportion to the frequency these words occur in a document and in inverse proportion to the frequency of the words use in all documents from the sample. TF-IDF is frequently applied to present documents as numeric vectors reflecting the significance of each term from a certain term set (a number of terms determines the vector dimension) in each document. For each vector we have taken into account not only separate terms but also digrams, that is, pairs of consecutive terms.

We have conducted a number of experiments to determine the best data for learning. To do that we have checked several data sets including: number of comments, likes, reposts, views, number of words in a post. All these values have been scanned in accordance to their average value in a community the corresponding text was taken from. We have also considered the vectors of significance for the comments to the posts retrieved the same way, as well as for the posts texts. After that we have determined the best data set for this task: significance vectors of the words in the posts, the scanned number of words and the number of comments, likes, reposts and views.

Based on the obtained data we have built the machine learning models. We have conducted a number of experiments, where we have categorized the samples as the one for learning and the one of a text, with their subsequent validation to select the most accurate model to classify categories and attitudes. After that we have checked the models of Gradient Boosting, where we have used a prediction model as an ensemble of weak predictive models and the Random Forest with variations of hyper parameters. In the end we have selected the models demonstrating the best result for the corresponding task. We have implemented the gradient boosting from LightGBM library. We have validated the data to determine the accuracy of the obtained models. The accuracy of the categories classifier is 73%. The accuracy of the attitudes classifier is 77%.

Subjective quality of life index for regions of the Russian Federation

After that we have built the subjective quality of life index (SQoL) for each selected region. The method of aggregates such as the index is widely used in various quality of life and life quality studies. In this article we have also used the indices of online activities to calculate the SQoL. We have calculated the SQoL according to the following formula:

$$I_{kjt} = \frac{A_{kjt}}{B_k} \quad (1)$$

where

I_{kjt} – Online Activity Index (OAI) for the region (k) for this subjective quality of life value (j) for the certain attitude of message. This index determines the intensity of discussion of this topic in the certain attitude in the certain region. The online activity index demonstrates how topical the subject of the message is (quality of life value) for the region and subjective assessments of this value by the social network users.

A_{kjt} – value on online activity in the certain region for the certain value of subjective quality of life; it is calculated according to the formula:

$$A_{kjt} = L + 2 \times C + 5 \times R \quad (2)$$

where

L – the amount of likes collected by the messages on or around a certain value of subjective quality of life in the certain region in the certain attitude.

C – the number of comments collected by the messages related to the certain value of subjective quality of life in the certain region. We have equated each comment with 2 likes, because, in our view, this action of a user is an evidence of importance of these messages for the commentator. Here a like is a passive form of demonstrating support of this message.

R – a number of reposts of the messages on the certain value of subjective quality of life in the certain region. We have equated each repost with 5 likes, because, in our view, a repost is an evidence of complete and active support of this message by the user. This action means that the user not only expresses his or her consent with this message but also openly demonstrates his or her solidarity with the message. As compared to various forms on online activities, a repost is an evidence of the greatest topicality of this subject for the user.

B_k – total number of subscribers in all selected communities in the region. This value demonstrates a relative value of online activity for this region.

k – number of each region (1 to 83). The study involves 83 out of 85 regions of the Russian Federation. We have not managed to collect reliable data for two regions: Mordovia and Chechnya.

j – topic of messages, that is, an indicator of quality of life, which we have included into the model of life quality (1 to 19) (according to Table 1)

t – attitude of messages (0, 1 or 2).

Thus, I_{kjt} shows intensity of discussion of a topic in the selected communities in the selected region. It is an evidence of urgency and topicality of this subject for the population of the region. I_{kjt} has been calculated for each attitude, that is, for each region OAI has three values: one for positive attitude, one for negative attitude and one for neutral attitude. Attitude is defined as an emotional evaluation of a message, thus, the positive attitude means that the message contains some positive evaluation or expression of approval of some news or situation mentioned in the message; the negative attitude means it contains disapproval, resentment towards the contents of the message, while the neutral attitude means the message is purely informative and contains no evaluation.

We have calculated the monthly value of the index for each subject and each attitude; after that we have calculated the mean monthly value for each subject and each attitude. Mean monthly values have been calculated by addition of the online activity index for definite attitude and dividing the sum by 12. Later, by simple subtraction of mean values of the online activity index for positive and negative attitudes, we have calculated the mean value of the subjective quality of life index $SQoL_{kj}$ for the corresponding region and for the corresponding topic/value of subjective quality of life:

$$SQoL_{kj\Delta m} = I_{kjm1} - I_{kjm2} \quad (3)$$

where

I_{kjm1} – monthly online activity index with the positive attitude;

I_{kjm2} – monthly online activity index with the negative attitude.

We have not included neutral messages into the SWBI. We have calculated the total Russian value of subjective quality of life $SQoL_{sum}$ as the sum of the index for all quality of life subjects/values for each region:

$$SQoL_{sum} = \sum SQoL_{kj\Delta m} \quad (4)$$

The suggested method is perfect to study the life quality of the 'digital' population in the region, that is, the part of the population, which can be referred to as active users of social media. This study does not include the population groups, which, for whatever reasons, do not use social media. The second limitation is caused by technical aspects of this method: we have not used botnets in the social networks to manipulate the public opinion. We have not managed to level up this issue. Another limitation is related to psychological peculiarities of the users' behavior. It is a well-known fact that users tend to react to negative messages, thus, the obtained results demonstrate the general subjective 'ill-being' rather than quality of life. Besides, this method enables obtaining the general subjective quality of life assessment for the region, but quality of life of a separate person cannot be assessed. Surveys are a better option for that.

As compared to surveys, this method has some advantages. It is fast, relatively cheap and scalable. In future the method of life quality assessment based on the social media data should be coordinated with the results of surveys; some objective data have to be identified, which influence the online assessment of life quality.

The indices were calculated based on statistics obtained from the largest Russian social network VKontakte. This social network was created in 2006; as of the beginning of 2020, it had more than 581 million registered users. It should be noted that it is the total number of users registered within the whole period Vkontakte exists, that is, since 2006. Some accounts were already deleted by the users, while some users create more than one account. Nevertheless, its monthly audience is 97 million people. According to the SimilarWeb, VKontakte is at the 10th position among all websites according to popularity and at the 4th position among the world's social networks. This social network is used by 65% of Russians (among those who use social networks, as of December 2017) (Pol'zovanie Internetom 2018). According to the results of the same study, 20% and 7% of Russians of those who use social networks visit Facebook and Twitter respectively. Another study demonstrates that 28% of Russians having accounts in social networks use VK every day or every other day, while only 4% and 1% respectively use Facebook and Twitter on the daily basis (Kazhdomu vozrastu - svoi seti 2018). VK is more popular among young users (aged 12 to 34). It should be noted, that VK is used by people living in settlements of all sizes and types. According to Mediascope, in November 2019 the monthly audience of VK (number of users logging in the social network at least once) was 70.5 million users living in all types of Russian settlements (cities, towns and villages) (Web-index VK.com 2020).

Results

Based on our results we are able to draw conclusions on two parameters of online discussions of various subjective quality of life indicators: attitude and intensity of these discussions. On the one hand, we see prevalence of negative publications (we observe negative values in all indicators), which means that the online activity index value for the negative attitude was higher than the one for the positive attitude (Table 2). Thus, we come to the conclusion that in general the population is not satisfied with its quality of life. On the other hand, we see that safety is an unprecedented leader of all parameters, meaning that this topic is a subject of the most heated online discussions. Such topics as relationships between people, infrastructure, housing and utilities, and environment attract far less attention. Then, we have a close group consisting of such parameters as the condition of medicine, employment, remonstrative potential in the region, goods (assessment of the commercial state of the region), and assessment of political decisions taken by the regional authorities.

Table 2 : Subjective Well-being Index for specific well-being indicators

Quality of life indicators	$SQoL_j$
Education	-0.01495
Housing and utilities sector	-0.15315
Medicine	-0.0596
Infrastructure	-0.17183
Safety (situation in the city)	-3.75174
Environmental science	-0.10836
Relationships between people	-0.2136
General emotional state	-0.0005
Employment	-0.04948
Goods	-0.04006
Taxes	-0.00533
Lending and entrepreneurship	-0.00778
Social support from the state	-0.00722
Media freedom	-0.00011
Remonstrative potential	-0.04253
Election freedom	-0.00678
Attitude to authorities	-0.00923
Political decisions	-0.03837
Domestic politics	-0.01864

Such topics as domestic politics, education, assessment of actions of certain political figures, as well as lending and entrepreneurship, social support by the state, freedom of elections and taxation attract even less attention. Thus, the suggested quality of life index is an indicator of social problems. It demonstrates the degree of dissatisfaction of the population with living conditions and indicates the most urgent issues for the people.

Such topics as freedom of speech in the media and general emotional state of the population cause the least interest. Low intensity of discussion of one's own emotions can be explained by both cultural factors (reluctance to openly discuss one's feelings and spirits) and the specific character of the selected communities (mostly they are informative communities discussing general problems typical for a certain region and settlement, problems faced by communities and not by individuals). It is possible that surveys can help to obtain more accurate data on this parameter. Low interest in freedom of speech in the media can be explained by the fact that this topic is discussed within the context of general political issues. So, freedom of speech in the media is blended with the general discourse on protests.
If we look at the data on the regions (Table 3), we see that in most regions the subjective quality of life index is negative. The exception is the Chukotka Autonomous Region, where the online activity index with the positive attitude is higher than the one with the negative attitude. The total positive life quality index in this region is made up from such parameters as the condition of infrastructure, employment, social support by the state, assessment of political decisions and domestic politics. The remaining parameters are either negative or zero.

Table 3: Total Subjective Well-being Index for all regions for 2018 (sum of all life quality parameters for a certain region)

Region	$SQoL_{sum}$	Region	$SQoL_{sum}$
Adygei	-0.04637	Nenets Autonomous Area	-0.07537

Kostroma Region	-0.09263	Tyva	-0.00853
Krasnodar Territory	-0.04428	Tyumen Region	-0.07588
Krasnoyarsk Territory	-0.05809	Udmurtia	-0.09363
Crimea	-0.0212	Ulyanovsk Region	-0.069
Kurgan Region	-0.07369	Khabarovsk Region	-0.02739
Kursk Region	-0.05522	Khakassia	-0.0664
Leningrad Region	-0.08755	Khanty-Mansiysk Autonomous Region	-0.0202
Lipetsk Region	-0.04889	Chelyabinsk Region	-0.07561
Magadan Region	-0.00687	Chuvashia	-0.01696
Mari El	-0.0412	Chukotka Autonomous Region	0.009571
Moscow	-0.01925	Yamal-Nenets Autonomous District	-0.04034
Moscow Region	-0.03322	Yaroslavl Region	-0.08844
Murmansk Region	-0.08631		

The regions with a 'high' negative subjective quality of life index, but close to 0, include a number of national republics in the North Caucasus (Ingushetia, Kabardino-Balkaria, Karachai-Cherkessia, North Ossetia - Alania), as well as Altai Republic. The Pskov and the Ryazan Regions, the Kamchatka and the Perm Territories, and the city of Saint Petersburg have somewhat negative value of the life quality index. At the opposite pole of this list we see the highest value of the life quality index represented by the Orenburg Region and a number of regions in the Western Siberia (Altai Territory, the Tomsk, the Novosibirsk and the Kemerovo Regions). This group also includes the Vologda, the Saratov, the Tambov and the Sakhalin Regions.

Factors That Determine the Market of Security Tokens Offering in The World

Joanna WIEPROW

WSB University, Wroclaw, Poland
joannawieprow@wsb.wroclaw.pl

Abstract

The financial industry was the first to perceive a huge potential in the blockchain technology. With the emergence of blockchain and smart contracts, a new method of raising capital for business projects has developed: digital tokens. Issuing tokens, through Initial Coin Offering (ICO), has become a popular method of financing projects, mainly technological ones. As a result of irregularities and frauds related to this, there was a loss of investor confidence and the ICO market collapsed. Hence, there is the emergence of Security Token Offering (STO). This innovative business model has an opportunity to revolutionize the financial market, while offering to its participants new opportunities to raise capital for startups and, on the other hand, new opportunities for investors. The aim of this article is to identify the factors that have an impact the development of the market of Security Token Offering in a global perspective and to create a model of interrelations between these factors. On the basis of the goal formulated in this way, a thesis was put forward that the STO market has a large growth potential; however, there are a number of factors that determine its development. The identification of those factors that have an impact on the development of the market under examination is based on an empirical analysis of the global STO market and an evaluation of its potential. Those challenges that face this market are also identified.

Keywords: Security Token Offering (STO), Initial Coin Offering (ICO), blockchain, security tokens.

Introduction

The dynamic development of blockchain technology and the accompanying development of electronic forms of payment, including cryptocurrencies, has led to the creation of new forms of investment activity and opportunities for enterprises to obtain financing. The central role in this area is played by the so-called token concept. It has made a rapid career in the digital world, to the extent that it is perceived by some as a means with a potential of revolutionising traditional financial and capital markets, while being a common and simple instrument for raising capital. This is possible by ICO, i.e. issuing utility tokens and raising capital through crowdfunding.

The year 2018 saw the largest development of ICO, where, in global terms, more than 7 billion dollars were raised (*4-th ICO/STO Report 2019, p. 1*). However, many investments were misleading, which resulted in a loss of investor confidence and the need to create safer financial instruments. Therefore, utility tokens started to be replaced by security tokens. Since 2019, there has been a dynamic increase in the number of the issues of security tokens, which translates into the amount of capital raised for investment projects, mainly technological ones, as well as an increasingly growing ecosystem of cryptocurrency markets. The advantage of security tokens is that they reflect real assets such as stocks, bonds, real estate or works of art. Furthermore, they are liquid and are widely available to investors. This creates opportunities to raise capital for businesses, especially startups, and offers new investment prospects.

One of the major challenges facing this market is the issue of an appropriate regulatory framework, related to the cryptocurrency market, including the issue of security tokens. Many countries are adapting legislation to the changing market requirements as well as to the development and use of

blockchain technology. However, there are countries where trading in security tokens is still prohibited; examples include China, South Korea, Ecuador, Algeria (*The Ultimate Guide to Security Token Offerings, p.27*).

The aim of this article is to identify those factors that have an impact on the development of the market of Security Token Offering in the global perspective and to create a model of interconnections between the said factors. On the basis of the goal formulated in this manner, a thesis was put forward that the STO market is characterized by a large growth potential; however, there are a number of factors that determine its development. The identification of factors that have an impact on the development of the market under examination is based on an empirical analysis of the global STO market and an assessment of its potential. The challenges facing this market were also identified.

The originality of this article is evidenced by a comprehensive analysis of the global STO market, including the ecosystem, benefits for issuers and investors, an identification and an assessment of those factors that have an impact on the market development and an identification of the potential and challenges facing the market. This analysis complements the theoretical gap in the functioning of the global market of security tokens.

Literature Review and Clarification of Concepts

Blockchain is a decentralised electronic database. This is a method of data collection based on global and decentralized registers. Individual blocks are linked by cause and effect relationships with other blocks, and together they form the so-called chain, i.e. a blockchain. Each block contains the end of the previous block, allowing them to be linked into a chain (Yan, Shi, 2017, pp. 220-230). Therefore, this is a decentralized electronic database, which is based on the records of subsequent data blocks. Each block contains information about the operation performed (including the date and result), and it is linked to the previous and the subsequent blocks as links in the chain.

The blockchain technology differs from other distributed database solutions in that it possesses the following characteristics (Schatsky, Muraskin, 2015, pp. 2-3):

- reliability and accessibility: the number of participants in the blockchain network guarantees that even if one participant fails (e.g. it registers incorrect data), the remaining participants will still maintain correct, verified and authenticated data,
- transparency: blockchain operations are available to participants in the network, who may control them, thus ensuring their safety and reliability,
- permanency: in order to reverse the operation, information contained in the blocks of all the participants of a given network would need to be changed, which is practically impossible (Skinner, 2016, p. 189),
- irreversibility: cancellation of a registered operation is practically impossible,
- digitization: the document can be saved and stored in a block in a digital form.

Blockchain operations are tamper-proof and fraud-resistant as they are constantly confirmed by a decentralised network of computers. Each new record in the chain is verified by a peer to peer (P2P) network and any false records are rejected. Therefore, in order to manipulate blockchain data, at least half of the computing power of the entire decentralised network would have to be controlled. It is Bitcoin that is based on a decentralized, transparent and anonymous blockchain database (Houben, Snyers, 2018, p. 31).

Bitcoin is the first virtual currency, known as cryptocurrency, created with the use of the blockchain technology. According to the definition provided by the European Banking Authority, "virtual currencies constitute digital representations of values, not issued by a central bank or a public authority, not necessarily linked to a specific country's currency, yet they are recognised by natural and legal persons as a means of payment that can be transferred, stored or traded electronically" (European Parliament, 2016/2007(INI)). Given that cryptocurrency systems are based on open source software

and P2P networks, there are already several hundred units – that are alternatives to Bitcoin - in the network. Ether is considered to be the most serious competition.
One of the possibilities of intelligent contracts is to issue tokens that may represent any asset: real estate, works of art, securities, metals and precious stones as well as any other tangible and intangible goods.

The issuance of tokens is to a significant extent easier than the creation of a new cryptocurrency, it does not require the creation of a new chain of blocks; what it only needs is an adjustment to the standards of the network within which they are issued. For the ethereum network, the ERC-20 standard has been created, which defines the common features of tokens and facilitates their uniform management. Tokens created in this manner can immediately be traded. They can be treated as successive cryptocurrencies or as shares in ventures (Żuława, 2018, p. 64). Tokens can be created primarily in the Ethereum network using smart contracts, i.e. applications that run within the protocol.

Tokens possess no material dimension, they constitute a digital record based on the blockchain technology. A vast majority of tokens are created on the Ethereum platform, or more precisely in the ERC20 standard (other less popular platforms include Nem, Neo, Waves and Omni). They have a number of applications: they may serve as a utility, marketing, billing or investment purpose as well as being a hybrid of these. Depending on their intended use, they are used in settlements for an access to specific resources of IT systems, they are a tool to raise funds required for a start-up and development of a start-up or a specific project; they reflect the shareholdings of the company, and they prove to be a marketing tool (Burilov, 2019, p. 8).

Tokens have many similarities to bitcoins, yet there is much more to them than merely a currency because they can be used in a wider range of applications. Due to their different application possibilities, tokens can be divided into (*The Ultimate Guide to Security Token Offering*, p.11):

- Utility tokens: these provide access to the functionality of IT systems, applications and services, and they are the means and method of payment;
- Security tokens: these are instruments that are analogous to securities and reflect their ownership.

"Another category that can be emphasized might be called as "real cryptocurrencies" or payment tokens — this type has its own blockchain and is often considered as a mean of payment. However, there is one big difference between SEC (United States Securities and Exchange Commission) and FINMA (Swiss Financial Market Supervisory Authority): while SEC focuses on comparing tokens with securities, FINMA is focused on the economic functions of tokens. Each type of token has key features" (*Types of tokens. The four mistakes beginner crypto-investors make*).

Tokenisation is an innovative form of business digitisation, based on the decentralised blockchain technology. It consists in creating tokens and assigning these strictly to a given company, specific project or person. Along with the development and adaptation of the blockchain technology, the potential of tokenization is enormous and it allows one to tokenize all kinds of assets while reducing the cost of their transfer. The most common method to use tokenization is ICO (Initial Coin Offering). ICO is a means of community funding for start-ups by raising capital through newly created cryptocurrencies and tokens. It consists in selling them in exchange for another legal tender, especially Ethereum and Bitcoin. It is based mainly on the business model recorded in the form of the White Paper document, which is equivalent to the prospectus for shares. ICO can be defined as a process where tokens are presented for purchase to an unlimited number of customers. The funds collected in this way are allocated for the purposes of launching an investment project.

Security Tokens Offering

Blockchain technology based projects can raise funds using ICO, which enables investors from all over the world to invest in innovative projects. However, the low credibility of ICO, high risk and regulatory issues have led to the development of a new method of financing: STO (Security Token Offering). STO

offers tokens that possess the characteristics of securities and are regulated and meet all the requirements associated with them. It is therefore a much safer method of financing considering the obligation to issue asset tokens in the blockchain network, within the legal requirements for the prospectus, thus allowing token buyers to hold shares in a real company.

It is worth mentioning that all over the world, every country has its own definition of the security token. In the context of American law, the Howey test is used to assess whether a given token is a security token. "According to the Supreme Court's judgement, a transaction is to be called an investment contract if it fulfills the following criteria, and thus becomes subject to the securities registration requirement, (*Security Token Offering: what, where and how, p. 5*):

- it must be an investment of money or anything of value,
- there is an expectation of profit,
- the investment is in a common enterprise,
- the profit is to be generated by the efforts of a third party".

Security tokens represent assets such as shares in actual primary titles, companies or profit streams, and rights to dividends or interest payments. In terms of their economic function, tokens are analogous to shares, bonds or derivatives (*Types of tokens. The four mistakes beginner crypto-investors make*).

The following can be distinguished among security tokens (*The Ultimate Guide to Security Token Offerings,* pp. 13-14):

- equity: partial ownership of a company or project;
- debt: a company's outstanding liabilities, comparable to a bond or mortgage;
- royalty: a return on your investment, and a form of passive income.

All security tokens must comply with the legal rules set out by a regulatory body in each country. This ensures that all tokens are legal and secure, thus protecting the token holder's investment. Unlike most ICOs (which were start-ups without a proven business model and they frequently did not have any product on the market), many of the emotions associated with security tokens come from their ability to create tokenized digital asset-backed securities. Asset-backed tokens are based on established real resources. This means that they open up opportunities for investors to buy and trade those assets that were previously very difficult to access.

The possibility to create security tokens has a great potential and it may bring a number of benefits to investors and issuers alike. Table 1 presents the most significant benefits of issuing security tokens.

Table 1: Security tokens: benefits for issuers and investors

Investors	Issuers
Increased investment opportunities Easier access to global markets Regulated by law: greater security Transparency of transactions Liquidity: possibility to sell tokens on the secondary market No intermediaries Low entry threshold	Possibility to reach investors all over the world Increased liquidity through the possibility to split the underlying assets into smaller units Faster and cheaper transactions Wider opportunity to raise capital to finance investments Lower costs of raising capital compared to listing on a regulated stock exchange

Source: author's own study.

Market of Security Token Offering: current state

The popularity of ICO began to grow rapidly in 2017 and early 2018, which was influence of growing cryptocurrency rates and the ability to raise capital in a relatively simple manner. In 2017, ICO collected USD 6,226,689,449 (875 transactions). In 2018, this was USD 7,812,150,041 (1,253 transactions). This means an increase in the value of capital raised by 25.5%. However, by the end of August 2019, projects on the global ICO market raised USD 346 million in 88 issues. It seems that the value of the ICO market in 2019 may not exceed the barrier of USD 0.5 billion (*Funds raised in 2018*).

According to the report from the InWara analytical platform (*3 Reasons why Token Sales are raising less funds*), in the first quarter of 2019, the number of ICOs decreased by nearly 60% on a year-on-year basis. In 2018, the sale of tokens within ICO accounted for 94.85 per cent, while for STO this was 4.23 per cent. These shares significantly changed their proportions in 2019, as the sale of tokens within ICO accounted for 52.94 per cent and for STO: 10.08 per cent. It is worth adding that about 37 per cent of all tokens sold worldwide were IEO (Initial Exchange Offering), which may, apart from STO, replace ICO in the coming future. IEO is characterized by the fact that the sale of tokens takes place through cryptocurrency stocks, and not directly to investors, as in the case with ICO (*Executive Summary of InWara's Half-Yearly report - H1 2019*).

According to a report prepared by ICObench, the amount of funds raised in the first quarter of 2019 by ICO was about one billion dollars: half a billion less than in the last quarter of 2018 (*ICO Market Trends. ICObench*, 2019). In 2018, the ICO raised a total of USD 2.94 billion. This is related to two well-known ICO projects. The first is the Telegram, a project that raised USD 1.8 billion. The second one is a government project for the emission of the Petro Token in Venezuela, which is covered by natural resources, mainly crude oil. The amount collected was USD 5 billion. However, there is still controversy surrounding this project, especially as there was a violent change of power in Venezuela in January 2019.

It can be concluded based on the data presented above that the value of the ICO market is decreasing. To a certain extent, this is due to the reversal of the general trend in the crypto market. However, a very important reason for the problems with ICO is the loss of the reputation of this form of crowdfunding caused by numerous scams, which could affect up to 78% of the issuances (*Cryptoasset market coverage initiation: network creation*, 2018). These irregularities included forged documents for investors, false promises of profit or false data related to the managers. Inexperienced investors had no access to tools required for assessing such information. Furthermore, there is a persistent problem with hacker attacks.

Security Token Offering offers a response to these problems and the lack of trust in ICO. STO is a digital representation of real assets that can be admitted to trading on secondary markets after the creation of dedicated platforms. These in turn have to comply with regulatory requirements related to investor identification (know your client, KYC), anti-fraud and anti-money laundering (AML). Security tokens have built-in compliance mechanisms, the violation of which prevents any operation on such value tags. After all, they are smart contracts, i.e. computer programs that have clearly defined mechanisms of operation. In this way, conditions are created to ensure security both for issuers and investors. Needless to say, however, this depends on the legal regulations that are in force in a given country. Many countries have taken steps to adapt their laws to the changing conditions on the cryptocurrencies market and to guarantee security to the participants of this market. Table 2 provides examples of legal solutions in selected countries in the context of digital token trading.

Table 2: Exemplary STO jurisdictions in selected countries

Country	STO jurisdictions
United States	Regulator (SEC) generally regards tokens distributed via ICOs as securities, with the exception of cryptocurrencies. Howey Test is applied to determine securities (very broad application). Additional state regulation supporting STOs (e.g. Wyoming).
Germany	Regulator (BaFIn) regards cryptocurrencies in general as financial instruments. Regulator approved first German STO in Q1 2019.
Switzerland	Regulator (FINMA) distinguishes between asset tokens, utility tokens und payment tokens; asset token based ICOs can be considered as STOs.
Estonia	Regulator (EFSA) categorizes tokens: donations, utility tokens, security tokens. Token can be defined as security token, if it gives the investors rights in the issuer company or is tied to profits.
China	China has announced a ban on STO. Hong Kong Securities and Futures Commission (SFC) has announced a set of regulations for exchanges and STOs, opening the Chinese market to the benefits brough about by security tokens.

Source: author's own study based on 4-th ICO/STO Report, Strategy&pwc, 2019.

Favourable legal and economic conditions for the development of the blockchain technology and the issue of security tokens translate into the number of STOs conducted in particular countries. Chart 1 shows the percentage share of countries in the total number of STOs performed in the first quarter of 2019.

Chart 1. Participation of countries in the distribution of STO (Q1 2019)

Source: author's own study based on data from State of the Security Token Ecosystem: Part One – Security Token Offerings (2019).

As evidenced by an analysis by the STN Platform, the largest number of issues in the first quarter of 2019 were carried out in the US, accounting for 40% of all the issues. The European Union comes second in the world (excluding the UK) with 18%. The EU leader is the UK with the STO number

representing 8% of the total. Switzerland is also an important player on this market (7.3%). Another significant player in the global STO industry is the Cayman Islands, where 10 companies have decided to introduce their offers. Despite a relatively small population and economy, the absence of corporate tax and other business-friendly regulations, the Cayman Islands constitute a friendly centre for the development of STO (*The Security Token Ecosystem, STN*).

An important element worth noting is a very small representation of Asian countries (5.3% of the research sample). Paradoxically, the largest cryptocurrency exchanges: Binance, Huobi and OKEx operate in Asian countries. This is influenced by several factors. As The STN Platform analysis indicates, Asian countries still focus on ICO, and they invest in projects that classify their tokens as utility tokens. In conclusion, it can be stated that the increasing concentration of projects in certain regions is linked to the creation of the necessary legal framework for STO in order for it to become the main method for raising capital (*The Security Token Ecosystem, STN*).

One of the main elements of the STO ecosystem are exchanges where tokens are traded. In order to function, token exchange platforms need to obtain regulatory approval from regulatory bodies in connection with the management of STO and cooperation with the relevant authorities. Currently, there are many cryptographic exchanges in the world where security tokens can be traded. The STO market is mainly concentrated in North America and in Europe. This proves that the market is currently highly polarised between the two continents. The low share of Asia is mainly due to the lack of a favourable climate for the development of the cryptocurrencies market on this continent. Binance, one of the largest stock exchanges in the world, may serve as an example here, where 8 million users from all over the world are registered, and the average daily trading volume amounts to one and a half billion dollars. Shanghai used to be the original seat of the exchange, which then moved to Hong Kong and, finally, it moved to Malta. Malta has introduced a number of regulations aimed at attracting investors operating in the area of new technologies. Whether Asian countries will start catching up remains uncertain and this will depend on decisions on the part of those in power.

As the analyses of the token market indicate, the is a growing interest in STO. In 2017, ca. USD 22 million were raised in the framework of 2 STO issues. In 2018, 28 STOs raised USD 442 million. The biggest STO in 2018 was tZERO (i.e. a subsidiary of eCommerce giant overstock.com), which managed to raise USD 134 million in Q3 2018. From January to May 2019, a positive development of STO continued. The largest STO introduced in 2019 was BoltonCoin, which managed to raise ca. USD 68 million (*5-th ICO/STO Report*, 2019).

In second half of 2019, STOs did not experience any significant growth, but continued to strengthen their general scope/relevance in global crypto token offering sphere (6-th *ICO/STO Report*, 2020). In 2020, a further growth and an increased importance of this financing method is expected, provided that regulations related to the issue and trading of tokens are introduced.

Potential for STO

There is a growing interest on the part of investors around the world in digital assets due to a number of related benefits. Security Token Offering allows one to use digital solutions while complying with legal regulations. Many markets are implementing their own solutions in this area, aimed at efficient, but above all, secure use of the potential of security tokens. The growing popularity of STO, the emergence of new markets and the increasing value of capital raised for investment projects: they all prove an enormous potential of security token offering.

Instead of issuing paper certificates for equity, a small company, a start-up or even a corporation can tokenize its equity and make fractional ownership of the organization available to the public. This significantly increases liquidity while offering an opportunity of possessing micro-shareholdings in the company and a creation of completely new business models.

While financial markets are becoming increasingly complex, security token offerings constitute an alternative to traditional institutional investments. Their compliance with legal regulations reduces the

barrier of trust faced by ICO or traditional crowdfunding. In addition to this, companies can raise capital from the global community, including investors outside of financial markets or with a limited access to them.

STO also offers the possibility of tokenization of less liquid assets, such as real estate or works of art. Security tokens allow individual owners to sell shares in real estate and convert these into cash. Token holders may obtain capital gains from future cash flows resulting from the ownership of a part of real estate.

The same is true for works of art. Owing to security tokens, smaller investors have an access to valuable works of art in the world. An additional advantage is that both the issuers and holders of tokens do not bear any costs associated with the mediation, as they do when buying a work of art in auction houses (*Art Tokenization: What Is It? How Does It Work?*).

Another possibility of using STO is the music industry. STOs enable individual musicians to finance their projects and tours. Artists can offer tokens through platforms such as Soundeon. The holder of a token is entitled to a portion of royalties, intellectual property licenses and access to music (*Unlocking Value in the Music Industry*).

The potential of STO can also be used for charity purposes. Many charities face a lack of trust from the public. Blockchain transparency and the ability to track funds accurately will enable these organisations to act more openly. Token holders may be kept informed on how their funds have been used for the project that they have supported.

Sports betting market can also benefit from the potential of security tokens. By adopting the developing digital technology, betting markets can dramatically reduce fees, better organize the hierarchy of prizes and protect themselves against fraud.

Factors that have an impact on the development of STO market in the world

The potential of STO is wide. Its use is determined by a number of interconnected factors which may contribute to the dynamic development of the STO market, or which may constitute a barrier to its growth. Therefore, these factors may both constitute an opportunity and a threat to the development of this business model. On the basis of an analysis of the current state of the security token market, certain groups of factors can be distinguished which form this market. The groups of factors including their description are presented in Table 3.

Table 3. Factors that have an impact on the development of STO market

Factors	Description
Economic	State of the world economy Number of enterprises including start-ups Level of capital demand for enterprises Development of innovation Risk
Legal/organizational	Legal regulations that enable security tokens trading Introduction of global standards of token trading Adaptation of legislation to market requirements Cooperation between regulators, central banks, banks Development of market ecosystem to facilitate token trading
Social/educational	Level of investor confidence Knowledge of how to use the possibilities of blockchain technology, including the issue of security tokens
Technological	Blockchain technology development Access to the Internet Protection against cyber attacks

Source: author's own study.

One of the groups of factors that have an impact on the development of the STO market includes economic factors. The investment activity of entities in the financial market depends on the overall condition of the economy. This is also related to the development of innovation and the number of enterprises, including start-ups, and the demand on the part of these entities for capital. At the same time, it is worth emphasizing here that the number of participants involved in the security tokens market is determined by social and technological factors. In the case of social factors, trust on the part of investors is of a great importance because its level, after numerous irregularities in ICO and cyber-attacks on cryptocurrency exchanges, is currently quite low. The issue of tokens would not be possible without the existence of the blockchain technology. Therefore, its development determines the development of the token market. Furthermore, one of the benefits of the issue of tokens, both for investors and companies, is their availability. This in turn is linked to the wide availability of the Internet. An important factor that has an impact on the functioning of the entire market is the existence of national legal frameworks for tokens trading, as well as cooperation with regulators and central banks. The lack of legal standards prevents tokens trading. Therefore, it can be concluded that it is the lack of legal adaptations that constitutes the greatest threat to the issuance of security tokens and the development of this market. What is also required for smooth operation is an introduction of standards for security token exchange worldwide.

On the basis of the analysis of the security market conducted, its elements and logical inference, the author created a model of connections between those factors that determine the development of the market described herein. In the model, both factors and mutual relations between them are indicated.

Figure 1 presents a model of relations between the factors that determine the development of the STO market.

Figure 1. Model of relations between the factors that determine the development of STO market

Challenges facing STO market

The ICO crisis should be treated as a stage in the evolution of cryptocurrencies. The development of STO is a consequence of decreased investors' confidence in ICO; hence, since 2019, a clear increase in the popularity and development of the Security Tokens Offering market has been observed worldwide. Although security tokens are promising both for investors and entrepreneurs, they have to overcome several challenges to become a permanent element of the investment portfolio and a source of project financing. Currently, STOs are available to accredited investors only. Table 4 presents the most important (in the author's opinion) challenges that are currently facing the STO market.

Table 4. Challenges facing STO

Challenges	Description
Introduction of legal regulations	For the safety of investors and companies, it is necessary to introduce legal regulations in individual countries. Many countries have already introduced such solutions, others are in the process of adapting the law, but still in countries such as China, Algeria, Ecuador or South Korea, token trading is prohibited.
Appropriate infrastructure for the global exchange of security tokens	In order for the market to function properly and efficiently, it is necessary to create an appropriate infrastructure. This will allow buyers and sellers to smoothly exchange security tokens around the world.
Building investor confidence	ICO anomalies have caused investors and companies to lose confidence in the issue of tokens. It is therefore necessary to restore confidence in new investment instruments.
Blockchain is a young technology.	Blockchain, owing to which STO is possible, is a new and still developing technology, with a variety of applications.

Source: author's own study.

Conclusions

Blockchain is yet another stage in the development of the Internet. Owing to its properties, such as accessibility, security through a distributed ledger and transaction transparency, a new possibility to raise capital for investment projects has been created by issuing tokens. Hence, the emergence of ICO. However, the irregularities related to the issue of utility tokens caused a loss of trust among investors and a collapse of the ICO market. The appearance of STO was a natural consequence of this crisis, as security tokens have the characteristics of securities, they are subject to legal regulations, meet all requirements related to them, and they reflect real assets.

The development of STO is strongly connected with an introduction of regulations related to cryptocurrencies trading and token emission. The largest number of emissions is observed in those countries where the regulatory framework for the functioning and development of cryptocurrency exchanges has been created. Switzerland appears to be a promising market, where the decision issued by the Swiss Financial Market Surveillance Authority (FINMA) came as a breakthrough in the issue of Security Token Offering. This decision authorized companies from the fintech category registered on the territory of that country to store deposits from raising funds in the amount of 100 million USD. In 2020, the Swiss SIX Digital Exchange announced the introduction of STO, while the Tokenstate platform announced that it had conducted the first digital transaction based on the Ethereum blockchain technology using Swiss francs.

The development of the STO market is determined by economic, legal, social and technological factors. Of all these, the most important factor seems to be the one related to legal regulations in a given country, as it determines the tokens trading. Apart from this, the introduction of legal standards has a positive influence the level of trust on the part of market participants and the risk related to investments in the STO market. The general condition of the world economy and investors' moods are also important.

Security Tokens are bringing fundraising to a new and, above all, more secure level. They solve the existing liquidity problems in connection with paper assets. In traditional financial institutions, many intermediaries are involved, which increases the time required for the transaction to be performed. Security tokens allow one to bypass these, which significantly speeds up the processes (e.g. the payment of dividends), and it reduces fees (no commission for intermediaries). It is automation that makes security tokens gain strength and become an attractive investment. Undoubtedly, this will be a challenge for the traditional financial market. However, this market is facing a number of challenges: an introduction of legal regulations adapted to technological changes, the necessary development of cryptographic market infrastructure or a restoration of trust of on the part of investors and enterprises. STOs constitute a certain bridge between the traditional world of finance and the blockchain technology, and they will certainly contribute to the development of the capital market.

The coming years will prove it whether the STO market can meet the challenges it is facing. It can be assumed that in the nearest future, the full potential of the blockchain technology will be revealed. STOs may appear to be a breakthrough in investing and raising capital, especially if those obstacles that limit a global adaptation can be overcome.

Co-Creating Enterprise Innovation with Users of Social Media

Katarzyna SAMEK

Nicolaus Copernicus University in Torun, Faculty of Economic Sciences and Management, katarzyna.samek@umk.pl, ORCID: 0000-0002-5519-8558

Abstract

Contemporary organizations should be aware that current users of social media have the potential to create and develop new innovative solutions, constituting a valuable tool for competing in the market environment. Information posted on social media is a unique source of innovation sourced from customers. Their use can take place at any stage of the innovation process. Enterprises can create crowdsourcing platforms to collect ideas at the stage of creating innovations, or improving products at the stage of innovation development, as well as test virtual products at the stage of launch. Getting ideas from social media users is not a simple task, however. Companies must create the conditions and incentives that will encourage users to co-create innovation, as well as take into account the risks associated with it. The specificity of social media is based on high interactivity and quick evaluation, which makes it difficult for companies to control the actions taken by users (Peters, Chen, Kaplan, Ognibeni, Pauwels 2013). This requires constant monitoring of the actions taken by social media users, especially in the innovation process. The key task of modern organizations is to encourage and monitor the actions of social media users to create innovation. The aim of the article is therefore to describe social media and the actions taken by clients in order to co-create innovation in enterprises. For this purpose, the Internet survey method was used. 356 social media users participated in the study. Research results show that customers accept the trend of co-creating innovation using social media. Few of the respondents, however, contribute to the creation of a new product / service offer using dedicated crowdsourcing websites. This suggests that enterprises should make better use of customers' potential in social media and encourage them to become more involved in the process of co-innovation.

Keywords: Social Media, Innovation, Business

Introduction

Modern enterprises face a huge challenge, which is to function and compete in a turbulent and changing market environment. The current ways of communicating with customers, their needs and preferences are either questioned or irretrievably passed. The offered products and services are constantly modified to meet new consumer expectations, and it is increasingly difficult to maintain a stable competitive position.

The experiences of leading companies on the market prove that the winners in the market battle are those companies that provide innovative products and at the same time respond to customer needs. Scientists and business representatives agree that the main task of modern enterprises is to constantly improve the products already offered and create new ones (Cushman, King, 1995). It is emphasized in the literature that innovations are changes consisting in the absorption of the knowledge obtained by an organization. Therefore, for companies aspiring to be innovative, an extremely important task is to constantly obtain information enabling the improvement of products and technologies, in accordance with the needs of the changing market and current technological trends (Sosnowska, Łobejko, 2007).

The rapid development of Internet services is an opportunity for companies which, striving to become competitive and innovative, focus their attention on new communication channels. Virtual communities are no longer passive members of the Internet. These communities more and more often begin to interact with business entities which, using the knowledge and experience of customers, create innovation (Hildreth, Kimble, & Wright, 1998).

Cite this Article as: Katarzyna SAMEK " Co-Creating Enterprise Innovation with Users of Social Media" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Customers are more and more often involved in the process of creating innovation, which is why the concept of co-creation was introduced to the subject of innovation. It is defined as the conscious involvement of the client in the design of a new product or modification of the current product (Tseng, Kjellberg, Lu, 2003). For this purpose, enterprises use social media, which gathers more and more users, i.e. potential customers, from year to year. They are an effective tool for obtaining information about consumer preferences and suggestions, improving the current or creating a new product offer. Currently, direct marketing is less and less effective, and online communities shape opinions about enterprises and the goods or services they propose.

The process of creating enterprise innovations with the participation of social media users

The traditional innovation process consists of several stages, from the idea of innovation to the launch of the finished product on the market.

W. D. Hoyer and others emphasize that **at the stage of generating ideas**, companies use social media in order to increase customer expenditure and the costs of acquiring ideas lower than in traditional methods (Hoyer, Chandy, Dorotic, Krafft, Singh, 2010). For example, netnography, which is used by companies, allows them to capture the attitudes, behaviors and needs of customers reported on social media. This allows you to get ideas and innovative solutions by reading the conversations of social media users. An example is the company Beiersdorf, which has collected the insights of social media users using netnography to find out what antiperspirant they need. Thus, the company found out that customers wanted an antiperspirant that leaves no stains on their clothes. Responding to the needs of consumers, Beiersdorf introduced the innovative Nivea Black & White deodorant (Bilgram, Bartl, Biel, 2011). At the stage of creating ideas for innovation, monitoring texts as part of the netnography method is an alternative way of collecting innovative ideas without actively involving customers. The information used in the innovation process is extracted by the company from informal texts and data posted on social media. On the other hand, organizing online competitions or crowdsourcing already requires active participation of social media users in the process of creating innovation. For example, American Express launched the "YourBuzz" application to collect customer feedback from media such as CitySearch, Yelp, Facebook and Twitter. Clients exchanged comments about the company. American Express, on the other hand, launched the "YourBuzz" application, from which it obtains customer opinions about the company from such social media as Facebook, Twitter and Yelp (Chan, Li, Zhu, 2015). A company may use various social media activities to generate ideas for innovation. Organize online contests to generate ideas or provide prototypes of products for testing for the purposes of innovation development. The literature lists proactive and reactive activities carried out by companies in social media. The first group is the creation of online competitions or word of mouth campaigns, and the second - media monitoring and data mining. Therefore, each company should define its range of possibilities in social media to ensure an efficient and effective innovation process (Roberts, Piller, Lüttgens, 2016).

At the stage of implementing innovations, awareness of the use of social media is key. H. Kim and D. M. Hanssens emphasize that the company's activity in social media before introducing innovations to the market is an effective form of advertising (Kim, Hanssens, 2017). It encourages potential users to search for these new products and triggers the phenomenon of viral marketing. In turn, once the innovation is implemented, social media allows companies to access feedback. At the same time, strengthening relations with the environment and increasing customer involvement in the activities of the organization.

At the stage of diffusion of innovation, social media such as wikis can create a space for the joint development of concepts, product prototypes. They enable active interaction and knowledge exchange between people. As a result, companies can develop their own design tools and use them effectively in product development (Cui, Wu, 2015). A relatively small number of contemporary companies use social media at the stage of development of the innovation process. Instead, it seems that many organizations at this stage rely on internal systems and closed networks within their own structure. For example, BMW uses the "BMW-Mini" wiki to personalize car designs by internet users and then post them on social media to gather feedback (Piller, Vossen, Ihl, 2015).

The relationship of social media and innovation

The relationship between social media and innovation is described in the literature. Table 1 presents selected authors of publications on innovations in which they emphasize the importance of social media.

Table 1: Social media and innovation - the approach of selected authors

AUTHOR	DESCRIPTION
H. Bugshan	Social media is an engine for online participation and free expression, and an economic source of open innovation
D. Roberts, F. Piller, D. Lüttgens	The use of information from social media can be beneficial for the development of new products and lead to a competitive advantage
A Androutsopoulou, Y. Charalabidis, E. Loukis	The characteristics of social innovation determine the degree of use of social media
F. von Briel	Social media can be a driver of innovation, but the success of its use is based on creating a social culture and employee readiness
H. Simula	Social media can help create innovation, but how much information a company should provide to its customers in the innovation process remains debatable
C. Laurell , C. Sandström	Social media can facilitate innovative activities in practice
W. Ooms, J. Bell, R. A. Kok	Social media is a tool that allows companies to improve their innovation capacity
J. Q. Dong, W. Wu	Social media enables the creation of open innovations, and allows organizations to take advantage of strategic management opportunities based on user-generated content

Source: own study based on H. Bhimani, A.-L. Mention, P.-J. Barlatier, Social media and innovation: A systematic literature review and future research directions, "Technological Forecasting and Social Change", 17 October 2018, p. 124.

There is also a typology of social media used by organizations for innovative activities in foreign literature. The first group of *Public Social Media* includes platforms such as YouTube, Facebook, Twitter and LinkedIn. They enable companies to communicate with customers and create a space for discussion about the company and products. In this way, organizations obtain feedback, which they use to improve products. The second group of *Company-built social media*, which includes platforms based on social functions developed internally by the organization. They are used to interactively use interactions (e.g. NASA @ work) or measure the perceptions of external users (e.g. IBM JAM, Dell IdeaStorm, etc.) (Guinan, Parise, Rollag, 2017). The third group consists of the so-called *Company-licensed social media* are proprietary solutions developed by companies that are usually used as an internal social media platform (e.g. IdeasProject, MS 365 Yammer). They enable employees to communicate internally and collaborate on projects. The last group consists of the so-called *Innovation intermediary social media*, represents organizations referring to specialized innovation tools, such as Innocentive, Get Satisfaction, etc., to create innovative services tailored to the needs, such as internal or external competitions on social media (King & Lakhani, 2013).

Social media is changing the way companies communicate with the internal and external environment. They are based on participation, creativity and low entry barriers. Thus supporting the process of creating innovation. There are two main approaches to using social media to drive innovation in today's organizations. In the basic approach, already innovative companies use them to obtain ideas to improve existing products and services or to develop new ones. Such organizations actively participate in the life of Internet communities, listen to and participate in online discussions (Nambisan, Nambisan, 2008). In turn, at an advanced level, companies adapt social media for internal use. They use Facebook groups for internal communication or build their own social media. For example, the IBM project "Innovation Jam" allows the company to transform the sources of ideas into new products and solve problems reported from its colleagues and partners (O. M. Bjelland, R. C. Wood, 2008).

The use of social media in innovation can take many forms. It can be creating ideas, broadcasting information, creating a communication forum, tracking trends, motivating and collaborating users to

participate in the company's activities. The purpose of all these activities is to collect and analyze information from the stakeholders who make up the social media environment. Choosing the right type of social media depends on the complexity of the information sought. It can therefore be assumed that organizations deliberately use various types of media to obtain rich and diverse sources of information.

Co-creating innovation of enterprises with users of social media - selected research results

Methodology

Data on the co-creation of enterprise innovations by users of social media were obtained as part of a survey with the use of a questionnaire. Due to the specificity of the studied phenomenon - the general availability of social media - the spatial extent of the study was not defined. The study covered 1,500 people from closed groups of social media users, of which the feedback was 4.21%, in the number of 356 correctly completed questionnaires. Moreover, it was assumed that only people using social media would take part in the survey. For this purpose, a convenient method of sample selection (from the group of non-random methods) among 356 women and men was used. Microsoft Excel 2016 spreadsheet was used to analyze the data obtained from the study. In the future research will be continued using a more extensive research methodology.

The population covered by the study was homogeneous in terms of age (it is almost entirely composed of people aged 19-35), with a vast majority of women (69.40%) and people with secondary education (56.50%). The average user of social media is therefore, in the light of the obtained empirical material, a woman aged 19-35 with secondary education. This social media user profile is taken as the essential benchmark for further analysis. In addition, the specificity of social media allows us to say that they are mainly used by young people, aged 19-35. This justifies such a large representation of this age group in the sample covered by the study.

Before identifying the actions taken by users in social media to create innovation in enterprises, the types of media they use were analyzed. The list of social media in which the respondents declared their activity along with its frequency is presented in Table 2. In order to determine the frequency, a 5-point scale was used, the individual categories of which meant, respectively: 5 - very often, 4 - often, 3 - sometimes, 2 - rarely, 1 - very rarely, 0 - never. A median value was also determined for each value in the generic group. This allowed us to see what and to what extent it is preferred: the higher the median value, the clearer the preferences, the smaller - the more blurred and dispersed. More than one answer could be chosen.

Table 2: Average frequency of using social media by the surveyed users

SOCIAL MEDIA (SM)	AVERAGE FREQUENCY OF SM USE BY USERS (scale 1-5, where 0 - never 5 - very often)
Facebook	4
YouTube	4
Instagram	3
Wikipedia	3
Google+	2
Snapchat	2
Chats	1
Forums	1
Myfiles	1
Pinterest	1
Bank of Ideas	0
Blip	0

Blogger	0
Blogspot	0
Blox	0
Dailymotion	0
GoldenLine	0
Linkedin	0
Myspace	0
Picasaweb	0
Tumbrl	0
Twitter	0

Source: own study

Among the various social media, the respondents often (4) use Facebook and YouTube. Sometimes (3) from Instagram and Wikipedia. As for other social media, respondents rarely (2) use Google+ and Snapchat, and very rarely (1) use Pinterest, chats and internet forums. However, they do not use (0) such social media as: Bank of ideas, Blip, Blogger, Blogspot, Blox, Dailymotion, Flickr, GoldenLine, Linkedin, Myspace, NaszaKlasa.pl, Picasaweb, Tumblr, Twitter and Wordpress.com.

Later, the main issue of the activity that users undertake in social media in relation to co-creating innovations of enterprises will be discussed. This activity was divided into two groups:

1. Activities undertaken by enterprises in social media aimed at users of these media aimed at using their ideas to co-create innovation (Table 3).
2. Actions taken by users of social media on their own initiative that can be used by enterprises to co-create innovation (Table 4).

Table 3: Activities undertaken by enterprises in social media aimed at users of these media aimed at using their ideas to co-create innovation

ACTIVITIES UNDERTAKEN BY ENTERPRISES IN SOCIAL MEDIA AIMED AT USERS OF THESE MEDIA AIMED AT USING THEIR IDEAS TO CO-CREATE INNOVATION	PARTICIPATION OF SOCIAL MEDIA USERS	
	n	%
Reacting to company posts (e.g. using the buttons "I like it", "great", "ha ha", "I'm sorry", "wrr")	68	19,1
Share company posts with friends	38	10,7
Active participation in competitions organized by enterprises	35	9,8
Reporting product defects	34	9,6
Report product benefits	34	8,7
Active contact with company employees (e.g. reporting problems via Facebook Messenger, chat, etc.)	23	6,5
Reporting willingness to test products of enterprises	21	5,9
Reporting opportunities to improve marketing activities	9	2,5
Reporting product improvement opportunities	8	2,2
Active participation in crowdsourcing websites of enterprises	5	1,4
Reporting opportunities for improvements in ongoing business processes (e.g. customer service)	4	1,1

Source: own study

The results of the survey show that a small proportion (21.9%) of the surveyed users of social media participate in activities undertaken by enterprises in these media aimed at using their ideas to co-create innovation. Significantly more respondents (78.1%) do not participate in this type of activity. Users who engage in pro-innovation activities carried out by enterprises in social media show their activity

mainly in responding to company posts (19.1%), sharing company posts with friends (10.7%), and actively participating in competitions organized by enterprises. The smallest number of social media users surveyed reported to the company the possibility of improvement in their business processes (1.1%). It is noteworthy that only 1.4% of users actively participate in crowdsourcing websites of enterprises, which means that the use of this tool in the process of creating innovation is not very popular. This may result from the fact that most enterprises still create innovations in a "top-down" manner, relying solely on the knowledge and skills of their employees. To a small extent, using external ideas, tips or ideas inherent in social media.

Contemporary users of social media also take their own initiative to co-create innovation. Consequently, Table 4 shows the own-initiative actions taken by social media users that can be used by enterprises to co-create innovation.

Table 4: Actions taken by users of social media on their own initiative, which enterprises can use to co-create innovations

ACTIONS TAKEN BY USERS OF SOCIAL MEDIA ON THEIR OWN INITIATIVE, WHICH ENTERPRISES CAN USE TO CO-CREATE INNOVATIONS	PARTICIPATION OF SOCIAL MEDIA USERS	
	n	%
Posting your own opinions, recommendations and reviews of products / services	126	35,3
Like company fanpages	77	21,6
Observation of company fan pages	60	16,9
Evaluating products (e.g. using the so-called "stars")	58	16,3
Posting information that enables the improvement of marketing activities	43	12,1
Responding to the company's activity	36	10,1
Posting information about preferences and shopping needs	11	3,1
Post solutions to problems related to the use of products	6	1,7
Posting information that enables the improvement of ongoing business processes	5	1,4

Source: own study

The most common activities undertaken on their own initiative by social media users to co-create innovation include:

- posting own opinions, recommendations and reviews of products / services (35.3%),
- liking the company's fan pages (21.6%),
- monitoring company fan pages (16.9%).

The smallest number of users publish information that enables the improvement of their business processes (1.4%).

Discussion

Research shows that customers accept the trend related to co-creating product innovations in social media and undertake various activities in this area. Most of them post their own opinions, recommendations and reviews about products or services. Few of the respondents, however, contribute to creating a new product / service offer, for example through crowdsourcing websites. This suggests that companies should make better use of their clients' potential in social media and encourage them to become more involved.

Today's social media businesses demonstrate top-down communication, which means conveying certain content to buyers. However, the presence of companies in social media cannot be based only on the exchange of information, but should be based primarily on gaining opinions and ideas. Therefore, organizations should focus less on creating controlled messages, and more on creating

online communities whose members freely exchange opinions about products and services, as well as willingly co-create innovative solutions.

However, it should be hoped that the experiences of leading companies will be an example for other companies of how to effectively use social media in creating innovations, and that a new phenomenon - social media marketing - will be discovered by an increasing number of marketing specialists. The task of modern companies is to make social media users aware of the role they play in the development of their organization. They must not forget about encouraging customers to conduct pro-innovation activities in social media. Clients and users of social media must perceive themselves not only as the recipient of enterprise innovations, but also as their co-authors. Customers decide about the success of innovative solutions.

Summary

Due to the dynamics of changes in both domestic and international markets, modern companies are required to function flexibly, react quickly to changes, and above all, an innovative approach to management. Organizations that base their competitive position on stability, do not respond to market changes, do not provide innovative solutions, have no chance of market success. Permanent observation of the market, quick reaction to changes and delivery of innovative products and / or services are a must today. Such activities bring the company many benefits. However, changes must be implemented and approved by employees. Innovations often affect changes in the organizational structure of the company. The involvement of employees, their mobility and flexibility significantly affects the effectiveness of the introduced changes and the company's market position. The level of the company's competitiveness depends on the activity and courage of an enterprise in introducing innovative, innovative ideas.

In the era of globalization and increased competitiveness, the ability to create innovation becomes the main condition for the success of an organization. Most modern companies recognize, and others seek to recognize innovative activities as a fundamental issue. Innovations increase the attractiveness of products and services, which entails an increase in sales, and this in turn determines the competitive position of the company.

Modern models of mass collaboration differ from the existing ones. More and more companies are open to cooperation with customers. For this purpose, they transfer their problems, ideas and activities to the virtual world. The analysis of the research results obtained in the course of this study allows us to identify several solutions for enterprises. Their use will allow organizations to take advantage of the opportunities offered by social media in creating innovation. The following tips should be indicated:

- Organizations aspiring to be innovative should "listen" to their clients who are present on social media. Users, feeling a certain anonymity, signal problems related to the use of a given product or the operation of a given company, as well as indicate market needs and expectations. These are the key issues in creating innovations that every company should take care of - catch these problems and try to solve them. In this way, the company, acquiring the knowledge of customers, is able to better match the shape, functionality, usability of new products or services to market needs. The information obtained in this way can be used by the company to create innovations within the product;
- Companies should be aware that through their activity in social media they acquire new customers who constitute a new source of ideas and information for them to create innovations
- A company conducting pro-innovation activities in social media should not focus only on one age group of its recipients. It is worth reaching younger users with the message and advertising. Young people more often than older people know what is popular on the market, what products are popular, what activities of companies are the most desirable, and finally what innovations they would like to be available to them. This is valuable knowledge for any company. The key is to encourage the young generation to take actions aimed at co-creating innovation in a given enterprise. In this context, it is important to adapt the form of communication to the appropriate age group. However, this does not change the fact that in

order to obtain the so-called Feedback from social media users must encourage them to do so and demonstrate creativity that will stand out from the competition. An effective solution here are prizes, gadgets, products to be tested, which are handed over to customers in return for the ideas submitted.

– On the one hand, the widespread use and growing popularity of social media bring benefits to companies, but on the other hand, the abundance of information makes it difficult to extract the information that is important in creating innovation. On social networking sites, customers are eager to share their opinions on products and services of various companies. Often, these opinions provide guidance on what needs to be improved, improved or implemented. A company that captures such information in time can deliver innovation to the market in line with customer needs, and at the same time strengthen its position on the market. It is therefore necessary to constantly monitor social media. The use of solutions such as Brand24, Squarelovin, Sotrender, Social Blade, SentiOne or Google Analytics facilitates constant monitoring of the content posted by social media users. These tools allow you to analyze statistics on any brand and provide tips and recommendations in the field of company activities in social media. In the context of creating innovations, this data provides the company with information on whether the introduced innovation is popular with potential recipients or requires some improvement.

Many modern enterprises treat social media only as an effective marketing tool (for promotion, for communication with clients). They are rarely seen as an instrument for creating innovation. On the Internet, there are invaluable amounts of knowledge, information and tips that can be successfully used in designing a new or expanding the current product offer. It will be an innovative and competitive enterprise that sees this information and the innovative potential of social media sooner than its competitors. In order to achieve this, the company must know not only the mechanism of operation of these media, but also know how to monitor the content posted on them. It is necessary here to constantly expand knowledge in the field of new technologies by employees responsible for marketing and innovation. The modern, highly competitive market is characterized by social media monitoring tools. The competitive position of an organization depends not so much on the awareness that such tools exist, but on their effective use.

Due to the fact that social media is a phenomenon that has only gained popularity in the last few years, there is a lack of scientific studies devoted to social media in business. These topics are so far only a small part of scientific publications on the Internet and Internet marketing. However, it is hoped that the examples of large companies will become an inspiration also for smaller entities that will learn to successfully use new possibilities of communicating with customers and obtain valuable information from them, which is carried by social media.

Abstract

Manufacturers and retailers of the food industry in Hong Kong are adapting their businesses to the disrupted market triggered by the coronavirus pandemic, social and political issues, economic recession, and trade tensions. The adoption of blockchain technology is revealed as a breakthrough to transform the food industry for serving the market with new consumption behaviours and adjusted supply-chain practice. Industry giants like Nestlé and Walmart are utilising the blockchain technology to improve business performance, while consumers' acceptance of using the blockchain-enabled application in purchasing food is not yet known. This conceptual paper aims to explore literature and propose a conceptual model related to consumers' acceptance of blockchain-enabled applications in purchasing food to address this research gap. Combining the technology acceptance model (TAM) and the unified theory of acceptance and use of technology (UTAUT), social influence and self-efficacy are proposed to determine consumers' intention to use the blockchain application with perceived usefulness and perceived ease of use as the intermediating variables.

Keywords: blockchain, food market, TAM, UTAUT

Background

Hong Kong business market is facing a tough situation owing to COVID-19 outbreak, social unrest, China-US trade tensions, global financial recession, and political uncertainty. The retail sales are expected to shrink 19.7%, approximately HKD 346 billion, for the full year of 2020 (PricewaterhouseCoopers, 2020). According to the statistics released by Census and Statistics Department (2020), the value of total retail sales for the first six months of 2020 dropped by 24.8% compared with the same period of last year. The sales of medicines and cosmetics had the most significant drop of 57.4% and followed by jewellery and luxury goods (-56.5%), books, newspapers, stationery and gifts (-41.3%), footwear and clothing accessories (-39.7%), wearing apparel (-38.8%), as well as food, tobacco, and alcoholic drinks (-13.%). However, there are segments showing resilience. The sales of commodities in supermarkets (+4.5%), fuels (+8.4%), and furniture and fixtures (+0.3%) recorded a slight increase in the same period.

Although the market was disrupted, new consumption behaviours and supply chain practice evolved that open up new opportunities and plans for food retailers. Consumers shifted their shopping practice from brick-and-mortar stores to online shops (PricewaterhouseCoopers, 2020). They have more expectations on the purchase experiences than before, and this change will become permanent. Also,

Cite this Article as: Helen WONG, Carmen SUM And Hau-ling CHAN "Consumers, Are You Ready to Accept Blockchain Technology In Purchasing Food?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the supply chain has been reconfigured to apply dual or multiple channels in response to the supply chain disruption. Some manufacturers and retailers also integrate the C2M (customer to manufacturer) model into physical channels to meet customer demands. Online and social channels are used to facilitate transactions with ultimate customers.

The market disruption and behavioural change ignited food retailers' transformation towards digitalisation to catch up with the emerging trend (Xiao & Fan, 2020). Manufacturers and retailers are heading to different recovery and revitalisation strategies to restart their businesses, and that directed the spotlights on the use of blockchain technology. Nestlé and Walmart are embracing blockchain technology to improve operational costs and efficiency, transaction speed and transparency, as well as data security and trust (Castillo, 2020). However, are customers ready to accept the blockchain technology or its application when purchasing food? Lian *et al.* (2020) raised the perception gap existed between service providers and consumers, and that deserved further investigation. Consumers' acceptance of using blockchain application in the food industry has not yet been covered in the literature. This conceptual paper intended to explore the literature about consumers' acceptance of blockchain technology, and then propose a conceptual model to measure their acceptance of blockchain-based applications in the food retailing sector.

Literature Review

Blockchain Technology

Blockchain technology is a distributed ledger. It was first created by Satoshi Nakamoto for the cryptocurrency network (Reiff, 2020). It began with the digital currency, Bitcoin, in October 2008 (Clohessy & Acton, 2019). Its second generation was applied to assets and trust agreements – smart contracts. This idea was initiated by Ethereum, which was a blockchain-based software platform. The coming generation of blockchain will focus on scaling and address the problems in transaction process times and bottlenecking (Reiff, 2020).

Blockchain could be categorised as public, private, and permissioned blockchains (Seth, 2018). A public blockchain has a self-governed, decentralised, and authority-free nature. It is open to everyone to join, leave, read, audit, and contribute to the blockchain network. Bitcoin is an example of the public blockchain. A private blockchain is a closed network with an authentic and verified invitation that is available for selected and trusted parties. The owner of the blockchain has the rights to edit, delete, or override the entries on the blockchains. The last one is permissioned blockchain, which allows anyone to join after verification of the identity. Each participant will be granted designated permissions to perform certain activities on the network. For example, suppliers could manage a permissioned blockchain for its business partners and customers with different access rights. Wholesalers and retailers are permitted to access and edit information about the products and distribution while customers may be granted to read product information only.

Blockchain Technology for Food Retailing

Every food product has a story from birth to consumption. Blockchain technology enables the traceability, certifiability, verifiability, and trackability of food products (Montecchi *et al.*, 2019). These blockchain capabilities enhance the transparency of provenance and supply-chain information for food products (Edwards & Strathcole, 2020) and minimise customers' perceived risks in transactions (Montecchi *et al.,* 2019). Payment and loyalty programme could be facilitated as well (Baird, 2019; Bryanov, 2019).

The origins and supply chain histories of foods could be traced and revealed without faults (Montecchi *et al*., 2019). Suppliers, channel partners, and consumers could trace the food journey about the origin, the processing stages and handlers, and other supply chain information, which instil confidence in the products and transactions among trade partners and the ultimate consumers (Accenture, n.d.). More information about the foods, for example, fair trade, environmental initiatives, potential allergens, and

specific ingredient could also be accessed in an easy way (Accenture, n.d.). Ultimate consumers can get accurate product information to facilitate their purchase decision. Perceived financial risks could be minimised (Montecchi *et al*., 2019).

Moreover, blockchain technology allows for certifications and verifications (Montecchi *et al.*, 2019). Its digital ledger record could certify the authenticity and integrity of goods, which offers an anti-counterfeiting solution for food products. Under the permissioned setting, some permitted parties could add or edit the information on certifications while some other parties like retailers and consumers could only access the certificate information. This function could avoid any unauthorised changes and ensure the information validity. To the manufacturers, the food quality is affirmed while the brand image is enhanced. This verification system also allows them to differentiate from those without such a system. To the customers, they could avoid fraud and counterfeiting goods. It could ease their decision-making process. Customers' perceived psychological, physical, and social risks could be reduced (Montecchi *et al*., 2019).

When blockchain technology is used, product custody could be tracked and assured (Montecchi *et al*., 2019). The food quality, storage and delivery information are revealed along with the supply chain process. Consumers can easily access provenance knowledge, like faulty logistics and transportation and improper product storage, which reduce the performance risks in their purchase (Montecchi *et al*., 2019). To suppliers, they could rely on the information to evaluate the quality of intermediaries and determine the partnership or cooperation in the future. The corporate image of suppliers could be enhanced.

Blockchain technology could also facilitate transaction payment with cryptocurrencies without any intermediaries and enhancing customer experiences and loyalty with a more flexible loyalty programme (Baird, 2019; Bryanov, 2019). Blockchain is safe and secured to provide the above functions, provided that no more than 50% of blocks are controlled by one group of miners (Binance Academy, 2020).

Development of Conceptual Model and Research Propositions

Research Gap

As a kind of technological innovation for different industries, blockchain technology is receiving more focus in the literature. Related research is lacking, and scholars are asking for more investigation, for example, further empirical validation (Grover *et al.,* 2019), additional constructs or drivers (Albayati *et al.,* 2020; Knauer & Mann, 2020), supplier and consumer perception gap (Lian *et al.,* 2020), different samples (Lee *et al.,* 2019; Queiroz & Wamba, 2019), analytical research (Nuryyev *et al.,* 2020), updated study to address the innovation diffusion stage (Lian *et al.,* 2020), and the inclusion of more factors for the retail industry (Miraz *et al.,* 2020). Given the above gaps, we suggest focusing on the food retailing sector and address essential drives in the acceptance model.

Research Scope

We propose to study the blockchain application in the food retailing sectors, including fruits, meats, dairy, and vegetables. They are necessities that consumed daily. More product information could minimise consumers' perceived risks, facilitate their decision-making process, and enhance their satisfaction and repurchase intention. Blockchain technology could take an essential role in the food business. It facilitates the traceability, certifiability, verifiability, trackability and payment of food products. Although some corporations and brands are using blockchain technology in business, there is a need to examine consumers' acceptance of blockchain application in purchasing food (Miraz *et al.,* 2020).

Conceptual Model & Research Propositions

In the information system research, technology acceptance model (TAM) developed by Davis (1985) was mostly used. It received significant support in its simplicity, generalisability, and validity across domains and technologies (Nuryyev *et al.*, 2020; Turner *et al.*, 2010). TAM had been adopted to examine the acceptance of blockchain technology with reliable support in its model fit and explanatory power at both end-user and supplier levels in the literature (e.g. Albayati *et al.,* 2020; Francisco & Swanson, 2018; Kamble *et al.* 2019; Lian *et al.*, 2020; Nuryyev *et al.*, 2020). It has four core constructs: intention to use, attitude towards technology, perceived ease of use, and perceived usefulness (Davis, 1985). Different factors were to have a significant effect on perceived ease of use and perceived usefulness of blockchain technology or its application. Examples included social influence (Albayati *et al.,* 2020; Nuryyev *et al.*, 2020), Individual-technology fit and task-technology fit (Lian *et al.*, 2020), innovativeness (Nuryyev *et al.*, 2020), subjective norms (Kamble *et al.* 2019), and self-efficacy (Nuryyev *et al.*, 2020). The effect of some other factors was absent in blockchain research, for instance, perceived safety and network externality (Lian *et al.*, 2020), discomfort and security (Kamble *et al.* 2019).

Another popular model used in predicting the adoption of blockchain technology is the unified theory of acceptance and use of technology (UTAUT). It was formulated by Venkatesh *et al*. (2003) through unifying eight information system acceptance models in research. It contains one dependent variable (use behaviour) and one intermediating variable (behavioural intention), and four predictors (performance expectancy, effort expectancy, social influence, and facilitating conditions). Its performance expectancy overlapped TAM's perceived usefulness, whereas its effort expectancy equals to perceived ease of use (Venkatesh *et al*., 2003). Social influence corresponds to the social image, social factors, or subjective norms. Facilitating conditions imply perceived behavioural control, self-efficacy, or compatibility. The path relationships and model fit derived from UTAUT in blockchain research received mixed support. Some of the UTAUT predictors were considered as the antecedents of attitude and behavioural intention of the TAM in other blockchain research.

Considering the generalisability, reliability, and validity of TAM and UTAUT in blockchain research, we propose to combine these two models to explore consumers' acceptance of blockchain technology in the food industry with internal and external predictors (Figure 1). The interrelationships among perceived usefulness, perceived ease of use, and behavioural intention will be examined, following the study of Nuryyev *et al.* (2020). The following research propositions are proposed:

P1: Consumers' perceived usefulness positively influences their intention to use the blockchain application.

P2: Consumers' perceived ease of use positively influences their intention to use the blockchain application.

P3: Consumers' perceived ease of use positively influences perceived usefulness of blockchain application

Secondly, two antecedents are proposed to predict consumers' acceptance of blockchain application – social influence and self-efficacy. Social influence is an external factor (e.g. peers or people surrounding) that drives consumers to adopt new technology. It interchanges with subject norms and social image. Its effect on perceived usefulness was mostly supported across studies using TAM or UTAUT, for instance, Albayati *et al.* (2020), Kamble *et al.* (2019), Nuryyev *et al.* (2020), and Queiroz & Wamba (2019). Another predictor is self-efficacy, which is an internal factor about an individual's belief in their ability to use new technology (Nuryyev *et al.,* 2020). It equals to facilitative conditions or behavioural control, which has been considered as the direct predictor of behaviour intention in UTAUT. However, mixed findings were reported in blockchain research, no matter TAM or UTAUT was used. Self-efficacy was found to have a strong effect on perceived ease of use (Nuryyev *et al.*,

2020) while its influence on behavioural intention was weaker (Kamble *et al.,* 2019; Queiroz & Wamba, 2019). We propose to measure the effect of self-efficacy on perceived ease of use. The following two research propositions are presented:

P4: Social influence positively influences perceived usefulness of blockchain application

P5: Self-efficacy positively influences perceived ease of use of blockchain application

Abstract

In this paper we review the state of the Social Security system in Greece in September 2020, after the economic crisis and during the health crisis of coronavirus. **A**. The major reforms to the Social Insurance System were initiated by the Laws **4387/2016 and 4670/2020.**The above Laws are important and need to be analyzed because International assignees, their assignment program managers and their international tax service providers need to take note of these important changes, which will impact the administration of social security in Greece. **B**. More specifically, the new rates and thresholds may raise international assignment costs as a greater number of employees are now part of the Social Security "net" and employees and employers may be subject to higher contribution rates**. C.** We present the functions of the Unified Social Security Fund, named **"E.F.K.A."** and the Unified Supplementary Insurance and One-Off Benefits Fund, named "**E.T.E.A.E.P**." **D**. Furthermore, we compare the countries which belong to the Organization for Economic Cooperation and Development (OECD) with respect to two important and internationally recognized measures for the depth and intensity of Social Policy. The measures which we use are the following: **Net Pension Replacement Rate (NPRR) and Gross Pension Wealth (GPW).**

Keywords : Social Security System ,Greece, Coronavirus

Introduction

Greece's *Law 4387/2016* has reformed the country's social security system. It has streamlined the system and its very disparate programs and introduced a number of new concepts. Furthermore, the new law expands the application of insurance coverage to other areas of compensation and imposes *revised contribution rates*. It also attempts to defer some contributions to the future. Because of the extent of the changes, there remain a number of uncertainties that we expect will be clarified through the issuance of Ministerial Decisions.The new Social Security funds,introduced by Law 4387/2016 are presented in the sequel.(See KPMG)

FRANGOS, Konstantinos C.FRANGOS, Panagiotis PLAKUDAKIS And Panagiotis EVANGELOPOULOS " On the State of The Social Security System in Greece in 2020 And Projections of The Strength of The Merged Social Security Funds After the Economic and The Health Crisis of Coronavirus" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Unified Social Security Fund (E.F.K.A.)

A new Social Security fund is established, the "Unified Social Security Fund" (E.F.K.A.). As from 2017 it has absorbed the existing main social security funds (i.e., I.K.A. – E.T.A.M., E.T.A.P. – M.M.E., E.T.A.A., O.A.E.E., etc.).

Unified Supplementary Insurance and One-Off Benefits Fund (E.T.E.A.P.)

The existing "Unified Supplementary Insurance Fund" (E.T.E.A.) is renamed "Unified Supplementary Insurance and One-Off Benefits Fund" (E.T.E.A.P.).

New Common Registry

A Common Registry is to be established for all persons and entities that are liable to pay both social security contributions and taxes. The Registry will provide for common policies for registration, filing, payment and the issue of certificates of payment.

Social Security Contributions: Base and Rates

Fixed amount of Renumeration Included in the Base

Employee renumeration of any type, excluding extraordinary benefits of a social nature (wedding, birth of children, death, and severe disability benefits) and up to a stated ceiling (see below), is subject to social security contributions.

As of the publication of the law, the maximum monthly remuneration (ceiling) which is subject to insurance contributions of any type is limited to ten (10) times the basic employment salary of a non-married employee of over 25 years of age.

Therefore, the current ceiling is now increased to EUR 5,860.80 from EUR 5,543.55 per month.

However, due to uncertainty in the law, it appears that the basis of calculation for the health element of social security contributions might not be limited to the above ceiling.

Individuals/Employees Covered

In accordance of the law, the following categories of people and earnings are covered, for the first time, under the provisions governing "earned income from employment":

- managers, general managers, managing directors, or cooperating board members, administrators of companies or cooperatives.
- members of Boards of Directors.
- salaried lawyers, irrespective of the year they were insured,
- insured persons who, until the entry of the law in force, were insured with E.T.A.A. and are employed by virtue of an employment agreement (for instance, engineers, doctors), irrespective of the year they were insured,
- self-employed persons paid on the basis of invoices issued for their services to one or two clients (it is not clear from the law how this provision will be applied in practice).

Contribution Rates

Main Pension Contributions

All the above employees and professionals are subject to the main pension contributions of 6.67 percent of their total remuneration as defined above, plus 13.33 percent paid by the employer.

Supplementary Pension Contributions

- As of 1 June 2016 and until 31 May 2019, the supplementary pension monthly contributions rate is set at 3.5 percent for the employee and 3.5 percent for the employer calculated on amounts as above described.
- The above rates are reduced to 3.25 percent and 3.25 percent respectively as of 1 June 2019 and until 31 May 2022, and thereafter at the rates in existence at 31 December 2015, i.e. 3 percent each.
- The above supplementary pension rates can be reduced during the six-year period from 1 June 2016 to 31 May 2022, by a decision of the Ministry of Employment, Insurance and Social Solidarity depending on the level of collectability achieved.

Health Care Contributions

Health contributions for employees and other categories insured with E.O.P.Y.Y. are set at 7.10 percent of the remuneration of any nature, with 4.55 percent being borne by the employer and 2.55 percent being borne by the employee. The E.O.P.Y.Y. is the National Organization for Healthcare Provision, which resulted from the unification of most of the health-care funds in Greece, including the Private Employees' Fund (I.K.A.), the Farmers' Fund (O.G.A.), the Public Employees' Fund (O.P.A.D.), and the self-employed/Entrepreneurs' Fund (O.A.E.E.). The E.O.P.Y.Y. furnishes health services to participating members, pensioners, and their registered dependents.

One-off Benefit

As of 1 January 2017, the one-off benefit contributions payable by insured persons who were insured as of 1 January 1993 and after to funds to be absorbed by E.F.K.A. will be set at 4 percent of the employees' remuneration subject to insurance and of the net taxable income of the self-employed individuals. No employer's contributions are envisaged.

The contributions of persons insured before 1 January 1993, continue to be regulated by the provisions of the original funds absorbed by E.T.E.A.P., as long as they provide for such a benefit.

Consequences of implementation of Law 4387/2016

According to Mouratidou(2019),the implementation of Law 4387/2016 is a severe step backwards which inhibits people from being optimistic about the future of social security in Greece,for the following reasons:

(a). Law 4387/2016 has introduced the establishment of the Unified Social Insurance Institution (EFKA).

(b). It also changed the pension system from "pay as you go" to a "funded" pension scheme based on individual accounts from 2002 onwards. However, the earnings of prospective pensioners have been shrinking since after the

onset of the crisis. This means that in the future the pensions will be very low.

©. This Law also sets the gradual abolition of the Social Solidarity Pension Allowance (EKAS) and repeals it in full from those who retired after its enactment. EKAS was granted to support pensioners with low income (Law 2434/1996). The abolition of this allowance is expected to have negative impact on those pensioners.

(d). This Law also includes harsh limitations on survivors' pensions.National pension amounts to €384.00 but it is reduced proportionately for those who have not completed 20 years of insurance throughout their working lives or for those residing in Greece for less than forty years.

According to Tinios(2010), Robolis(2013), Fragos et.al. (2012), Petmesidou(1991;1996;2006;2010;2011;2012;2013a;2013b;2014), although the country still needs to

deal with effects of the latest economic downturn,the interventions of the post-crisis governments do not differ from those in the past.

New Social Security Law enacted

Law 4670/2020, enacted on 28 February 2020, introduces significant changes to the Greek social security system, some with retroactive effect to 1 January 2020.

Key features of the new law include the following amendments applicable from the dates shown.

Main features of Law 4670/2020

As from 1 January 2020:

- The social security contributions (SSC) payable by salaried lawyers, engineers, and doctors in respect of welfare (lump-sum pension), are calculated according to certain SSC categories and not the individuals' gross income.
- For lawyers, the same basis (certain SSC categories) applies to SSC in respect of the supplementary pension.
- The SSC payable by freelancers and self-employed individuals is calculated according to certain SSC categories and not the individual's taxable income.

As from the date of enactment of the legislation (28/02/2020):

- Individuals receiving a pension who also derive income on which SSC are payable (e.g., from salaried employment, freelance work, or self-employment) will be subject to a 30% reduction in their gross pension.
- Salaried employees who also are self-employed may be exempt from paying SSC in respect of their income from self-employment where their gross monthly salary exceeds EUR 930.
- Directors whose monthly gross fees exceed the statutory minimum gross salary (EUR 650) will be entitled to benefits for 25 days per month.

As from 1 March 2020:

- The Social Security Institute for Main Pension & Medical Care (EFKA) will be renamed e-EFKA. The Social Security Institute for Supplementary Pension & Welfare (ETEAP) will be abolished and its functions transferred to the e-EFKA on the same date.
- New insured persons will be registered electronically with the e-EFKA, and no longer will have to go to the local social security office.
- Employers involved in private construction projects will be registered electronically with the e-EFKA.
- Medical opinions provided by doctors authorized by the e-EFKA, required for the payment of sickness allowances, maternity allowances, and salary paid during sick leave, must be submitted electronically by the doctor to the e-EFKA. Salaried employees must apply electronically to the e-EFKA for the payment of sickness allowances.
- The data contained in employers' monthly SSC return (Form APD) will be electronically cross-checked prior to submission with the data on the "ERGANI" database system. The APD must then be finalized and submitted by the deadline.

As from 1 June 2020:

- The SSC rates for full time salaried employees will be reduced by 0.9% (a 0.42% and 0.48% reduction in the employee and employer contribution, respectively). The reduction will apply

to employees who are insured with the e-EFKA with respect to the unemployment (OAED), Workers' Health Organization (OEE), and Workers' Housing Organization (OEK) components of the social security scheme. (see Miltsanidis,A.(2020)).

Comparison of the Countries which belong to OECD with respect to Net Pension Replacement Rate (NPRR) and Gross Pension Wealth (GPW).

First of all,we give the following definitions:

Definition 3.1
Net pension replacement rate

In a study by OECD (2020) The net replacement rate is defined as the individual net pension entitlement divided by net pre-retirement earnings, taking into account personal income taxes and social security contributions paid by workers and pensioners. It measures how effectively a pension system provides a retirement income to replace earnings, the main source of income before retirement. This indicator is measured in percentage of pre-retirement earnings by gender.

Source: OECD (2020), Net pension replacement rates (indicator). doi: 10.1787/4b03f028-en (Accessed on 12 September 2020)

Definition 3.2

Gross Pension Wealth

Gross pension wealth shows the size of the lump sum that would be needed to buy a flow of pension payments equivalent to that promised by the mandatory pension system in each country. It is affected by life expectancy and by the age at which people take their pensions, as well by as indexation rules. This indicator is measured as a multiple of annual gross earnings by gender.Table 1 presents the Data for Net Pension Replacement Rate for each country of OECD. Table 2 presents the Data for Gross Pension Wealth for each Country of OECD. Men. Multiple of annual Gross Earnings by Gender.

Table 1: Data table for: Net pension replacement rates, Men, % of pre-retirement earnings, 2018 or latest available

Concluding Remarks

Considerable progress has been done on the improvement of Greek Social Security System by Law 4670/2020.

From table 1 we find that Greece occupies the 34th position out of 49 Countries,with score 51.1 below the European Union(28 Countries average(=63.5))

From table 2 we find that Greece occupies the 17th position out of 49 Countries,with score 10.2 above the European Union(28 Countries average(=9.2))

This shows that the size of the lump sum that would be needed to buy a flow of pension payments equivalent to that promised by the mandatory pension system in Greece is large because the life expectancy rate in Greece is the biggest out of all the Countries in European Union.

Abstract

Given the very large sums being spent in public procurement systems, it is very important to analyse the distribution of procurement contracts by types (products, services and works) as it may reveal a number of deficiencies in terms of value, evolution and distribution by destination (consumption or investment) in various economic periods. The article describes the significant particularities of public procurement of services, products and works, the differences between them, analyses the use of public procurement of works (investment) as a factor for accelerating the economic recovery in case of the 2009-2010 economic crisis and studies the evolution of the types of public procurement contracts awarded in Romania between 2007 and 2017. Also, an estimate of the value of the contracts of works attributed by simple exponential smoothing method is developed in the article, the result of the estimation being compared with the actual data.

Keywords: Public Procurement, Procurement Procedure, Contract, Framework Contract, Works, Outsourcing.

Introduction

According to art. 3, paragraph (1), letter l) of Romanian Law no. 98/2016 regarding public procurement, public procurement contracts are of three types: products, services and works.

Product supply contracts may include procurement by the contracting authorities of products such as: cars, tractors, computers, phones, pharmaceuticals, food, construction equipment, fuels, IT equipment, sanitary equipment, etc.

Service contracts cover the purchase of services such as: security, vehicle repair, transportation, catering, cleaning, compulsory and optional insurance, etc.

Works contracts may include the purchase of landscaping works, building, motorways, bridges construction, overhead electric lines, upgrades or capital repairs for buildings, etc.

Compared to product purchases, the purchase of services has a peculiarity.

To a large degree, the government sector is a domain where a large part of the external sourcing refers to services. In Europe around 50% of the overall external sourcing in central, local or regional

Cite this Article as: Ionel PREDA, Doina I. POPESCU And Cezar-Petre SIMION "The Evolution of the Types of Public Procurement Contracts in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

government is services contracts, such as maintenance work, social services, construction work, garbage collection, network services, public transport, etc. Due to an developing service industry situation (caused by a global trend that led to the increase of outsourcing in both the private and public areas), buying services is becoming a more and more important matter. Now, support services like security, catering and cleaning are contracted out. Furthermore, outsourcing is chosen for other types of services, more precisely services provided for all the citizens. For the implementation of outsourcing, the keyword taken into consideration is value, which means making taxpayers' money to better fulfil the needs of the public (Thai et al., 2009).

Among the most important issues of service procurement are the setting of specifications included in the tender book and the monitoring of their performance (Audit Commission, 1993). In fact, one of the most important things is keeping in the organization the skills for determining specifications and for controlling the performance of the services provided, because if these skills are lost, it may be very difficult to carry out the procurement procedure and control the performance of the contract, and once these skills are lost, these are very difficult to repair.

It is known that the service buying process is less standardized and more complex than the buying of products. Because the subject of the purchase is invisible, the service acquiring process is characterised by an increased need for written technical specifications referring to the content of procurement. Graw and Maples (1994) consider that for the same reason, judging the skills and qualities of a service provider or a contractor and taking references are regarded as more important. Also, ensuring a good communication between the provider and the beneficiary is of crucial importance, particularly in the context of managing unforeseen events that may occur in the provision of services.

Related literature

The majority of the specialised studies on the subject refers to the differences between product and service procurement, outsourcing and the use of public procurement as a factor for accelerating the economic recovery during economic crises.

The differences between product and service procurement have been analysed by many specialists in the field. According to Shostack (1977) and Berry (1980), there are four characteristics that make services distinct from products: intangibility, inseparability, perishability and heterogeneity. Berry and Parasuraman (1991), Grönroos (1990) and Normann (1992) claim that:

- in service production there is a high level of staff resources involved;
- there are more difficulties in measuring and specifying the quality and output of services (including many problems with delayed effects);
- consumption and production are happening simultaneously, frequently involving the customer;
- services are not possible to buffer or transport. Also, services are intangible;
- services are mostly performed in multiunit companies, with dispersed locations.

The inseparability is the most important characteristic of a service, because the purchaser is involved in the delivery process. This implies that the purchaser may have a direct impact on the result of the service which is delivered. The inseparability of consumption and production forces the sellers and buyers into intimate contact (Grönroos, 1978). Payne (1995) considers that through interpersonal relationships, long-term customer relationships are built, thereby ensuring customer satisfaction.

In the last period, public organizations have paid increased attention to reducing costs, increasing efficiency, flexibility, basic skills, and outsourcing of nonessential activities.

The definition of outsourcing is services that are contracting-out and were performed in-house, in the past (Thai et al., 2009). Outsourcing is a procurement strategy frequently selected as a way of increasing efficiency and effectiveness (Steane and Walker, 2000). Outsourcing can also have an

effect on employees, with conditions and terms of employment getting worse after outsourcing. The main risks of outsourcing are losing knowledge and in-house expertise (Boston, 1996), reductions in quality and unintentional loss of control (Lei and Hitt, 1995).

In the case of outsourcing, there are approaches in the research literature that refer to both the controversial issue of choosing between providing services in the organization or making-or-buying, as well as of maintaining or reducing staff within the organization.

One of the main problems of contracting-out is considered to be the cost of monitoring. The organisation of the monitoring function can be made in different modes. At one extreme there's a trust on the service beneficiaries (for example garbage collection). Public authorities have different ways to evaluate the delivery of services (for example customer surveys). At the other extreme, there are very strictly organized inspections many times a week (Thai et al., 2009).

Because it is a way to increase efficiency and effectiveness, outsourcing has also been very much applied in the private sector, even more so than in the public sector, because, unlike state organizations, private companies operate in a competitive market economy that influences the prices, quantities and quality of products / services.

Public procurement (especially those of works) may be a factor in accelerating economic recovery. In times of economic crisis the state can invest more in infrastructure (and not only) by allocating additional funds and initiating a larger number of procurement procedures.

An interesting approach is that of Murray (2009), referring to the public procurement strategy as a factor for accelerating the economic recovery during economic crises. In the case of the economic crisis of 2009-2010, the author notes that Britain's local government strategy had changed very little due to the recession, that existing practices have acted against accelerating economic recovery, and that a short-term strategy containing more measures would have been justified. The author considers that a strategy for accelerating the economic recovery must include the following measures:

- the strategy needs to be validated by the parliament;
- the procurement strategy should be synergistically linked with a regional or local economic development strategy. It is very important that a thriving competitive business community to continue to exist;
- the long-term contracts should be put away in favour of short-term multi-sourcing contracts utilizing ‘lots’. In doing so, the exposure to risk is reduced for both suppliers and public authorities;
- during a time of recession, in all contracts should be embedded social clauses, such as combating unemployment;
- the reduction of payment deadlines (Murray, 2009).

Research Methodology

This study is an exploratory study that uses secondary data analysis and forecasting. The study analyzes statistical data on the evolution of the types of public procurement contracts in Romania from 2007 to 2017.

The purpose of the research is to study public investment procurement as a factor for accelerating the economic recovery in Romania in the case of the economic crisis between 2009 and 2010.

The main objectives of the study are to analyze the evolution of the number and value of investment contracts between 2007 and 2017, the consequences of the measures taken by the political factors to increase the funds destined for salaries and pensions to the detriment of investments and to provide an estimate for 2017 of the value of the works contracts using Brown's economic-mathematical model of simple exponential smoothing.

The research questions are the following:

- What was the evolution of the number and value of investment contracts in Romania between 2007 and 2017?
- Have the public procurement in Romania been used to stimulate the economic recovery in the event of the economic crisis between 2009 and 2010?
- The estimation for 2017 of the value of the works contracts using Brown's economic-mathematical model of simple exponential smoothing is confirmed by real data?

In order to examine the evolution of the types of public procurement contracts in Romania throughout the period 2007-2017, the research methodology comprises the next steps:

- examination of the specialized studies in the area of research;
- data gathering;
- data analysis and the elaboration of the research results.

The principal source of information and data utilised in the research was the official reports published by the Romanian National Agency for Public Procurement (ANAP), different statistical indicators for public procurement procedures and some information for the general public in Romania.

The utilisation of the official reports of the Romanian National Agency for Public Procurement presented the next advantages:

- the high accuracy of the information;
- the information comes from the Romanian electronic procurement system;
- the high relevance of these information and data about the national coverage of the Romanian procurement system.

The evolution of the types of public procurement contracts in Romania

The distribution by type of contracts and framework agreements awarded in Romania in the year 2017 is described in Table 1.

Table 1: Distribution by type of contracts and framework agreements awarded in Romania in 2017

No.	Type of contract / framework agreement	Number of contracts / framework agreements awarded	Weight
1	Supply	60,324	80.73%
2	Services	9,643	12.90%
3	Works	4,760	6.37%
Total contracts / framework agreements awarded		**74,727**	**100%**

Source: Romanian National Agency for Public Procurement (ANAP, 2017)

From Figure 1 it can be seen that the highest number of contracts / framework agreements awarded in 2017 was for supply (80.73% share) followed by services (weight 12.90%), the number of works contracts having a weight of only 6.37%.

Figure 1: Graphical representation of distribution by types of contracts and framework agreements awarded in Romania in 2017

Source: Based on the data in Table 1

The main statistical indicators for the public procurement carried out in the period 2007-2017 in Romania are presented in Annex 1.

Table 2: Values of contracts awarded between 2007 and 2016

Line no. Annex 1	**1**	**2**	**3**	**5**	**7**
Indicator/ Year	**Value of works contracts (thousand lei)**	**Weight of the value of works contracts out of the total value of the awarded contracts (%)**	**Value of supply contracts (thousand lei)**	**Value of service contracts (thousand lei)**	**Total value of awarded contracts (thousand lei)**
2007	13,085,026	58.59%	5,680,100	3,568,533	22,333,659
2008	24,846,622	46.56%	15,591,811	12,932,023	53,370,456
2009	**25,798,228**	**54.91%**	**10,299,029**	**10,882,883**	**46,980,140**
2010	**22,188,322**	**51.18%**	**11,295,511**	**9,870,914**	**43,354,747**
2011	34,343,766	58.11%	12,987,973	11,772,966	59,104,705
2012	30,020,584	53.87%	13,996,708	11,712,090	55,729,382
2013	29,644,985	54.79%	13,247,906	11,210,527	54,103,418
2014	35,971,725	53.57%	18,636,669	12,542,725	67,151,119
2015	37,058,725	54.00%	21,403,124	10,161,736	68,623,585
2016	17,262,769	38.87%	17,404,320	9,746,296	44,413,385

Source: (ANAP, 2016)

From the analysis of the evolution of the indicators presented in lines 1, 3, 5 and 7 of Annex 1, respectively the values of the works, supply, services contracts and total values of contracts for the period 2007-2017, it can be noticed that in 2009 and 2010 the total values of the contracts awarded amounted to 46,980,140 thousand lei and to 43,354,747 thousand lei compared to 2008 and 2011,

when the values were of 53,370,456 thousand lei, respectively 59,104,705 thousand lei (Table 2 and Figure 2). The weights of the works contract values for the period 2008-2010 varied between 46.56% and 54.91%, while in 2007 and 2011 these were of 58.59% and 58.11%, respectively.

Figure 2: Graphical representation of the evolution of the value of contract awarded between 2007 and 2016

Source: Based on the data in Table 2

Thus, it can be seen that **during the economic crisis of 2009-2010**, **public procurement in Romania has not been used as a factor for accelerating economic recovery**. Consequently, **the conclusions formulated by Murray (2009)** (who determined that in the economic crisis of 2009-2010, the UK local government strategy changed very little due to the recession and that the existing practices have acted against the acceleration of economic recovery) **are also confirmed in the case of Romania.** In this period of economic crisis, the state would have had to allocate additional funds (especially for infrastructure investments) and initiate a larger number of public purchases.

NAO, (2018) uses three criteria to evaluate the value for money of government spending:

- efficiency (spending well) which means the relationship between the output from services or goods and the resources used;
- economy (spending less) which means minimising the cost of resources used (inputs);
- effectiveness (spending wisely) the relationship between the intended and actual results of public spending or outcomes (NAO, 2018).

A general economic principle is: "Buy in times of economic crisis and sell in periods of boom". In the analysed case, namely in terms of public procurement during periods of economic crisis, prices are low and implicitly the efficiency, economy and effectiveness of using the budgetary funds are maximum, namely the best value for money ratio is obtained.

Also, from the analysis of the evolution of indicators presented in lines 1 and 2 of Annex 1, namely the value of works contracts and their weight in the total purchases made, it can be noticed that **due to the measures taken by the political factors regarding the increase of the funds for the salaries and pensions to the detriment of investments, in 2016 the works contracts** (which had as main object investments in infrastructure - highways, roads, bridges, facilities etc.) **decreased to 17,762,769 thousand lei** (from 37,058,725 lei in 2015), **namely from a weight of 54% in 2015 to a weight of 38.87% in 2016**. Unfortunately, these measures continued in the period 2017-2019.

The trend of the work contracts decrease can also be seen from the analysis of the indicators in lines 10 and 11 of Annex 1, respectively the total number of works contracts and its weight in the total number of awarded contracts (Table 3).

Table 3: Total number of works contracts and their weight in the total number of contracts awarded during 2007-2017

Line no. Annex 1	10	11
Indicator/ Year	**Total number of works contracts**	**Weight of the number of works contracts out of the total number of contracts awarded (%)**
2007	5,979	17.47%
2008	19,240	16.23%
2009	13,699	13.20%
2010	10,188	11.58%
2011	8,595	11.48%
2012	6,891	10.41%
2013	5,412	9.73%
2014	4,383	8.21%
2015	5,576	8.72%
2016	3,717	6.67%
2017	4,760	6.37%

Sources and adaptation from: (ANAP, 2016), (ANAP, 2017)

As can be seen in Figure 3, **the weight of the number of works contracts in the total number of awarded contracts decreased steadily between 2007 and 2017,** from 17.47% in 2007 to 6.67% in 2016 respectively 6.37 % in 2017.

Figure 3: Graphical representation of the evolution of the weight of the number of works contracts in 2007-2017

Source: Based on the data in Table 3

Continuing this trend can lead to dangerous situations, due to the non-assurance of the amounts necessary for the safe operation of the existing infrastructure. The main consequences of reducing investment funds are:

- very crowded traffic on public roads leading to a large number of traffic accidents resulting in significant material damage and loss of lives;
- interruption of the electricity supply of some localities;
- the collapse of some bridges;
- derailment of some trains or subways;
- interruption of water or heat supply to neighbourhoods or even cities.

Estimate of the value of awarded works contracts

In order to highlight the influence of the political factor on investment (works contracts), we estimate for 2017 the value of awarded works contracts (line 1 of Annex 1) and we compare this estimated value to the actual value. The evolution of the value of the works contracts awarded for the period 2007 - 2016 is presented in Table 4.

Table 4: Total value of works contracts awarded during 2007 – 2016

Line no. Annex 1	**1**
Indicator/ Year	**Value of works contracts (thousand lei)**
2007	13,085,026
2008	24,846,622
2009	25,798,228
2010	22,188,322
2011	34,343,766
2012	30,020,584
2013	29,644,985
2014	35,971,725
2015	37,058,725
2016	17,262,769

Source: (ANAP, 2016)

To estimate the total value of contracts in 2018, Brown's economic-mathematical model of simple exponential smoothing will be used.

Brown's model of simple exponential smoothing has the following form:

$$F_t = \propto X_t + (1-\propto)F_{t-1} \quad (1)$$

or $$F_{t+1} = \propto X_t + (1-\propto)F_t \quad (2)$$

where:

X_t = total value of contracts awarded in period t;
F_t = estimated value in the period t-1 for contracts awarded in period t;
F_{t+1} = estimated value in period t for contracts awarded in period t + 1;
α = smoothing constant, $0 \leq \alpha \leq 1$.

For the estimation, the *QM for Windows / Forecasting / Time Series Analysis* software was used.

The estimate for the year 2017 of the value of the works contract awarded for the smoothing constant α = 0.61 (which is optimal *α* in relation to the mean squared error) is presented in Table 5. For α = 0.61 the lowest MSE average squared error is 77,335,630,000,000.

Table 5: Estimate for 2017 of the value of the awarded works contracts for smoothing constant α = 0.61

The graphical representation of the actual data (the value of the awarded works contracts) and the estimation for the year 2017 of the value of the works contracts awarded for the smoothing constant α = 0.61 is presented in Figure 4.

Figure 4: Graphical representation of actual data and estimation for year 2017 of the value of the awarded works contracts

According to the presented economic-mathematical model, the value of the awarded works contracts recommended to be taken into account for 2017 is 24,449,474 thousand lei, because the lowest MSE average squared error is 77,335,630,000,000, this being obtained for $\alpha = 0.61$.

Considering the fact that in 2016 the value of the awarded works contracts amounted to 17,262,769 thousand lei, it follows that the estimated value resulting from the application of the economic-mathematical model for 2017 (24,449,474 thousand lei) is 41.63% higher than the value of the previous year.

In fact, the investment expenditures in Romania in 2017 (economic growth year) were only of 12.1 billion lei, by 30% lower than in 2016, the lowest investment expenditures in the last 12 years (ZF, 2017), which means that for the estimation of the value of the awarded works contracts, Brown's economic-mathematical model of simple exponential smoothing is not confirmed by actual data.

This is due to the measures taken by the political factors in Romania which led to the increase of the budget destined for salaries and pensions and the decrease of the investment budget.

Conclusions

The study notes that in public procurement in Romania the largest weight belongs to the supply contracts, and the smallest share to the works contracts for investments.

The analysis of the evolution of the types of contracts also revealed that, in the case of the economic crisis from 2009 to 2010, public authorities in Romania did not use public procurement to stimulate economic recovery. Measures taken by policy makers have acted against economic recovery, the budget funds for public procurement being very low, which has resulted in the worsening of the effects of the economic crisis.

The study also revealed that in the period 2007-2017, the share of works contracts in the total number of contracts awarded decreased steadily from 17.47% in 2007 to 6.37% in 2017.

In 2016, the Romanian policy makers took a series of measures that led to the increase of the funds for pensions and wages and to the reduction of the funds allocated to the investments, a situation that led to the aging of the existing infrastructure and to the non-assurance of its safe operation.

Also, the tendency to decrease investment expenditures continued in the period 2017 - 2018. The estimate for 2017 of the value of works contracts awarded by the use of Brown's economic-

mathematical model of simple exponential smoothing (the estimated result representing a 41.63% increase as compared to the previous year) was not confirmed by actual data (30% less than in the previous year), this situation being due to the measures taken by the political factors in Romania, which led to the increase of budget expenditures for pensions and wages at the expense of investments.

Abstract

The article discusses branding of a territory (city or region) as a tool to enhance its competitiveness and stimulate its socio-economic development. We focus on the case of Ekaterinburg (Russia), describe the competitive advantages of this city, and show the need for building a stronger city brand. We also compare the position of Ekaterinburg in various national city rankings. The conclusion is made that rankings that use formalized (objective) indicators are quite effective in the evaluation of a city brand's performance and territorial branding in general.

Keywords: Branding, Brand of a Territory, Region's Brand Image, City Brand.

Introduction

The modern city is not just a socio-economic system but a major force shaping market relations and business communications. A city can help realize the cumulative potential of the surrounding territory and maximize the advantages of the whole region. To help cities acquire and maintain their competitive edge on national and international markets, marketing techniques and instruments can be used.

As cities engage in economic relations with various actors competing for investment, talent and other resources, the authorities increasingly rely on various market mechanisms and methods in their municipal management practices.

A strong brand is a way to promote a city's individual personality and make it recognizable. Brand is an effective tool that can help a city capitalize on its advantages, enhance its marketing potential, attract investors and boost socio-economic development, thus improving the quality of life of its residents.

Literature Review (Research problem)

With the advent of the digital economy, it has become essential to have a viable territorial branding strategy to realize the territory's potential. 'Brand of a territory is a combination of unique qualities and timeless values, reflecting the uniqueness and original consumer-oriented characteristics of this territory and community, which are well-known, publicly recognized and enjoy strong demand among the consumers in this territory' (Vazhenina, 2012). Regional image (Sushnenkova, 2011) is defined as a coherent symbolic representation of a region existing in the public or individual consciousness and resulting either from personal experience or from the impact of the media.

Cite this Article as: Natalia V. GONCHAROVA And Liudmila V. DAINEKO "Territorial Brand Development and Evaluation (The Case of Ekaterinburg)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

To evaluate a regional image (Vizgalov, 2011), the following factors are usually considered: structural (location, climate, history); changeable (size of the territory, population, landscape, cultural traditions); and symbolic (symbols, significant events and personalities). Culture is an important element in each of these factors since the image is often aligned with specific cultural symbols and representations, which can become the core of the evolving brand. A strong territorial brand makes the city easily recognizable and distinguishes it from competitors. A brand cannot be realized through external effort alone (Bystrova & Kochetkov, 2017). Only a a living, vibrant brand can attract people, which is why a city brand should be a result of cooperation between brand specialists and urban residents. Involvement of local communities into the process of brand creation enhances the quality and efficiency of applied marketing strategies (Zenker & Petersen, 2010). Territorial branding stimulates social and economic development of regions and cities (Eidelman et al., 2016; Veleshchuk, 2015); rural areas (Moroz et al., 2020); and national parks (Ferrari, 2020), as well as the development of regional tourism (Eidelman & Fakhrutdinova, 2016). In their pursuit of distinctiveness not only do brands of regions and cities compete for recognizability but they can also network and cooperate with other territories (Pasquinelli, 2013). It should be noted that residents' view of their home cities and the views of tourists are not mutually exclusive but should be in agreement, otherwise the city's image and authenticity will suffer (Merrilees et al., 2009).

Research problem

In order to respond to the challenges of globalization, territories have to be able to make the most of their competitive advantages, enhance their economic well-being and the quality of life of their residents. To address this task, it is necessary to reconsider the city (or region) promotion strategies by supplementing them with those based on marketing and branding principles. Our hypothesis is that the performance of a territorial brand can be evaluated by using the data of the rankings based on formalized (objective) indicators. Rankings that rely on unformalized subjective evaluations and those that tend to constantly change their indicators and scale are less suitable for this purpose.

Purpose of the Study

A city's brand is its identity (Vizgalov, 2011). Therefore, the larger is the city, the more positive aspects and resources the brand can reflect. However tempting the idea to show all the positive sides may be, it is better to select just a few to ensure the brand's recognizability. This study aims to gain a deeper understanding of the theoretical and methodological aspects of territorial brand evaluation. Brand evaluation is necessary to identify the territory's own resources that could be used for marketing purposes and the external resources that should be attracted for better results.

Methodology

The study uses general scientific methods and relies on the data of the Federal State Statistics Service (Rosstat), open research data from other studies, and rankings data.

Results

Territorial branding is aimed to ensure a long-term presence of a particular territory in the information space, increase its recognizability, encourage the public’s positive interest in the goods and services produced in this territory, attract investment and strengthen the territory’s appeal as a tourist destination. Promotion of the territory's positive image among external audiences contributes to the creation of long-lasting positive associations this territory evokes.

A strong city brand is bound to have a positive effect on the brands of local businesses and vice versa, if the city's image is negative, local businesses will also suffer. Therefore, entrepreneurs, especially those who own unique local businesses, should be no less interested in the development of the city brand than owners of hotels, restaurants, tourist agencies, transport companies and the local authorities. The key to success is to create a unique and memorable city brand. The brand concept should not contradict the city's identity but, on the contrary, reinforce it. The more fully and more adequately the brand reflects the city's identity, the more appealing it will be for target audiences, both internal and external.

For quite a while, there has been a perceived need to create a proper brand identity for Ekaterinburg. Until December 1990, Ekaterinburg (Sverdlovsk before 1992) had been closed for foreigners. The city was freely accessible to Soviet citizens but foreigners needed to have a special invitation, which means that inbound tourism was out of the question. In the post-Soviet period, however, Ekaterinburg started hosting diverse cultural, sport and political events, which attracted foreign visitors.

On more than one occasion has Ekaterinburg become a venue for high-profile international events, which made the local authorities interested in the creation of a distinctive visual brand identity (among such events were SCO Summit in 2008; BRIC Summit in 2009; German-Russian forum 'Petersburg Dialogue' in 2010, in which participated President Dmitry Medvedev and Chancellor of Germany Angela Merkel; the 31st Russia-EU Summit, involving European and Russian leaders; the 10th Russia-Kazakhstan Interregional Cooperation Forum in 2013, in which participated the presidents of the respective countries; the 6th Forum 'Russia - Azerbaijan: Interregional Dialogue-2015'; the ICPC International Collegiate Programming Contest in 2016; FIFA World Cup in 2018; the Boxing World Cup Final in 2019; the 10th Eurasian Economic Youth Forum 'Russia – Asia – Africa – Latin America: the Economy of Mutual Trust' in 2019; the 2019 Youth Match Racing World Championship). The city also submitted a bid to host the World Expo 2020. In 2023, Ekaterinburg will host the World University Games.

Russian territories, especially capital cities Moscow, St.Petersburg and Kazan (especially after the 2013 Summer Universiade) are now actively developing their own brands.

Many cities are primarily associated with particular architectural objects, known for their artistic, cultural and historical value; these objects may constitute an important part of their cities' brands. More often than not, the role of city symbols is performed by religious buildings, which can take incredibly diverse and innovative architectural forms and may have a rich and contradictory history. Not only do old buildings such as 16th century St.Basil's Cathedral in Moscow, the Church of the Intercession of the Holy Virgin on the Nerl River (built in 1165) and the Church of the Holy Sepulchre in Jerusalem (built in the 4th century) become symbols but also new ones, for example, Hallgrimskirkja in Reykjavik (designed in 1937 and finished in 1975) and the Cathedral of Christ the Saviour in Moscow (rebuilt in 1999). There are many architectural sites all over the world that are essential to city brands. In the beginning, these sites did not always bear any particular symbolic meaning and many acquired such meaning only years later. The Eiffel Tower in Paris, for example, was not conceived of as a city symbol, this famous landmark was originally built to celebrate the 100th anniversary of the French Revolution. Similarly, the Statue of Liberty in New York was a gift of the people of France to the people of the United States to commemorate the centennial of U.S. independence. Other stories like this include that of the Sydney Opera House built in 1973 and Burj Al Arab, built in 1999, and so on.

Territorial branding is a lengthy and complex process which requires considerable administrative and financial resources. It starts from the preliminary evaluation of the already existing city brand, which has evolved naturally, then the brand concept is designed based on the region's characteristics and advantages. After that, this concept is implemented and the brand is promoted. Finally, the performance of the city brand is monitored and evaluated (this can be done with the help of various rankings).

To make a city brand world-famous, it is necessary to formulate a comprehensive strategic plan and to work persistently to improve brand awareness, for example, by conducting unique symbolic events. For instance, Ekaterinburg, known all over Russia for its rock-scene, since 2015 has become a venue for unique festival Ural Music Night (https://uralmusicnight.ru/). The end of the FIFA World Cup in 2018 in Ekaterinburg coincided with the music festival, and the city benefited from this opportunity to show foreign audiences its great potential as a concert venue and a centre of music culture even though it was only for one night. It should be noted that a symbolic event of such a scale can have an enormous emotional impact on the target audience.

It is highly desirable that the city brand concept should emphasize positive aspects of the territory while minimizing negative ones.

In the Soviet period, Sverdlovsk (now Ekaterinburg) was known as an industrial city with smoking factory pipes, soaring crime rates and also as a place where the last Russian tsar and his family were brutally murdered. Thus, to create an effective city brand and make the city attractive, it was necessary first and foremost to overcome the negative brand perceptions and turn them into positive ones.

Currently there is no sightseeing spot, place or event that could be considered as the main symbol of Ekaterinburg. The most famous symbol of the city is Sevastyanov's house, which was chosen as the official architectural symbol of Ekaterinburg for the FIFA World Cup 2018. It was also this building that was selected to represent Ekaterinburg in the large-scale graffiti project in Moscow. In the 2016 public vote held to decide on the symbols and cities that would illustrate the new banknotes, it was Sevastyanov's House and Iset Hotel that got the majority of votes in Ekaterinburg. Sevastyanov's House is located in the historical centre of the city, right next to the dam on the city pond (a favourite walking place among the locals, known as 'Plotinka'). The House traces its history back to 1817. In the late nineteenth century, architect A.I. Paduchev oversaw the reconstruction of the house, originally built in the classical style, and turned it into an outstanding example of the neo-Gothic style, artfully combining Gothic and Barocco elements. Since the early twenty-first century, the House has been the regional Governor's residence.

Iset Hotel is an iconic Constructivist monument, built in the 1930s as a part of the so-called Chekists' Quarter. Originally, it was built as a dormitory-style accommodation for the staff of the Cheka (NKVD) but was later turned into a hotel.

Although the above-described architectural sites are of enormous cultural and historical value, they remain virtually unknown beyond the borders of the region and attract few tourists.

One of the most famous sightseeing spots in Ekaterinburg, the centre of the cult of Tsar-Martyr Nicholas II and his family and a popular destination for Orthodox pilgrims from Russia and other countries is the Cathedral-on-the-Blood (The Church on Blood in Honour of All Saints Resplendent in the Russian Land). It is an active Orthodox cathedral built in 2003 on the site of demolished Ipatiev House, where the Romanov family were kept and executed on the night of 16–17 July 1918. Despite the fact that this place is popular with tourists and is also widely used for religious and other events, it is connected to the tragic death of the royal family and, therefore, triggers strong negative associations. Therefore, in our view, it is not suitable for promoting the territory's image among external audiences. Thus, the question about the place that could become a distinctive symbol of Ekaterinburg still remains open.

There is currently no single methodology for measuring the performance of a territorial brand. In Russia, there are various rankings of cities and regions created by different experts and organizations and using a variety of indicators. Many rankings rely on experts' evaluations and may suffer from flawed sampling. Let us consider the main national rankings and compare Ekaterinburg's position with those of Moscow and St.Petersburg – the two capital cities with the strongest brands in Russia.

The on-line project 'City of Russia' was launched in 2013 (https://город-россии.рф). Its purpose is to support national development and preserve cultural and historical heritage of the Russian state. The best city is chosen by free vote on the project's web-site: visitors to the site may vote every day without prior registration. Table 1 shows the results of the vote in 2012-2019.

Table 1: Ekaterinburg in 'City of Russia' ranking (2012-2019)

Period	Position	Number of votes
2012	49	2,441
2013	37	3,463
2014	14	27,841
2015	41	9,614
2016	49	6,070
2017	48	7,094
2018	37	7,012
2019	35	7,727

In 2019, the leader was Cheboksary while Moscow and St.Petersburg ranked only 24th and 32nd respectively. It should be noted that this ranking is not promoted in publicly accessible sources. We thus believe that it is not very objective and presents a somewhat distorted picture.

Yet another example of a highly subjective, much-hyped ranking is the Quality of Living Ranking of Cities, available on portal Domofond.ru. The best city is chosen by daily voting: residents of Russian cities are asked to evaluate the quality of life in their home cities. The evaluation scale and criteria are changed every year. For example, in 2019, the criteria were safety, cleanliness, environment, public transport, roads and parking spaces, shops and markets, sport and recreation, child-friendliness, neighbours, utility services, the income to cost of life ratio. The cities' performace in these criteria were evaluated on a 10-point scale, ranging from 0 (totally disagree) to 10 (totally agree). Ekaterinburg' position in the ranking in 2017-2019 is shown in Table 2.

Table 2: Ekaterinburg in the Quality of Living Ranking of Cities (2017-2019)

Period	Position	Number of respondents	Average score	Environment	Cleanliness	Housing and utilities	Neighbours	Child-friendliness	Sport and recreation	Shopping	Transport	Safety	Cost of living	Roads/parking space	Noise
2017	71	258,000		174	150	89	149	20	20	79	34	163	9		
2018	47	64,870	7.2	6.5	5.9	5.9	7.4	7.2	6.5	8.5	7.6	6.5	5.1	5.0	6.4
2019	63	90,000	6.4	6.4	6.1	5.5	7.2	7.0	6.5	8.7	7.1	6.5	4.5	4.4	

In 2019, Tyumen was at the top of the ranking with Moscow and St.Petersburg ranking 6th and 26th respectively.

A good example of how a city's or a region's performance can be adequately measured is the Urban Environment Quality Index, calculated by the Ministry of Construction, Housing and Utilities (https://индекс-городов.рф). This ranking was launched in 2018 as a part of the national project 'Housing and Urban Environment'. The Index is based on the evaluation of six types of urban space: residential buildings and surrounding territory; green spaces; social and business facilities and

surrounding territory; social and leisure facilities and surrounding territory, street network; and other public areas. The set of six criteria includes safety, comfort, environment and health, identity and diversity, technological innovation, efficient management. For each type of space there is one key criterion. The resulting evaluation matrix comprises 36 indicators used for desk review based on official statistics, data of GIS-systems and remote zoning of territories. Each city's performance in each indicator is evaluated by using a 0–10 scale. The integral index is calculated as a sum of all scores in all the indicators. The maximum index value is 360 points. The best cities to live are considered to be those that score more than 180. A region's index is calculated as an average of the indices of the cities located in this region. Table 3 shows the results of the Urban Environment Quality Index for Ekaterinburg and Sverdlovsk region in 2018-2019.

Table 3: Ekaterinburg and Sverdlovsk region in the Urban Environment Quality Index (2018-2019)

Period	Ekaterinburg	Sverdlovsk region
2018	191 points	165 points
2019	188 points	172 points

Unsurprisingly, Moscow and St.Petersburg, Russia's most famed cities and its former and present capitals, are at the top of this ranking.

The centre of information communications 'Ranking' in 2015 launched a project 'National Ranking' to study domestic and inbound tourism and compile annual rankings of Russian cities and regions depending on their popularity among tourists (http://russia-rating.ru/). The National Tourism Ranking is based on the following criteria:

- hotel accommodation and infrastructure (the number of hotels in the region, the number of bed places in hotels);
- the role of tourism in the region's economy (number of tourist agencies in the region, persons employed in the tourism industry as a share of the region's population);
- profitability of the tourism and hospitality industries in the region (hotels' revenues, volume of paid services, revenues of catering businesses);
- popularity of the region among Russian tourists staying for more than one day (number of Russian tourists staying at hotels; number of nights spent in hotels);
- popularity of the region among international tourists (number of foreign tourists staying at hotels);
- unique tourist attractions (the number of monuments and sightseeing spots included in the Unified State Register of Objects of Cultural Heritage and UNESCO World Heritage Sites);
- crime rates (offences per 100,000 population);
- interest in the region as a travel destination among Internet users (number of search queries);
- the region's media presence (number of publications in the mass media)

Table 4 illustrates the position of Sverdlovsk region in the National Tourism Ranking. Sverdlovsk region continues a steady climb in the ranking, its scores in the nine key criteria are constantly increasing (the statistical data for evaluation can be easily accessed from the official sources).

Table 4: Sverdlovsk region in the National Tourism Ranking in 2015-2019

Period	Position	Score
2015	-	Less than 50
2016	17	60.9
2017	10	83.5
2018	7	92.2
2019	10	100.2

In 2018, Sverdlovsk region moved to the seventh place in the ranking after hosting matches of the FIFA Football World Cup. Traditionally, Moscow and St.Petersburg occupy the top positions in the ranking: in 2019, Moscow scored 114.7 and ranked first while St.Petersburg came second with the score of 113.7.

Conclusions

The above analysis shows that even though there is a considerable gap between Moscow and St.Petersburg and other Russian cities, Ekaterinburg has a good chance to stand on a par with the leaders and build a strong brand by capitalizing on the key advantages of Sverdlovsk region. Ekaterinburg is a major industrial, economic and business centre of Russia with developed transport, business and hotel infrastructure. It ranks first in the country in terms of the amount of retail floorspace, third in terms of retail turnover, and fourth in terms of population. The city also has resources for tourism development.

Over 50 Orthodox churches and cathedrals make Ekaterinburg an attractive destination for religious tourism and pilgrimage. The most popular sites are the Cathedral-on-the-Blood and Ganina Yama - a complex of seven churches built on the place where the remains of the royal family were buried after the execution. The city has a vibrant cultural life with over 30 museums, 16 professional theatres (including the world-famous private Kolyada-Theatre), concert halls, a circus and a zoo. A number of state-of-the-art sporting venues, including the stadium Ekaterinburg-Arena (Central Stadium), which can accommodate 35 thousand spectators, makes the city suitable for hosting large-scale sport events. With its large exhibition centres ('Ekaterinburg-Expo, Centre of International Trade, 'Ural Exhibitions' Centre), Ekaterinburg provides abundant opportunities for business tourism: every year it hosts over 200 exhibition events, including the international exhibition and forum of industry and innovation INNOPROM. As for active tourism, Sverdlovsk region has 17 ski resorts and over 500 natural sites, which means large opportunities for natural tourism and eco-tourism.

An important thing to remember while building a brand is that in modern digital environment, information, positive and negative alike, spreads very easily. For example, in May 2019, Ekaterinburg became an arena for the confrontation between the authorities and local citizens over the plans to build a cathedral in honour of Saint Catherine. This conflict attracted considerable public attention in Russia. In June 2020, yet again Ekaterinburg turned up in the centre of a scandal surrounding the conflict between dissident priest Schema-Hegumen Sergii and the metropolitan bishop. Being in the centre of such scandalous events means that the city gains negative media publicity, which can be detrimental to its brand. Therefore, all of the key stakeholders (residents, regional authorities, businesses, historians, cultural activists and religious leaders) should participate in the development of the city's branding strategy. For successful promotion of the brand, it is necessary to use positive symbolic and unique events such as the forthcoming celebration of the 300th anniversary of Ekaterinburg and the World University Games (Universiade) in 2023.

Success of Ekaterinburg's branding strategy and the strength of its brand can be further monitored with the help of rankings that use objective indicators.

Abstract

The phenomenon of terrorism based on Islamic fundamentalism is one of the biggest problems threatening the modern world. The main research objective of the article was to analyse the new strategy of terrorist attacks and assess their threats to Europe's security. The authors not only pointed out the potential terrorist threats to European countries, but also outlined the ways to combat them. In their view, the fight against terrorism should be supranational. The main research problem of the article is the analysis of terrorist strategies and the assessment of their threats to European security. The number of terrorist attacks has decreased, but their effectiveness in terms of fatalities has increased. Most of the attacks in the examined period were separatist. The total global cost of economic losses due to terrorism was estimated at $14.1 trillion for 2018 or 11.2% of global GDP. Europe is the second-best performing region after Central America and the Caribbean, according to GTI. Only eight European countries have worsened this indicator.

Keywords: Terrorism, Terrorist Tactics and Strategies, Terrorist Threats, State Security, Counterterrorism

Introduction

One of the biggest problems threatening the modern world is the phenomenon of terrorism based on Islamic fundamentalism. In the 21st century, in the era of digitization and global access to the Internet and media, terrorist organizations spread their propaganda with great ease. The ever-expanding democratization has provided an excellent basis for the development of terrorism, often referred to as the 21st-century bubonic plague due to its rapid spread. Using one of the main principles of democracy, the one concerning respect for minority rights, terrorists are recruiting new fighters and encouraging so-called "lone wolves" through social media and the mass media. In the fight against terrorism, civil liberties, despite their many advantages, also have many disadvantages. One notable example in this context is the media, as already mentioned.

Based on the experiences, in 2005, the Council of Europe drew up a document entitled "The Media and Terrorism," recommending that the media did not support terrorists by increasing public fear, because terrorist attacks are about creating as much panic and chaos as possible, and the images and information they present are often exaggerated to gain as much publicity as possible, an Świeca Candle, 2017; Szmidtka, 2016].

According to statistics, the number of terrorist attacks and their victims in Europe has decreased compared to the years 1970-1990, when there were up to 10 attacks a week, mostly by separatist organizations such as the Irish Republican Army (IRA) and left-wing ones such as the Rote Armee Fraktion (RAF) [El Ghamari, 2016; START, 2018b].

Despite the statistical decline in terrorist threats, governments cannot make their vigilance sleep and, therefore, continue to strengthen their cooperation in the international arena by improving their security systems [Tomasiewicz, 2014, p. 126; Wojciechowski, 2009].

Cite this Article as: Danuta MIERZWA And Marek TOMASZYCKI " Evolution of Terrorist Strategies and Their Impact on European Security" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

All the outlined above in this synthetic way contribute to creating a problematic situation that should become an object of interest and scientific investigation. The research area formulated in this way is interdisciplinary and includes, among other things, issues and problems remaining in the area of military sciences, humanities, the theory of organization and management, and praxeology.

It should be stressed that this is a dynamic scientific area that is constantly changing and should be systematically researched, analyzed, and improved if necessary. It is not possible to introduce specific solutions and stop there when the area of responsibility is the security and lives of its citizens. Fear often paralyzes people and prevents them from making free and fully informed decisions. A reliable assessment of the threats that may disrupt the current order can effectively predict terrorist attacks [Krzysztoń, 2016, p. 105; Kubiński, 2017, p. 201; Mierzejewski, 2011, p. 7].

The main research problem was the identification and characterization of the new terrorist attack strategy and the assessment of the risks arising from it to Europe's security.

This issue seems to be interesting and important, as it remains in the sphere of deliberations and discussions of the leaders of the world's major powers.

The effectiveness of the research was achieved through the application of selected theoretical and empirical research methodology used in the management, security, and defense sciences. The main research methods included analysis of source documents, scientific observation, induction and deduction, and synthesis. According to J. Sztumski [2020], J. Pieter [1967, p. 317nn] and T. Michalski [2008], these methods are ideal for comparing specific phenomena over time. Their greatest advantage is the possibility to use abstract thinking in them, thanks to which we can apply them in various combinations. Another important determinant was the concept and limitations of the article, as well as material, technical, and organizational conditions. The research process was conducted based on studies of subject literature, legal acts, Internet sources, and military studies. The sources mentioned above were used to draw as much objective information as possible from them.

The Theory and History of Terrorism

There are many definitions of terrorism in the literature. At the very beginning, it is essential to indicate the differences between terrorism and terror. The notion of terror is used primarily about the methods that governments apply to their people. The term terrorism, on the other hand, refers to the use of violence by society against the state authority. Nevertheless, both terms are now used as synonyms [Dietl, Hirschmann, and Tophoven, 2009, p. 27; Department of Homeland Security Strategic Framework for Countering Terrorism and Targeted Violence p. 12-19, Jerrold, 2004 p.22;].

For the purposes of this article, only a few of them will be given. The Global Terrorism Database (GTD) defines a terrorist attack as the threat or actual use of illegal force and violence by a non-state actor to achieve a political, economic, religious, or social goal through fear, coercion, or intimidation [START, 2018a;] Another definition of terrorism, according to the authors the shortest and most concise, comes from the "Dictionary of National Security Terms" [1996, p. 109] and reads: a form of violence consisting of deliberate action to extort or intimidate governments or particular social groups for political, economic, or other purposes.

In turn, the European Union has defined terrorism as acts which, by their very nature and context, can cause serious harm to a country or an international organization when committed with the aim of seriously intimidating a population, or unduly compelling a government or international organization to act or abstain from acting, or severely destabilizing or destroying the fundamental political, constitutional, economic, or social structures of a country or an international organization.

Given the examples, a generalization can be made, and it can be assumed that the characteristic feature of the definitions is that **they intimidate the communities and authorities of states with the intention to achieve specific benefits.**

When speaking of terrorism, it is worthwhile to know its elements and features, which are most commonly found in definitions. It will be helpful in further consideration of the subject. Table 1 shows a comparison of the occurrence of common elements and features of terrorism in the definitions in the analyzed articles made by the team of the Schmidt & Jongman and the team of l. Weinberg, A. Pedahzur, S. Hirsch-Hoefler. The first team analyzed 109 definitions, while the second 73 definitions of terrorism.

Table 1: Frequency of the occurrence of common elements, characteristics of terrorism in definitions (in %).

Element	**A. Schmid (1988)**	**Weinberg et al. (2002)**
1. Violence, force	83,5	71
2. Political nature	65	60
3. Fear, emphasis on terror	51	22
4. Threat	47	41
5. (Psychological) results and (anticipated) reactions	41,5	5,5
6. Diversified victim - target	37,5	25
7. Intentional, planned, systematic, and structured action	32	11
8. Combat methods, strategy, tactics	30,5	31,5
9. Abnormality, conflict with accepted rules, no humanitarian restriction	30	0
10. Extortion, enslavement, submissiveness	28	5,5
11. The publicity aspect, advertising	21,5	18
12. Randomness, impersonality, discrimination	21	0
13. Civilians, non-violent persons - neutral and standing aside as victims	17,5	22
14. Intimidation	17	11
15. Stressing the innocence of the victims	15,5	10
16. A group, movement, organization as perpetrator	14	29
17. Symbolic aspect, demonstrating force to others	13,5	5,5
18. Incalculability, unpredictability, unexpected violence	9	1

19. . Secret, hidden character	9	7
20. Uniqueness, seriality or advertising nature of violence	7	0
21. Criminal (aspect)	6	5,5
22. Demands towards the third parties	4	1

Source: Weinberg, Pedahzur and Hirsch-Hoefler, 2010.

After getting acquainted with the definitions and the most important elements and features contained in them, we will go down in the history of terrorism. A brief historical outline begins with the period after the Second World War, believing that earlier periods, although rich in terrorist experiences, would not significantly contribute to the publication. During that period, terrorist activity was modeled on large quasi-military organizations. Examples include the Irish Republican Army (IRA), which consisted of units of the military division and the legitimate political party Sinn Fein and organizations such as the Women's Movement and Irish Volunteers.

In the 1960s, there was a visible weakening of left-wing terrorism in favor of right-wing and national liberation organizations. Examples of right-wing organizations operating at that time are the French Organisation L'Armee Secrete and the Sicilian national liberation Esercito Volontario per l'Indipendenza Della Sicilia or the Cypriot Ethnic Organosis Kiprijon Agoniston, which fought against the British colonists, and the Tirol Befreiungsausschuss Sudtirol, which was active as a terrorist until 1970 with around 250 terrorist acts.

In the 1970s, left-wing terrorism, which militarized the so-called class struggle, began to dominate. The Italian Red Brigades, which dealt with the kidnappings and murders of their ideological and political opponents, were to the fore [Tomasiewicz, 2014, p. 126; Kraj, 2012]. In the same years, in Germany, the Rote Arme Fraktion (RAF) was active. It pursued its views through bombings, among others at the headquarters of American troops in Europe in 1972, kidnapping and murdering its political opponents, holding hostages, as was the case in Stockholm in 1975 when the organization occupied the German embassy. The RAF also robbed banks to obtain money to finance their activities [Holub, 2016, p. 62].

Today, terrorist groups can be formed under any conditions, from a poor to a highly industrialized European or Asian city. In general, underdeveloped countries and “failed states” are mainly seen as the most attractive places for criminals and terrorists because they carry little risk of interference by state and local authorities. The last decade has seen the most significant increase in terrorist activity in the last fifty years. It can be challenging to know precisely which terrorist groups are most active today and for which quantities of criminal acts they are responsible, as many of them have regional branches operating under different names. According to official statistics, the most active groups during this period include Boko Haram, Al-Shabaab, ISIL (the Islamic State of Iraq and Levant, often referred to as ISIS or DAESH), the Khorasan Chapter of Islamic State, and the Taliban (Figure 1).

Figure 1: The four most active terrorist groups in 1998-2017 [START, 2019, p. 15].

The Evolution of Terrorist Tactics and Strategies

The methods and types of violence used by terrorists in individual years indicate a slow but constant evolution of terrorist tactics and strategies, including traditional ones such as murders, bombings, arson attacks, taking hostages, kidnapping, sabotages, mystification, and suicide attacks [Adamski, 2007, p. 60].

Newer tactics may include unconventional forms of terrorism, for instance, nuclear terrorism (making a dirty bomb, attacking a nuclear reactor, etc.), high-tech terrorism involving cyber-attacks, environmental terrorism (threatening to destroy the environment), or biological terrorism (using biological weapons) and terrorist attacks aimed at destroying cultural heritage. The evolution of methods and forms of terrorist activity is shown in Table 2.

Table 2: Evolution of methods and forms of terrorist attacks

Methods and forms of terrorist activity	Old	New
Assassinations against passenger aircraft	Taking hostages	To be used in suicide attacks
Assassinations against aircraft in general	Detonation of explosive devices with a timer	Use of MANPADS[1] or detonation of IEDs[2] assembled during flight
Assaults against ships	Taking hostages on passenger ships	Aiming to sink valuable war and white fleet vessels (tankers)
IED attacks	Using wire and time detonators. Use of ready-made explosives, available on the market	Use of remote explosion initiation systems. Use of military and self-made explosives
Armed attacks	Mainly on VIPs, military bases, police headquarters	Mainly hotels, bazaars, religious places of worship, lower level officials, isolated stations, civilians
Attacks against key state infrastructure	None	Coordinated attacks on oil and oil pipelines and power, communication, computer and drinking water distribution networks
Assassination methods	Hit-and-run tactics	Suicide bombings and combined attacks
Purpose of the terrorist action	Carrying out a spectacular attack that will draw the attention of the media and societies	Carrying out an attack that will result in as many victims as possible, which will draw the attention of the media and societies
Planned attacks at the management level of the organisation	Attacks planned against selected sites or a group of sites, without a "wider strategic vision"	Planned strategy of attacks, coordinated in terms of form, place and time

Source: Adamski, 2007, p. 60.

The techniques and tools used during attacks are also evolving. A quantitative list of the main techniques used by terrorists during attacks between 2002 and 2018 is presented in Figure 2.

[1] MANPADS - Man–Portable Air-Defense System.
[2] IED - Improvised Explosive Device.

Figure 2: The number of individual techniques used by terrorists in attacks between 2002 and 2018 [START, 2019, p. 36]

When analyzing Table 3, it is easy to see that between 2015 and 2018 there was a reduction in the number of attacks carried out.

Table 3: The number of terrorist attacks carried out in the world between 2015-2018

Year / Category	2015	2016	2017	2018
Number of attacks	11 774	11 072	8584	8093
Number of countries where attacks took place	92	104	100	84

Source: Country Reports on Terrorism, 2019.

Unfortunately, this is an illusory picture of reality, because, at the same time as their number decreased, their efficiency grew, increasing the number of fatalities (Table 4). Only such a comparison, the number of attacks to the number of people killed in them, gives us a real picture of the effects of terrorist activities. It also makes us aware that nowadays it is not the quantity, but the size of the most important effects for terrorist organizations as it gives publicity in the media and ”fame.”

Figure 3 displays the causes of the terrorist attacks between 1970 and 2018.

Figure 3: Terrorist attacks in the West by type, 1970-2018. [START, 2019, p. 47]

As can be seen, most of the attacks during the period considered were of a separatist (to a lesser extent political) nature, the number of which started to fall from 2000. From 2010 to 2018 a growth in politically and religiously motivated attacks can be observed.

Table 4: Global human losses due to terrorism in 2015-2018

Year / Category	2015	2016	2017	2018
Killed	28 328	25 621	18 753	32 836
Injured	35 320	33 932	19 461	22 651
Kidnapped	12 189	15 664	8937	3534

Source: Own study based on: Country Reports on Terrorism, 2019.

To continue to be effective, terrorist organizations must not only win on "battlefields" but also gain knowledge and evolve and win people's hearts and minds. If a terrorist group lacks the ability to learn, its effectiveness in achieving its goals will largely be determined by chance. Learning capabilities allows a terrorist group to adapt its actions to ever-changing circumstances through:

- developing, improving and using new weapons or tactics that can enable them to develop their capabilities over time,
- improving their members' skills in using existing weapons or tactics,
- collecting and using intelligence information needed to conduct operations effectively,
- combating measures to counteract their activities and thus enhancing the chances of survival of attempts to destroy the organization,
- preserving developed capabilities, even in case of loss of some members [Piekarski, 2015, p. 244; START GTD, 2018a; UNODC, 2018].

Therefore, the terrorist group‘s learning and change capabilities are a significant determinant of the level of threat it poses, as learning and change are the way organizations can seek solutions to problems that limit their freedom of action and limit their ability to achieve goals.

Each group brings its knowledge and experience, from which others can benefit. Lessons learned from the experience of other rebels and their techniques, tactics, and procedures result in a multiplication of strength.

Threats/Contemporary Terrorism/Today

Terrorist groups and individual terrorists have always used their environment and society to achieve their objectives. The development of civilization has brought more sublime ways of carrying out attacks in the 21st century. The technological development we are witnessing has been used perfectly by terrorist organizations, which has led to a 'new quality' of threats. The changes in terrorist groups' activities have also been greatly influenced by globalization, which has facilitated rapid access to many countries and places. Besides, the development of the information society has helped to increase fear. The Internet is now a tool used in psychological warfare, and one can say that it is a new kind of weapon used by terrorists, but also a new front of the fight.

The most dangerous terrorist groups in the world include Boko Haram, Al-Shabaab, ISIL, Taliban, and Al-Qaeda. Although there are probably cells of only one of them (ISIL) operating in Europe, all terrorist groups are a threat. There is little doubt that they will want or need to act together in the short or long term. That, in turn, will make a united, single-purpose grouping a considerable threat to Europe. Another growing security problem is that of the so-called "lone wolves" mentioned above, who watch terrorists from comfortable homes, assimilate with them, and radicalize themselves. Due to the lack of direct links and contacts with terrorists, they are tough for the services to work out.

The understanding of the term "lone wolves" has also recently acquired a new meaning. At the end of the fighting in Iraq and Syria with the so-called Islamic State (ISIL), strongly supported by Al-Qaeda and volunteers from almost all over the world, an order was probably given to some fighters to withdraw from the fighting and infiltrate countries of the Western World, mainly Europe and the USA. One group's task is to take cover, create a good starting point, and prepare for individual terrorist actions. These actions are to be carried out occasionally, according to the decision of the fighter or by order. Another group is to carry out "work at the base," spreading Jihad, building groups of social dissatisfaction, and creating new structures. Their task is also to recruit volunteers to carry out suicide actions and help in their organization.

In addition, given the social discontent caused by the influx of Muslim immigrants, it is possible to increase the problem of extreme right-wing terrorism[3], as in the case of Breivik or the 2019 attacks on mosques in New Zealand.

Terrorists use many tactics and techniques, mainly in Western countries, among other attacks using buses or trucks to drive passers-by or ram vehicles. That is the simplest and most effective way to carry out attacks. At the same time, such action is tough, and often impossible to predict, because the vehicle is most often conquered immediately before the action. Despite the controlled trade in weapons in Western countries and the increasing difficulty of access to them for law-abiding citizens, attacks with firearms or white weapons still cannot be underestimated. Bomb attacks or the use of chemical or biological weapons are also likely, but on a smaller scale, due to difficult access to components useful for creating such means of destruction and complicated procedures for preparing for action.

In addition to the threats to Europe's security that directly result from terrorist activity, there are several other aspects that can significantly impact the ability to prevent and combat terrorism effectively [CONTEST, 2018; NSS, 2017; National Strategy for Counterterrorism, 2018].

[3] Extreme right-wing (ultra-right) terrorism is based on an ideology combining various admixtures of racism, xenophobia, chauvinism, anti-Semitism, sexism (mainly misogyny), homophobia, anti-liberalism. It is limited to a form of militia (beating with dangerous tools and destroying property). The targets of extreme right-wing terrorist groups are most often immigrants, refugees, people of a different race, LGBT people, as well as people with a different worldview from the extreme right (left-wing, pro-choice, feminist, ecological, liberal, centrist, and moderately right-wing).

Let us look at the situation in Europe after World War II. Until the 1990s, the citizens of the world were seriously afraid only of the aftermath of the Cold War, but also a nuclear war that would ultimately destroy their homes, schools, and places of entertainment and contaminate the earth for hundreds of years. The real problem was the vision of the nuclear apocalypse caused by the two world powers, the United States (USA) and the Soviet Socialist Republics (USSR). Such a perception of the importance of threats distracted attention from terrorism and its importance for security, and at the same time, offered great opportunities for terrorist groups to act. Today we have a similar situation. We are coming closer and closer to a situation like that before 1990. Again, we have more and more tensions between the USA, Europe, and the rest of the so-called Western World and Russia and China. Once again, the specter of a global conflict using nuclear or other weapons of mass destruction is becoming a danger. The question is: *will this push the fight against terrorism into the background?*

Various types of pandemics can also pose a threat to an effective fight against terrorism. Let us pay attention to what happens during a COVID – 19 pandemic. In principle, we do not see another topic or threat is just a pandemic. We should consider it from the point of view of terrorists: *Are they also afraid of a pandemic?, Have they interrupted their preparations for subsequent attacks?* Knowing their determination, they use this time with even higher activity to prepare for the next attacks.

The last problem raised by the authors is the financing of expenditure on the fight against terrorism. It is directly related to the last two threats since the money will also be divided into increased needs resulting from them.

Since the terrorist attacks of 11 September 2001, international support for more effective counterterrorism measures and responses has led to closer international cooperation in counterterrorism matters and a widespread tightening of the approach to prosecuting "terrorists." More money was then allocated, from $76 billion in 2001 to $111 billion in 2014 (Figure 4). It was imperative in the context of the observed increase in exports and globalization of terrorism by groups such as Al-Qaeda and the so-called Islamic State in Syria and Levant (ISIL) [Thomas, 2018]. However, the trend is not showing clear signs of the decline of its scale and popularity.

Looking at the following years, however, we see a significant drop - 38% in spending (Figure 4) from $54 billion in 2017 to $33 billion in 2018.

Figure 4: Global costs of counterterrorism spending in 2000-2017 (in billion). [START, 2019, p. 29]

With such a downward trend, there may not be enough money for an effective fight against terrorism. The total amount of global economic losses resulting from terrorist attacks is estimated at $14.1 trillion for 2018, or 11.2% of global GDP [START, 2019, p. 31].

Estimating these costs is very cautious, as they do not take into account the long-term consequences of terrorism resulting from limited tourism and related business, production, and investment activities. The economic impact of terrorism varies in regions, as shown in Table 5. In Europe, the effect of terrorism on economic losses is estimated at 0.6.

Table 5: Economic impact of terrorism by region, $US billions, 2018.

REGION	ECONOMIC IMPACT OF TERRORISM (US$ BILLIONS)	REGIONAL ECONOMIC IMPACT AS PERCENTAGE OF THE GLOBAL TOTAL
sub-Saharan Africa	12.17	37%
Middle East and North Africa	11.9	36%
South Asia	5.87	18%
Asia-Pacific	1.22	4%
Europe	0.6	2%
South America	0.59	2%
North America	0.49	1%
Russia and Eurasia	0.23	0.7%
Central America and the Caribbean	0.12	0.4%

Source: START, 2019, p. 47.

The impact of terrorism on individual European countries has been estimated according to the GTI[4]. Europe recorded an improvement in 25 out of 36 countries in 2018 and is the second best-performing region after Central America and the Caribbean, as shown in Table 6.

[4] It is based on the Global Terrorism Database (GTD), which is the most reliable source of data on terrorism. The GTI has been developed in consultation with the Global Peace Expert Panel on the GTI Index. The GTI assesses each country on a scale from 0 to 10; where 0 means no impact of terrorism and 10 represents the most tangible impact of terrorism. Countries are ranked in descending order with the worst results listed first in the index.

Table 6: Europe GTI score, rank & change in score, 2002-2018.

Country	Overall Score	Regional Rank	Change 2002-2018	Change 2016-2018
Turkey	6.533	16	2.365	-0.503
United Kingdom	5.405	28	1.102	-0.205
France	5.008	36	1.269	-0.467

Only eight countries worsened their index, while three countries recorded changes in their score. According to Europol (TE-SAT, European Union Terrorism Situation, and Trend Report), between 2013 and 2015, the number of terrorist attacks, both failed or thwarted, as well as those carried out, has steadily increased within the EU. In 2013, there were a total of 152 attacks, in 2014. - 201, and in 2015. - 211 The above trend changed in 2016 when the number of attacks fell (142). In the past year, they took place in the UK (76), France (23), Italy (17), Spain (10), Greece (6), Germany (5), Belgium (4), and the Netherlands (1). For several years now, the number of injured or victims of terrorist acts has remained at a similar level in the European Union. In 2015, 151 people were killed, and 360 were wounded across the EU, while 142 were killed and 379 wounded in the late year.

Another important aspect is the number of people arrested in European Union countries on charges of terrorism. In 2013 it concerned 535 cases, in 2014 – 774, and in 2015 - 1077. The trend changed in 2016 when there was a slight decrease to 1002 cases. In this context, a particularly worrying trend is the increase in the number of arrests for terrorist activities motivated by Jihadist ideology. In 2012. It was 159 in 2012, 395 in 2014, and 718 in 2016. It should be noted that in the past year about 70% of all detainees for terrorist activities were Islamists, compared to 50% two years earlier. In 2016, the highest number of such cases was registered in France - 429 (a total of 456 people was detained in France for various activities related to terrorism). Spain (69), Belgium (62), the Netherlands (36), Austria (30), Italy (28), Germany (25) were also in the lead. It is worth noting that in 2016 no Islamic arrests took place in the United Kingdom, although it is there that one of the largest Muslim communities in Europe lives, and the local population of radical Islamists is currently estimated at around 20,000. Moreover, as already noted, in 2016, the most significant number of acts of terrorism in the United Kingdom was recorded (but only on separatist grounds). The extent of this phenomenon in individual EU member states is shown in the summary [Wojciechowski, 2017].

To sum up the problem under consideration, it is safe to say that the real threat of terrorism to European countries exists, and the emerging new security picture does not allow us to look optimistically into the future. Therefore, there is nothing left to do but to be prepared for an effective fight against terrorism, especially anti-terrorism [Morell,Michael 2015 ;Jones, 2014;] and counterterrorism (direct combat) [de Sousa, Mirza, and Verdier, 2009; Warner and Matfess, 2017].

The knowledge about terrorist threats should be steadily spread among society, not based on intimidation because it has a negative effect, but building awareness.

What is more, it should be stressed that only joint action by all countries in Europe and its immediate environment can allow these tasks to be performed effectively. The European Union should be the leading organization responsible for legal regulations and the organization and efficient management of the implementation of tasks in practice. It is worth considering building supranational anti-terrorist forces, able to act quickly in separate operational areas.

Conclusion

Summarizing the above considerations, we can formulate some important conclusions for European security:

- There is still a real threat of terrorism to European countries, and the emerging new security environment does not allow us to look optimistically to the future.
- Knowledge about terrorist threats should be constantly spread among the public, not based on intimidation because it has a negative effect, but building awareness.
- Preparation for an effective fight against terrorism, mainly through anti-terrorism (prevention) and counterterrorism (direct combat), should become one of the most important objectives of the European Union countries and Europe.
- The European Union strategy [2005] on combating terrorism sets out four areas of action: protection, prevention, response, and prosecution. The strategy, in line with the opinion of European law experts, has given Member States individual responsibility.
- Only joint action by all countries in Europe and its immediate environment, as well as cooperation with other partners of the broad coalition of states to fight global terrorism, can make it possible to carry out these tasks effectively, and this implies a change in the European Union's (counterterrorism) strategy towards team responsibility (see above).

- The European Union should be the leading organization responsible for legal regulations, as well as for **organizing and efficient direction of task performance in practice**.
- Counterterrorist activities (direct combat) should include the creation of transnational counterterrorist forces, capable of rapid action in separate operational areas, at the disposal of separate regional headquarters (command centers) of the European Union (with the possibility of participation of non-EU countries, voluntarily declaring their intention to take part in the program).
- Attention should be paid to the possibility of using the potential of the EU forces, which has not yet been properly (in principle) used.

Abstract

Biometric technologies are in a period of rapid development, and the interest of potential users is focused on the advantages and disadvantages that this technology offers, in terms of security, economy and convenience. The purpose of this paper is to show the design results for implementing the biometric control system for a door access. The prototype of the assembly was done with the help of a Creality CR-10 3D printer, through FDM - Melted Filament Modeling Method.

Keywords: Biometric Technology, Security Control Access, 3D Printing

Introduction

The development and improvement of information collection and processing systems have led to the modernization of access systems. Thus, security systems based on biometric technologies are presented as a viable, low-cost alternative to systems based on magnetic cards, barcodes or passwords.

The use of biometrics to identify and authenticate human subjects has begun to offer some unique advantages over traditional methods. Only biometric authentication is based on the identification of a certain intrinsic part of the human being. Systems based on magnetic cards, barcodes or physical keys can be lost, stolen or multiplied. The security offered by biometrics can be assisted by keys, passwords, PIN codes, so that the validation of the access depends on the person who requests it, not on what he knows, or what he has, but on what he is. It should be noted that biometric security resources are based on the person using them, effectively eliminating the risk that was associated with the old technology, while providing a much higher level of security that suits both users and system administrators.

Theoretical Aspects

Biometric Technology

Biometric technologies involve capturing a person's biometric data, transforming it into a biometric pattern (template), storing it in a database, and then verifying that person's identity by comparing the biometric pattern with the individual's appropriate characteristic. These systems ensure rapid identification and have a low failure rate. Obviously, identification with a fingerprint reader is faster than using, for example, an identity card. At the same time, because identification is done through a unique characteristic of the person and by eliminating the human factor, identification is more secure.

A fingerprint or iris scan is much easier to use than a normal password, especially if you want a long one. Most modern smartphones only need a few seconds to recognize a fingerprint, giving the user access. The biggest advantage of biometrics is that a hacker must be physically nearby to find out the

necessary information. This narrows the circle of suspects if someone finds out only user-known information. Proximity is also a factor that can help catch the perpetrator, which cannot be applied to a hacker from another continent.

In this context, biometric technologies are structured on the following principles or stages of operation (Fig 1):

- capture of information to be analyzed;
- information processing and creation of a data file - signature file;
- stage (verification phase);
- transmission of the results of the comparisons to the decision factor (user).

A fingerprint is the representation of the epidermis of the finger: it consists of a pattern of ridges and grooves interspersed as mentioned by Maltoni et al (2009). Peak discontinuities (eg, terminals or bifurcations) are called characteristic points (minutiae).

Fig. 1*: Principle structural scheme of biometric technology*

Identification algorithms, based on characteristic points, usually consider each characteristic point as a triplet $m = \{x, y, h\}$ encoding the spatial coordinates and the angle of the ridge. The set of attributes belonging to the characteristic points extracted from a fingerprint is called a template. Fingerprint matching consists of comparing two patterns to determine if the two sets of characteristic dots come from the same finger. Two characteristic points are considered matched if the spatial distance between them is less than the given spatial threshold and their directional difference is less than the given angular threshold. Such thresholds are needed to compensate for the inevitable errors made by characteristic point extraction algorithms and to take into account distortions caused by skin elasticity. Matching the characteristic points in practice can be a difficult task.

In the book by Lee and Gaensslen (2001), there are two important technologies used for fingerprint sensors: optical and capacitive. Optical sensors require a light source that is refracted through a prism. The finger is placed on a glass plate. The source illuminates the fingerprint and the image is captured. Capacitive sensors no longer require the optical device, the fingerprint image is obtained by measuring the voltage created between the skin and the polycarbonate plate of the reader. The capacitive sensors must have a surface similar to that of the finger. They are susceptible to noise, including 50 Hz noise from the user's network, as well as the internal noise of the sensor affects them. Electrostatic discharge, salt from perspiration or dry fingers may interfere with image capture from the sensor. As shown in the book by Ashbaugh (1999), data regarding the relative placement of lines, notches, forks and intersections are stored in a file of the user's database and then compared with the data entered into the computer by this user. Following the instructions, the subject enters a 1-9 digit PIN code by typing. At the signal, the finger is positioned on the reader board and then retracted. A numeric code is created. At the signal, the finger is positioned again, several times, for comparison. The whole operation must take less than 2 minutes. The file size is between 500 and 1500 bits.

Analysis and representation of fingerprints

The papillary impression is a reproduction of the epidermis on the finger, produced when the finger is pressed on a smooth surface. The most obvious structural feature is the pattern of ridges and valleys; In an image of a footprint, the ridges are closed areas and the valleys are open, Fig 2.

Fig. 2: Ridges and valleys in an image with a fingerprint

In the book by Maltoni et al (2009), fingerprint-specific features are generally described on three levels. The Level 1 feature set can be detected globally and includes singular points (core and delta), papillary structure, ridge orientation field, and ridge frequency.

In addition to the orientation field, the frequency (density) of the papillary ridges can be extracted, which represents the average number of ridges traversing a segment of a certain length centered in the pixel for which the ridge orientation was calculated and oriented orthogonally thereon, Fig. 1.3 (b). In general, the information provided by the orientation field is much more important than that extracted from the density of the ridges.

Analyzed globally, the fingerprint model exposes one or more regions in which there are distinctive shapes (characterized by large curves), as mentioned by Jain et al (2007). These regions (called *singularities* or *singular regions*) can be classified into 3 typologies: *loop*, *delta* and *whorl*, Figure 3 (a).

The loop and whorl define singular nucleus points, associated with the point of maximum curvature of the papillary ridges.

Single regions are generally used to define the fingerprint pattern, on the basis of which fingerprint classification can be performed, in order to simplify fingerprint retrieval and search applications. According to Roddy and Stosz (1997), fingerprint pattern is one of four features that can be extracted globally from the fingerprint image.

The Level 2 feature set is calculated locally and refers to the details in the fingerprint image called minutiae. "Mint" means small detail and in the context of fingerprints refers to the many ways in which papillary ridges can be broken or divided.

The thickness of the papillary ridges, their shape, their curvature as well as the details such as incipient ridges, scars, warts, and the most important pores, form the set of Level 3 features.

Fig. 3: Level 1 global features: (a) single points, fingerprint pattern, (b) ridge frequency, (c) ridge orientation field.

If the images are acquired at a high resolution (eg 1000Dpi), the sweat pores can be clearly identified, Fig 3 (a). In fact, every ridge on the epidermis (the skin surface) is dotted with sweat pores along its entire length. In a study developed by Stosz and Alyea (1994), it is mentioned that, although the information provided by the pores (number, position, shape) is very distinctive, very few automatic fingerprint matching techniques use these pores because a very high resolution and very good image quality are required.

Modeling the Sliding Door Assembly

The design and realization of the assembly was done with the help of a Creality CR-10 3D printer, through FDM - Melted Filament Modeling Method.

Using this method, a filament of a molten thermoplastic material is extruded through the nozzle at the end of the filament removal system onto the layered surface to make the designed objects.

Each new layer will be deposited on top of another layer and attached to it because the extruded material hardens almost immediately after being removed through the nozzle. FDM printers usually use ABS plastic, PLA, biodegradable polymers, and some more "eccentric" ones even use concrete, chocolate, sugar or other unusual foods.

3D printable models can be created with 3D design software or 3D scanning. Figure 3 shows a model of the designed sliding door. The sketch corresponds to the scale of the real object, all dimensions being measured and designed so as to facilitate the work in the mechanical assembly stage.

Before printing a 3D model from an STL file, it must first be processed by a software, commonly called a "slicer", which converts the model into a sequence of subtitle layers and produces a series of commands. travel on the three axes of travel and information on the deposition of material. These commands form G-Code (in the case of the printer studied in this paper), but the name may differ depending on the printer or software used. There are several such slicer programs including Skeinforge, Slic3r, KISSlicer, Cura, etc.

Fig. 4: Creality CR-10 3D printer diagram

The 3D printer follows the instructions in the G-Code to deposit successive layers of material to form the final object. These layers, which correspond to the virtual sections of the CAD model, are automatically joined and glued, thus achieving the final shape.

The main advantage of this technique is the ability to create almost any desired geometric shape. The printer resolution describes the thickness of the deposited material layer, the X-Y resolution in number of dots per inch (dpi) or micrometers (µm). The thickness of a layer is usually around 100 µm, ie 250 dpi, although there are printers that can make layers of tens of µm. From the software, we can change this thickness according to the requirements of the application. The XY resolution is comparable to the resolution of traditional laser printers. The points are about 50 - 100 µm in diameter.

Fig. 5: 3D model designed for the sliding door

The block diagram of the sliding door system

The block diagram consists of CPU (central processing unit - development board with an ATmega328 microcontroller) that executes the program through arithmetic and logic operations, as well as system input / output operations, R305 fingerprint scanner sensor module, 4x3 matrix keyboard, 1602 LCD module, a pulse driver and a bipolar stepper motor. A threaded rod is connected to the motor shaft on which the sliding door runs. There is also a DC power supply (Fig 6).

When powering the system, the LCD displays a message for entering the password code, once the correct code is entered, the CPU allows the fingerprint to be scanned, if the fingerprint is correct the CPU sends the signal to the driver who controls the motor step by step; it opens the sliding door, after the interval of 2000 micro seeds the door closes and the system returns to its original shape.

The motor chosen for this application is NEMA 17 (National Electrical Manufacturers Association), from the category of bipolar stepper motors.

Fig. 6: Block diagram

A bipolar motor has two coils that are permanently fed, the torque obtained having an optimal value compared to the unipolar model where only one of the two coils is fed, thus resulting in a low torque. The bipolar motor has four connecting wires and the unipolar one has six, and is controlled by reversing the current through the two coils, in turn. The NEMA 17 motor, model 103H5208-10U41 has the following main features: 1.8°/step, recommended voltage varying between 12 volts and 24 volts, phase current of 2 amps and torque of 59 Ncm.

Fig. 7: Driver interconnection scheme

Fig. 8: Interconnection diagram for module R305

The motors perform a complete rotation in a number of 200 steps, to which is added the level of the desired resolution, and multiplying these two values, we will obtain the number of effective steps of a complete rotation.

Hardware drivers are used for motor control. The driver model is A4988 and it was chosen due to its easy-to-use control interface and easy configuration and interconnection. The interconnection diagram with the microcontroller and the stepper motor is shown in Fig 7.

R305 print sensor module with TTL UART interface was used for direct connection to the microcontroller or PC via the MAX232 / USB-Serial adapter (Fig.8). Connect the microprocessor or system with TTL communication and send data packets to take pictures, detect prints, hashes and searches. Up to 162 fingerprints can be stored on the built-in FLASH memory. The supply voltage is in the range of 3.6 - 6.0VDC, while the maximum current is 120mA. LCD 1602 module with blue backlight was used to display the messages, the supply voltage is 3.3 V.

To control the password code, a 4x3 matrix keyboard was used, with 12 buttons (numbers from 0 to 9 and special characters: "*", "#"). Maximum supply voltage 24VDC, maximum current 30 mA, 8 output pins.

Fig. 9: The prototype door

Programming the microcontroller

The programming of the microcontroller was made in the C ++ programming language, language in which the following source code was elaborated, from which a fragment is presented:

```
... #include <LiquidCrystal.h> //display library
#include <Keypad.h> // keyboard library
#include <Adafruit_Fingerprint.h> //fingerprint lib
#define mySerial Serial
int pozisyon = 0;
const byte ROWS = 4; //4 columns
const byte COLS = 3; //3 rows
bool s= false;
int MotorStep = 9;
int MotorDir = 10;
int MotorEN = 11;
    ...
```

After displaying the message "Enter password" enter the code set in the first part of the code "8989"; if it is entered correctly the message "Password is Correct" is displayed, and the message "Fingerprint Verification" appears; if the code was incorrectly entered, the message displayed is "Password is incorrect."

```
    …
delayMicroseconds(1000);}
      delay(2000);
      for (int i=0; i<2070; i++){
      digitalWrite(MotorDir, LOW);
      digitalWrite(MotorStep, HIGH);
      delayMicroseconds(1000);
      digitalWrite(MotorStep, LOW);
      delayMicroseconds(1000);}
      digitalWrite(MotorEN, HIGH);
  lcd.clear();
  s=false;
  return finger.fingerID;
}
```

Conclusions

Using biometric technology, the employer can check if the employees have complied with the work schedule and, at the same time, if they have fulfilled their duties on time. Also, fingerprint models are very useful in limiting staff access in certain areas, or when using certain machines. Only those specially trained to program a machine will be able to start, adjust or use it, thus avoiding errors that can sometimes have serious consequences on the production line.

One of the first implementations of security biometrics is access to special places of maximum security (bank, laboratories, weapons room), offering access only to persons enrolled in the system. They are effective because it is necessary for the person to be present, a system that is very difficult to break.

Biometrics can also be used in automation, it can help start machines, laptops, equipment or production machines only to authorized persons.

It is easier to access that person's database, which could be introduced at the airport or portable devices connected to the network to help state bodies to more easily find out the identity of certain people, which is necessary for anti-terrorism or wanted persons. The practical way of biometric systems is that it can replace a credit card, driver's license, passport or identity card, once the data is entered into a network.

Last but not least, biometric technology could offer a personalized driving experience: when the car "recognizes" the driver, elements such as car temperature, music, navigation system or seat position could be automatically adjusted based on his preferences.

Abstract

The main goal of this paper is to understand whether there are different motivational factors of decision-making processes to attend a conference from people of different nationalities (namely Portuguese and Germans) as well as their social media usage and preferences. After the literature regarding the topic was analysed in order to guide the research, a quantitative empirical research in the form of an online survey of 20 questions was conducted. 53 respondents in Germany and 56 respondents in Portugal were analysed. The findings revealed no significant differences between the 2 markets. The results gained from the empirical research revealed useful to be used as guideline for the development of a social media-marketing plan in Germany for a company responsible for the organization of a big annual event for Product Managers in the Southern part of Europe that collaborated with this study.

Keywords: Online communication, Conference, Attendees Motivation, Marketing.

Introduction

The social media usage in recent years has been increasing dramatically due to the growing number of social networking sites, instant messaging services, online forums and mobile smartphones (Lai & To, 2015). And nowadays, social networks are one of the important components of marketing strategies and campaigns of companies aimed at attracting customers (Nadaraja & Yazdanifard, 2013). But without a correct social media strategy and social media plan, there is no chance to successfully run the companies (Saravanakumar & SuganthaLakshmi, 2012).

The company's existence in social media networks helps build close relationships with customers in various industries around the world (Sashi, 2012) and event management industry is not an exception. The event management industry continues to prosper offering attendees more and more event choices from which they can choose (Global Meetings and Events Forecast, 2019). Due to the industry's rapid growth, it is having difficulty attracting more attendees to events; therefore, developing a reliable and effective system for assessing the factors considered by the participants of the event is in the interest of contribution to the event marketing practice (Yoo & Chon, 2008). Competition between venues and events underlines the need for a better understanding of the attendee's behaviour and their decision-making process (PCMA Survey, 2003, as cited in Severt, Wang, Chen & Breiter, 1987).

Cite this Article as: Hanna KAZAK And Ricardo Fontes CORREIA "The Relevance of Online Communication for Conference Attendees Motivation. Differences between German and Portuguese Participants" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Which factors influence attendees when deciding to attend an event, what are the main reasons for attending the event, what social media channels attendees use and which sort of content is the most attractive, as well as other important questions that are related to the habits of using social networks, must be answered for the successful event planning and communication.

The goal of this research is to explore and understand if there are differences between German and Portuguese attendees' motives for the decision to participate in a conference, their social media usage and preferences and whether it is worth to adjust social media marketing plan for each of these 2 different markets.

This paper is divided in four main sections. The research starts with the literature review and an overview of the main definitions regarding social media and the conference industry. Secondly, we describe and justify the methodology used in this research. Then we introduce the empirical research results and discussion of the research main findings. The paper ends with the limitations of the study and suggestions for further research.

Literature Review

Social Media

The 21st century is experiencing a social media revolution that has already led to enormous changes in how consumers receive and use marketing communications (Williams, Crittenden, Keo & McCarty, 2012). On average, people spend a quarter of their free time on the Internet (Meesad, Sodsee & Unger 2017). But even though social media networks has become one of the main part of our everyday life, the companies are still struggling to understand the customers in their social media and why and how they use it (Whiting & Williams, 2013). For consumers, digital media is now not only a resource for researching the products and services they want to purchase, but also to engage with the companies and other consumers (Garretson, 2008). Therefore, social media should be one of the components of the company's marketing strategies (Nadaraja & Yazdanifard, 2013). And the companies that really understand the online behaviour of their customers have an advantage to engage with them (Woodcock, Green & Starkey, 2011). But before implementing a social media marketing plan, it is essential to clearly define goals and target audience (Preston, 2012). Moreover, McCann and Barlow (2015) emphasized that a company should have a clear strategy and understanding of how and what it will be used for. According Castronovo and Huang (2012) by formulating a social media strategy, a variety of social media tools can be used based on the goals of the strategy and the trends in social media usage among the target market. Defining the right strategy as well as conducting research on the target audience for this strategy are the main components of effective social media development for companies (McCann & Barlow, 2015).

Nowadays, the Internet is considered as the most cost-effective and more efficient way to engage with people (Castronovo & Huang, 2012). Social media facilitates the interaction between buyers and sellers and gives the opportunity to better understand customers (Sashi, 2012). Social media marketing can be used to achieve various goals, including increasing traffic, increasing search engine rankings, or increasing sales of a product or service (Weinberg, 2009). The increase of market share and brand awareness could also be achieved by creating an appropriate social media strategy, which would be less costly than using traditional marketing tools (Rafiee & Sarabdeen, 2013). Even companies with a limited budget can run successful social media marketing campaigns with little or no cash investment (Nadaraja & Yazdanifard, 2013). Moreover, social media platforms give comprehensive opportunities to customize user engagement (Hanna, Rohm & Crittenden, 2011). And Farook and Abeysekera (2016) also emphasized that one advantage of social media is its positive effect on customer online engagement.

Conference Customer Engagement

In recent years with the evolution of the Internet and various social media channels, the concept of customer engagement has increased its importance. Patterson, Yu and De Ruyter (2006) define customer engagement as the level of different "presence" of the customers, such as physical, emotional or cognitive in their relationship with the organization. Farook and Abeysekara (2016) examined that the content of social media posts plays an important role in customer online engagement and noted that the higher the impact of social media marketing, the higher the customer engagement. According to Kilgour, Sasser and Larke (2015), in order to increase the social media engagement, it is important to understand the various user groups and their interaction on social media channels.

People attend conferences for various reasons and their decision depends on their priorities, interests, and tastes and marketers approach should reflect their preferences in building a marketing plan (Preston, 2012). However, Preston also emphasized that different approaches should be used aimed at separate market segments that is why it is important to research and analyse the target market of potential customers.

In order to improve a strategic marketing campaign, it is important to understand people's motivation and their decision-making process for attending various events (Gitelson & Kerstetter, 2000). Potential attendees have different requirements and motivational factors and participate in the conferences for various reasons (Hoyle, 2002).

Multiple motivations are usually the norm for the decision to travel and attend conferences. Rittichainuwat, Beck & Lalopa (2001), divided the conference motivations into 2 groups: the push factors related to human needs which motivate to travel an attend conferences, and the pull factors more related with the conference attractiveness and technical features. They also consider facilitators and inhibitors factors. The facilitators "refer to factors that encourage travel, such as availability of time, money, and good health" and inhibitors, "which are exemplified by the lack of money, time, and good health, discourage conference participation." (Rittichainuwat, Beck & Lalopa 2001, p.47). According to the authors the top five major conference motivations were "Education", "Networking" "Interesting conference programs", "Career enhancement" and "Traveling to desirable place". The top three major conference inhibitors were money, time, and distance. And the top four major conference facilitators were "Covered travel expense from my employer, school", "Affordable conference costs", "Affordable transportation costs", and "Time availability".

Getz, (2007) classify the motivators in 2 large groups: the first one is the 'intrinsic motivators', which are related with escapism that connects the event with a desired leisure pursuit. This escapism "leads people to events for the generic benefits of entertainment and diversion, socializing, learning and doing something new" (p.416). The second group named as "the pull or seeking factors" is related "to those with special interests who want a specific set of benefits offered by the event." (Getz, 2007, p.416) and the professionals who have to attend certain conferences because of their content or unique networking possibilities are mostly included here.

Oppermann and Chung (1997) were the first who developed a conceptual framework for decision-making of participation in conventions. This model represents how different variables influencing the decision-making of potential attendees. Personal or business factors, association or conference factors, location factors, and intervening factors are the four main factors that influence an individual's decision-making process when attending a conference. The figure below represents the conference participation decision-making process.

Personal or business factors. The first factor that any potential attendee takes into account when deciding whether to attend the conference or not is the conference accessibility that includes the conference cost, family concerns, health of attendees and time availability of participants. Moreover, one of the conference attendance motivators that are related to personal and business factors is the desire to learn something new to become a better specialist in the field and professional advancement.

Figure 1: Conference Participation Decision-Making Process. Source: Oppermann & Chon (1997 p.186)

Association or conference factors. This factor is associated with the involvement of a person in the corresponding association: networking and job opportunities, personal interaction with like-minded people and making professional contact play a major part in deciding whether to attend the conference or not.

Location factors. Favourable conference locations nearby the airport or home are important factors considering whether to attend the conference or not. Moreover, the closest location will save time and money and decrease the expenditure cost of attendees. For some people, the climate of the country where the conference is held can also influence decision making to attend the conference.

Intervening factors. Oppermann & Chung (1997) emphasized that conferences should not only compete with each other for attendees but also compete against other related products or services. Other conferences, for example, are taking place in another more attractive location, at different times or with better speakers and programs can be one of the intervening options for potential attendees. It may also refer to a different way of spending the time rather than going to the conference. Such opportunities also include spending time with family, traveling or simply staying at home and watch the conference online.

Research and Data Collection Method

When choosing the research methodology and the way the data is collected, the aim of the research has a high influence. The aim of this research is to better understand the motivation of product managers to attend conferences, and to collect information about social media usage and preferences of product managers to improve consumers' engagement. Moreover, we wanted to understand whether there are different motivational factors of decision-making processes to attend the conference from people of different nationalities (namely Portugal and Germany) as well as their social media usage and preferences.

Considering the goal of the research we follow a non-experimental quantitative research. Due to geographical limitations the quantitative primary research in the form of online survey was chosen to collect the data. The non-probability sampling technique was used throughout the research using a convenience sampling design.

The survey was distributed, with the help of the marketing department of a company responsible for the organization of a big annual event for Product Managers in the Southern part of Europe. The survey, which was constructed in English and had identical questions for both German and Portuguese respondents, was placed on social media channels of Facebook, LinkedIn, Instagram and Twitter, sent in the company newsletters of the 6th and 14th of November 2019, and sent by email to the attendees of the conference organized in 2019 by the company that collaborated with the study.

In total 135 people participated in the survey, however, after the preamble to survey for consent to participate in research and the question of where do respondents live, 26 respondents were eliminated because they didn't meet the requirements for the survey. 109 respondents were selected for further analysis: 53 respondents from Germany and 56 respondents from Portugal.

Both German and Portuguese attendee's online survey consists of 20 questions and was grouped in 4 categories: demographic characteristics, attitude toward the conference, motivational factors and social media usage and content preferences. This survey was designed to better understand the motivation of product managers to attend conferences and the factors that influence decision making to attend professional events.

Results

Decision Making and Attractiveness Factors.

Attitude toward the conference. Two questions were asked in order to analyse the attitude of respondents toward the conferences in terms of how often they attend the conference per year and if there are any other resources besides going to the conference to develop themselves as a product management professionals. Almost all the respondents (46 (87%) from Germany and 51 (91%) from Portugal) indicated that they read blogs, articles, books and other resources that are on topic. 36 (68%) respondents from Germany and 35 (63%) from Portugal mentioned that they attend the conferences. What concerns how many conferences do participants attend, on average, in a year, the majority of respondents 41 (77%) from Germany and 37 (66%) from Portugal attend conferences 1-2 times per year.

Motivational factors. A block of questions in this section was asked to find out what factors influence the respondent when deciding to attend the conference. Respondents were asked to evaluate factors in terms of importance from 1 - not important at all, to 5 - very important. From the Figure 2 below it is clear that the most important factor for both German and Portuguese attendees are prestigious speakers, ease of access and the price of the tickets. Travel expenditures are not too far behind. And the expectations related to a partnership with organizations that protect the environment and famous brand name of the company are the least important for attendees.

Figure 2: Bar graph. Average evaluation of respondents' factors to attend the conference.

When respondents were asked to evaluate their motivation to attend the conference using the level of measurement in the range from 1 to 5, from the not important at all to very important, the results showed that the most important motivational factors for attendees to get theoretical knowledge and to get inspired (Figure 3).

Figure 3: Bar graph. Average evaluation of respondents' motivation to attend the conference.

Respondents were asked where would they first search for the conference if decided to attend the conference. 25 respondents (47%) from German and 32 (57%) from Portuguese attendees mentioned that google search in most cases is the most preferable way of search for the conference. In the second place, 30% of German attendees and 27% of Portuguese attendees prefer to search in social media.

The respondents were asked with whom they attend conferences. Results revealed that 32 respondents (60%) of German attendees prefer to attend the conference with their co-workers while only 18 attendees (32%) form Portugal mentioned that. Portuguese respondents are most likely to attend the conference alone and more than half of the respondents (59%) indicated that.
According to the survey, regardless of the country the majority of respondents 20 (38%) from Germany and 25 respondents (45%) from Portugal pointed that the best alternative to the conference is YouTube videos with speakers' talks. Live streaming of the conference goes after and accounts 26% of German answers and 32% of Portuguese.

Social media usage and content preferences. This part of the survey was moulded to collect information about the social media usage of respondents. Figure 4 below shows that the most popular social media platforms in terms of how often it is used is LinkedIn, Youtube, Instagram and Facebook.

Figure 4: Bar graph. Average evaluation of respondents' usage of different social media platforms.

From the question regarding which part of the day you are the most active on social media the majority of respondents, 34 (64%) from Germany and 27 (48%) from Portugal answered that they are most active in the evening. 13 (25%) of German and 8 (14%) of Portuguese are most active in the morning.

Respondents were asked to indicate their level of agreement with a statement with five-items focused on identifying what is their internal motivation for using social media (Figure 5). The most highly rated answers were "I use social media to connect and keep in touch with friends and family" and "I

use social media to know the latest news ". Social media as a source of relaxation and entertainment is also not far behind. It is meaning that respondent fall under 3 categories of social media users: social interaction, information seeking and entertainment.

Figure 5: Bar graph. Average evaluation of respondents' purpose of social media usage.

During the survey respondents were asked what types of content do they prefer when learning about companies and their products or services. The figure below (Figure 6) shows that the most frequent answers were long articles, videos and social media posts. However, German respondents value social media posts more than the Portuguese, while they prefer to watch videos.

Figure 6: Bar graph. What types of content respondents prefer when learning about companies and their products or services

While conducting the survey participants were asked to evaluate how interesting is each of the following content for them in social media channels (Figure 7). The level of measurement in the range from 1 to 5 was used from strongly disagree to strongly agree. The information about speakers and their talks as well as educational materials about product management are the most interesting content for German and Portuguese respondents. Information about backstage and sales or discounts is not relevant for both respondents groups.

Figure 7: Bar graph. Average evaluation of respondent's interest in the content of social networks.

Conclusions

While analysing the empirical research results there were no significant differences identified between the markets. But still is possible to identify small differences between the German and Portuguese Market. Firstly, German attendees commonly has 0-9 years of work experience, when Portuguese are more likely to attend conferences in the beginning of their career and has 0-3 years of work experience. Secondly, German attendees prefer to attend the conference with their co-workers while Portuguese are most likely to attend the conference alone. Moreover, long articles and social media posts are the most preferable type of content for German market, while Portuguese value more videos.

No other significant differences were identified between markets that assure that adapting social media marketing plan will not result in significant unsuspected issues in different markets. All the results will be used in the further development of managerial decisions of the company that collaborated with this study to improve its social media-marketing plan in Germany.

The study faces some limitations, such as time and geographic restrictions, as well as the fact that the survey was not conducted in the respondents' native language. Due to the research limitations the sample size was not big enough and can lead to bias interpretation of the results.

Abstract

Shelf space allocation is one of the most important processes in retail management. It influences not only this process performance and costs but also the quality of relationships with customers and customers' satisfaction. The shelves on which products are displayed in retail stores are some of the most critical resources in the retail environment. The category management and shelf space allocation decisions are therefore issues very important to the retail industry. The objective of this paper is to develop a practical shelf space allocation models with vertical position effects to compare retailers' profit, considering it as linear and non-linear with space elasticity parameters. A comparison of the developed models is also presented. Results obtained from experimental data sets using the CPLEX solver show a significant difference between these solutions.

Keywords: Merchandising, Planogram, Retailing, Shelf Space Allocation, Solver.

Introduction

Shelf space allocation is one of the most important processes in retail management. The traditional form of sale is still important, despite the rapid growth of e-commerce. Even during the Covid-19 pandemic, customers make shopping in traditional form, especially in the food industry. It influences not only the process performance and costs but also the quality of relationships with customers and customers' satisfaction (Flamand et al., 2018). Moreover, the choice of shelf space allocation approach can have a significant impact on sales forecasting, delivery planning, procurement, financial flows, and other retail processes. Often the retailer can also stimulate the purchases of products even if they are not really in the customer's needs (Frontoni et al., 2017). Therefore, decisions related to shelf space management and allocation are the critical factors influencing retail companies' efficiency. The literature presents a great variety of shelf space allocation problem (SSAP) models with the common goal of maximizing the total profit by deciding on the number of product facings on each shelf, without considering their location on the vertical shelf level or horizontally within the shelves. One of the major drawbacks of the SSAP literature is that shelf space allocation models pay no attention to merchandising rules based on fast moving products and the product price, i.e. they neglect vertical shelf levels for basic and luxury products. The next reasonable limitation we figure out is that the SSAP literature totally omits such allocation features as capping and nesting, which provide the retailer with additional revenue. Capping signifies allocation of a product on the top of another one with the possibility of changing the orientation of the top product to allocate more products. Nesting signifies allocation of a product inside another one as a bucket.

The objective of this paper is to develop a practical SSAP models with vertical position effects to compare retailers' profit considering it as linear and non-linear with space elasticity parameters. Our contribution is related to developing mathematical models consider different vertical levels based on product prices, which makes the planogram visually attractive to customers as well as generating more revenue for the retailers allocating more expensive products on eye-level. To the best of our

knowledge, such a model has not yet been developed. Therefore, the main contribution of this study is extending the shelf space allocation theory with SSAP models with a linear and non-linear profit function considering vertical position effects with regard to four constraint groups (shelf constraints, product constraints, multi-shelves constraints, and category constraints). We also provide an experiment comparing these two models on various practical problem sizes with the CPLEX solver.The rest of the paper is organized as follows. Section 2 presents an analysis of the related works and Section 3 provides the problem definition. The mathematical models for both problems are presented in Section 4. Numerical results of the computational experiments are given in section 5. Conclusions are drawn in Section 6.

Related Works

Shelf space is one of the most critical resources which attract customers' attention in a retail store. Currently, there is a lot of ongoing research on SSAP. Appropriate shelf management decisions enable customers to easily find, compare, and approach the products sold at the store (Düsterhöft 2020). Flamand et al. (2016) performed experiments to measure the elasticities. The data had been collected from wide retail chains with a high number of stores. Within these series of experiments, only category elasticities were estimated, and shelf space allocation decisions were not considered. The researchers' experiments proved that impulse buying products have higher space elasticities, i.e. increasing the shelf space for them results in increased sales. The major drawbacks of their experimental studies are time, cost, and inefficiency. The reliability of the results is doubtful if the product is presented in multiple places within the store. Moreover, a significant promotion on a similar product, or holiday or seasonal items can totally change the demand for the product being examined. What's more, product elasticity parameters do not remain the same during a long period; they also should be continuously estimated (Dalkilic, 2007). Price, promotion, and assortment variety influenced by the category in the overall retail, own label programs, as well as advertising also affect product demand (Dhar et al., 2001). Commonly, category and shelf space decisions should consider substitution possibilities between similar features. But such substitution effects are difficult to predict, estimate, or obtain from a real store (Bianchi-Aguiar, 2015). Murray et al. (2010) developed a joint optimization SSAP model considering display orientation and product price. They included in their model price cross elasticity, which is much easier to be measured and predicted than cross elasticity. Chen et al. (2014) investigated the product placement problem in designing online product web listing pages, which an issue very close to retail SSAP. They developed an optimization model to determine how to allocate products of the same category over multiple Web pages with the goal of profit maximization. (Karampatsa et al. 2017) states, that shelf space allocation models do not clearly and comprehensively address assortment selection, neglect substitution effects between products, and ignore the stochastic nature of demand.

Problem Definition

With limited shelf space and plenty of regular and new products included in the assortment, the retailer must decide on each product's quantity and selling price and allocate the products as effectively as possible using the available shelf space. Many retailers are now turning to shelf space allocation models to maximize their total profit. Before presenting the mathematical models considered in this paper, we introduce some definitions related to shelf space allocation. Planograms are graphic representations of product allocation on the fixtures or shelves which allow the retailer to define the position of the product on the shelf and its number of facings. The number of facings, which is a very important variable in SSAP, is defined as the quantity of items that can be directly displayed on planogram shelves. Items, which cannot be seen, are not considered in this research. In our research, we define the following variables and parameters. Subscripts mean a variable's indexes, superscripts mean a variable's mnemonics and don't mean indexes or powers.

Parameters and indices: K - total number of categories; G - total number of subcategories; S - total number of shelves; P - total number of products; k - category index, $k = 1,...,K$; g - subcategory index, $g = 1,...,G$; i - shelf index $i = 1,...,S$; j - product index, $j = 1,...,P$.

Parameter of a category $k : m_k$ - minimum category size as percentage of the shelf length.

Parameters of a shelf $i : s_i^l$ - length; s_i^d - depth; s_i^h - height.

Parameters of a product $j : p_j^w$ - width; p_j^d - depth; p_j^h - height; p_j^s - supply limit; p_j^u - unit profit; p_j^k - category; p_j^g - subcategory; p_j^n - nesting height, $p_j^n \le p_j^h$, or $p_j^n = 0$ if a product can't be nested;

$$p_j^{o_1} = \begin{Bmatrix} 1, & \text{if front orientation is available for product } j \\ 0, & \text{otherwise} \end{Bmatrix}$$ - front orientation binary parameter;

$$p_j^{o_2} = \begin{Bmatrix} 1, & \text{if side orientation is available for product } j \\ 0, & \text{otherwise} \end{Bmatrix}$$ - side orientation binary parameter;

p_j^l - cluster; $f_j^{\min}$ - minimum number of facings; $f_j^{\max}$ - maximum number of facings; $c_j^{\max}$ - maximum number of caps per facings group; $n_j^{\max}$ - maximum number of nests of one facing; $s_j^{\min}$ - minimum number of shelves on which the product can be allocated; $s_j^{\max}$ - maximum number of shelves on which the product can be allocated; α_j - scale parameter; β_j - space elasticity.

Decision variables:

$$x_{ij} = \begin{Bmatrix} 1, & \text{if product } j \text{ is placed on the shelf } i \\ 0, & \text{otherwise} \end{Bmatrix}$$

f_{ij} - the number of facings of the product. c_{ij} - the number of caps of the product.

n_{ij} - the number of nests of the product.

$$y_{ij}^{o_1} = \begin{Bmatrix} 1, & \text{if product } j \text{ on the shelf } i \text{ on front orientation} \\ 0, & \text{otherwise} \end{Bmatrix}.$$

$$y_{ij}^{o_2} = \begin{Bmatrix} 1, & \text{if product } j \text{ on the shelf } i \text{ on side orientation} \\ 0, & \text{otherwise} \end{Bmatrix}.$$

The problem can be formulated as follows. On a given planogram, a retailer offers K merchandise categories. The retailer determines P products and assigns them to K categories and G price subcategories. Merchandising rules define how products are placed on shelves by identifying product categories into which products should be grouped and price subcategories assigned to the shelves. The retailer can manage its merchandise categories defining the minimum occupied space by each category on the planogram in order to make it visually attractive, which improves customers' satisfaction. The common practice is that categories are vertical, i.e. products are grouped and arranged inside the category. The customer's basket depends on product prices and various levels of

categories. On the planogram, the price subcategories are horizontal, i.e. the more expensive or the more branded product is, the higher it is placed on eye-level. Obviously, cheaper products can be placed on lower shelves as well as upper ones. In contrast, more expensive products can't be placed on lower shelves. The retailer's profit-maximizing problem is to find the optimal shelf space for each product while defining its quantities.Fig. 1 presents the merchandising rules of allocating products in vertical shape categories (A, B, C) on a planogram. Numeric values signify horizontal level price subcategories. The darker the products on Fig. 1 are, the more expensive in a real store they are, which means that they can't be placed on lower shelves. Unlike cheaper products, marked with light colours, which could be placed on any shelf. The products with medium colours must be placed no lower than the medium shelf. There are two possible product orientations for a product. For the front orientation, the width p_j^w is taken as a line parameter. For the side orientation, where the product is rotated at 90 degrees, its depth p_j^d is taken as a line parameter. Products with similar features, functions, or tastes, according to the store's merchandising rules, are grouped by the retailer into clusters and placed together on the same shelf. This is done to ensure the substitution effect of similar products if one of them is out of stock.

Fig. 1: Allocation of the categories and price subcategories on a planogram

Generally, in scientific research, facings are considered as a product quantity parameter. But in reality, based on the physical parameters of packaging, products can be capped, nested, or neither. Capping occurs when a product is placed on the top of another one in another rotated orientation. Most rectangular boxes, such as boxes containing coffee or sweets, can be capped. Nesting means placing a productinside another one, which concerns products such as bowls or plates. Fig. 2 and Fig. 3 show a method for allocating caps and nests. It could be observed that for front-orientated products the number of facings in one capped group is $\lceil p_j^h / p_j^w \rceil$ (otherwise for side-orientated products this number is $\lceil p_j^h / p_j^d \rceil$). The maximum possible caps in one capped group models the situation if too many cappings are placed above the facings in the row below, the items below may be broken or destroyed, or upper cappings could fall off the shelf. A similar situation occurs with nestings - if too many nested plates are placed inside the lower plate on the shelf, the plate below may become damaged or destroyed, or the upper plates could fall off the shelf. In this research, the total number of product items combines facings, caps, and nests.

Fig. 2. Caps allocation

Fig. 3. Nests allocation

In the current research, we investigate one (top) row of facings with cappings or nestings above it. The facings in the vertical dimension are not taken into account. Because of this fact, the shelf height and product supply limit are modelled only for one top row of facings incorporating capping or nesting above. The same situation is with the depth of the products and the depth of the shelf, which are modelled also for the facings' top row. To solve the retail SSAP, the goal is to determine the number of facings f_{ij}, caps c_{ij}, and nests n_{ij} of a product j which is allocated on the shelf i considering 4 classes of constraints: shelf constraints, product constraints, multi-shelves constraints and category constraints, in order to maximize the profit gained by the retailer.

Mathematical Models

With the notation presented above, the SSAP model with a linear objective function that maximizes profit can then be formulated as follows:

$$\max \sum_{j=1}^{P} \sum_{i=1}^{S} x_{ij} p_j^u (f_{ij} + c_{ij} + n_{ij}) \tag{1}$$

The SSAP model with a non-linear profit function can then be formulated as follows:

$$\max \sum_{j=1}^{P} \sum_{i=1}^{S} x_{ij} p_j^u \alpha_j (f_{ij} + c_{ij} + n_{ij})^{\beta_j} \tag{2}$$

In equation (2), the objective function maximizes profit by changing the expected demand for the products that depend on the space occupied by the products. α_j is a scale parameter identified as the base demand for the product or demand for the product with one facing. β_j is a space elasticity parameter.

The constraints used in both models are described below.

Shelf Constraints

shelf width (for all $i = 1,...,S$): $\sum_{j=1}^{P} f_{ij} (y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d) \le s_i^l$ (3)

shelf depth (for all $i = 1,...,S$, $j = 1,...,P$): $x_{ij}(y_{ij}^{o_1} p_j^d + y_{ij}^{o_2} p_j^w) \le s_i^d$ (4)

product height including caps' and nests' height (for all $i = 1,...,S$, $j = 1,...,P$):

$$x_{ij}\left(p_j^h + \left\lceil \frac{c_{ij} x_{ij}}{\max\left(\left\lfloor \frac{f_{ij}(y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d)}{p_j^h} \right\rfloor, 1\right)} \right\rceil \cdot (y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d) + \left\lceil \frac{n_{ij} x_{ij}}{\max(f_{ij}, 1)} \right\rceil \cdot p_j^n\right) \le s_i^h \quad (5)$$

Product Constraints

supply limit (for all $j = 1,...,P$): $\sum_{i=1}^{S} (f_{ij} + c_{ij} + n_{ij}) \le p_j^s$ (6)

minimum and maximum number of facings (for all $j = 1,...,P$):

$$f_j^{\min} \le \sum_{i=1}^{S} f_{ij} \le f_j^{\max} \quad (7)$$

maximum number of caps (for all $i = 1,...,S$, $j = 1,...,P$):

$$c_{ij} \le c_j^{\max} \cdot \left\lfloor \frac{f_{ij}(y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d)}{p_j^h} \right\rfloor \quad (8)$$

maximum number of nests (for all $i = 1,...,S$, $j = 1,...,P$): $n_{ij} \le n_j^{\max} f_{ij}$ (9)

Multi-Shelves Constraints

minimum and maximum number of shelves (for all $j = 1,...,P$):

$$s_j^{\min} \le \sum_{i=1}^{S} x_{ij} \le s_j^{\max} \quad (10)$$

side orientation is possible (for all $i = 1,...,S$, $j = 1,...,P$): $y_{ij}^{o_2} \le p_j^{o_2}$ (11)

only one orientation (front or side) is available (for all $i = 1,...,S$, $j = 1,...,P$):

$$\begin{cases} y_{ij}^{o_1} \cdot y_{ij}^{o_2} = 0 \\ y_{ij}^{o_1} + y_{ij}^{o_2} = 1 \end{cases} \quad (12)$$

the same product orientation on all shelves (for all $j = 1,...,P$):

$$\max_{i=1,...,S}(y_{ij}^{o_1}) \ne \max_{i=1,...,S}(y_{ij}^{o_2}) \quad (13)$$

the next shelf only (for all $j = 1,...,P$, $a,b: |a-b| \neq 1 \wedge a < b,\ \ a,b = 1,...,S$):

$$x_{aj} \cdot x_{bj} = 0 \tag{14}$$

the same number of facings on all shelves (for all $i = 1,...,S$, $j = 1,...,P$):

$$f_{ij} \leq \left\lceil \frac{\sum_{i=1}^{S} f_{ij}}{\sum_{i=1}^{S} x_{ij}} \right\rceil \tag{15}$$

the same cluster on the same shelf (for all $i = 1,...,S$, $a,b: p_a^l = p_b^l,\ \ a,b = 1,...,P$):

$$x_{ia} = x_{ib} \tag{16}$$

Category Constraints

the minimum category size if the products of this category are located on the shelf (for all $i = 1,...,S$, $k = 1,...,K$):

$$(\sum_{\substack{j=1,\\ p_j^k=k}}^{P} f_{ij}(y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d) \geq \left[s_i^l \cdot m_k \right]) \vee (\sum_{\substack{j=1,\\ p_j^k=k}}^{P} f_{ij} = 0) \tag{17}$$

$[...]$ means rounded value.

the possibility of allocation of the products based on their price subcategory (for all $i = 1,...,S$, $j = 1,...,P$): $x_{ij} \leq \min(\max(s_i^g - p_j^g, 0), 1)$ (18)

Decision Variables

if the product are located on the shelf (for all $i = 1,...,S$, $j = 1,...,P$):

$$x_{ij} \in \{0,1\} \tag{19}$$

the number of facings (for all $i = 1,...,S$, $j = 1,...,P$):

$$f_{ij} = \{f_j^{\min} ... f_j^{\max}\} \tag{20}$$

the number of caps (for all $i = 1,...,S$, $j = 1,...,P$):

$$c_{ij} = \{c_j^{\min} ... c_j^{\max} \cdot \left\lfloor \frac{f_{ij}(y_{ij}^{o_1} p_j^w + y_{ij}^{o_2} p_j^d)}{p_j^h} \right\rfloor\} \tag{21}$$

the number of nests (for all $i = 1,...,S$, $j = 1,...,P$):

$$n_{ij} = \{n_j^{\min} ... n_j^{\max} \cdot f_j^{\max}\} \tag{22}$$

if the product is placed on front orientation (for all $i = 1,...,S$, $j = 1,...,P$):

$$y_{ij}^{o_1} \in \{0,1\} \tag{23}$$

if the product is placed on side orientation (for all $i = 1,...,S$, $j = 1,...,P$):

$$y_{ij}^{o_2} \in \{0,1\} \tag{24}$$

Experimental Studies

Consistently with prior shelf space research, we conducted computation experiments to compare the sensitivity of two different model approaches. We designed an SSAP with linear (1) and non-linear (2) profit functions (LPF, NLPF accordingly). Because of commercial confidentiality, the data for the tests were simulated. We simulated the product profits consistently with the guidelines by Yang (2001) and Bai and Kendall (2005) – randomly, by a normal distribution. The product widths and heights were also brought about by a normal distribution. According to Eisend (2014)**Error! Reference source not found.**, the space elasticity β_j is assumed to vary between $0 \le \beta_j \le 0,35$ The scale parameter α_j depends on the maximum number of facings $f_j^{\max}$. The experimental data model the data from a real retailer's problem. In this research, we generated 75 stores in which different products had to be place in different shelf space locations. In our simulation, 5 product sets of 10, 20, 30, 40, 50 products were used, which we tried to allocate on 3, 4, 5 shelves on planograms with shelf widths of 250 cm, 375 cm, 500 cm, 625 cm, 750 cm. In all tests, the planograms combine shelves of the same widths as it usually arise in a real store. The number of vertical categories is 2 (for 10 and 20 products), 3 (for 30 products), 4 (for 40 products), 5 (for 50 products). The computational experiments were performed in IBM ILOG CPLEX Optimization Studio Version: 12.7.1.0.

The results of the financial performance of both models are reported in Table 1. Minimum, average and maximum values in Table 1 and Table 2 were calculated with the same shelf and products numbers with different shelf widths. The time limit for CPLEX solver was set to 5 minutes.

The columns "LPF is better" show the results when the goal optimization function was linear according to formula (1). Using the received solution values, we calculated the total profit according to formula (2) and compared by how many percent the LPF value is better than the value of NLPF. It is shown that the difference in solutions received by these two functions varies from 0.25% for 5 shelves with 10 products up to 176.84% for 5 shelves with 40 products. The effects of this mean that in a real retail store the difference expressed in dollars between these two approaches is significant. The average value varies from 8.77% for 5 shelves with 10 products up to 102.67% for 5 shelves with 40 products.

The columns "NLPF is better" show the results when the goal optimization function was non-linear according to formula (2). Using the received solution values, we calculated the total profit according to formula (1) and compared by how many percent the NLPF value is better than the value of LPF. It could be observed that the difference in solutions received by these two functions varies from 1.89% for 5 shelves with 30 products up to 63.40% for 5 shelves with 50 products. This also results in a significant difference expressed in dollars (but a little smaller than in the previous scenario). The average value varies from 6.91% for 3 shelves with 30 products up to 42.17% for 5 shelves with 50 products. These results conclude that when LPF is the goal optimization function, the solution

received by NLPF is approximately 2 times worse, otherwise, when NLPF is the goal optimization function, the solution received by LPF is only 1,5 times worse (comparing 102.67% to 42.17%).Table 2 reports the relative profit comparison of the two models when the goal optimization functions were expressed as LPF and NLPF. It is shown that the relative profit ratio of the solution received by these two functions varies from 1,35 for 4 shelves with 50 products up to 4.72 for 4 shelves with 20 products. Interestingly, the results also show that the quality advantage of these two models sometimes differs very slightly, but sometimes it differs approximately 5 times.

Table 1: Comparison of Linear and Non-Linear Profit Functions

Shelves	Products	Categories	LPF is better			NLPF is better		
			Min	Avg	Max	Min	Avg	Max

	50	5	25.93%	41.47%	53.17%	23.57%	42.17%	63.40%

Table 2: Linear and Non-Linear Profit Ratio Comparison

Shelves	Products	Categories	LPF/NLPF ratio		
			Min	Avg	Max
3	10	2	2.29	3.30	4.08
	20	2	2.64	3.41	4.22
	30	3	1.63	2.56	3,10
	40	4	1.51	2.50	3.06
	50	5	1.63	1.84	2.07
4	10	2	2.17	3.17	4.13
	20	2	3.22	4.14	4.72
	30	3	2.32	2.82	3.37
	40	4	2.16	2.79	3.26
	50	5	1.35	1.80	2.14
5	10	2	2.83	3.58	4.27
	20	2	3.60	3.98	4.47
	30	3	2.30	2.96	3.28
	40	4	2.67	3.10	3.52
	50	5	1.51	1.84	2.32

The results obtained during the experimental phase are shown in Fig. 4 and Fig. 5. The horizontal axes in Fig. 4 and Fig. 5 show the number of shelves, products and shelves width (separated by a dash). For the test instance with 3 shelves with 250 cm and 50 products, there was no solution found because it is impossible to allocate so many products on short shelves without violating other constraints.

Fig. 4 shows that almost in all cases the result attained by the LPF goal function was better than the result of the NLPF goal function on the same data set. But the deviation of the NLPF goal function is much lesser.

Fig. 5: Comparison of linear to non-linear ratio of profit functions comparison

Conclusions

Shelf space is one of the most critical resources in the retail industry. In this research, we focus on the retailer's total profit maximization models. Interestingly, with the goal optimization function expressed by LPF, the solution received by NLPF is approximately 2 times worse. In contrast, with the goal optimization function expressed by NLPF, the solution received by LPF is only 1,5 times worse. Nevertheless, if the profit is expressed in dollars in a real retail store, there is an enormous difference between these solutions. So, the SSAP model should be planned very carefully and should use the most up-to-date data considering all possible external factors and constraints.

The developed models can be used in practical solutions. It can be directly implemented in the logistics (warehouse) module in retail information systems, developed, for example, in H-structure (Becker and Reinhard, 2007). It should be fully integrated with the marketing module, which processes such data as the assortment and product policies (including goods planning), assortment planning, sales and turn-over planning, as well as product lists.

Some further issues could be investigated in the future. Obviously, both shelf space allocation models can be applied to most retail stores in which products are allocated on planogram shelves. But these models could also be adjusted to other types of planograms such as cubed walls (for shirts, skirts, jeans), pegboards (for socks, hosiery, kitchen accessories), pallets (for big heavy products), chests, and bins. Next, when the profit function is considered to be non-linear, the methods of calculating the scale parameter and the space elasticity parameter for each product must be adjusted more carefully, in a very small time-frame, and must be updated very frequently because of changing seasons, holidays, assortments, the introduction of new products , advertising of corresponding products etc. The more frequently retailers make such changes to store shelf space configurations, the more precise results from models can be received and the more profit can be earned.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10,721,040.00 PLN.

Abstract

Financial crimes have become dominant in the contemporary business environment. It is one of the most serious crimes endangering the national security and public safety of a country. It is directly associated with legal, social, human rights, political and development issues. This research provides a descriptive analysis of the professional traits of a forensic investigator in the investigation process expedition based on Malaysian evidence. Data for this study is collected through a questionnaire survey. A sample was driven from two enforcement agencies in Malaysia which are National Audit Department (NAD) and Malaysian Anti-Corruption Commission (MACC). Based on the descriptive statistic, Skills of Forensic Investigator question, "Critical thinking: the ability to differentiate between opinion and fact" scored the highest mean of 4.76. It implies that on average, that by having critical thinking skills the forensic investigator has the ability to differentiate between the opinion and facts of the fraudster. Next, Investigative Techniques of Forensic Investigator question, "Interviewing and Interrogation: An investigator needs to understand the subject's intention, effective inquiry, techniques of ethical and legal aspect in obtaining information" scored the highest mean of 4.80. It shows that on average, the respondents agreed that interviewing and interrogation technique will help in understanding the subject matter and thus expedite the investigation process. Lastly, Knowledge of Forensic Investigator question, "Anti-Money Laundering Act 2001: Act enacted dealing with money laundering and anti-terrorism financing" scored the highest mean of 4.77. The respondents agreed that having knowledge of the Anti-Money Laundering Act 2001 will eventually help in the expediting investigation process. As a conclusion, the professional traits of a forensic investigator can aid the government to combat financial crimes. These include skills, investigation technique and knowledge of the forensic investigator. Hence, this research provides insight for the Malaysian government on the importance of forensic investigator professional traits in expediting the investigation process.

Introduction

Accounting practices of international financial institutions have been moved forward as a result of a series of events involving financial crimes (Romanus, 2014). Monetary abuses and misrepresentation are wonders throughout the world. Activities involving financial crime include misrepresentation, misappropriation, plundering, illegal tax avoidance, negligence outside of trade and oil bunkering. According to the Association of Certified Fraud Examiners (ACFE), there are many forms of fraud or better known as occupational fraud, and it is classified into three types: bribe and corruption, misappropriation of assets and Fraudulent Financial Reporting (Association of Certified Fraud

Examiners, 2019). Money-related misdeeds are inspired by monetary need caused by eagerness, betting, bonds, business investments, poor speculation or attempts to maintain a lavish way of life (Mukoro, 2013). Detecting fraud and white-collar crime has been part of the conventional accounting function. The internal and external auditors are supposed to uncover fraud through the audit process (Anti-Corruption Network for Eastern Europe and Central Asia, 2011). However, auditors only check for compliance of the company's book towards generally accepted accounting principles, auditing standard and also company policies. Thus, a new group of forensic investigators are needed to detect fraudulent transactions. It is known as forensic investigators. Forensic investigators work in two primary areas, investigative accounting and litigation services. Forensic investigators investigate the operation of an organization and prepare information that may be used in a criminal or civil court case.

Forensic investigators are trained to uncover fraudulent practices which resulted from litigation activities. Forensic investigators utilize a wide understanding of business and management, financial reporting system, accounting and auditing standards, evidence gathering and investigative techniques and litigation process (Bhasin, 2007). They are more proactive towards risk reduction role by performing extended audit procedures, acting as advisors to audit committee and uncover financial fraudulent activity. Hence, forensic investigators are in a growing need for the country in confronting major financial crimes problem (Bhasin M. L., 2013). Malaysia has faced a major problem of financial crime. The lack of a forensic investigator's knowledge and skills has led to a situation in which government and corporate entities trick law enforcement to their advantage in financial crimes (Bhasin, 2017). The issue arises from the fact that a forensic investigator is still new to most businesses as well as to Malaysia's public awareness. According to KPMG (2002), most companies agreed that fraud is a major problem in Malaysia and the negative effect of bribery on the general public and the economy by financial fraud is inevitable (Urien, 2019).

Forensic investigators are trained to look beyond numbers and deal with the business realities of the situation. They play an important role in analysis, interpretation, and presentation of complex financial and business-related issues. They are also familiar with legal concepts and procedure (Bhasin, 2017). There are several activities usually being carried out by forensic investigators which are investigating and analysing financial evidence, the evolvement of computerised application in analysing and presentation of the financial evidence and communicating their findings in the form of a report with exhibit and collections of the report (Bhasin, 2017). These professional capabilities will assist them in legal proceedings, such as testifying in courts as an expert witness in preparing visual aids to support the trial evidence. However, the lack of knowledge, skills and the use of forensic investigations techniques in the battle against money-related corruption could also be a contributing factor (Ocansey, 2017) to delay the process of investigation.

In conclusion, a broad knowledge of forensic investigators is a key to success for the entry-level of forensic investigators (Anyaduba, 2013). This is to assist in the investigation procedure and also expedite the process. A big save in time and cost can be earned when the case investigated can be solved successfully within the dateline. Thus, any fraudulent cases involving financial crime can be solved by immediate action and prevent effectively. Thus, the country can be benefited by this with the existence of forensic investigators as fraudulent activities involving companies' book can be uncovered and traced magnificently. Concerning the above, it is crucial for this research to be conducted since it will provide an understanding of the professional traits of the forensic investigators that enables the expedition of the investigation process.

Literature Review

Investigation Process Expedition

Financial investigation is a procedure that is carried out to investigate and prosecute economic crimes and are allowed to collect evidence in corruption investigations (OECD, 2011). Different methods and strategies used to perform economic or property investigations have been described based on experience in actual cases of financial crime. For example, money movements are tracked using databases and registers (for example, company registers, stock exchange data), disclosure forms (asset

disclosures, public officials and other persons' financial and tax statements) and available wage, income and expenditure information (bills, expenditure reports). It was emphasised that a comprehensive, integrated review of these records is essential in financial investigations (OECD, 2011). Once evidence of corruption was discovered through the study of publicly available information, various examples of wrongdoing are examined. Multidisciplinary teams are created in many countries to investigate and prosecute crimes against corruption. A prosecutor led the team, consisting of prosecutors and investigators, as well as various law enforcement agencies. Every organization can conduct functions during such a group investigation if it has the best experience and different powers. For example, the Service for Investigation of Financial Crimes conducted an analysis of financial and economic records of the political party and related enterprises and seizure of such documents. Experts analysing electronic data gathered key evidence to prove that political party systematically received illegal funding. An investigator would probably not be able to do it on his own (OECD, 2011).

A report on forensic accounting tools available in private audit firms revealed that while audit firms do not have similar powers to law enforcement agencies, they have resources and skills that can be useful in helping to uncover corruption, particularly active corruption. Many forensic accounting tools have been presented, in particular, analysis of open source information (mass media, internet, etc.), analysis of corporate databases, accounting and other company documents (accounting records, agreements, payment orders, bank statements, etc.), interviews with company employees and professional organizations, collection of information within an industry, a procedure to match lifestyle with a predicted income. It has been mentioned that, for example, focused interviews with financial officers can be a good source of information about schemes used to channel this company's money. It has been emphasized that the strength of forensic investigator lies in a combined information analysis (OECD, 2011). It is also important to note that a comprehensive approach or a combination of the investigative methods and approaches mentioned above can help to effectively detect and prosecute financial crimes. It is necessary to use all available investigative techniques and rules, not just specific laws on corruption. It appears that a comprehensive approach is needed to effectively investigate and prosecute corruption, combining a variety of methods from collecting and examining public and non-public documents to monitoring, collaborating with witnesses and others (OECD, 2011). The role of witnesses in co-operating with investigators and prosecutors is also vital to expedite the investigation process.

Skills of Forensic Investigator

The American Institute of Certified Public Accountants (AICPA) recommended that forensic accounting techniques and procedures should be gradually combined in the detection of financial reporting, as forensic investigators and auditors have distinctive training, skills and mentalities (American Institute of Certified Public Accountants, 2004). Forensic investigators must have exceptional expertise in dealing with the issue of economic and financial crimes. It follows logically from these clarifications of forensic investigator techniques and skills that having these uncommon and explicit skills is important in effectively assisting the forensic investigator in speeding up the investigation process. These are the essential skills to be possessed in the investigative phase expedition by a forensic investigator. A forensic investigator should therefore have a conspicuous ability to help expose misleading information. In this way, creative reasoning skills can benefit the forensic investigator immensely (Ramaswamy, 2005). These skills will help them to understand the explanations for the perpetrator's practices, legal and moral issues, and provide assurances and evidence to individuals with little or no accounting knowledge (Ramaswamy, 2005). Forensic investigator abilities in verbal communication are exceptionally critical (Wells, 2007). It will trigger the forensic investigator's achievement in speeding the investigation process. It is certainly consistent with Malaysia's underlying goal of reducing fraud activities. Before the establishment is authorized by law, personal communication skills are included as a favourable position or required forensic investigator skills (Wells, 2007) as it will change them to be an additional alarm and accurate in the expediting investigation process.

According to Crumbley (2006), the forensic investigator should have good information skills learned due to the different number of documents required during the investigation process. Appropriate documentation filtering can allow them to identify success more precisely. The need to track their work

and write interpersonal skills is therefore important as this will allow them to provide an elegantly written document to assist the jury in litigation. Essentially, the investigation process can be expedited with the relevant skills learned by the forensic investigators.

Investigative Technique of Forensic Investigator

To use information technology, the forensic investigator is required to perform informative undertakings because most of the financial violations involve the use of software or virtual assets (Smith, 2005). By using information technology, an investigator can also benefit from data mining, which is characterized by the ability to use factual calculations to recognize patterns in a set of data. Consequently, the investigator may have the option of revealing patterns that may show misleading activities. Nevertheless, the data mining procedure is extremely iterative (Sharma, 2012). In this way, the forensic investigator's integrity in conjunction with the use of information technology is crucial. In addition, the forensic investigator's knowledge and implementation of questioning and interrogation methods is a significant investigative skill (Hoffman, 2005). It further clarifies how criminological investigators adapt and approach the method of interviewing and questioning to collect information. Whether the individual was dishonest or otherwise could be identified by verbal or non-verbal actions. It is necessary to learn the effective ways of the questioner or interviewer in conducting the investigation (Golden, 2006).

Another forensic investigator's investigative technique is surveillance and suspects profiling skills. It is close observation and collection of data concerning someone or potential fraudster (Gray, 2011). This includes collecting significant data for the investigation and creating a suspect profile if there is a suspicion. Surveillance also requires individual identification to collect information from any suspect and determine the attributes of the suspect (Gray, 2011). Information on aptitude test is essential for a forensic investigator to gather information from the subject involved (Gray, 2011) and processed to identify criminal capacity, disposition and objectives. Nonetheless, there is no doubt that skilled and trained professionals with forensic expertise can be a major advantage for corporate-sector and help improve their corporate governance structures (Wells, 2007). According to Alabdullah et., al (2014) researchers considered the rise of forensic accounting to be fundamental to the economic situation of the nation. Forensic investigators need to become capable along these lines and have professional core skills to assist in the expedition of the investigation process. Subsequently, the reliability of surveillance is critical in detecting cases of financial crime in organizations.

Knowledge of Forensic Investigator

Financial knowledge is essential to the detection of financial crimes by a forensic investigator. The two key categories of valuable skills for the forensic investigator are in-depth analysis of financial statements and the ability to conduct the investigation fundamentally. According to Bhasin M.L (2013), these skills assist forensic investigators in the discovery of anomalous examples in bookkeeping data, understanding of misrepresentation plans, including misappropriations of assets, money laundering, bribery and corruption, risk assessment control structure, achieve management, comprehensive knowledge of the financial statements and the ability to analyse them objectively. With the expansion of financial knowledge, it will assist forensic investigators in uncovering and perceiving abnormal patterns in accounting information, an exhaustive understanding of fraud schemes, including but not limited to misappropriations of assets, tax evasion, corruption and also the ability to understand corporate internal control systems (Bhasin M. , 2013). It thus shows that the skills of a forensic investigator are important and positively interacts with financial crime detection.

In a study by Anyaduba (2013) demonstrated that forensic investigators are a group of individuals in the specialized accounting field who use auditing and analytical proficiencies to assist in legal matters arising from current and potential disputes or litigation. It is therefore part of an investigation that is reasonable for the court of law to have a higher level of assurance. At the end of the day, the investigation will consist of a mixture of bookkeeping, examination, and the ability to disclose the reality. This comprises knowledge on generally accepted accounting, accounting and auditing standards to determine losses or profits, assets, damages, the efficacy of internal controls and fraud for

the use of the legal system in criminal and civil litigation (Zysman, 2001). Nonetheless, a legal procedure requires a request for accounting; thus, it provides the highest level of certainty using rational means to achieve a generally accepted connotation (Akintoye, 2008) and to provide the requisite results in the resolution of disputes. It strongly supports the need for forensic investigator legal information in the course of expediting investigation. In summary, a forensic investigator is an expert in a specialized area of accounting that uses accounting, auditing, investigative and legal knowledge to provide evidence of legal-related information.

Research Method

Data Collection

This research uses a survey of the questionnaire. This study approached the forensic investigators of the National Audit Department and the Malaysian Anti-Corruption Commission in Malaysia. The questionnaire survey was distributed by an online survey via a form on Google. A total of 83 survey questionnaires were collected and used based on the Google form's data extraction. The respondents in this study remained anonymous and were not given any financial incentives to encourage voluntary participation in completing the questionnaire. In this study, the survey instrument will include questionnaires that will provide a different component section consisting of Sections A, B, C and D. Section A will cover gender, age and many more in the demographic section. Sections B and C will cover independent variables that focus on forensic investigator's skills and forensic investigator's knowledge respectively. Finally, Section E is the coverage that is the dependent variable in this study on the detection of an investigation process expedition. Respondents in this section will be measured following their years of specific field investigation experience. The questionnaires used in this study were adapted and have been tested and confirmed by the previous researchers in a large-scale study (Ocansey, 2017; Ahmed, 2016).

Findings And Discussion

Demographic Analysis

This section provides descriptive analyses of the demographic characteristics of the respondents consisting of the frequency and the percentage of the nominal questions. Table 1 shows the frequency of respondents based on their gender. The total respondents for this study are 83 forensic investigators. It indicates that 37 or 44.6% of the respondents are male whilst 46 or 55.4% of the respondents are female.

Table 1: Frequency of the Respondents' Gender

	Frequency	Per cent
Male	37	44.6
Female	46	55.4
Total	83	100.0

Table 2 explains the education level of the respondents. The respondents are categorised into 4 groups of their education level which includes Diploma, Bachelor's Degree, Master's Degree and Doctorate. About 49.4% of the respondents hold a Master Degree followed by the respondents with a Bachelor Degree of 28.9%. There are 11 respondents who are Doctorate holders representing 13.3% of the total respondents whilst 7 respondents is a Diploma holder represents only 8.4% of the total respondents.

Table 2: Frequency of the Respondents' Education Level

	Frequency	Per cent
Diploma	7	8.4
Bachelor Degree	24	28.9
Master Degree	41	49.4
Doctorate	11	13.3
Total	83	100.0

Table 3 depicts the frequency of the respondents' years of working experience. Out of 83 respondents, 36.1% has working experience for more than 10 years, 33.7% has a working experience of 6-10 years whilst 28.9% has a working experience of 1-5 years.

Table 3: Frequency of Working Experience by the Respondents

	Frequency	Per cent
1-5 years	24	28.9
6-10 years	28	33.7
More than 10 years	30	36.1
Total	83	100.0

Descriptive Statistics

Table 4 shows the descriptive statistics of the dependent variable namely, the investigation process expedition based on the results of the questionnaire. The highest mean score goes to question number 1, "An investigator needs to understand the subject matters: by studying the case thoroughly: the background and available pieces of evidence of the offender." where the mean score response of the question is 4.80 i.e. greater than 3.00. This finding implies that on average, the respondents agreed to the statement that the investigator needs to have a good understanding of the subject matter in handling cases which eventually will expedite the investigation process. The average standard deviation (SD) of the response is 0.462. This indicates that the respondents' perceptions were close or similar to one another. The lowest mean score goes to question number 6, "Political influence has an impact on the process and reporting of findings." where the mean score response of the question is 4.35 i.e. greater than 3.00. This finding implies that on average, the respondents slightly agreed to the influence of political matters in expediting the investigation process. The average standard deviation (SD) of the response is 1.098 which is higher than 1. This indicates that the respondents' perceptions were a bit far or differed to one another.

Table 4: The Investigation Process Expedition

	Mean	Std. Deviation
(1) An investigator needs to understand the subject matters: by studying the case thoroughly: the background and available pieces of evidence of the offender.	4.80	0.462
(2) An investigator needs to complete procedures within the time frame given.	4.53	0.817
(3) An investigator needs to request an extension of findings most of the time.	4.35	0.930
(4) An investigator needs to handle several cases at one time.	4.35	1.041
(5) An investigator needs to conduct an investigation regardless of high profile or low profile individuals.	4.67	0.646
(6) Political influence has an impact on the process and reporting of findings.	4.35	1.098
(7) Commitment and involvement from other enforcement agencies can speed up the reporting process.	4.70	0.599
(8) Successful audit trails can speed up the reporting process.	4.72	0.570
(9) The ability to get complete documentation in handling cases can speed up the reporting process.	4.78	0.542
(10) Advance information technology systems can speed up the reporting process.	4.72	0.591

Table 5 shows the descriptive statistics of the first independent variable namely, skills of a forensic investigator. Based on the result of the questionnaire the highest mean score goes to question number 1, "Critical thinking: the ability to explain between opinion and fact." where the mean score response of the question is 4.76 i.e. greater than 3.00. This finding implies that on average, the respondents agreed to the statements on the ability to explain between opinion and facts by having critical thinking skills. The average standard deviation (SD) of the response is 0.554 which is lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another. The lowest mean score goes to question number 5, "Unstructured problem solving: the ability to deal and establish statement/opinion on each case independently." where the mean score response of the question is 4.53 i.e. greater than 3.00. This finding implies that on average, the respondents slightly agreed to the statements on the unstructured problem-solving will helps the ability of the forensic investigator to deal and establish statement/opinion on each case independently. The average standard deviation (SD) of the response is 0.738 which is lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another.

Table 5: Skills of Forensic Investigator

	Mean	Std. Deviation
(1) Critical thinking: the ability to explain between opinion and fact.	4.76	0.554
(2) Communication: The ability to effectively communicate in both writing via reports and speech.	4.69	0.603
(3) Analytical Proficiency: the ability to prepare complete documentation.	4.76	0.508
(4) Deductive analysis: the ability to detect red flags during audit findings/investigation.	4.65	0.633
(5) Investigative flexibility: the ability to move away from extended audit procedures and able to conduct a thorough examination.	4.53	0.738
(6) Unstructured problem solving: the ability to deal and establish statement/opinion on each case independently.	4.61	0.659

Table 6 shows the descriptive statistics of the second independent variable namely, Investigative Techniques of Forensic Investigator based on the result of the questionnaire. The highest mean score goes to question number 1, "Interviewing and Interrogation: An investigator needs to understand the subject's intention, effective inquiry, techniques of ethical and legal aspect in obtaining information"

where the mean score responses of this questions are 4.80 i.e. greater than 3.00. This finding implies that on average, the respondents agreed to the statements on the investigative technique where interviewing and interrogation technique will help in understanding the subject matter and thus expedite the investigation process. The average standard deviation (SD) of the response for question 1 is 0.488 which is lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another. The lowest mean score goes to question number 2, "Using Computer-Based Software Tools: An investigator needs to be information technology (IT) literate" where the mean score response of the question is 4.59 i.e. greater than 3.00. This finding implies that on average, the respondents slightly agreed to the statements on the importance of computer-based software usage and being IT literate. The average standard deviation (SD) of the response is 0.716 which is slightly lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another.

Table 6: Investigative Techniques of Forensic Investigator

	Mean	Std. Deviation
(1) Interviewing and Interrogation: An investigator needs to understand the subject's intention, effective inquiry, techniques of ethical and legal aspect in obtaining information.	4.80	0.488
(2) Using Computer-Based Software Tools: An investigator needs to be information technology (IT) literate.	4.59	0.716
(3) Offender Profiling: An investigator should know the technique to identify the offender and also able to link together several individuals/organisations/events.	4.71	0.595
(4) Surveillance: An investigator needs to have a follow-up and a continuous observation over someone or something in obtaining information.	4.69	0.697
(5) Observation and Documentation: An investigator needs to document in written or through observation notes and able to interpret the findings.	4.77	0.477

Table 7 shows the descriptive statistics of the third independent variable namely, knowledge of forensic investigator based on the result of the questionnaire. The highest mean score goes to question number 3, "Anti-Money Laundering Act 2001: Act enacted dealing with money laundering and anti-terrorism financing." where the mean score response of the question is 4.77 i.e. greater than 3.00. This finding implies that on average, the respondents agreed to the statements on knowing the Anti-Money Laundering Act 2001 will eventually help in the expediting investigation process. The average standard deviation (SD) of the response is 0.611 which is lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another. The lowest mean score goes to question number 4, "Financial Accounting and Auditing Knowledge: the ability to understand basic Accounting Principles and International Auditing Standards (IAS)." where the mean score response of the question is 4.64 i.e. greater than 3.00. This finding implies that on average, the respondents agreed to the statements on the requirement know basic Accounting Principles and International Auditing Standard in investigating cases. The average standard deviation (SD) of the response is 0.725 which is lower than 1.00. This indicates that the respondents' perceptions were close or similar to one another.

Table 7: Knowledge of Forensic Investigator

	Mean	**Std. Deviation**
(1) Malaysian Anti-Corruption Commission Act 2009: Act enacted to provide for the establishment of MACC to make better provision for the prevention of corruption.	4.75	0.490
(2) Whistle-blower Protection Act 2010: Act enacted to combat corruption and other wrongdoings, and to protect individuals who whistleblow to the relevant enforcement agencies.	4.71	0.530
(3) Anti-Money Laundering Act 2001: Act enacted dealing with money laundering and anti-terrorism financing.	4.77	0.611
(4) Financial Accounting and Auditing Knowledge: the ability to understand basic Accounting Principles and International Auditing Standards (IAS).	4.64	0.725
(5) Specific Legal Knowledge: the ability to understand basic legal processes and legal issues.	4.67	0.543

Conclusion

Forensic investigation is the utilization of specialized investigative skills in carrying out an inquiry conducted in such a manner that the outcome will have an application to a court of law. Forensic investigation is the examination of evidence regarding an assertion to determine its correspondence to established criteria carried out in a manner suitable to the court. To successfully exercise good investigation expedition, there is a need for internal controls and one aspect of these controls relates to financial oversight. Unfortunately, the number of financial frauds that have been continually perpetrated within the country that raises serious questions as to whether traditional financial controls are working. This study examines the skills of forensic investigators and investigation process expedition. It means that traits such as knowledge, qualification, skills, and experience of the investigator affect the investigation process expedition. However, skills seem to be disputable issues among the traits as it is very subjective. Often, skills and investigation techniques are comprising one trait. Forensic investigator skills represent exceptional skill sets and techniques developed to detect the proof of fraud amongst other specialized knowledge areas of forensic accounting. Besides, investigative techniques of the forensic investigator are also determined in this study. Interview and interrogation are two major technique used to elicit responses from the accused. The evidence can be gathered by practising these two methods that can be used to approve or disprove the act in use in the investigation process. In this technological world, computer forensics and data mining techniques are crucial for investigators to expertise into uncovering technological fraud. Forensic investigators are expected to be the specialist in any accounting and legal field. In this profession, it is very imperative to have a thorough knowledge of accounting system and at least a basic understanding of the legal system. Besides, good knowledge on company's corporate governance policies, laws that regulate this policy and also command a civil and criminal law as well as the legal system and court procedures will assist the investigators to uncover fraudulent financial reporting. Therefore, the skills of forensic investigators, the investigative techniques of forensic investigator have a strong and statistically affect the investigation process expedition while the skills of forensic investigator do not affect the investigation process expedition.

example, the article analyzes the features of the formation of human potential of two very different and very significant regions of Ukraine: Volynska and Kharkivska oblasts.

Keywords*:* human potential, demographic crisis, socio-economic development, potential, factor analysis, region, Ukraine.

Relevance of the research

XXI century has exacerbated many global problems of the world community. A number of crises and catastrophes have engulfed all countries in the world without exception. In different parts of the world they manifest themselves in different ways. However, all the problems are related to intensive globalization, and therefore the qualities of people and the total human potential come to the fore. In many developed countries, the formation of human potential, its ability to withstand crisis challenges, is affected by a severe demographic crisis, which creates a number of socio-economic problems and troubles. Such countries include Ukraine, whose demographic problems, like most post-Soviet countries, are surprisingly acute. The demographic crisis in Ukraine is systemic, leading to the deterioration of all parameters of the country's development. Among its causes are the change of social life and, first of all, the system of social production, as a result of which the coordinated functioning and development of its components has been disrupted, which also has an impact on the formation of human potential. The demographic crisis is seen as a consequence of this systemic crisis in the most important spheres of society, the emergence and exacerbation of contradictions that affect on demographic processes and cause different socio-spatial models. Since the basis of human potential is the population, it is timely and relevant to research its formation in a demographic crisis. The authors consider the human potential of Ukraine as a component of the integrated potential of the territory, and therefore the analysis is conducted in terms of regions of Ukraine. Among the important tasks of the research are the substantiation of the factors of human potential formation and the analysis of this situation in the regions of Ukraine in particular, and in the state as a whole.

The Review of Previous Research

Studies of certain aspects of the formation, development and realization of human potential and its individual components are widely covered in the scientific literature. In particular, they were discussed at previous IBIMA international conferences. In particular, Veronika Humlerova analyzes the impact of human potential on the economic development of rural settlements on the example of individual territories of the Czech Republic [3], considers the peculiarities of regional development in view of intensification of migration and population change, the impact of human capacity of municipalities on subsidies from EU funds [2]. A number of works are devoted to the assessment of opportunities and transformation of human capital in terms of technological development and informatization of the economy [4].

In this aspect, Michael WENZEL examines the current challenges facing most German companies in view of demographic change in economically developed countries and the digitalization of the economy, identifying areas for the best symbiosis of senior workers' experience and the skills of young professionals [24]. The impact of demographic changes on the labor potential and labor market in Central Europe is considered by Jiri CERNY, studying the population structures in Central Europe and policy measures with a focus on the labor market, identifying potential areas of labor market development in view of structural changes in society [1].

Some aspects of the demographic component of human potential are covered by Andrzej Skibinski, who examines current demographic trends as a source of change in human resource management through the assessment of demographic change in Poland and Slovakia through quantitative and qualitative analysis of Eurostat statistical databases and author's sociological survey on intergenerational cooperation [22], considers the demographic conditions, processes and structures that determine the key internal factor of human potential, its impact on the economic development of the Visegrad Group [23].

In our previous researches, demographic potential has been identified as an object of socio-geographical research, methodology of its assessment [17] as a basis for socio-economic development of the region [7,18], features of its formation in the regions of Ukraine [20], demographic factors of regional development [16] and demographic situation as its indicator are determined [8]. At previous IBIMA conferences we discussed some issues of demographic processes, including migration, their impact on human potential and regional development in the world and in Ukraine [5,6,19,21].

Despite the large number of scientific studies on this issue, the questions remain: What are the components of human potential as a component of the integrated potential of the territory? What demographic processes and structures have the greatest influence on the formation of human potential? How to identify and evaluate their quantitative and qualitative impact? What are the features of the formation of human potential in a depopulated population and exacerbation of the demographic crisis?

Purpose and objectives

This article embodies an attempt to identify key features of the formation of human potential in the region in a demographic crisis. To achieve this research goal based on the analysis of scientific sources to determine the content of human potential as a component of the integrated potential of the territory, its components, demographic basis; based on the analysis of official statistics with the use of factor analysis to establish the spatial features of demographic processes and structures of regions of Ukraine as factors in the formation of human potential, to consider and to compare the main demographic trends of selected regions of Ukraine.

Information base and methods of research

The information base for the analysis of demographic processes and structures underlying the formation of human potential in the regions of Ukraine are official statistics: the 2001 Census of Ukraine [11], the State Statistics Service of Ukraine [14], the Main Department of Statistics in Volyn region [12], the Main Department of Statistics in Kharkiv region [13], analytical reviews, reports, scientific articles, the results of the authors' own research.

In the research were used methods of analysis and synthesis (to determine the content, components and factors of the formation of human potential; for establishment of spatiotemporal features of the formation of human potential in the regions of Ukraine), mathematical-statistical and demographic statistics (to process the official statistics, isolation and calculation of demographic indicators), rationing and linear scaling (to bring the data into normalized form, further processing by factor analysis, comparison of trends in demographic processes and structures of the studied regions of Ukraine), factor analysis (to establish the degree of factors of human potential, to determine their differentiation by the regions of Ukraine), comparison, systematization, generalization and others.

Presenting Main Material

Modern scientific developments of domestic and foreign scientists cover the study of human potential, human capital, human development, labor potential, life potential, demographic potential, reproductive potential, etc. In response to social demand, the development of economic research has led to the isolation of the demographic (human) factor of social development. Specialists in various sciences have studied individual issues of human potential from the standpoint of different sciences, differently interpreting the definition of "human potential", highlighting the most important features for a particular study from the standpoint of different scientific approaches. In general, human potential is a complex socio-economic system, its state is characterized by a set of indicators that complement each other: life potential of the population, investing in the formation and accumulation of human potential, scientific potential of society, employment potential, educational potential, health

potential, cultural potential, etc. Sometimes human potential is identified with demographic potential, considering the population, the share of the working population, age and gender characteristics, the dynamics of population movement, etc. Human potential is characterized by indicators of social development, quality of life, average life expectancy, adult literacy, GDP per capita, it includes opportunities for population reproduction and human development, a set of knowledge, skills, abilities and motivations of a person that have economic value. This potential increases as a result of a kind of investment (birth and upbringing of children, education of people, migration, etc.), considered in the context of the ideology of human potential, quantitative and qualitative potentials of its reproduction is a condition, basis and goal of society and state.

Taken into acount the complexity of socio-geographical research, the demographic potential of the territory is considered as a set of human resources of the territory, as a complex demographic, social, economic, settlement, ethnic, ecological phenomenon that reflects the overall characteristics of interconnected features of society. Accordingly, the blocks for assessing the demographic potential are determined: demographic, economic-demographic, settlement-demographic, socio-demographic, geodemographic, ecological-demographic [18]. Socio-geographical approach allows us to consider human potential as a component of the integrated potential of the territory. In the structure of the integrated potential there are a number of partial potentials, which are associated with the presence of certain types of resources and their groups on the territory. The leading role in the composition of integrated potential belongs to human potential, which includes demographic, labor (the main productive force, as it creates and uses labor, ensures the production of material and spiritual goods, favorable environmental conditions of people; its scale as a producer and consumer is a motivating force for the production of certain volumes of goods and services) and ecistic (scale of development and features of the settlement system of a region, taking into account also the available potential (prerequisites) that can ensure its development in the future). Demographic potential is an important component of human potential, includes all the features, properties and capabilities of the population necessary for the recovery of generations, ie the population with its structure and qualitative characteristics [15].

At the same time, most researchers agree that the basis of the region's human potential is the population and its socio-demographic characteristics; on the one hand, the population of a certain territory in the first approximation allows to determine the potential of the population of a certain territory, on the other - the features of demographic behavior of the population are the result and factor of transformations of human potential. Thus, human potential is, first of all, socio-demographic subsystem, it is self-organizing, has the ability to maintain its integrity and internal structure with significant changes in external conditions. The essence of human potential is manifested through structural indicators, because they represent it as a whole. For the same reason, the most informative is the process of reproduction of human potential and clarifying of the structure and role of its individual components.

According to the State Statistics Service of Ukraine, as of May 1, 2020, the current population was 41 806 223 people. It should be noted that the data of the State Statistics Service of Ukraine are based on information from registration authorities, so they include only those who are officially registered in Ukraine. These representations do not take into account the temporarily occupied territory of the Autonomous Republic of Crimea, the city of Sevastopol and part of the temporarily occupied territories in Donetska and Luhanska oblasts [14]. At the time of the proclamation of Ukraine's independence, the country had a population of 51.9 million, and in two years to 1993 there was an increase in population (52.2 million), which has never been recorded in the country's history. During this period, the population decreased by more than 10 million people, which indicates a high rate of depopulation and exacerbation of the demographic crisis, the essence of which is systemic and leads not only to rapid population decline, but also to significant deformations of its structure and demographic behavior that ultimately has a significant negative impact on the formation of human potential now and in the future.

Therefore, the formation of human potential is influenced by a number of factors that can be divided into economic, social and demographic. Let's consider which demographic processes have the greatest impact on the formation of human potential in the regions of Ukraine. The analysis of

factors influencing on the formation of human potential in Ukraine was carried out on the basis of factor analysis (the method of principal components with varimax rotation of factors), which allowed to calculate the factor load on each of the indicators. Taking into account the availability of statistical information for the research were selected 17 indicators that reflect the demographic characteristics in terms of regions of Ukraine. The initial data for factor analysis do not contain information about the Autonomous Republic of Crimea, Donetska and Luhanska oblasts, which significantly affected on the results. In order to determine the optimal number of factors, the dispersion of each of the factors was calculated (table 1).

Determining the optimal number of factors, we turn to three criteria:

- according to the criterion of Kettel's "stone rash": on the graph of dispersion (scree plot) there is a place where the decrease of dispersion from left to right is slowed down as much as possible. It is assumed that to the right of this point is only a "factorial rash". The graph of dispersion (Fig. 1) shows four factors;
- by Kaiser's criterion: only factors with a dispersion greater than 1 are selected (in our case four factors);
- by cumulative percentage: as determinants are selected those factors that cover a total of about three quarters of the original information, ie the cumulative percentage should exceed 75% (in our case, three factors).

Table 1: Absolute, relative and cumulative dispersion values of factors of human potential formation of Ukrainian regions

Factor	Dispersion	Percentage of total dispersio, %	Cumulative dispersion	Cumulative percentage, %
1	8,125886	47,79933	8,12589	47,7993
2	4,102946	24,13498	12,22883	71,9343
3	2,021965	11,89391	14,25080	83,8282
4	1,216138	7,15375	15,46693	90,9820
5	0,730383	4,29637	16,19732	95,2783
6	0,414360	2,43741	16,61168	97,7158
7	0,254729	1,49841	16,86641	99,2142
8	0,091616	0,53892	16,95802	99,7531
9	0,027312	0,16066	16,98534	99,9137
10	0,013363	0,07861	16,99870	99,9923
11	0,000880	0,00517	16,99958	99,9975
12	0,000339	0,00200	16,99992	99,9995

14	0,000037	0,00022	17,00000	100,0000

Fig. 1: Graph of dispersion ("stone rash") of factors of human potential formation of Ukraine (built on the results of factor analysis)

Thus, we will assume that the formation of human potential in Ukraine is most influenced by four factors. As a result of varimax rotation of the coordinate axes, a matrix of factor loadings was obtained (Table 2).

Table 2: Factor loadings (Varimax raw), extraction: principal components, marked loadings are > 0,7)

№ and characteristic	Factor loadings			
	factor 1	factor 2	factor 3	factor 4
1 – urbanization rate, %	0,392661	-0,279362	0,125766	0,754757

Based on the values of factor loadings, the content of factors influencing on the formation of human potential of Ukraine is established. The factor includes the indicator for which the factor loading is the largest, ie the closest in modulus to one. If the factor loadings of the indicator for each of the 4 factors are less than 0.7 ("threshold" value), this indicator was not included in the analysis because it is statistically insignificant. Taken the share of dispersion, we consider the main first two factors (the 1st factor accounts for 47.8% of the total dispersion of the original data; the 2nd - 24%). Based on the values of factor loadings, it is established that four factors influence on the formation of Ukraine's human potential. Interpretation of the results of factor analysis made it possible to determine the following hypothetical factors: demographic (nine indicators (Table 2)), structural (two indicators), migrational (three indicators), resettlement (two indicators).

According to the results of factor analysis, the values of factors in terms of regions of Ukraine were calculated (Table 3). Factor weights are indicators that assess the contributions of administrative-territorial units to each of the factors. The matrix of factor weights is calculated by multiplying the matrix of the original data by the matrix of factor loadings. They are interpreted as relative estimates of the manifestation of a certain factor in each individual administrative-territorial unit and serve as a basis for their grouping. If the value of the factor weights is about 0, then the impact of this factor corresponds to the impact on the country as a whole, if more (and especially more than 1) – the impact of this factor is significantly greater, and if minus (more than -1) – significantly less than in the country in general.

Table 3: Factor weights of manifestation of factors of human potential formation in the context of regions of Ukraine (factor scores, rotation: Varimax raw, extraction: principal components)

Fig. 2: Distribution of regions of Ukraine by the value of certain factors of human potential formation (built on the results of factor analysis)

The values of the current factors are significantly differentiated on the territory of Ukraine (Fig. 2). Demographic factor acquires the largest and smallest significance in Chernihivska, Sumska, Cherkaska oblasts and Volynska, Rivnenska, and Zakarpatska oblasts respectively. It is explained by the peculiarities of demographic processes, socio-demographic behavior of the population and so on. The migrational factor has a significant differentiation by the regions of Ukraine: it acquires the highest importance in Lvivska, Zhytomyrska, Kyivska, Sumska oblasts; the lowest – in Zakarpatska, Chernivetska, Khersonska, Zaporizka and Dnipropetrovska oblasts. The most effective influence of the structural factor is observed in Volynska, Rivnenska, Zhytomyrska, Vinnytska, Kirovohradska and Chernihivska oblasts, the smallest – in Lvivska, Sumska and Kharkivska oblasts. The resettlement factor is most pronounced in the city of Kyiv and Kyivska, Zaporizka, Dnipropetrovska oblasts, least - in Sumska and a number of western oblasts. Therefore, since the population itself is the basis of human potential, demographic processes and structures have a significant impact on its formation. Lets consider the influence of their individual components on the example of two regions in eastern and western Ukraine: Kharkivska and Volynska oblasts. Their example identifies indicators, characteristics, negative aspects of the demographic crisis, which in general affects on the socio-economic development of the whole state and the phenomena that affect on human potential.

Therefore, the selected for comparison Volynska and Kharkivska oblasts of Ukraine are not only located in geographically different parts of the country, but also have opposite demographic trends, distinguish the maximum diversity of demographic behavior of the population of different regions of Ukraine. We do not aim to compare the quantitative and qualitative composition of the human potential of these regions, we will determine the demographic prerequisites for its formation. For the convenience of analysis, the indicators are normalized to the national value (Fig. 3). Thus, Volynska oblast belongs to those regions of Ukraine where high reproductive activity, as evidenced by a relatively high birth rate (10 ‰ vs. 8 ‰ on average in Ukraine and 6.8 ‰ in Kharkivska oblast). As such a situation has been observed over the last few decades, a significant share of the younger age group in the population structure is traced (21% vs. 16% on average in Ukraine and 14.7% in Kharkivska oblast). Accordingly, the demographic burden of "children" is higher (349 ‰ against 278 ‰ on average in Ukraine and 239 ‰ in Kharkiv oblast). Similarly, the rate of depopulation in the oblast is much lower than in the state as a whole (-2.8 ‰ vs. -6.6 ‰ on average in Ukraine and 8.4 (in Kharkivska oblast). Volyn oblast is also characterized by a low level of population aging (13‰ vs. 17 ‰ on average in Ukraine and Kharkiv oblast). On the other hand, Kharkiv oblast is characterized by high migration attractiveness, a significant positive balance of birth migration (2 ‰ vs. 0.9 ‰ on average in Ukraine and Volyn oblast), and the oblast is characterized by a high level of urbanization (80.7% vs. 69% on average in Ukraine and 52% in Volyn oblast) and population density (86 people / sq.km against 70 people / sq.km on average in Ukraine and 52 people / sq.km in Volyn oblast). Thus, we can note the opposite demographic trends in the researched regions, respectively, the degree of influence of demographic factors on the formation of human potential in Volyn oblast is higher, while in Kharkiv oblast leading socio-economic factors.

Volynska oblast	Kharkivska oblast	average in UKRAINE	
10,1	6,8	8,1	*birth rate, ‰*
12,9	15,2	14,7	*mortality rate, ‰*

51,8	86	70	*density, pers/sqKm*

Fig. 3: Comparison of demographic indicators of human potential formation in Volynska and Kharkivska oblasts (calculated and built on the basis of [12,13])

Conclusions

The research of human potential development in a demographic crisis is a topical issue today. After all, for many countries of the world, including Ukraine, the demographic problem is painful, and the demographic crisis is exacerbated from year to year. Human potential is a complex socio-economic system based on population; at the same time, human potential is influenced by a number of factors. Our research demonstrates the multifaceted impact of factors on the formation of human potential of the country. Using factor analysis, the article identified the main factors influencing on the formation of human potential in the demographic crisis in Ukraine as a whole, as well as in selected regions. The values of the current factors are significantly differentiated on the territory of Ukraine. For in-

depth analysis, such oblasts of Ukraine as Volynska and Kharkivska were selected, which show different demographic trends and driving levers of influence on the formation of human potential, which are located in geographically different parts of the country and have opposite demographic trends, reflect the maximum diversity of demographic behavior of Ukraine. Volyn oblast is characterized by such influencing factors as high birth rate, low population aging, Kharkiv oblast is characterized by completely opposite influencing factors, namely the migration attractiveness of the region, high level of urbanization and population density. So, summing up, we can say that in the researched regions of Ukraine is observed the opposite demographic trends, respectively, the degree of influence of demographic factors on the formation of human potential in Volyn oblast is higher than in Kharkiv oblast for which socio-economic factors are leading. Recently, the development of human potential is becoming a major and determining factor in economic growth. Numerous researches have convincingly shown that the classification of countries by the level of their economic development is crucially determined by the quality of human potential. Ultimately, such parameters as the pace of scientific and technological progress, the organization and culture of labor, and its productivity also depend on it. The level of development of Ukraine in the future is determined by how effective the process of building the human potential of the country and its regions will be and how effectively this potential will be used in the state. In Ukraine, the priority areas of human potential development are the formation of a social market income system, the formation of a model of continuing education and self-education, providing a qualitatively new level of health care. In further research, the authors plan to use SWOT-analysis to consider in more detail the problems and prospects for the impact on human potential development in the context of the demographic crisis in the regions of Ukraine.

Abstract

Metropolises play an increasing role in the life of the global society, shaping the features of migration processes in certain regions and countries of the world. Ukraine is rapidly developing in this direction, playing a significant role in the geopolitical processes of Europe. The article is devoted to the problem of migration asymmetry of the population associated with the concentration of a significant part of the population of Ukraine in the metropolises. Metropolises and metropolitan regions are the centers of attraction for migrants, concentrating a huge industrial, labor, social, infrastructural and cultural potential. The purpose of the study is the analysis of the main features of migration processes in the metropolitan regions of Ukraine and the detection of the opportunities and threats which they have for the metropolises and the whole country. Based on foreign and native researches, the concept of "metropolis" is analyzed. It has been established that in Ukraine metropolitan functions are performed by Kiev, Kharkiv, Odesa, Dnipro, Lviv. All of them, Kiev is the exception, are monocentric metropolises of the all-Ukrainian level. Kiev is a metropolis of international importance and due to the intensive processes of suburbanization, it acquires the features of polycentricity. The factors of migration attractiveness and types of migrations that prevail in a particular metropolis are revealed. The main indicators of migration are considered: the number

of arrivals, departures, the balance of migration along metropolises and regions in which they are located. The opportunities and threats of population migration for metropolitan regions are analyzed.

Keywords: metropolis, metropolitan region, internal migration, migration process, migration flow, migration growth, Ukraine.

Introduction

In recent years, the territory of Ukraine has been characterized by intense migration transformations, which form the territorial unevenness of the settlement of the country's area. Large cities – metropolises – become recipients of the largest migration flows while rural areas and the most part of small and medium-sized cities experiences a significant outflow of the working-age population. It increases the depression of these regions and increasingly aggravates the polarization of the socio-economic development of settlements in the center-periphery direction. Migration is becoming one of the main factors of qualitative changes in the structure of the city's population and has a significant impact on the processes of spatial transformations of the urban environment. The fact that the city is a "magnet" of migration flows, entails the uneven socio-economic and demographic development of the country's territory as a whole, tells about the relevance and necessity of this study. In addition, an important aspect of this article is detection of opportunities for the socio-economic development of metropolitan areas due to migration population growth and the threats that metropolitan regions of Ukraine face in a process of population migration.

The purpose of the study is to analyze the main features of migration processes in the metropolitan regions of Ukraine and identify the opportunities and threats that they pose for the metropolises and the country. To achieve the purpose of the study, the team of authors sets the following tasks: to analyze the theoretical foundations of the definition of the concept "metropolis" in the measurement of Ukrainian cities; analyze the migration situation in these cities and identify the factors of their migration attractiveness; to explore the possibilities and threats of migration for the metropolitan regions of Ukraine, taking into account the interdependence of the development of these processes in Europe and the world as a whole.

Research Methodology

The research was carried out using a number of general scientific and specific scientific research methods. Among them: statistical (main indicators of population migration in metropolitan regions); method of analysis and synthesis (for analyzing migration flows from the periphery to metropolitan areas); problem method (for identifying threats of migration flows for metropolitan regions); a graphical method (for visualizing research results in the form of diagrams, graphs, diagrams, etc.) and some others which will be disclosed during the research.

The data of the State Statistics Service of Ukraine *(Derzhavna sluzhba statystyky Ukrainy)*, the State Migration Service of Ukraine *(Derzhavna mihratsiina sluzhba Ukrainy),* the Ministry of Social Policy of Ukraine *(Ministerstvo sotsialnoi polityky Ukrainy)* were used. Analytical reviews and reports, scientific articles and publications of foreign and Ukrainian authors were studied.

Analysis of Major Publications

Population migration, its causes and directions are a complex multidisciplinary industry, which is dealt by representatives of social geography, demography, sociology, public administration, economics, politics and others separately and in cooperation.

So, Jorge Bravo, in the General secretary's report about the work of the 51st session of the Commission according to Population and Development, calls cities as centers of social, economic and political activities and mobilities of people which attract internal and international migrants. At the same time, the author calls that the processes of globalization are the main factor in increasing the flow of migrants to the cities *(Bravo, 2018).*

M. Lerch predicates that many large cities and metropolises of the world are characterized by an increase in the population precisely because of migrants, primarily external ones, which is mainly facilitated by the processes of urbanization, which entail an improvement in living in the cities *(Lerch, 2017)*.

Exploring the characteristics of migration of rural areas and towns, Carle C. Zimmerman identified a certain relationship between the level of socio-cultural development of migrants and the place of their migration *(Zimmerman, 1928)*. So, representatives of the lower strata of the population, if they decide to move, they prefer to migrate to the towns not too far from their former place of residence. At the same time, people with a higher level of education and labor qualifications choose large cities or other countries.

Also it is interesting the research written by Jorge Rodríguez-Vignoli, Francisco Rowe, in which, using a quantitative assessment method, was revealed the influence of internal migration on the structure of the local population in eight large cities in Latin America *(Rodríguez-Vignoli, Rowe, 2018)*. Internal migration tends to reduce the sex ratio of the population under the age of 14, as well as to increase the percentage of young people (aged 15-29) among the local population.

The Study of the Impact of Migrants on Urban Communities in the United States by Franklin J. James, Jeff A. Romine, Peter E. Zwanzig confirms the positive impact of migrants on the socio-economic situation in large cities. Migrants did not reduce employment opportunities in the United States, on the contrary, they strengthened a number of sectors in the economy of large cities, including small business, finance, construction and industry, also they increased exports *(Morar, Dulca, Nagy, 2016)*.

For Ukrainian researchers, the issues of migration and its impact on the development of the territory are also relevant, taking into account the European and global socio-economic space. In the national report "Ukrainian society: the migration dimension" employees of the Institute of Demography and Social Research named M.V. Ptukhy NAN of Ukraine give an comprehensive description about migration processes in the context of the country and separate regions *(Ukrainske suspilstvo..., 2018)* Wherein, the influence of urbanization on the distribution of the main flows of migrants is called one of the main factors, but there is no analysis of this process in the most developed cities of the country (metropolises). And T. Drahunova in her study calls the regional centers as the main centers of attraction of migration flows in the country, and among the most important reasons for migration calls social *(Drahunova, 2011)*.

N. Lykhovid overlooks the features of the influence of cities on migration processes, trying to analyze the main consequences and effects of migration processes in Ukraine *(Lykhovid, 2017)*. Among them she calls the depopulation of some regions of the country, the change in the structure of the population, the loss of an able-bodied highly qualified population and the need to develop and correct the country's migration policy.

L. Niemets, O. Suptelo, M. Lohvynova, L. Kliuchko, I. Telebienieva also tell about the uneven socio-economic development which occurs as a result of the outflow of the population from peripheral areas and the influx into large cities, which become the so-called "poles of growth" *(Niemets, Suptelo, Lohvynova, Kliuchko, Telebienieva, 2020)*.

Thus, despite the available researches about the migration activity of the population in metropolitan areas, there are certain “blank spaces” requiring additional study with an integrated multidisciplinary approach. In our opinion, “blank spaces” are a detailed study of migration processes in each ukrainian metropolis, identification of the factors of attractiveness of migrants and, of course, positive and negative aspects of the impact of migration on Ukrainian metropolises. This study does not seek to fill the existing gaps but it is a certain background to a complex study of these points and provides an incentive for further discussions of many scientists according to this problem.

Presentation of the Main Research Material

Modern migrations are characterized by a significant segment of temporary, rotating movements. Therefore, the number of people who were (worked, studied) in metropolises at a certain period of their life and, thus, got or brought the features of other cultures significantly exceeds the number of people who currently live in non-native regions where *(Malynovska, 2009).*

For O. Denysenko, metropolis (from the Greek. Metropolis – the main city, capital) is a form of territorial organization of society, which develops on the basis of separate cities and is characterized by flexibility and diversification of the structure of their socio-territorial complexes, the activity of innovative movement and high sectoral , inter-sectoral and territorial integration, special properties of the socio-cultural environment (saturation with objects and connections, dynamism, contact, social mobility). It allows them to realize their metropolitan functions *(Dronova, 2014).* The adjacent zone of the most intense influence of the metropolis with the city forms a functional integral metropolitan region *(Denysenko, 2012).*

Following the development of the metropolis a metropolitan area is formed, which differs from the agglomeration that it includes a suburban area, which is closely connected with the central city by labor migrations, independently of whether the settlements of the suburban area merge with the central city or not *(Melnyk, 2013).*

According to the opinion of the staff of the Institute of Demography and Social Research named after M.V. Ptukhy, there were only six cities in Ukraine performed metropolitan functions at the beginning of the new millennium. Today t Kiev is part of the global metropolitan network, Kharkiv, Odesa, Dnipro, Lviv are regional metropolises of the all-ukrainian level. In connection with the hostilities in the East of Ukraine and the occupation of a part of the territory of Donetsk and Lugansk regions, Donetsk has actually lost such functions *(Ukrainske suspilstvo..., 2018).*

According to E. Dronova's opinion, metropolitan functions are concentrated in super-large cities (in cities with one million population). They transform such cities from national into regional and transnational centers performing organizational and managerial, innovative and creative, transport and communication, spiritual, cultural and informational-representative functions *(Dronova, 2014).*

In Ukraine the number of such cities is decreasing, because at the beginning of the 21st century the five cities of Ukraine, in which more than a million people live, left Donetsk. However, according to experts, in 15-20 years the growth of their share in the total population may exceed 25% on the background of a general reduction population and migration flows from peripheral areas. It tells about a significant deformation of the structure in the settlement system in the state and may lead to undesirable consequences.

O. Denysenko notes that such interregional centers as Kiev, Kharkiv, Lviv, Dnipro, Odesa and others acquire metropolitan features – functions which are especially important for social development. Their implementation goes beyond the state and ensures its interaction with the global economic system *(Urbanistychna Ukraina…, 2017).*

Most of the Ukrainian metropolises are monocentric. They have one core (regional center), adjacent cities and rural settlements. They have stable, well-defined economic and social centripetal connections in labor markets, educational institutions, between business entities, as well as in communication relations between companies and local authorities forming migration flows in the corresponding direction (*Ukrainske suspilstvo..., 2018)*. Recently, Kiev metropolis has been acquiring signs of polycentricity, which manifests through the synergistic functional influence of the central cell (the city of Kiev) on the surrounding space with the transfer of growth poles beyond it against the background of the preservation of the defining dominant of the center. In this regard, one can clearly see the re-profiling of the industrial functions of the core, the removal of non-capital sectors of the economy to the peripheral zone and, as a consequence, the redistribution of pendulum migrations in

favor of satellite cities and settlements where high-tech enterprises of the construction, light, food-chemical, perfumery and cosmetic industries operate *(Pokliatskyi, 2009).*

All Ukrainian metropolitan cities are covered with the processes related to residential suburbanization: selective transformation and fragmentation of rural settlements in the nearest suburban area; construction of new cottage townships and transformation of historically formed garden and dacha cooperatives into permanent housing around metropolitan centers; construction of new residential complexes in neighboring settlements with high transport accessibility; "Internal suburbanization" of the cities ("internally" suburbanizedcities' neighborhoods) *(Urbanistychna Ukraina…, 2017).*

As a rule, the increase of the population in metropolitan areas is due to the migration movement of the population outside their borders as a pendulum migrations. In the metropolises we investigated, satellite city mostly perform a residential function, therefore, the main flows of population movement are periodic labor and educational pendulum migrations (Table 1).

Table 1: Characteristics of migrations in the metropolises of Ukraine

Name	Factors of migration attractiveness	Types of migrations
Kiev metropolis	The capital region, the largest city in Ukraine by population, financial, infrastructure, industrial, educational, cultural center of Ukraine; positioning as a Smart city; high standard of living of the population; the most developed labor market, labor needs; high employment in the tertiary sector; the presence of innovative enterprises; favorable investment climate and significant investment attraction; developed transport infrastructure both around the city and with satellite cities; the transfer the industrial enterprises to the peripheral zone and a certain redistribution of pendulum migrations in favor of satellite cities and settlements with industry concentrated industry.	labor, educational, both permanent and pendulum.
Kharkiv metropolis	Developed labor market and growing demands for labor; priority development of the service sector, financial sector, trade; development of high-tech industries, IT industry; a high level of development of science, education (Kharkiv is a student capital of Ukraine); positioning the city as a Smart city; a high level of development of agriculture and the demands for labor in this industry; wide transport intercity and intraregional communication; neighborhood with regions including temporarily occupied territories.	labor, educational, both permanent and pendulum, forced migrations of immigrants from Donetsk and Lugansk regions
Odesa metropolis	High integration of the city and nearby settlements, which promotes the intensity of pendulum migrations; development of the suburban area, where prices for real estate and land are much lower; good transport links between Odesa and satellite cities; good intra-regional communication; an increase in the intensity of migration in the summer due to the opening of the tourist season; seasonality of migrations because of the employment in the agro-industrial complex, tourism, recreation, as well as transport and logistics; development of the secondary and tertiary sectors of the economy.	labor, educational migrations, high intensity of pendulum migrations.
Dnipro metropolis	Favorable transport and geographical location; industrial development and the presence of large industrial enterprises; demand for labor from small businesses; development of the tertiary sector; neighborhood with regions including temporarily occupied territories.	labor, educational, both permanent and pendulum, forced

		migrations of immigrants from Donetsk and Lugansk regions
Lviv metropolis	Lviv is a historically formed center with a powerful concentration of financial and economic, socio-cultural, material and informational capitals; wide transport links of the regional center with the adjacent territory, which creates prerequisites for expanding the geography of pendulum migration; development of cross-border cooperation; powerful IT sector (SoftServe, Intellias, ELEKS, Lohika, GlobalLogic); the development of the fuel and energy and petrochemical, food industry, mechanical engineering; the presence of a large number of institutions of higher education;	labor, educational, both permanent and pendulum, mostly abroad.

Consider the indicators of migration in the metropolitan regions of Ukraine and metropolitan cities in more detail. Fig. 1 shows that all metropolitan regions and metropolitan cities, except for the Dnipropetrovsk region and the Dnipro, have a positive migration balance. Among the migration flows internal migrations of the population prevail in all, without exception, regions (Fig. 2). The largest flows of migration are concentrated in the capital region – Kiev region and Kiev. In 2019 the population of Kiev region increased by 27.343 people. due to migration growth (because of internal migration of the population), the population in Kiev increased by 17.175 people. In 2019 Dnipropetrovsk region and Dnipro demonstrate a negative balance of migration in the number of 1.426 and 39 people respectively, although internal migrations make for a small migration increase in the regional center.

Fig. 1: Indicators of the population migration in metropolitan centers and regions for all migration flows (constructed by the authors according to (Derzhavna sluzhba statystyky Ukrainy)

Today internal migration in Ukraine significantly exceeds international. It does not substantially affect the number and content of the country's population as a whole, but it causes changes in its location, sex and age structure of certain regions, is a consequence and an important factor of regional differences, is directly related to the processes of industrialization and urbanization,

depopulation of the village *(Malynovska, 2009).* The largest flows of intraregional migration (Fig. 2) of the population are directed to the capital – Kiev, which is associated with its metropolitan functions. However, a fairly high migration growth of the population is provided by Odesa, mainly due to seasonal population movements and their employment in tourist and recreational activity and the service sector. It is characterized by a clear seasonality of tourist and health migration, which creates many problems for the city.

In the investigating metropolises there is a positive balance of international migration (Fig. 3), however, Lviv region is characterized by insignificant negative indicators which is connected with the border position of the region, and as a result, labor migration of the population abroad.

Fig. 2: Indicators of population migration in metropolitan regions by the number of intraregional migrants (constructed by the authors according to (Derzhavna sluzhba statystyky Ukrainy)

Fig. 3: Indicators of population migration in metropolitan regions by the number of international migrants (constructed by the authors according to (Derzhavna sluzhba statystyky Ukrainy)

The influence of metropolises on the formation of internal migration flows of the population is carried out through the intensification of the processes of economic reproduction of the labor force, the formation of self-regulation and self-maintenance mechanisms of the professional mobility of the economically active population and the growth of opportunities to satisfy its information and communication needs. It is important to expand the range of administrative services which can be obtained on the basis of the best service with minimal bureaucratic barriers, high standards of public and private specialized medical care, and access to educational and cultural infrastructure as well.

Based on the analysis of the factors of the migration attractiveness of territories and statistical information about the rates of migration in metropolitan cities, we can conclude that the main trends of internal migrations connected with the formation and development of metropolises are the high concentration and intensity of pendulum migrations to the satellite cities – metropolis with the purpose of labor, educational, administrative, cultural, informational, recreational and health migration of the population. This is facilitated with the developed intraregional and interregional transport links. In addition, Kiev, Kharkiv, Dnipro metropolises have become a place of migrants' concentration from the temporarily occupied territories of Ukraine – internally displaced people. There is a dependence of the intensity of migration movements of the population to the center-periphery from the peculiarities of the spatial development of metropolises: the farther from the center, the lower business activity and the level of living of the population and accordingly the more incentives to look for work outside the place of residence.

The asymmetry of migration flows in Ukraine from the periphery in favor of the metropolitan areas and their development as centers of attraction for migrants causes a number of socio-economic problems because of the growing imbalance between the number and structure of the permanent and actually existing population. Migrants carry out a significant load on the labor market, increase competition, and influence on the transport, engineering and social infrastructure of metropolises. First of all, such a load arises due to pendulum migrations from satellite cities and suburban areas. On the other hand, internal migration stimulates housing construction, which should improve the quality of life of the population, but in practice it often threatens the social and technological security of settlements because of carrying out with violation of construction requirements and without taking into account real social needs. Often, such settlements haven't got the necessary infrastructure: kindergartens, schools, clinics, physical culture and sports centers, which influence on existing social facilities. Suffering the utility services of metropolitan areas is increasing which are already morally and technically outdated and physically worn out. The migration increase in the population of metropolises causes the growth of the level of technogenic pollution, the growth in expenses for solving transport, housing and communal and other socio-economic problems. Also, in connection with the concentration of the population, the need to branch out the network of infrastructure for processing or burying solid industrial and domestic waste is constantly growing *(Ukrainske suspilstvo..., 2018).*

Beside that the rapid development of metropolises accelerates the dehumanization of certain territories, primarily with a high concentration of towns and small villages. Active migration of young people from rural areas aggravates the depopulation, increases the problems of the countryside, increases its depression and leads to significant socio-economic problems in these territories.

Conclusion

The world processes of globalization and intensive urbanization are the main factors attracting the majority of migrants to the metropolis cities. The level of development of these cities, social infrastructure and urban policy attract migrants both from other regions of the country and from abroad. At the same time, the adaptation of such migrants is much more effective precisely in large cities, the evidence of which can be considered the positive indicators of the migration balance. Metropolitan regions and metropolises are areas of maximum concentration of the population with fitting conditions for their life.

As usual among Ukrainian cities, the most attractive city for migrants is Kiev. With the status of the capital and a favorable socio-economic and transport position, the city attracts about 3.5 thousand internal and 4 thousand international migrants per year. Other metropolitan regions of Ukraine: Kharkiv, Dnipro, Odesa and Lviv regions are less popular than Kiev but in the context of the country they have high positive indicators of the migration balance.

The main threat of the direction of migration flows in Ukraine to the metropolitan areas is the uneven distribution of the population around the country, which causes unevenness and instability of socio-economic development. At the same time, migrants can play as one of the factors in the intensity of the development of these regions, creating competition in the labor market and in production, thereby improving the quality of the final product, increasing its cost.

In the context of this study, an important point is the analysis of the demographic and social structure of migrants, which will help to clarify the reasons of migration and the impact of migrants. Unfortunately, the official statistics services do not have this information, therefore, part of the study of migration flows in Ukraine towards the metropolitan regions and their impact depending on the "quality" of migrants will be made by the authors in the future.

Today, the development of metropolitan cities in Ukraine is taking place in conditions of a significant concentration of migrants due to the high need for concentration of capital. In our opinion, first of all metropolises will continue to attract internal migrants because they have got all necessary conditions for the life and work of the population. Perhaps, in the future, the structure of the formation of flows will change in favor of migrations “city-metropolis” and small volumes of return migration to the countryside and small towns of the country will remain. The last question is especially relevant today because of the sharply deteriorating ecological state of cities and the desire of the population to live in more comfortable and healthy conditions. Further research of the development of metropolises and large cities in modern conditions is also required, including pandemics, which significantly affects the life of the global society. These questions will be further investigated by the authors.

Abstract

The growth of cities and urban population, the development of urban space as a result of improving the socio-economic standard of living of urban residents, stimulate the attractiveness of cities among migrants. This article presents the results of a study of the impact of different groups of migrants on the urban space of Kharkiv as one of the largest cities in Ukraine. Kharkiv is migratoryly attractive not only for domestic but also for international migrants. It is an indisputable fact that immigrants influence the urban space, bring elements of their own culture and traditions. This study identified the main groups of migrants arriving in Kharkiv and their general characteristics. According to the purpose of migration and the term, the impact on the urban space of the city differs. It was found that short-term migrations of internal migrants do not have a significant impact on the urban space, the reason for which is primarily the affinity of socio-cultural traditions in most regions of Ukraine. Instead, long-term international migration, especially forced migration, encourages immigrants to adapt to new conditions and, in turn, to adapt urban space to their own needs, changing it.

Keywords: migration, urban space, migration processes, segregation, transformations, Kharkiv, Ukraine.

Introduction

Rapid urban development and urban population growth have become one of the most important factors in the transformation of world society at the beginning of the XXI century. Economic, social and cultural activity of the population became closely connected with the development of the city and urban space. Structural demographic changes directly affect the transformation of urban space. The principles of the "new urbanism" and the global tendencies of anthropocentrism contribute to the creation of a city for people, that is, the maximum consideration of the needs of urban residents in the planning and development of the city and urban space.

The processes of globalization, openness and accessibility of most countries of the world and a number of other factors, including economic, cultural, social, stimulate the intensification of migration flows. Migrants act both as a promising resource and a threat to development for host communities and territories. Therefore, there is a need to assess the impact of migrants on the development of territories and identify threats and prospects that may arise in the process of adaptation of migrants.

The migration movement of the population and the migrants themselves have a significant impact on the development of certain territories, both in Ukraine and for most countries around the world. This applies mainly to the development of large cities. The situation in eastern Ukraine has stimulated an increase in the flow of internal migrants and changes in the direction of international migration *(Ukrainske suspilstvo…, 2018).* Such changes affected primarily the cities closest to the conflict zone, such as Kharkiv, which has traditionally been attractive to certain groups of migrants.

Relevance of Research

In 2019, the total migration increase in Kharkiv amounted to 6609 people, including the migration increase of international migration - 2612 people. In 2019, the city received 58.3% of all migrants in the region, including 90.6% - international migrants *(Mihratsiynyy rukh…).* This indicates the migratory attractiveness of Kharkiv among both domestic and international migrants.

Kharkiv is being transformed on the basis of "new urbanism" and anthropocentrism, being at the stage of transition from the industrial to the post-industrial stage of development, declaring development intentions as a Smart city At the same time, considerable attention is paid to the needs of the population and mutual influence on the transformation of urban space, taking into account the needs of the city and its inhabitants *(Mezencev, Olìjnik, Mezenceva, 2017).*

Although, during the study period, the percentage of migrants in Kharkiv does not exceed 3% of the total population of the city, migrants have a significant impact on its development and transformation of the urban space. This is manifested both in the emergence of new public spaces and in the adaptation of existing ones. After all, a significant proportion of migrants, adapting, move to the category of residents *(Niemets, Suptelo, Lohvynova, Kliuchko, Telebienieva, 2020).*

The purpose of this study is to identify and analyze the impact of migrants on the transformation of public spaces in the city of Kharkiv as one of the largest cities in Ukraine. ***The main objectives*** of the study are: 1) to identify the main groups of migrants who influence the transformation of the urban space of Kharkiv; 2) characteristics of urban spaces created or adapted for the needs of migrants; 3) identification of threats and prospects for the development of the urban space of Kharkiv in the context of the impact of migrant activities on it.

Research Methodology

This article is based on a set of philosophical, general scientific and specific scientific research methods. Main methods: analytical, synthetic, inductive-deductive, problem search (detection of the influence of migrants on the transformation of urban space), retrospective (analysis of migration

flows in different periods due to historical circumstances) statistical (operation of statistical data), graphical (to visualize research results in in the form of graphs, charts, cartographic charts). The use of the method of morphological analysis occupies a significant place in the study. It is morphological analysis, which aims to study the objective world of urban space through field examination and photofixation and its systematization, allows to identify functional qualitative and quantitative changes in the urban environment and draw conclusions about the quality of space organization. As M.V. Ragulina notes, the method of morphological analysis allows to create a spatial "portrait" of the city and to reproduce its essential features as much as possible *(Ragulina, 2012).* According to A. Lefebvre, urban space is a set of representative tangible and intangible images and "texts", the analysis of which gives an idea of the city itself, its spaces and inhabitants *(Lefebvre, 1991).*

Analysis of Previous Research

The city, its inhabitants and their interaction are in the field of research of many sciences. Moreover, special and different approaches have been formed both to the interpretation of the phenomenon of the city and urban space, and to the mechanism of its analysis. The main aspect of this study is to establish the characteristics of the interaction of non-native residents of the city (migrants) with the urban space. The growing role of the city in the life of society in the middle of the twentieth century stimulated the development of the concept of "right to the city". Its founders Andri Lefebvre and David Harvey declared that all city dwellers, without exception, regardless of social status, have the right to participate in decisions about the transformation of urban space, as it belongs primarily to urban dwellers. This concept was formed on the basis of studies of a number of groups of the population not included in the urban society, in particular, the homeless and migrants *(Harvey, 2006; (Lefebvre, 1991).*

At the 51st session of the Committee on Population and Development, Gora Mboup in report "Urbanization and Migration – Two Global Mega Trends:Diversity, Opportunities, and Challenges" states the relationship between urbanization and migration on the development of both society and territory *(Mboup, 2018).* After all, the steady growth in the number of cities and urban residents is largely due to increased mobility of the population in the context of globalizationAt the same time, the influence of migrants does not always have a positive vector, often it is the significant number of people in the city that leads to the deterioration of living conditions of its population (favelas in Rio de Janeiro).

That is why a number of scientists consider one of the most important tasks - the adaptation of migrants in the socio-cultural, economic and political space of the city. Marluci Menezes, Judith Allen, Lia Vasconcelos in the study of the impact of immigrants on public spaces, the main emphasis is on the development and transformation of the cultural landscape of cities *(Menezes, Allen, Vasconcelos, 2009).*

Instead, Valeria Monno and Silvia Serreli state the fact that very often migrants are not included in the urban space and city life. As a result, socio-economic inequality of the population is formed and segregation processes are intensified. As an alternative to this, the authors consider the development of inclusive policies in cities towards vulnerable groups, including migrants *(Monno, Serreli, 2020).*

For Ukraine, migration processes have a significant impact on the development of both the country and individual cities. That is why a number of Ukrainian scientists study the interaction of migrants and migration processes and their characteristics with the city, urban space and local residents. In particular, O. V Senyura names the social aspects of migration among the factors of urban space transformations *(Senyura, 2015).* A.A. Mozhovyy, notes that urban space is the center of conflict formation *(Mozhovyy, 2014).* Agents of the conflict can be both city residents and the urban environment. For cities that are transforming, urban conflicts are very common *(Morar, Dulca, Nagy, 2016; Morar, Nagy, Dulca, Boros, Sehida, 2019).* One of the preconditions for increasing the conflict-generating nature of urban space is significant flows of migrants, which can lead to negative forms of urbanization such as pseudo-urbanization and covert urbanization.

In the context of the socio-political situation in eastern Ukraine, a significant part of research related to migration processes and urban space is aimed at studying the peculiarities of adaptation of internally displaced persons (as one of the groups of migrants) to new urban spaces. Yu. R. Khachaturyan reveals the theoretical context of the adaptation of migrants to urban space on the example of a cohort of children from the group of forced migrants *(Khachaturyan, 2017)*. Given this, it is extremely important to study the transformations of the urban space of large cities in the context of interaction with migrants, in particular one of the Ukrainian cities with a population of millions in Kharkiv.

Presentation of the Main Material

Migration is a continuous process that is the subject of political, social and economic discussions. Managing human flows is one of the most significant challenges for both developed and developing countries. Different reasons and directions of migration create additional problems for governments and local governments, as it is necessary to take into account the motives that motivated people to move. This is especially important for Ukraine, given the rapid decline of rural areas and rural settlements, especially sparsely populated. The problem of migration is becoming even more significant in cities, because it is there that migrants are looking for a better life. At the same time, living in cities allows for greater integration into society. Cities, in addition, provide a decent level of housing, education, medicine, transport, etc. This article is devoted to the peculiarities of the influence of different groups of migrants on the urban space of the post-socialist city at the stage of transformations – Kharkiv *(Niemets, Husieva, Suptelo, Sehida, Kobylin, Kliuchko, 2018).*

One of the largest cities in Ukraine, both in terms of economic development and population, Kharkiv is attractive to both domestic and international migrants due to its border position and high socio-economic development. During the period of independence, Ukraine has been an active participant in international and domestic migration processes and has suffered relevant socio-economic and political consequences:

- Changing the structure of the population: diversification of the ethnic composition of the population;
- Decrease in the working population: labor migration abroad;
- Uneven settlement of the population within the country: the predominance of migration flows in the direction of "periphery - center";
- Intensification of urban processes and socio-economic decline of the village.

In the context of the interaction of urban space and migration processes, the most relevant is the presentation of the impact of immigrants. Moreover, there is no doubt that the representatives of internal migrants easily adapt to urban space and urban lifestyle and subsequently assimilate without having a significant impact on the transformation of urban space. Instead, international migrants, according to differences in culture and traditions, are much more difficult to adapt, less likely to assimilate, but are included in urban society by making changes to the urban space.

The inclusion of individuals in the new conditions of existence in the country has two manifestations: adaptation or isolation with exclusion from society. The analysis of urban space makes it possible to assess the level of adaptability of immigrants. Examples of immigrants' adaptation to new conditions in the urban space are: the emergence of social, cultural and spiritual spaces (educational institutions, cultural centers, religious institutions); economic activity based on authentic traditions of immigrants (traditional productions and outlets); visual transformations of urban spaces (ergonomics traditional for immigrants, architecture, street culture, etc.).

The population migrates due to a number of reasons, which are determined mainly by the duration of this process. In Kharkiv, as an active participant in the migration process, the following main groups of immigrants were formed:

- internal labor migrants, including pendulum migrants from the suburbs;
- internally displaced persons from the conflict zone in eastern Ukraine;
- educational international and domestic migrants;
- refugees and workers from other countries.

Each of the representatives of these groups of migrants, one way or another, has an impact on the transformation of urban space, along with residents of the city, regardless of the duration of mobility. Next, consider the existing changes in urban space that are caused by the activities of each of these groups of migrants.

1. Labor internal migrants, including pendulum migrants from the suburbs: mainly the intensification of pendulum migrations contributes to the development of the transport network in the suburban direction, as well as the "convergence" of the suburbs with the city. As labor migration is generally temporary, such immigrants do not have a significant impact on the transformation of urban space.

2. *Internally displaced persons from the conflict zone in eastern Ukraine:* as of 2019, about 1.4 million IDPs are registered in the country, of which about 130,000 are located in the Kharkiv region, most of whom (66.7%) live in *Kharkiv (Niemets, Husieva, Lohvynova, Kandyba, Kliuchko, 2018).* The main manifestation of the change in the urban space of IDPs was the construction of modular towns for their residence (Fig. 1).

On the one hand, the construction of modular towns has attracted to social functioning mostly abandoned and unpromising areas of urban space, and on the other hand, this kind of neighborhood usually has a negative social effect.

3. *Educational international and internal migrants:* Kharkiv is called the city of students, because a large number of diverse higher education institutions attract a significant number of students, including from abroad. To meet the needs of students, the following transformations were carried out in the urban space: combining the space of study and living of students in a number of universities in the city; emergence of research and educational spaces; formation of auxiliary institutions and institutions of trade and public catering, entertainment around educational institutions.

Fig. 1. Modular town of IDPs in Kharkiv

Fig. 2. «Karazin Student Hall»

Students often continue living in Kharkiv after graduation. At the same time, local students easily adapt and eventually change the urban space alongside the city's residents. Most international students return home, but those who stay, due to their excellent culture and traditions, can significantly influence the transformation of urban space, up to the formation of a kind of urban segregation. Thus, traditionally, in Kharkiv, in the area between the metro stations Botanichny Sad and Oleksiyivska, a kind of campus has been formed, which has a fragmentation of accommodation of Ukrainian and foreign students. Foreign students often stay in the same areas for permanent residence after graduation. Eventually, commercial, entertainment, or social facilities began to appear for some nationalities.

4. ***Refugees and labor migrants from other countries.*** The vast majority of members of this group purposefully migrated to Ukraine during the period of unstable socio-political and economic situation in their countries. Labor migrants mainly come to Ukraine from less developed countries and more of them settle in the capital, large cities and engage in heavy low-paid work *(Niemets, Lohvynova, Sehida, Husieva, Kravchenko, 2019).* Usually, migrant workers are a temporary phenomenon, so they do not have a significant impact on the transformation of urban space. Instead, a group of forced migrants who choose Ukraine as their permanent residence and have a significant impact on both the city's and the city's socio-cultural space are refugees. The largest groups of national minorities in Kharkiv, with the exception of Russians, Belarusians and Jews, who traditionally live here, are Armenians, Azerbaijanis, Tatars, Georgians, Vietnamese, Poles and Koreans. Recalling the history of military and political conflicts in migrant donor countries for Ukraine, it is obvious that the majority of these national minorities are refugees. Having lost their physical connection with their homeland, the refugees are actively influencing the urban space of Kharkiv. They adapt it to their own needs. Thus, a significant number of catering establishments with traditional cuisines for these immigrants arise. (fig. 3)

Restaurant «Georgia»

Cafe "Armenia"

Restaurant «"Rising Dragon"»

Restaurant "First Chaikhana"

Fig. 3: Restaurants of Kharkiv, which were established by national minorities

Over time, representatives of lador migrants, students, refugees from different countries form diasporas, which as a full-fledged community have a social impact on the city and urban space. Religious institutions (Fig. 4), schools, educational and cultural centers are being built.

Fig. 4: Religious buildings of Kharkiv of representatives of national minorities

In general, Kharkiv is migratoryly attractive for both domestic and international migrants, as evidenced by migration flows (Fig. 5).

Fig. 5: General migration flows in Kharkiv for the period 2002-2019 (created by the authors according to (Mihratsiynyy rukh…)

Analyzing the urban space, we can conclude that significant transformations for the needs of migrants, which would be disharmonious or would interfere with the daily practices of residents, especially the emergence of urban segregation, were not detected. This can be explained by the loyalty and adaptation of the local population to migrants. This was facilitated by the history of the formation and development of the city and its diverse ethno-national composition, as well as active processes of adaptation of immigrants.

Considering immigrants in terms of prospects for the development of Kharkiv, the following main points should be noted:

- creation of a more diverse socio-cultural segment of the urban space of Kharkiv;
- attracting tourists, including those associated with local diasporas.

The threats to the development of urban space under the influence of migrants include the following:

- the threat of losing the authenticity of the city of its space under the pressure of culture and traditions of migrants;
- the emergence of competition between residents and migrants in various spheres of city life.

The study of the impact of migrants on urban space is a complex multidisciplinary problem. After all, undoubtedly, the influence is mutual. And the main task is to strike a balance between adapting and imposing one's own traditions and culture.

Conclusions

The processes of transformation of urban space are a complex object of study, because the number of agents who influence the urban space is unlimited. One of the most important factors in the transformation of urban space is migration and the migrants themselves.

As an migration-attractive city, Kharkiv needs to control and resolve issues related to migration and migrants at the city policy level. Traditionally, taking into account the history of development and the current state of functioning of Kharkiv, four large groups of migrants have been formed: labor internal migrants; students; IDPs, refugees and international migrant workers. According to the authors, the latter group has the greatest impact on the urban space of Kharkiv, because it is in the city the longest of all and has a significant need to restore the usual living environment. Mainly, the influence of migrants on the urban space of Kharkiv is manifested in the opening of traditional representatives for this group of food and trade, religious and educational institutions.

Migrants can have both positive and negative impacts on the urban environment. By diversifying the urban space and thus attracting tourists and other migrants, they threaten the uniqueness of the urban space. Further research plans a more detailed analysis of the social impact of certain groups of students on the socio-cultural landscape of the city of Kharkiv and their interaction with city residents. The world is changing rapidly, there are many tensions and conflicts in local and global society. But the sustainability of the latter lies in the great diversity of cultures, relationships, different supranational groups, and so on. These issues require comprehensive interdisciplinary research, and therefore will continue to be in the field of view of the authors' research.

Abstract

The article discusses possible options for changing intraregional migration flows in Ukraine, associated with the processes of decentralization – reforms to consolidate and unite settlements (cities, villages, townships) into enlarged territorial units – the so-called ***united territorial communities (UTCs)*** in order to transfer significant powers and budgets from government agencies to local governments. Undoubtedly, the successful implementation of this reform will lead to the emergence of new migration directions and the redistribution of the population within the country. The purpose of this article is to analyze the redistribution of migration flows in Ukraine, caused by the processes of decentralization and to identify the impact of migration flows on the development of united territorial communities. The main directions of migration flows associated with the processes of decentralization, in our opinion, will be the following directions: 1) united territorial communities – large cities; 2) migration to UTCs located near large cities and centers of economic development, as an intermediate point for further migration to cities; 3) territorial movements of the population between several UTCs; 4) territorial movements of the population within the UTC from the peripheral regions to the center of the UTC. The main characteristics of UTCs that operate in the regions of Ukraine are considered – their number, the area occupied by UTCs from the area of the region and the share of the region's population living in UTCs. The Western Ukrainian regions and the Dnieper region, where the implementation of this reform is much ahead of the overall Ukrainian

pace, are already experiencing new directions of migration flows. The opportunities and threats of population migration for the united territorial communities are analyzed.

Keywords: Internal Migration, Decentralization, Migration Flow, Migration Gain, United Territorial Communities, Ukraine.

Introduction

In terms of volumes, internal migration in Ukraine significantly exceeds international migration. Internal migration does not affect the size and composition of the country's population as a whole, but it causes changes in its distribution in certain regions and communities, and is a consequence and an important factor of regional differences. It is directly related to the processes of industrialization and urbanization, depopulation of the countryside, socio-economic and political transformations, in particular with the processes of decentralization. It is caused in general by the same reasons as international migration, has a similar motivation, that is, the need to improve living and working conditions, therefore it is directed mainly from depressed regions and communities to those that are dynamically developing, usually from peripheral rural areas to large industrial cities or centers of communities. In connection with the processes of decentralization, which are actively implemented in Ukraine, there is a redistribution of migration flows and population in most regions of the country. The emergence of new poorly managed migration flows, the low efficiency of state management and local self-government have complicated the solution of other, no less important for society, problems in the field of education, employment, health care development and modernization of the social protection system. At the same time, migrants make up a significant share of the population of developed cities, and more recently, the centers of united territorial communities, acting as an indicator of socio-economic development, possessing high intellectual, industrial, social, and financial potential. Therefore, it becomes relevant to study new migration flows in Ukraine caused by the processes of decentralization, to identify the threats that migrants pose to the united territorial communities (UTCs) and the opportunities that communities receive due to the human potential of migrants.

The purpose of the study is to analyze the redistribution of migration flows in Ukraine, caused by the processes of decentralization and to identify the impact of migration flows on the development of united territorial communities. The authors set themselves the following main research questions: How have the main directions of migration flows in Ukraine changed in connection with the processes of decentralization? Do migrants influence UTCs? Is it possible the emergence of threats to UTCs in connection with the migration activity of the population?

Research Methodology

This research cannot be performed without using a complex of interdisciplinary approaches and methods. The research relies on both philosophical and general scientific methods and special methods and techniques.

To achieve the goal and search for answers to key research questions, the team of authors used the following methods: analytical (including the method of analysis and synthesis, abstraction), problem-search (to identify the impact of migration on UTCs), systematization (to systematize data on migration flows with the aim of a comprehensive study of their impact on UTCs), classification (to highlight the main migration flows in the context of decentralization), statistical (statistical data for analysis), SWOT analysis (to identify the strengths and weaknesses of migration processes in the context of decentralization, as well as opportunities and threats of their influence for communities), graphic (to visualize research results in the form of graphs, diagrams, schematic images).

The study used data from the State Statistics Service of Ukraine, the Internet portal "Decentralization gives opportunities" (Ofitsiinyi sait portalu "Detsentralizatsiia daie mozhlyvosti"), the Ministry for Communities and Territories Development of Ukraine (Informatsiia pro monitorynh rozvytku silskykh terytorii), which provides reports on monitoring the socio-economic development of UTCs

in each region of Ukraine. Other analytical reviews and reports, scientific articles and publications of foreign and Ukrainian authors were also studied.

Analysis of Previous Studies

Many publications of foreign scientists are devoted to the influence of decentralization processes, since in developed countries this reform has long been completed, and the direction of migration flows that arose in the context of decentralization are almost completely studied. However, there are practically no such publications among Ukrainian scientists.

Studying the impact of decentralization on migration processes, George W. Hammond, Mehmet S. Tosun note that the positive impact depends on the area of the administrative-territorial unit and its economic indicators. Positive migration growth is observed in metropolises, where per capita income and general employment are increasing. On the contrary, peripheral areas experience significant population outflow (Hammond, Tosun, 2009). A supporter of decentralization C. Tiebout noted that in the presence of a large number of territorial units and intensive migration of the population, decentralization creates conditions for the production of public goods, since migrants directly affect the production of public goods and the payment of taxes (Tiebout, 1961).

D. Satterthwaite, C. Tacoli note the uneven socio-economic development of territories as a result of the decentralization process, large enterprises are concentrated in large cities and economic centers, while the periphery remains as a rule rural, which leads to a difference in income between the center and the periphery of the communities and thus generates migration flows in the direction from the periphery to the center of the communities (Satterthwaite, Tacoli, 2003).

M. Klupt, studying the center-peripheral relations in modern Europe, notes that intensive migration, combined with a rapid increase in life expectancy, also pushes the problem of aging in the recipient regions of migrants into the background, but causes aging in the periphery, as well as in depressed regions. Migration flows, increasing the structural and institutional heterogeneity of the European center, do not eliminate the differences between it, the semi-periphery and the periphery, but, on the contrary, contribute to their reproduction. Streams of highly skilled migrants move to the central regions, which concentrate high-tech and knowledge-intensive activities, the semi-periphery absorbs unskilled migrants, and the periphery becomes a source of labor resources for the center and semi-periphery (Klupt, 2015).

Poorly managed flows of migrants to cities and centers of united territorial communities lead to negative consequences for sustainable development – gentrification, which can lead to a sharp rise in housing prices and, consequently, an increase in inequality, which can also seriously hinder sustainable development. The pressure on finances and city budgets to serve a growing number of different population groups with different needs is a serious problem for public administration (Migrants and cities…, 2017).

J. von Braun also talked about increasingly strong links between urban and rural areas due to the migration activity of the population, which is a problem for the sustainable development of territories. This is confirmed by the fact that the poorer (peripheral, agricultural) communities do not benefit as much from decentralization as the wealthier, and in some cases decentralization even aggravates their situation (Braun, 2014).

J. Jütting, C. Kauffmann, I. Mc Donnell, H. Osterrieder, Ni. Pinaud and L. Wegner examined the impact of decentralization on poverty in peripheral regions in 19 countries around the world. They argue that in those countries where the central government does not fulfill its main functions, decentralization can be counterproductive, it can be a powerful tool for reducing poverty in the country as a whole, but it can lead to imbalances in territorial development and population migration within its regions (Jütting, Kauffmann, Mc Donnell and etc., 2004).

R. Bird, E. R. Rodriguez also note the importance of migration in the process of decentralization. In the absence of major economic changes in communities, there is an outflow of the population. Scientists note how migrants can cause external negative effects to the regions they leave, and similar negative effects and costs on the regions to which they are sent (Bird, Rodriguez, 1999).
Staff members Ptoukha Institute for Demography and Social Studies of the National Academy of Sciences of Ukraine agree with foreign scientists. The national report "Ukrainian Society: the Migration Dimension" (Ukrainske suspilstvo: mihratsiinyi vymir: nats. dopovid, 2018) analyzes the reform of the initial stage of the decentralization reform in Ukraine, as well as analyzes the impact of decentralization on migration flows in the country with an optimistic, pessimistic and realistic version of the implementation of the administrative-territorial reform in Ukraine. The links between the central and peripheral regions of the Kharkiv region, which are manifested, as a rule, in labor and educational migration, were studied by L. Niemets, O. Suptelo, M. Lohvynova, L. Kliuchko, I. Telebienieva. Cities become "points of growth" due to migration attraction, provide ample opportunities for obtaining a higher income, therefore, they attract migrants from peripheral areas, which also confirms the subsequent uneven socio-economic development of regions due to migration losses of the periphery and opportunities due to migrants in cities (Niemets, Suptelo, Lohvynova and etc., 2020).

Since the main consumer of human potential in Ukraine is the capital region, M. Chaikovskyi, A. Kovtun talk about the transformation of Ukraine's regions into the inner periphery. The main mechanism of internal peripheralization, according to the authors, is labor migration from the periphery to the center and industrialized regions, educational migration, which contributes to the loss of peripheral regions of intellectual potential and its greatest concentration in the center, which thereby strengthens its competitive offers relative to other territories (Chaikovskyi, Kovtun, 2019). In the context of these publications, the study of new flows of internal migration in Ukraine associated with the processes of decentralization is an important scientific task, since migration is an important resource for the development of communities, but at the same time it is a threat to the socio-economic prosperity of territories with low migration activity and outflow of the population.

Presentation of The Main Research Material

Decentralization reform is the key reform in Ukraine today. The reform is being carried out through the unification of basic territorial communities (cities, villages, townships) into enlarged territorial units – the so-called united territorial communities (UTCs) with the transfer of significant powers and budgets from state bodies to local governments. The merger takes place on a voluntary basis (up to 2020 inclusive). Among the main goals of decentralization in Ukraine are the prevention migration from rural areas, the fight against poverty, the expansion of employment, ensuring equal opportunities and meeting the needs of the population, improving the quality of life, providing opportunities for personal development and improving the state of social development (Detsentralizatsiia v Ukraini…, 2018). The unevenness of the socio-economic development of urban and rural areas is associated, first of all, with unequal opportunities in financing, which directly affects the socio-demographic processes in the peripheral regions, contributes to the outflow of the working-age population from the periphery to the center, from the village to the city. Decentralization implies that a more equitable balance of budget expenditures, investments in infrastructure, and an increase in funding for programs for the economic development of rural areas should be achieved between urban and rural areas (Detsentralizatsiia: korotko pro holovne, 2019). The introduction of this reform in Ukraine will undoubtedly affect the migration processes within the state.

The formation of UTC is carried out taking into account:

- the ability and capacity of local self-government bodies to solve public issues related to their competence to meet the needs of the population;
- historical, geographic, socio-economic, cultural development of settlements;
- state of infrastructure development;
- financial support of the corresponding administrative-territorial units;
- features of labor migration of the population;

• the availability of services in the relevant areas (Monitorynh protsesu detsentralizatsii vlady, 2020).

As of January 2020, 1,029 united territorial communities have been created in Ukraine, in 980 of which local elections have already taken place. The largest number of communities in Ukraine was created in the West of the country (in Volyn, Zhytomyr, Ternopil, Khmelnytskyi regions), as well as in the Dnieper region (Dnipropetrovsk and Zaporizhia regions). It is planned that after the local elections in October 2020, the sub-regional level will change, in which 130 districts will remain (instead of 490). At the basic level, 1470 UTCs will remain, which include cities, towns and villages (Fig. 1) (Monitorynh protsesu detsentralizatsii vlady, 2020; Ofitsiinyi sait portalu "Detsentralizatsiia daie mozhlyvosti"). Geographically, UTCs occupy more than a third of the territory of Ukraine, where a quarter of its population lives.

Fig. 1: Current and prospective (after the local elections in 2020) administrative-territorial structure of Ukraine (built by the authors according to (Ofitsiinyi sait portalu "Detsentralizatsiia daie mozhlyvosti")

Changes in the administrative-territorial structure of Ukraine can lead to the formation of new intra-regional migration flows, as well as to the formation of new centers of attraction for migrants. Migration flows in Ukraine in the context of the successful implementation of the administrative-territorial reform can be formed in the following directions (Fig. 2):

Fig. 2: Directions of migration flows in Ukraine associated with the processes of decentralization (built by the authors according to (Ukrainske suspilstvo: mihratsiinyi vymir: nats. dopovid, 2018; Tilikina, 2019)

Migration direction "united territorial communities – large cities". Large cities, which are centers of concentration of production, investment, intellectual, information, educational and other resources, have long attracted the working-age population, since they give higher chances of employment, increase their own income and provide quality services (Niemets, Suptelo, Lohvynova and etc., 2020). Migration flows in this direction can be either constant or periodic (pendulum).

Migration to UTCs located in close proximity to large cities. Such migration is directly related to the process of suburbanization. The united territorial communities have a more favorable socio-geographical position, good transport accessibility, are considered as a bridge between the city and the periphery, have a higher business activity and a favorable market environment compared to the peripheral zone, developed infrastructure and services. In addition, the high cost of housing in large cities and the ability to search for affordable housing in the nearest UTCs strengthens UTCs ties with large cities, regional administrative centers and centers of socio-economic development due to periodic flows of pendulum migration. As a rule, the positive migration balance of such UTCs is due to the process of reurbanization – a stable population of UTCs, their renewal, including due to urban planning reconstruction.

Territorial displacement between UTCs. Such movements include labor migration, educational migrations from outsider UTCs to better-off UTCs with high labor opportunities; labor migration between UTCs partners; territorial movements between residents of neighboring UTCs, caused by family ties and personal factors. The prospect of this direction of migration flows is due to the need to combine the efforts of neighboring UTCs or UTC-partners to attract investments, build enterprises, arrange infrastructure and social facilities.

Territorial movements within the UTCs in the direction "periphery – UTCs center". Often the administrative and economic center of the UTCs is a powerful focus of concentration of local migration flows. Under the influence of the implementation of financial decentralization (an increase in their own financial revenues of local budgets and the possibility of obtaining additional funds due to the expansion of sources for the formation of a revenue base), communities will have the

opportunity to increase their financial potential for the proper maintenance of infrastructure facilities, communal property institutions, and the provision of public and utility services. This will revive migration contacts between the community's population and activate the migration movement (Ukrainske suspilstvo: mihratsiinyi vymir: nats. dopovid, 2018).

Since the planned UTCs have not yet been fully formed in Ukraine, and also taking into account the experience of European countries, it can be noted that the influence of decentralization processes on intramigration processes in the country will only increase (Milbradt, 2018). Therefore, we can assert that first direction of migration – movement in the direction of "united territorial communities – large cities" will include the most large-scale migration flows. This is due to the fact that it is in the cities where the necessary social infrastructure is concentrated (housing and communal services, educational institutions, medical institutions and recreational facilities, social security institutions, cultural and leisure institutions) and most enterprises. In rural areas all this is absent or underdeveloped. However, in our opinion, the dynamics and directions of the migration movement will largely depend on the difference in the living conditions of the inhabitants of the united territorial communities – more successful UTCs will attract a larger number of migrants due to a higher level of economic development, local budget income, wages, the possibilities of social infrastructure (Niemets, Lohvynova, Sehida and etc., 2019).

Therefore, in the near future, one should expect an increase in the positive balance of migration in communities with high financial solvency, which are distinguished by high indicators of their own income and capital expenditures per capita, with a powerful business sector, developed infrastructure and social sphere, that is, in which the basic prerequisites for the preservation and enhancement of human potential within the territorial community are formed (Mihratsiia yak chynnyk rozvytku v Ukraini).

Fig. 3: The main characteristics of UTCs that operate in Ukraine (built by the authors according to (Ofitsiinyi sait portalu "Detsentralizatsiia daie mozhlyvosti")

In the future, the greatest impact of the decentralization process on migration flows will be noticeable in those regions where communities occupy a significant area of the region's territory and also concentrate a significant proportion of the population (Fig. 3). We can assume that large-scale active movements within a community from the center to the periphery and between neighboring communities will be observed in Sumy (where 70% of the region's population lives in the UTCs), Zhytomyr (67%), Ternopil (64%), Volyn (58%), Ivano-Frankivsk (52%), Chernihiv (50%) regions. It should be noted that it is the Zaporizhia and Dnipropetrovsk regions that have the largest area

occupied by UTCs – 66.6% and 68.8%, respectively. However, taking into account the proportion of the population that lives in UTCs (28% and 30%, respectively), it can be assumed that in these regions flows will prevail in the direction of "united territorial communities – large cities" and "migration to UTCs located in close proximity to large cities". he same directions of migration flows will increase in those regions where the center of the region is metropolises – Kiev, Kharkiv, Odessa regions. This is confirmed by the low proportion of the population living in the UTCs (Fig. 3).

Let's analyze the indicators of internal migration within the settlements of the united territorial communities of the regions of Ukraine. Based on fig. 4 we can see the tendency of active migration inflow in the communities of the Luhansk region (55.6% of communities with a positive migration balance), Zakarpattia (50%), Ivano-Frankivsk (47%), Kirovohrad (46.2%), Mykolaiv (41.4 %), Khmelnytskyi (41.2%), Ternopil (41.0%) regions, that is, in those regions where there is no large city that performs the functions of a metropolis of regional significance (Fig. 4) (Ofitsiinyi sait Ministerstva rozvytku hromad ta terytorii Ukrainy). In this case, the centers of attraction for migrants are those communities that have high financial security, good transport accessibility, a wide labor market, developed infrastructure, etc. In those regions where metropolises are present - Kiev, Kharkiv, Odessa, Dnepropetrovsk, Lviv regions, those communities that are in close proximity to the metropolises, are part of their agglomerations and communities that are most developed in the socio-economic aspect will have a positive migration balance. In such regions, metropolises will create an asymmetry of migration flows, attracting to themselves most of the migrants (Korniienko, 2018).

Fig. 4: Indicators of the migration increase in internal migration of the population within the settlements of the UTCs for 2019 (built by the authors according to (Ofitsiinyi sait Ministerstva rozvytku hromad ta terytorii Ukrainy)

The largest population decline due to migration is observed in the communities of the Rivne region (a decrease in 50% of communities), Poltava (41.0%), Chernihiv (40.5%), Dnipropetrovsk (39.7%), Sumy (38.7%), Donetsk (38.0%), Mykolaiv (37.9%), Ivano-Frankivsk (35.9%) regions (Fig. 5). Migration losses are observed in communities with low resource potential, insufficient financial solvency and passivity of civil position. Financially secured UTCs, as a rule, maintain a positive migration balance in the exchange of population with UTCs outsiders (Ofitsiinyi sait Ministerstva rozvytku hromad ta terytorii Ukrainy).

Fig. 5: Indicators of the reduction in internal migration of the population within the localities of the UTCs for 2019 (built by the authors according to (Ofitsiinyi sait Ministerstva rozvytku hromad ta terytorii Ukrainy)

Fig. 6: Communities in which the indicators of internal migration of the population in 2019 did not change compared to the previous year (built by the authors according to (Ofitsiinyi sait Ministerstva rozvytku hromad ta terytorii Ukrainy)

Migration flows in Ukraine associated with decentralization processes can have a positive impact on UTCs, since migrants of working age, as a rule, have a high educational and qualification level. This indicates a significant accumulated human capital, which can act as an important factor in the development of high-tech industries and services with intensive use of knowledge in communities with high migration activity (Lohvynova, 2019). In the socio-economic sphere, migration activity leads to an increase in the number of enterprises and organizations due to a surplus of labor. In addition, thanks to migrants, the least popular vacancies for the local population in the labor market are being filled, which leads to cheaper production of goods, increased requirements for the range and quality of goods and services. Thanks to migrants in communities, the social activity of the population is increasing and the number of social initiatives that the local population actively supports and develops together with the migrants is increasing. At the same time, the activation of migration flows and changes in the structure and composition of the population can have many threats for the further development of the territory (Table 1).

Table 1: Influence of migration flows on united territorial communities (compiled by the authors for (Lohvynova, 2019; Khymynets, Tsimbolynets, 2019; Niemets, Husieva, Pohrebskyi and etc., 2020; Ukrainske suspilstvo: mihratsiinyi vymir: nats. dopovid, 2018)

Opportunities	***Threats***
* increase in the population of UTCs due to the influx of migrants; * development of communities at the expense of migration capital, which saturates the economy of communities; * opening new enterprises, providing jobs for residents of UTCs due to the entrepreneurial activity of migrants; * filling unclaimed vacancies in the labor market, easing tension on labor market, as a consequence of the decrease in the unemployment rate of the UTCs; * the creation of high-tech jobs and the attraction of productive investment (including foreign direct investment); * increasing the professional and qualification level of labor resources due to the intellectual potential of migrants; * promoting the development and diversification of business and the formation of clusters; * development of infrastructure, introduction of energy efficient technologies; * growth of social activity of the population due to new social initiatives; * replenishment of the local budget of the UTCs at the expense of taxes paid by migrants; * development of the consumer market, improving the range and quality of products; * improvement of the state of social infrastructure, construction of new social infrastructure facilities and reconstruction of existing ones; * consolidation of efforts of migrants, society, government, business on the basis of partnership; * improving the image of the community at the local and regional levels.	* a decrease in the population size in UTCs outsiders and communities with low financial activity; * uneven socio-economic development of individual communities, uneven development within the community, depressiveness of the periphery of the community; * deepening of regional identities among the population within the UTCs; * possible conflicts between migrants and the permanent population of UTCs, which leads to an increase in social tension in society, a possible increase in the level of crime; * the load on the housing stock, the need to provide housing for migrants, the rise in prices in the real estate market; * increased depression in rural areas due to the outflow of a part of the highly qualified population; * increasing the load on institutions of preschool, general secondary and higher education, medical institutions; * growing load on social welfare departments, pension fund departments, city employment centers; * increased competition in the labor market; * increasing social inequality; * an increase in the socio-cultural difference (in traditions, values, lifestyle, etc.).

Migration redistribution of the population on the territory of Ukraine can lead to serious threats to the united territorial communities. These threats consist in the increasing demographic burden on the population of the working-age population of the centers of the UTCs, the unevenness and asymmetry of the socio-economic development of the territories of individual UTCs due to competition for capital, including human, production, financial, cultural (Ukrainske suspilstvo: mihratsiinyi vymir: nats. dopovid, 2018). Large migration losses of the population will be experienced by communities with low resource potential, insufficient financial solvency and passive social position of residents. The loss of population due to migration outflow can lead to the loss of the economically active labor force, as a result, to the prevalence of the number of elderly people and depopulation. However, in the communities-recipients of migrants, an influx of population can fill unclaimed vacancies in the labor market, but on the other hand, lead to a shortage of housing, a worsening crime situation, destruction of local cultural and spiritual wealth, transformation of the mental characteristics of the population, lead to conflicts between communities, which poses a direct threat even to the integrity of the country.

Conclusions

The implementation of the decentralization reform in Ukraine should reduce territorial disparities in the socio-economic development of regions. The reform is aimed at increasing the employment of the population by opening new enterprises and organizations, increasing the income and well-being of the population of the united territorial communities, preventing large-scale migration of the population from the countryside and the depressiveness of the Ukrainian countryside. Of course, the unification of settlements into communities affects the direction of migration flows. In our opinion, the main directions of migration flows associated with the processes of decentralization will be the following directions: migration from united territorial communities to large cities, regional and district centers, centers of high socio-economic development; migration to UTCs located near large cities and centers of economic development, as an intermediate point for further migration to cities; territorial displacement of the population between several UTCs, UTCs outsiders to UTCs leaders; territorial movements of the population within the UTCs from the peripheral regions to the center of the UTCs.

To date, the reform of decentralization in Ukraine is at the stage of active implementation, 1029 UTCs have been created out of 1470 planned. In the Western Ukrainian regions and in the Dnieper region, UTCs occupy more than half of the region's area. In regions such as Sumy, Zhytomyr, Ternopil, Volyn, Ivano-Frankivsk, Chernihiv regions, more than half of the region's population lives in UTCs. This may indicate active population movements between UTCs or within one UTC from peripheral areas to the center.

Migration flows can positively influence UTCs. But if communities will have a population less than the minimum permissible norm (5 thousand people), their chances of keeping the population from migrating, and even more so creating a positive migration growth, are very small. Higher financial incomes, the possibility of attracting investments, smart management can lead to the socio-economic well-being of some communities and the presence of socio-economic problems in others. And the migration of the population from outsider communities to community leaders will increase the disproportions in the social and economic development of communities. However, given a developed transport infrastructure, such migrations can be of a pendulum character.

The positive impact of migration flows for communities consists in an increase in the population of the community, its qualitative composition, since, as a rule, migrants are people of working age with high intellectual potential and labor qualifications. Due to the migration capital, it is possible to attract investments, open new enterprises and create new jobs, thereby reducing the unemployment rate in the community, developing infrastructure facilities, etc.

Thus, the prospects for the transformation of internal migration flows in the country as a whole and in its regions depend on the conditions for the implementation of the administrative-territorial reform and the success of decentralization changes in terms of improving the quality of life in territorial communities. Therefore, at the end of the implementation of the decentralization reform in Ukraine, a comprehensive analysis of migration redistribution should be carried out, taking into account the financial and other socio-economic indicators of the UTCs.

Because the reform of decentralization in Ukraine is completely incomplete, 441 UTCs that are still planning to create will obviously be quite problematic. This process requires additional research. In particular, what factors hinder the creation of these UTCs (qualitative characteristics of the population of these territories, income, labor and intellectual potential). The authors intend to further study these problems. After that, it is possible to solve the issues of optimization of intramigration processes, to propose models for their comprehensive improvement in order to ensure the sustainable development of territorial communities

The issues of completing decentralization in Ukraine require special attention and interdisciplinary study. As a result, the schemes of socio-economic zoning of Ukraine should be adjusted. All this will

help to ensure the development of the socio-economic, demographic foundations of Ukraine for enhanced integration into the EU and the world community of developed countries.

Abstract

The modern world of global humanity can be described as traveling and migrating. This extremely complex modern phenomenon has many causes and factors of influence on the one hand, on the other – it affects the lives of most countries. Labor migrations are especially important. Ukraine, which until recently was on the sidelines of these processes, is increasingly participating and influencing their course, in particular, in the context of European integration. The intensification of migration processes creates a number of difficulties for both Ukraine and many EU countries, causes destabilization in the labor market, generating certain socio-demographic changes, etc. A number of documents and programs to resolve this situation in Ukraine are being developed and implemented at the state level. The authors consider the impact of ratification of the agreement with the EU on labor migration flows in Ukraine, analyze the state policy in the field of labor migration regulation, namely - the Strategy of State Migration Policy of Ukraine for the period up to 2025 in this paper.

Keywords: labor migration, illegal migration, migration flows, migration balance, population survey, Strategy of State Migration Policy of Ukraine, ratification of the association agreement.

Substantiation of the Research Problem

Population migration processes are one of the decisive factors influencing the change in the number and structure of the population, the interregional distribution of the population and the labor market.

Migrations differ in their intensity, vector of movement, duration, which are motivated by certain objective or subjective reasons.

Migration processes in the world in the current realities are acquiring global proportions, moreover, they can often be characterized by territorial disproportion, which is due to the uneven development of countries and regions of the world. The study of the features of the migration movement is relevant for many countries of the world, including for our state, because Ukraine is characterized by intensive international and intraregional migrations. In recent years, there have been significant changes in the economic, political and social life of the country in Ukraine. Migrant donor countries, including Ukraine, have many consequences of external migration, most notably the reduction of labor resources; disqualification of a significant part of migrant workers who work abroad outside the profession, demographic problems, etc.

There are also many functional consequences for these countries: alleviation of the unemployment problem due to the unloading of the labor market, cash inflows from migrants, which stimulate industry, improve economic dynamics, and so on. But at the moment, intensive labor migration not only reduces the supply of labor in the Ukrainian labor market, but also reduces its quality. As a result, for Ukraine, international labor migrations have become a factor in the spread of various kinds of challenges, which necessitates a comprehensive study of migration risks, in particular, in the socio-geographical aspect. Thus, the relevance of the study is determined not only by modern political and economic processes, but also by the need to improve the existing system of regulation of labor migration in Ukraine.

The intensification of cross-border mobility of the population has increased as a result of Ukraine's acquisition of a visa-free regime for travel to the European Union in June 2017. From June 2017 to June 2019, border guards recorded 42.6 million border crossings by Ukrainian citizens, including 9.2 million with biometric passports, including almost 3 million without visas. During the second year of visa-free travel (June 2018 - June 2019), citizens of Ukraine made 2.35 million trips to the EU without a visa, which is in 4.2 times more than during the first year of its validity (June 2017 - June 2018) *(Derzhavna mihratsiina sluzhba Ukrainy)*.

The migration presence of Ukrainians in Europe is growing at the present time. The number of valid residence permits for Ukrainian citizens in the EU has doubled over the past ten years and amounted to about 1.2 million in 2018. The largest number of Ukrainians lived in Poland (442 thousand), Italy (234 thousand), the Czech Republic (132 thousand), Germany (121 thousand) and Spain (92 thousand) *(Predstavnytstvo Mizhnarodnoi orhanizatsii z mihratsii (MOM) v Ukraini)*. The main reason for the labor migration of Ukrainians abroad is the difficulty in finding a decently paid job at home. Over the past five years, the economic factors of migration have intensified politically and socially, which has led to a rapid increase in migration sentiment and an increase in the intensity of migration.

The aim of the work is to identify the impact of the ratification of the agreement with the EU on the flows of labor migration in Ukraine, analysis of state policy in the field of regulation of labor migration, namely the Strategy of the State Migration Policy of Ukraine for the period up to 2025, identification of positive and negative causes of this phenomenon.

Review of Previous Research

Migration processes have long been the subject of scientific research. The basis of scientific understanding of migration was founded by A. Smith. He founded an approach that lobbied for unhindered international labor exchange to promote economic growth and poverty alleviation. One of the priority areas of such processes was the attraction of foreign skilled workers while prohibiting the migration of their citizens. The formulation of the classical theory of migration belongs to E. Ravenstein *(Ravenstein, 1885)*. E. Lee proposed the laws of migration and formulated a system of "attraction-repulsion" of migrants *(Lee, 1966)*.

At the end of the twentieth century. the so-called neoclassical theory of migration was developed, at the origins of which were D. Massey, A. Paloni, J. Durand and others. This approach is based on the migrant's calculation of possible economic gains or losses from the migration process. Such factors include: the cost of the trip itself, the possibility of taking a job, in the case of illegal migration – the risks of deportation. The moral and psychological aspects of migration by neoclassical theory include stress in finding a new job, the difficulty of being in a culturally foreign territory, the loss of stable ties *(Massey, 2002)*. But this theory has also been strongly criticized, particularly in terms of methodological principles.

Until the 60s of the twentieth century, domestic research on this topic was almost absent. The reason for this phenomenon is the unpopularity of this area of research due to the ban on the use of migration statistics, in particular, regarding foreign migrations. Such studies have become widely popular due to the mass labor migrations of the population in order to develop virgin lands. In the political aspect, these processes correlate with the times of "thaw". The main aspects of such studies were the scale (volume) of migration, their orientation and gender and age structure of migrants.

There was an emphasis on the theoretical foundations of migration and the interdependence between the intensification of migration processes and economic and political phenomena in society in the 70's and 80's of the twentieth century. It is at this time that the development of domestic methodological foundations for migration research, attempts to develop and implement migration policy.

The globalization of the scale of migration, in particular – international, took place in the XX – early XXI century, which only increased the interest of scientists in this issue. But it should be noted that the research of that time is fragmentary and rather imperfectly covers such aspects of migration as the problems of adaptation of migrants, the dynamics of their identity, and so on.

According to the K. Brettell and J. Holyfield's research, migration processes are interdisciplinary, so any study performed by the methodological apparatus of one science can not be complex (Brettell, Hollifield, 2015). According to the authors, the sciences that are designed to study migration processes are economics, geography and sociology. At the same time, each science should be responsible for a certain aspect of research, namely:

- sociology – features of adaptation of migrants, their identification and loss and their acquisition of social ties;
- economy – identification of socio-economic factors that were the basis of the migrant's decision to move and the corresponding economic consequences of these decisions;
- geography - identification of the dominant spatial patterns of migration.

However, the common denominator between these areas of research is that they try to specify various aspects of migration and explain their nature.

According to K. Brettell and J. Holyfield, extremely important in the implementation of the model of "attraction - repulsion" is the population density, and in the case of overpopulation is the repulsion factor, sparsely populated factor is the attraction factor. But at the moment the most densely populated, as a rule, are regions with significant economic development, cities, which themselves act as poles of attraction for migrants. This statement also calls into question the case of individual or mass migration. In individual migration, the force of "repulsion" can be economic difficulties and life difficulties: dismissal, death of relatives, divorce, etc. *(Brettell, Hollifield, 2015)*. Attractive factors include favorable living conditions, a significant difference in income and others.

S. Haug's scientific research emphasizes the relevance of interdisciplinary research, which should be based on tangential aspects of scientific theories. She is the author of the theory of rational choice. This theory explains the migration of the population through the behavior of a particular individual *(Haug, 2015)*.

An important role in the study of modern migration processes in Ukraine is played by studies of the Institute of Sociology of the National Academy of Sciences of Ukraine, in particular periodic sociological monitoring, which includes questions about the experience of labor migration, its intention and so on *(Instytut sotsiolohii NAN Ukrainy)*.

In previous studies, the authors considered the migration challenges of the 21st century and Ukraine's experience in resolving them (K. Sehida, N Husieva, L Niemets, O Suptelo, P. Kobylin, L. Kliuchko, 2018), problems and prospects of adaptation of internally displaced persons in Ukraine (Niemets L., Husieva N., Sehida K. Kraynukov O., Lohvinova M., Suptelo O., 2019), the impact of stationary migration on population reproduction, characterized migration mobility and features of the region (Niemets, Husieva, Lohvynova, Kandyba, Kliuchko, 2018), features, factors and consequences of migration processes in the countries of the European Union (Sehida K., Niemets L., Korenkov R., Nosyriev O., Dobrovolskaya N., 2020). Regarding the issue of labor migration, the motivators of labor migration, types of employment of labor migrants abroad and the positive and negative consequences of labor migration in Ukraine were considered (Niemets, Lohvynova, Sehida, Husieva, Kravchenko, 2019).

Research Methodology

In order to obtain representative results of the study of labor migration, we used a set of philosophical, general scientific, specific scientific methods. Sociological methods have played a significant role in the study, in particular, the survey method, its results make it possible to find out the independent opinion of the population about the experience of labor migration or the intention to carry it out. The comparative method was used to compare official data from state statistics and opinion polls. Methods of induction, deduction, analysis and synthesis, systematization and generalization, etc. were used to process the obtained materials. Mathematical-statistical method, method of formalization and ranking were used for processing data sets. To present the results of the study, a graphical method was used (construction of diagrams, Paretto graphs).

This research on migration in Ukraine is characterized on the basis of the number of migrant workers and foreigners working in Ukraine, the migration balance, which characterizes the migration increase (decline) due to migration, the number of migrant workers without regulated status, the volume of remittances of migrant workers.

For a comprehensive statistical study of labor migration processes, we used a systematic approach, that identified causal relationships and factors influencing the formation and scale of labor migration. It is the application of a systematic approach that has led to the development of practically significant conclusions and recommendations for the regulation of labor migration.

Presentation of Research Results

The study and analysis of the general migration situation in Ukraine is complicated by many factors, the main of which are the cancellation of the traditional population census, the lack of necessary data from the temporarily occupied territories, etc. For the last 18 years, internal migration in Ukraine has mainly been about migrations between cities (almost 50% of the total turnover). This trend correlates with the fact that large cities are regional centers of development, centers of service, and therefore they attract migrants. Let's analyze the features of migration growth in Ukraine for the period from 2002-2019 (fig. 1).

Fig 1. Dynamics of the migration balance in Ukraine (2002-2019)
(developed by the authors based on data Derzhavna sluzhba statystyky Ukrainy)

Analyzing this graph, we can see that the balance of migration was negative in 2002-2004, and further has positive values. The maximum migration increase for the study period is observed in 2012. Then the number of arrivals in Ukraine reached 76,361 thousand people. This was influenced by the European Football Championship "Euro-2012", which took place in Ukraine, in the largest cities: Kyiv, Kharkiv, Donetsk, Lviv. Already in the following years, the increase in migration gradually decreased, but in the future, the number of immigrants exceeded the number of emigrants. Since 2014, both the number of arrivals and departures has increased significantly. The reason for this is political reforms and the economic situation in the country. This process was also strengthened by the 2017 agreement on visa-free travel between Ukraine and the EU. According to the results of 2019, Ukraine has a positive migration balance. But the migratory mood of the population is changing quite rapidly, as evidenced by the results of population surveys (fig. 2).

Fig. 2: The results of a survey of Ukrainians regarding intentions of labor migration and experience of labor migration of both personal and family members,% (developed by the authors based on data Instytut sotsiolohii NAN Ukrainy)

According to the results of the annual survey conducted by the Institute of sociology NAS of Ukraine, 13.7% of respondents answered the question "Do you or any of your family members have

experience of temporary work abroad?" positively in 2012, and in 2018 – 25.2%. At the same time, 7.4% expressed their intention to go abroad to work in the near future, and in 2018 – twice as much – 14.3%. Labor migration abroad is quite common in Ukraine, the population has significant experience of labor migration, and the unstable economic and political situation is an important factor in "attracting" labor migration to other countries. Both the number of people who have had experience of labor migration and the number of those wishing to carry it out are growing.

In order to assess the scale and study the characteristics of labor migration of Ukrainians abroad, the State Statistics Service of Ukraine in 2008, 2012 and 2017 conducted large-scale population surveys, which surveyed more than 20 thousand households *(Zovnishnia trudova mihratsiia, 2018).* According to the data obtained, at least once 1.5 million people, or 5.1% of the working population of Ukraine, went abroad to earn money for 2.5 years before the survey or worked abroad at the time of the survey in 2008 – 1.2 million or 3.4% of citizens aged 15–70 years, in 2017 – 1.3 million or 4.5% of the population of the appropriate age (excluding the population of the temporarily occupied territories). Such studies did not take into account migrants who left with the whole family and persons, who carried out pendulum migrations in border areas, so the real number of migrants is much higher. According to many researchers, the number of Ukrainian labor migrants is currently over 3 million (Libanova, 2018).

The countries-poles of attraction of labor migrants for Ukraine are traditionally the neighboring countries: Russia, Poland, the Czech Republic, and also the countries of Southern Europe (Italy, Spain, Portugal). The situation in eastern Ukraine has significantly affected this structure, which has reoriented the migration flow from east to west (EU), the dominant country in terms of the number of migrants is Poland (fig. 3).

Fig. 3: Dynamics of the percentage of migrant workers by destination countries according to the results of surveys in 2008, 2012 and 2017,%
(developed by the authors based on data Zovnishnia trudova mihratsiia, 2018)

The transformation of Poland into the main destination country for labor migrants from Ukraine was facilitated by the procedure introduced in Poland in 2008, according to which Ukrainians can work for 6 months during a calendar year without a work permit, but only at the request of the employer registered by local local government administrations. Italy has long been ranked high in the ranking of countries attractive to Ukrainian migrant workers, as is the Czech Republic. Hungary is territorially close and attractive to migrant workers in the border areas of western Ukraine. The sixth country in the ranking of the most popular among migrants from Ukraine is Portugal, which has a fairly soft migration policy and is also favorable among migrants. In terms of intra-regional context,

it is important that previously about 70% of migrants from Ukraine to Poland were residents of the western regions, but now this trend has changed enough, and residents of central, southern and eastern regions also take an active part in migration in this direction.

Migrant workers have a high impact on Ukraine's domestic foreign exchange market. According to various estimates, remittances from migrant workers account for about 2–5% of our country's GDP (fig. 4).

Fig. 4: Dynamics of private money transfers to Ukraine in 2007–2018 (developed by the authors based on data Ministerstvo finansiv Ukrainy)

Based on the volume of private transfers, which is a component for calculating the country's balance of payments, it should be noted that payments have a steady upward trend (except for the crisis of 2008 and 2009, 2014, due to the occupation of Crimea and the start of hostilities in Donbass). As of 2018, the volume of private transfers reached 11.1 billion USD, which was 8.5% of GDP. It is noteworthy that this amount is several times higher than the volume of foreign direct investment in Ukraine. In this aspect, there is a similar structure of countries: until 2014, the main country of origin of transfers was Russia, which received a third of all transfers, and in recent years the share of Russia decreased and in 2018 amounted to less than 10% (1.09 billion USD). In contrast, in 2018, Ukraine received 32.8% of all transfers (3.6 billion USD) from Poland. Transfers from the Czech Republic almost doubled compared to the previous year (7.6% of all transfers, or 846 million USD) *(Predstavnytstvo Mizhnarodnoi orhanizatsii z mihratsii (MOM)*).

The impact of private remittances of migrant workers on Ukraine's economic growth is quite controversial. On the one hand, there may be a reduction in unemployment and accumulation of human and financial capital, which has positive consequences for economic growth, on the other – it causes a distortion in the labor market, which reduces the investment attractiveness of the region and the country.

Ukraine is not only a donor of migrant workers, but also a host country. As of 2018, 16,000 foreign workers are officially employed in Ukraine (fig. 5).

Fig. 5: Dynamics of the number of foreigners who are temporarily worked in Ukraine with a permit for employment, at the end of the year, thousand people (developed by the authors based on data Ministerstvo sotsialnoi polityky Ukrainy)

Labor immigrants are mainly employed in trade and repair, industry, information and telecommunications in Ukraine. The most numerous among them were citizens of Turkey (about 3 thousand people), the Russian Federation (1.6 thousand people), China and Belarus (about 1 thousand people) in 2018 *(Ministerstvo sotsialnoi polityky Ukrainy)*.

Unregulated migration is relevant for Ukraine in two dimensions. Firstly, a certain part of Ukrainian citizens who go abroad to earn money, stay there or engage in paid activities without proper permits and documents.

Secondly, the territory of Ukraine is used for illegal transit to European countries from many countries in Africa, the Middle East and Central Asia. It is worth noting that according to 2018, almost one in four migrant workers worked abroad without any legal status or only a tourist visa (fig. 6).

Fig. 6: Dynamics of the percentage of Ukrainian labor migrants, who were abroad without a regulated status (including those who worked with tourist visas) in 2008, 2012, 2017 (developed by the authors based on data Ministerstvo sotsialnoi polityky Ukrainy)

In 2008, the largest number of illegal migrants was registered in Poland, Italy and the Czech Republic, in 2012 their number decreased, the minimum was in the Czech Republic, the maximum - in Poland, Italy and Russia. In 2017, the largest number of illegal migrants was detected in Russia, which is due to the strict policy against Ukrainian labor migrants. A large number of illegal labor migrants are also registered in Portugal and Romania.

The aggravation of the problem is also confirmed by the statistics of European countries on Ukrainian citizens who are violators of the migration legislation of the host countries (fig. 6).

Fig. 7: Dynamics of the number of detected illegal migrants-citizens of Ukraine on the territory of the EU in 2012-2018 (developed by the authors based on data Eurostat: Enforcement of migration legislation)

The graph shows a gradual increase in the number of illegal Ukrainian migrants in the European Union. Since the ratification of the agreement in 2017, the number of illegal migrants from Ukraine in the EU is more than 30 thousand people. In 2018, the number of illegal labor migrants detained at the border increased sharply - 50 thousand people, which indicates the strengthening of border

control. The number of deported labor migrants has also increased significantly. Thus, the ratification of the agreement with the EU has helped to increase not only the flow of legal labor migration, but also its illegal manifestations. The main reasons for illegal migration are the unwillingness to work officially and draw up the necessary documents, political reasons and armed conflicts.

The problem of unregulated migration of foreigners to Ukraine or transit to EU countries remains relevant today. In 2018, 1.1 thousand people were detained while trying to cross the state border illegally, 11.1 thousand migrants with unregulated status were found on the territory of Ukraine, 92% of them were violators of stays (fig. 8).

Fig. 8: Dynamics of the number of illegal migrants, detained by the Border Guard Service of Ukraine in 2012-2018 (developed by the authors based on data Derzhavna mihratsiina sluzhba Ukrainy)

The studied indicator has no tendency to increase or decrease, fluctuates during the studied period in the range from 0.8 to 1.1 thousand people. Regarding the countries of citizenship of migrants with unregulated status, identified by the State Migration Service of Ukraine in 2018, it should be noted that most of them were citizens of Russia (1994 persons), Azerbaijan (1918 persons), Uzbekistan, Armenia, Moldova and Georgia (about 1000 persons) *(Derzhavna mihratsiina sluzhba Ukrainy)*.

The obtained results indicate the need to apply mechanisms to regulate labor migration in Ukraine, both for migrants and immigrants. In 2017, the Strategy of the State Migration Policy of Ukraine for the period up to 2025 was developed and implemented, which is focused on 2 stages: 2018-2021, 2022-2025.

The document envisages reducing administrative barriers to the freedom of movement of the population of Ukraine, reconsidering the permitting nature of documents for travel / stay abroad. The task is to promote the reintegration of Ukrainian migrants who return, develop cooperation with the Ukrainian diaspora and encourage the repatriation of representatives of the diaspora. It is the regulation of labor migration that is one of the main objectives of the Strategy *(Stratehiia derzhavnoi mihratsiinoi polityky Ukrainy na period do 2025)*. The objectives of the Strategy, the positive consequences and issues of their implementation in the context of regulating labor migration are considered (table 1).

Table 1: Analysis of the goals of the Strategy of the state migration policy of Ukraine for the period up to 2025 in the context of regulating labor migration (developed by the authors)

№	*The purpose of the Strategy*	*The main tasks*	*Problematic aspects of implementation*
1	*Reduce administrative barriers to the freedom of movement of the population of Ukraine*	Accounting and registration of the population, clear control over the movement of migrants across the border, issuance of chipped identity documents. Use of information systems for the collection and storage of personal data. Use of mobile applications.	The place of residence according to the registration and the actual place of residence often do not coincide. In particular - young people who are quite mobile, and more often rent housing, and are quite active in terms of labor migration). Not 100% coverage of the country by the Internet.
2	*Reduce the negative consequences of emigration from Ukraine and increase its positive impact on the development of the state*	Gradual elimination of economic, social and other factors of public life that lead to emigration, development of alternatives to long-term migration (short-term employment), protection of citizens' rights in Ukraine.	The mismatch between the level of wages abroad and in Ukraine remains a powerful factor in attracting migrant workers, and even after short-term employment, migrants will intend to return to "earnings".
3	*Create the necessary conditions for the return and reintegration of Ukrainian migrants into Ukrainian society*	Providing access for returning Ukrainians to receive social services guaranteed to citizens of Ukraine by law, development of appropriate state and regional programs, providing information and advisory assistance to citizens of Ukraine returning to Ukraine.	The implementation of this goal is possible only under the condition of the economic development of the state, an increase in the level of wages, and the provision of social guarantees, which is a problem, because the issue is the taxation of the wages received by a migrant abroad, which forms this fund.
4	*Promote legal migration to Ukraine, consistent with social policy and economic development of the state*	Establishment of a mechanism for providing quotas for employment of foreigners, which will flexibly respond to the needs of the labor market, encourage the repatriation of members of the diaspora to Ukraine.	As Ukraine is a middle-level country, most labor immigrants are citizens of the same or lower level of development, who are employed in trade or industry.
5	*Ensure the successful integration of foreigners and stateless persons, who are legally in Ukraine, into Ukrainian society*	Increasing the level of cooperation with the environment of immigrants, involvement in the development of programs on integration and immigration, the formation of a culture of interethnic relations in society.	The difference between the traditions of life, religion, mentality of the population, which often leads to conflict situations in society.
6	*Effective use of the visa system and the capacity of diplomatic missions to manage migration*	Using the practice of the European Union, ensuring the rapid processing of visa applications, optimize the list of	Mentality of the population and the presence of experience of illegal labor migration, the availability of such migration

		documents.	across some parts of the state border.
7.	*Carry out border control of persons, adapted to changing migration flows and opportunities of integrated border management*	Automation of border control, control over "problem" areas of the border, creation of national databases of illegal labor migrants.	Long-term implementation of this goal, the presence of a condon with Transnistria, LPR, DPR, which creates problems in the formation of a single database.
8.	*Strengthen control over compliance with migration legislation within the state*	Improving the system of detection of illegal labor migrants within the state.	It is necessary to provide this service with equipment, qualified labor.
9.	*Ensure respect for the human dignity of returnees by encouraging them to return voluntarily*	Return policy should allow potential migrants to understand, that the only way to reap the benefits of immigration is to comply with migration laws.	The need to review the legal, financial and procedural aspects of the process of voluntary return of labor immigrants.
10.	*Introduce an appropriate mechanism and programs for regularization of illegal migrants*	Enabling foreigners, staying in a country in violation of the law, to obtain legal status.	The need to develop an algorithm for legalizing migrants with an emphasis on the benefits, that will motivate legalization.

In general, the Strategy provides for measures to support migrant workers throughout the migration cycle: from the intention and collection of information on employment abroad to return to Ukraine. At the same time, the implementation of certain provisions of the Strategy on migrant workers faces certain difficulties and needs to be refined.

Conclusions

The signing of the Association Agreement with the European Union was a big step forward for Ukraine and redefined our country on the world political and economic arena. External migration processes are quite active in Ukraine during the times of Independence, but the agreement brought them to a new level, finally changing the eastern vector of migration to the western one. In general, the balance of migration in Ukraine is positive, but since 2017 there has been a significant increase in migration flows, which reached a maximum for the study period in 2018. According to opinion polls, in recent years has increased not only the number of migrant workers who want to try themselves as a migrant worker (in 2018 – about 25% of respondents, compared to 14% in 2012). Statistics on the presence of labor migrants from Ukraine show a decrease in the number of labor migrants in Russia, an increase in Poland (almost 40% of migrants in 2018), Italy and the Czech Republic. Over the past 10 years, the volume of private remittances from abroad has also grown significantly, which not only improves the living standards of migrant workers' families, but also accounts for 8.5% of Ukraine's GDP. It is worth noting the large volumes of labor migration of Ukrainians: as of 2018, 16,000 migrants were officially employed, which is a fairly high figure, but it is difficult to compare with the number of emigrants. Unfortunately, illegal migrations are quite common, which are manifested both in European countries where Ukrainians migrate and on the territory of Ukraine.

The scale of labor migration requires new approaches to its regulation, because modern migration policy is not able to significantly affect the solution of labor migration. To this end, the Strategy of the State Migration Policy of Ukraine for the period up to 2025 has been developed and implemented in Ukraine. The analysis of the Strategy proved that it qualitatively differs from the previous documents regulating the migration policy of Ukraine, has clear goals and directions for implementation. The strategy assumes not only legal and economic, but also social aspects of labor

migration: promoting the reintegration of Ukrainian migrants, cooperation with the Ukrainian diaspora and encouraging repatriation, the integration of immigrants into Ukrainian society as a two-way process in which both migrants and the local population participate. But the implementation plan itself is superficial and not detailed, which determines the list of problems of implementation of the Strategy, which need to be addressed, namely: significant differences in wage levels in the EU and Ukraine, which is the dominant attraction of migrant workers abroad, long-term realization of many tasks, mentality of the population, etc. Migration is an extremely common phenomenon in the modern world, which is rapidly evolving and gaining new volumes, is influenced by a wide range of factors. In today's conditions, this topic is gaining new relevance, requires future research.

Abstract

The paper focuses on those features of the tourism development in Ukraine, that became dominant ones over the last decade. The problematic issues that the this industry faces in the context of the coronavirus COVID-19 pandemic have been identified, and the ways of their resolving have been proposed. It has been outlined that the domestic tourism is expected to be developed in Ukraine in the post-quarantine period mainly in its structure excursion. educational, health resort, and in active tourism domains.

Keywords: tourism in Ukraine, tourism domains, domestic tourism, foreign tourism, tourist flows, coronavirus COVID-19.

Statement of the Research Problem

The coronavirus COVID-19 pandemic dramatically affected the life of the Ukrainian society, in general, and the socio-economic development of the country, in particular. Implementation of the quarantine measures and actions literally suspended economic life in the country, what has provided the drastic impact on the development of the service sector of the Ukrainian economy. One of its branches , which is the most noticeable affected by quarantine steps, is the touristic branch of the economy. Development of the latter is primarily associated with the transport operational activity , it assumes mobility of service recipients and provides direct contacts of many people in various regions of the country and all over the world. Therein, the tourism as an economical sector faces new challenges due to seeking for solution in what way to restore the lost positions and develop its new domains and activities.

The purpose of this study is to analyze the situation on the tourist services market and justify the necessity of the new touristic domains and trends development in Ukraine in the coming post-quarantine period. This is highly crucial, because many countries of the world, first of all, the EU, remain closed for Ukrainians. Obviously, if the pandemic events go on in an indefinite period of the future, this process can ultimately ruin the tourism industry.

Review and analysis of Previous Research Materials

Since the coronavirus pandemic has hooked most of the countries all over the world and produced a strong impact on the development of tourism, both domestic and foreign - the study of its development problems is under the close scrutiny of the scientific community, and their solution is one of the priorities for the socio-economic and human policy of many countries.

The preventive pandemic impact measures and anti-crisis programs for the tourism development, taken by the EU countries in the context of the global economic crisis of 2008-2009, are indicative. Thus, the Greek government allocated the contribution to the travel industry in the amount of 200 million euros. The cost for promoting Greece abroad in 2009 was increased by 50% relatively to the 2008 advertising budget. Tourism programs for new types of recreation and extreme sports have been developed (*Maksimova, L., 2011*).

Many countries, which economies are based on the tourism industry, took active steps during this period so that to save and retain this economically important sphere. Thus, the Egyptian government freed the hotel industry from obligations to co-finance the governmental advertising campaign in the international market to facilitate the activities of tourism enterprises during the economic downturn. Fuel and airport taxes were reduced for charter carriers, and additional discounts were introduced for those airlines, which make at least 11 charter flights per month. The total amount of financial assistance to hotels and airlines amounted to $ 1.2 billion. USD. Egyptian overseas advertising campaign focused on the availability of recreation in this country. As a result, Egypt turned out to be one of the few countries to which, according to the results of 2009, the inflow of, e.g.,, Russian tourists only not decreased, but grew by 13% instead *(Yezhednevnaya elektronnaya gazeta...).*

Aviana, Ida Ayu Arintya Dian, & Alversia, Y. (2019) conducted a study of the effectiveness of the media influence on the image of a destination and intentions of tourists to return to the island Bali (Indonesia) after eruption of the Mount Agung and several earthquakes in 2017 - 2018. This study discovered that so-called word-of-mouth (WoM) social media communication and government social media provide the best influence on the image of a tourist destination in the aftermath of a disaster, while. this image broadly influences the intention of tourists to visit the country at least once again.

Global scale problems in the world are being greatly aggravated and also affect the tourism development. According to Kacetl, J., Klimova, B., Kuca, K. (2018), since 2015 France has been the most terrorist-prone country in Europe. From 2014 to 2015, the contribution of tourism to GDP in the country decreased by $ 1.7 billion. USD. By comparison, Italy, where no deaths from terrorism were

reported, expanded its tourism sector during the same period of time by $ 4.9 billion USD. The relevant studies demonstrate that contribution of tourism to GDP is twice as much in countries, where there are no terrorist attacks, compared to the countries, where there were such attacks. According to *Global Terrorism Index, 2019,* other countries that are under a high threat of terrorism in Europe are Belgium, Germany, Spain, Russia, Turkey and the UK. Thus, the Belgian economy suffered a loss of almost 1 billion euros after the terrorist attacks of the Islamic State in Brussels in March 2016. The most affected business areas were hotels, restaurants and tourism.

In 2020 the world was swept by the COVID-19 pandemic. According to the World Tourism Organization (*UNWTO, 2020*), the number of tourists arriving from abroad is expected to drop to 78%, leading to a loss of 1.2 trillion USD of export earnings from the tourism and 120 million direct tourism job losses, that is in 7 times more, than impact of the attacks in the US on September 11, 2001, and the largest decline in history.

Due to the COVID-19 pandemic, countries around the world have developed the most common measures to mitigate the effects of the crisis and accelerate recovery. These measures are named by the World Tourism Organization as follows:

- financial and monetary measures;
- measures to protect jobs and promote learning and skills;
- market research initiatives and public-private partnerships;
- measures and initiatives to restore tourism;
- promotion of domestic tourism (*UNWTO, 2020*)

Financial and Monetary Measures: Germany lowered the VAT rate to support the tourism and hospitality industry. In Turkey, the VAT on domestic flights of the airline was reduced from 18% to 1% for a period of three months. Egypt postponed payment of all fees for tourism and hotel establishments, exempted bazaars and cafes located in archaeological sites from paying rent until tourism resumes safely. Egypt's central bank launched a finance initiative to support tourism, cut the interest rate for loans with a maximum two-year maturity in addition to a six-month grace period. Cyprus has approved a fund to implement tourism support activities in cooperation with airlines and travel operators, as well as activities to increase tourism demand from October 2020 to March 2021.

Australia is assisting the aviation industry with the Aviation Industry Assistance Package, which includes exemptions from several passenger and aviation charges. China approved a special fund to reimburse expenses of travel agencies.

Examples of ***measures to protect jobs and promote learning and skills*** are the following: the government of Bulgaria will help businesses (including hotel, travel and tour operators, restaurants and fast food facilities) by covering insurance payments owed by employers. Workers in Greece whose work contracts are temporarily suspended will receive compensation, while the state will cover their social security and medical contributions. The Ministry of Tourism of Israel developed a comprehensive training program through professional webinars and web courses to preserve and enrich the human capital of the industry (hoteliers, travel agents, tour operators, tour guides and other tourism professionals). Chile is adapting a technical assistance program for businesses that incorporate a strong digital component into business and digital governance processes for tourism entrepreneurs. Egypt issued guidelines for all tourism staff on the steps to follow with respect to self-defense procedures, and provided staff training to raise awareness in the event of emergencies (*UNWTO, 2020*).

Market research and public-private partnership initiatives: the Bureau of the Tourism Sector Committee of France meets regularly to support the sector. Ecuador set up five working committees to revitalize the tourism sector. Thailand set up a project to develop a big data storage system, and surveys are regularly conducted among a number of tourist accommodation agencies in the Seychelles, Albania, Armenia, Estonia and other countries to assess the impact of COVID-19.

Measures and initiatives to restore tourism can be named as follows. Spain created a Certified Safe Tourism System, a guarantee mark and certification for the implementation of the Health Risk Prevention System against COVID-19, and released a series of guidelines to reduce the spread of SARS-COV-2 coronavirus in the tourism sector. Lithuania, Latvia and Estonia have opened their borders to each other's citizens since May 15, creating a tourism bubble in the Baltics. Kenya announced the gradual reopening of tourism facilities and the confirmation of bilateral tourism agreements and free Covid-19 certificates for East African countries. Bahrain is working on a crisis management action plan, including building trust-based coalitions, maintaining positive and ongoing contact with tour operators, focusing on co-marketing with other tourism partners. China conducted a market analysis to predict the share of domestic tourism in total tourism demand *(UNWTO, 2020)*.

Towards the ***promoting domestic tourism***, countries such as Australia, Botswana, China, Egypt, Georgia, Hungary, Iceland, Italy, Kenya, the Republic of Korea, etc. provide vacation vouchers for domestic travel, exempt domestic airlines from service charges, and co-finance small advertising projects in the domestic market (*UNWTO, 2020*).

The tourism development in general and its certain aspects were considered and analyzed in some of our previous papers, while studying characteristic features of pilgrimage tourism in Ukraine (Niemets L., Telebienieva, et al., 2019), trends and features of rural tourism development in Ukraine (Niemets, L., Sehida, K., et al. , 2018b), features of the transition to a polycentric model of the regional development (Niemets, L., Niemets, K., et al., 2019; Niemets, L., Sehida, et al., 2018a) formation and implementation of development strategies of the Ukraine's regions (Niemets, K., Sehida, K., et al., 2018), regional development in general (Niemets, K., Kravchenko K., et al., 2019), post-industrial development of the city of Kharkiv (Niemets L., Suptelo O ., et al., 2019a), industrial heritage as a component of post-industrial development of the city of Kharkiv (Niemets L., Suptelo O., et al., 2019b), brownfields in the city of Kharkiv (Niemets, L., Husieva, N. et al. , 2018), shopping malls as objects of tourist infrastructure (Niemets, LM, et al., 2016).

Research Methods and Techniques

Analysis, mathematical-statistical, graphic methods have been used for this research. By the mathematical-statistical method, the evolution of tourism development in Ukraine from 2011 to 2018 has been analyzed, and a number number of Ukrainian tourists traveling within Ukraine and abroad, as well as foreign tourists served by tour operators and travel agents in Ukraine have been highlighted separately. Using the graphical method, a histogram has been constructed mirroring this evolution (Fig. 1). The study is based on the analysis of statistical stuff on the development of tourism in Ukraine for the period from 2011 to 2019 with the use of expert assessments. The latter allow identifying the trends in the tourism development in Ukraine in the post-quarantine period.

Statement of this Research Content

Let us consider the features of tourism development in Ukraine over the past decade. It should be noted separately, that this industry has been developing in an expedite way in Ukraine during this period. At the same time, domestic tourism has not taken a sufficiently high position in the economy yet.

There were unstable dynamics in a number of tourists served by subjects of tourist activity in Ukraine during 2011 - 2017. From 2011 to 2013 a number of tourists had been increasing rapidly from 1.84 million to 3.45 million, or by 88%. This growth occurred mainly due to those Ukrainians, who traveled abroad. Their number increased twice over the indicated period - from 1.23 million to 2.52 million people. Another reason was foreign tourists, whose number reached its maximum value in 2012 for the studied period (more than 270 thousand people, which is in 2.4 times more than in 2011)which. This phenomenon was associated with holding the European Football Championship "Euro 2012" (*Dobrovolska N.V., Kandiba Yu. I., 2019*) (Fig. 1).

Fig. 1: A number of serviced tourists in Ukraine
(constructed by (Tourism activity in Ukraine in 2013); Tourism activity in Ukraine in 2015); Tourism activity in Ukraine in 2018))

This fact demonstrates that Ukraine already has an impressive potential for the development of not only the foreign tourism, but also the domestic one. It is facilitated by the rather favorable geographical position of our country, its natural and climatic conditions, significant potential of tourist resources of both natural, and anthropogenic origin.

Since 2014, the number of tourists who used the services of tour operators or travel agents has dropped sharply, reaching the lowest level of 2.02 million people in 2015. This happened because of a drop in demand for a domestic tourist product caused both by drastic deterioration of the socio-economic situation in Ukraine, and by decrease of the security level as a result of intensified hostilities in the east of the country.

Since 2016, the evolution of tourist flows has been becoming positive again concerning both Ukrainians traveling within their own country and travelling abroad, as well as the flow of foreign tourists to Ukraine. The lowest tourist activity of domestic tourists within Ukraine is typical for 2014, when tour operators and travel agents served 322 thousand tourists, which is in 2.2 times fewer, than in 2013 and in 1.4 times fewer than in 2018. The smallest number of Ukrainian tourists traveling abroad was observed in 2015 - 1.65 million people only, which is in 1.5 times fewer than in 2013 and almost in 2.5 times fewer than in 2018. In the next three years the number of tourists traveling abroad, served by the subjects of tourist activity in Ukraine, was growing and exceeded 4 million in 2018. This evolution is accounted for the increased interest of Ukrainians in tourist sites in foreign countries, what has happened due to the introduction of a visa-free regime with the EU and with a number of other countries contributed to the activation of the outbound tourist flow from Ukraine. This is undoubtedly because of the insufficiently high level of the tourist infrastructure development in Ukraine itself.

The introduction of quarantine in Ukraine from mid-March 2020 because of the spread of the coronavirus COVID-19 with its consequential morbidity significantly influenced the development of tourist activities in Ukraine. The tourist foreign flows have practically stopped - both Ukrainians abroad and foreign tourists to Ukraine. According to the chairman of the Association of the hospitality industry of Ukraine A. Liev, up to 20% of travel companies in Ukraine may be bankrupted (*Filonenko, O, 2020*). The govermental budget of Ukraine for 2020 provides an amount of 240 million UAH for the tourism development, which is only about 0.02% of the expenditure side of the budget. Because of the coronavirus epidemic, all the funds of the state budget of Ukraine allocated for the development of tourism have been redirected to mitigating measures of the consequences of the epidemic (*Turyzm pislya karantynu, 2020*). Thus, the tourism industry in Ukraine is practically left without state support. Unlike Ukraine, the EU plan to allocate up to375 billion EUR to rebuild the tourism industry after the

coronavirus pandemic. In particular, 255 billion EUR will be allocated to the governments to help the tourism sector of their countries and almost 120 billion EUR - to entrepreneurs and companies that suffered losses, so that to be able to continue their busines (*Sinyutka O., 2020*).

According to the National Institute for Strategic Studies of Ukraine (*Shchodo rozvitku turizmu v Ukraïní…*), the overall losses of the tourism industry in Ukraine are estimated at more than 1.5 billion US dollars. The share of tourism in Ukraine's GDP for the period from 2010 to 2018 amounted to 1.5 - 2% (*Yvtushenko, O.V., Kurinna, A.T., 2018*), which as of 2018 was about 2 billion US dollars per year. On the one hand, the small share of the tourism industry in Ukraine's GDP cannot drastically affect the overall socio-economic state of the country, and on the other hand, the losses of the industry itself in the amount of 1.5 billion US dollars per year can cause irreparable damage to the tourism industry. But since Ukraine is characterized by a relatively high share of domestic tourism in the overall tourism economy, the country has better conditions for preserving the national tourism industry.

The scale of losses to the tourism industry due to quarantine measures varies significantly in different regions of Ukraine. The regions of Western Ukraine are the most affected by the COVID-19 pandemic – Lviv, Ivano-Frankivsk, Chernivtsi, Ternopil regions, in which the number of cases and the increase in morbidity are the highest among the regions of Ukraine – both in absolute indicators and per 100 thousand residents. At the same time, these regions are one of the most attractive for both Ukrainian and foreign tourists, since they have rich natural, historical and cultural tourism resources.

As a result, the greatest blow to the tourism development was dealt precisely to the regions of Western Ukraine. It has a particularly negative effect on the socio-economic development of these areas, since tourism in them is a branch of specialization and it occupies a prominent place in the structure of the regional economy.

In the long term, with the gradual opening of state borders, the international tourism will recover its positions at a slow pace, which is largely due to decrease of the income level of the population of Ukraine due to the quarantine. In a situation like this, experts predict an increase of domestic tourism in Ukraine, which will compensate reduction of international tourist flows associated with the closure of state borders and decrease in the income level of the majority of our citizens. The active development of domestic tourism is also caused by psychological factors - the desire of people to "change the situation" after quarantine and the need for some kind of summer vacation and recovery.

The structure of of the domestic tourism sectors has also changed. The only branch of tourism that did not lose its tourists due to the pandemic is active one (primarily hiking, water and cycling), since tourists travel mainly to remote places from settlements, spend the night in tents or campgrounds, and not always attracted to cafes or restaurants in terms of food. At the same time, the most affected by the coronavirus pandemic are those sectors of tourism that are most associated with the transportation, food and with accommodation of a large number of tourists - excursion and educational tourism, business, religious and educational, entertainment, event activities. The sector of medical and health tourism is also delineated separately, which is traditionally one of the most popular sectors in Ukraine and even in the circumstances of the coronavirus remains at the level of previous years in terms of a number of tourists.

After a period of forced self-isolation, tourists should be expected to be greatly interested in short-term trips around Ukraine, weekend tours with an interesting program, which are affordable and at the same time able to provide a full range of impressions. According to the director of Coral Travel Ukraine T. Prokopenko, popular destinations after the finishing quarantine will be short weekend programs at a low price, family vacations by a sea and medical tourism (*U Derzhturyzmi rozpovily…*, 2020). Undoubtedly, large load on domestic tourism creates a number of difficulties. Many Ukrainians are accustomed to having a rest on the sea, which gives significant health improvement, in particular, to families with children. Therefore, the load on sanatoriums, rest homes of the Black and Azov Seas has sharply increased, which again leads to various negative results. Many beaches of Odessa and the region, as well as the coast of the Azov Sea, are already polluted and closed to tourists. It can cause a number of new diseases and negatively affect the state of the health care in the country.

A set of measures has been proposed to mitigate the negative impact of the COVID-19 coronavirus pandemic on the tourism industry of Ukraine *(Pandemíya COVID-19 ta íť naslídki…)*, (*Shchodo rozvitku turizmu v Ukraíní v…*). The most important, in our opinion, are measures of state support for the tourism industry of an economic nature, in particular: exemption of travel service providers from VAT, income tax and unified social contribution, land tax and tax on non-residential real estate; cancellation of tourist tax payment until the end of 2020; exemption from taxation when paying rent and land use, tenants of state and public property.

Losses of the state and local budgets from the lost tax revenues from travel operators and agents will not be critical due to the insignificant share of tourism in the economy of most regions of Ukraine. At the same time, the industry will receive additional financial opportunities for development during the crisis, which is very important for the regions of Ukraine, in which tourism is an industry of specialization, primarily in the western (Carpathian) and southern (coastal) regions.

Conclusions

Thus, the coronavirus COVID-19 PANDEMIC MADE new challenges to the tourism industry of Ukraine, as in many other countries of the world. Having lost government support, the tourism industry has to reorient to serving mainly “domestic tourists”, which is caused by continued isolation, step-be-step opening of state borders and decline of the purchasing power of a significant part of the native population. Therefore, the main task of the governmental authorities and local self-government is to create conditions for the development of domestic tourism, primarily -its active, "green", sightseeing and educational, and health resort sectors. This task should be resolved at the regional and local scales, using the opened options of the united territorial communities as units of the new administrative-territorial structure of Ukraine.

Further Research Perspectives

Taking into account the very difficult socio-economic situation in Ukraine at for the time being, the problem highlighted in this text needs a comprehensive efficient solution, since the economic well-being of many segments of the people and the whole country would depend on such solution. On the one hand, many relevant issues require thorough, comprehensive, and interdisciplinary investigations. This relates only to economic support for the transport industry, in particular, for air carriers, which are catastrophically bankrupted. Travel companies, tour operators and other representatives of the tourism industry need government support too.

On the other hand, fundamental research is crucially necessary on the development of domestic tourism identifying places for "green", ecological, active, health tourism. Ukraine is rich in the mentioned resources, it is necessary to study it, and develop specific routes, the objects for intensive development of infrastructure, providing economic support from the government.

These problematic issues are in the authors’ attention with respect to further research. Justification of new routes, estimation of the tourist load on these territories, etc., are being expected.

Abstract

The world is now being seriously overhauled, which is seen in economic digitalization and more frequent financial crises growing easily into global financial problems. Reproduction is an urgent matter both for the economic theory and practice, but the approaches towards its understanding have not changed for the last two hundred years. The reproduction process covers distribution and redistribution both on the micro and macro levels. Connection between the development of companies, territories and human capital occurs with the help of reproduction mechanisms. Commercial companies are not only taxation subjects, but also the key agent of distribution and redistribution relations, they form the income of households, take part in investment and social programs, infrastructure development and ensure demand for the products of related industries. Despite the fundamentality of definitions, digitalization promotes development of the balance methods, which undoubtedly covers some aspects of understanding the reproduction category. In modern practice the reproduction category roots in the notion of industry potential, which means that companies' functioning is a horizontal and vertical basis of the reproduction processes. The article deals with the influence of formalization of distribution and redistribution processes on the micro and macro levels on reproduction of agriculture companies' potential.

Keywords: Reproduction, Agriculture, Agricultural Companies, State Support

Introduction

Food provision may soon become one of the most urgent problems. Although part of the population of the planet has long switched to alternative sources of protein from natural sources, the bulk of the population remains committed to the traditional forms of products. This is why agriculture is one of the priority branches of the economy both regionally and globally. Many modern countries link their strategic development with agriculture. Commercial organizations are the basis of modern economy – they are the key to the development of territories, formation of infrastructure and the servicing

industries, social establishments creating a multiplication effect. Each production job creates up to 8-10 jobs in other economic areas. Although the key agricultural component is land, effective operations require the use of high quality seeds and planting material, highly productive animals, high-quality breeding stock, etc. We believe that lower effectiveness of company operations may trigger the impossibility of reproduction of the aforementioned components and destruction of agriculture potential.

Literature Review

The goal of commercial organizations is profit generation and the longer it happens the better it is for all participants of economic relations. High competition in a market economy and technological development lead to the need of constant investment and company resource upgrade. The economic theory views constant resumption of operations, their continuity as reproduction. Although the key goal is expansion of production meaning higher output, prosaic maintaining of the sales market is important nowadays. If a company fails to fulfill the last condition, the effect of shrinking production appears. The interrelation of reproductive processes helps us conclude that a chain of shrinking manifestations appears in the vertical and horizontal connections. This effect is very clear in agriculture – destruction of reproduction of a large agrarian company ruins sustainable development of rural areas, the impossibility of reproduction of its population, worsening of regional indicators. Besides, we should take into account that the issue of importance of biological resources, whose circulation is specific and requires close attention, appears in this sector together with the need of reproduction of labour, land and investment.

The theoretical basis of reproduction is outlined in many works written by the representatives of foreign and local economic schools. Such researchers as F. Quesnay (1960), K.Marx (1867) and others made the most conspicuous contribution to understanding this issue. The special features of agricultural reproduction, including in agricultural companies, were researched by I.V. Zagaitov (2006), K.S. Ternovykh (2006), etc. The works of other scientists, A.F. Shishkin, O.Yu. Ageyeva, A.N. Mikhailov (2007), outline modern reproductive factors. These studies lead us to the conclusion that modern agricultural reproduction is not only a constantly resuming and repeating process of public production, but also connection of the system of factors and relations in agriculture.

Research Question

The agricultural reproduction problems have specific and common features. A. Smith (1776) invented a classic formula of income generation -- labour, land(rent) and capital. The issues of investment and return on investment appeared along with the appearance of accounting -- a double entry helped determine the presence of assets and their disposal, while effective operations were preconditioned by the sales of all goods and means of consumption. Consequently, continuation of entrepreneurship required replenishment of stock, resources and used production means (equipment) not only in strict quantitative, but also qualitative compliance with the period and time of activity. When deliberating on late production, K. Marx (1867) established relations between the implementation theory, national wealth and crises. As a result, he made conclusions about the continuity and constant resumption of production, the relationship between production and circulation. The reproduction process is realized in connection between reproduction of the social product, production forces and production relations. Technological development changes the ratio of the components – initially human labour was replaced with machines, while now production relations are robotized and “smartized”. The interrelation of production, distribution, exchange and consumption make the existing distribution proportions doubtful. Poor consumption is not so noticeable in industry, but in agriculture it means hunger – demand for food should be backed by money or excessive production is liquidated and destroyed. Replacement of human labour with robots releases a large number of people since conceptually the issue of distribution of the surplus produced by the robots has not been resolved. The pressing problem is falling effective demand for agricultural products and results of their processing. Some states use aquaculture and alternative food in the form of insects, larvae and embryos, but the population of the developed states is not yet ready

to reject massively the classic nutrition scheme and agricultural production. The modern economic trend is wide-scale sanctions, which diminishes the effectiveness of global labour division and questions state security. While considering reproduction, B.N. Dikaryov (2006) suggested augmenting K. Marx' interpretation by a fifth chain – resumption of reproduction as a system of relations of continuous process. They suggest inclusion of fertility and land quality, rural population as the production force and carriers of industrial relations in the relations. We think that inclusion of crop productivity and productivity of animals, aquaculture, as well as technological inventions in the use of biological resources is reasonable.

The special features of agrarian production include its seasonality, production technologies, industrial use of biological capital (table1), which transform into an array of financial factors. Both intensive and extensive efficiency growth of agriculture almost always increases the environmental load on the territory of food production, the anthropogenic impact.

Table 1: The effects of natural and technological factors on the processes of agricultural reproduction

Transformation of natural and technological reproduction factors into financial and economic factors	
Seasonality	Tough deadlines for investment, disinvestment and capital circulation beyond a financial year or exceeding it several times
Production technology	The discrepancy between the calendar, actual and weighted average production and commercial cycles
Special features of biological capital use	Stage-by-stage entry of capital elements into the reproduction process and its sprawl
Natural factors' impact	Unsustainability of financial results and reproduction volumes
	The multiplication effect of risks connected not only with the special features of biological capital use, but also with economic factors, which boost the negative effect of environment

Thus, seasonality of agricultural production means dependence of the time of operations, and, as a consequence, reproduction cycles on technological stages of production processes -- the need in fixed and working capital is spread throughout the year. Production technologies require timely material-intensive, fund-intensive and labor-intensive work within a short time, which means high capital concentration in some periods and its relative idling in the others. For example, harvesting lasts from a few days to several weeks, while machines are on the company's books for a whole year. Their absence can mean a crop loss or the impossibility of processing products. Biological capital in the form of plants and animals has special features of organization and reproduction -- apart from completing the production cycle there is an issue of sources and ways of its regeneration. Besides, scantiness or excess of natural factors (heat, precipitation, temperatures) devalue even highly effective expensive agricultural technologies. G. Lawrence (2017) points to the transformation of food distribution and redistribution models, which also influences agricultural reproduction processes. Production is redistributed, competition between exporters and importers of traditional, modernizing and industrial production systems grows. In its turn, there is transformation of rural territories' economies, says A. Dobeson (2018).

We do not deny the importance of each reproduction system element, but we conclude that a company as its central part is important. Business is a modern development basis for the territories –

analysis of statistics shows that creation of jobs and an increase of their number boost households' income, it is beneficial for the quality of life in such settlements. An agricultural company cannot be isolated from the environment. Consequently, we can conclude that the reproductive processes of a company, industry, a rural area, a state as well as human capital are all connected logically. The system of reproductive relations in a company should be considered as an isolated system (a collection of subsystems, subdivisions, business processes), and simultaneously as an element of a wider and bigger scale category.

Even when price growth for food products can be restricted, we cannot deny the importance of profitability of agricultural companies as a criterion of effectiveness of the aforementioned system of relations. Like we said earlier, provision of expanded production based on primary accumulation is important from an economic point of view. From the financing point of view, profit is the source of growth and development of a company, it concentrates the interests of all participants of social and agrarian relations. In a classic scheme of costs recovery, a company's revenue from the core activity of selling products and services is used to pay indirect taxes, salaries, to cover amortization and tangible costs, taxes attributed to the financial result, to pay dividends and replenish funds.

Fig. 2: Scheme of enterprise's cost recovery system

However, when revenue is insufficient, the risk for the owners in the form of dividend nonpayment, spending of commercial funds and shrinking property becomes evident. Companies cut costs to balance profit and costs, but this is not always effective and exacerbates the situation, worsens the

financial state of a company. In agriculture, it also disrupts not only capital reproduction, but also the system of agrarian relations, undermines the possibility of its recovery. The system of balancing the financial results relative to participants of public relations is shown in figure 3.

Fig. 3: A system of balancing financial results relative to the participants of public relations

We should note that cost cuts cannot be endless – there is a point where irreparable disruption of relationships occurs. The lack of funds leads to violation of production technologies, falling fertility, the loss of productiveness, yields, labour quality. Such a situation is unacceptable, but possible. We believe that in a market system the possibility of agricultural continuity and reproductivity can be manifested in the influence of macroeconomic regulation on the effectiveness of the sector's operations. State, regional and local support compensates the objective and subjective injustice of distribution processes in agriculture and boosts the effectiveness of the cost compensation system of a company, increase tax collection, expand operations. Subsidiary responsibility of different management levels helps solve the problem of rural areas development and boost the life quality of rural population. Table 2 reflects indicators of agriculture support in central Russia.

Table 2: State and regional support of farmers

Regions	Farm fields, thousand ha	Transfers to agricultural producers from the budget of a Russian Federation subject, mln rbl.	Total state support, mln rbl.	Gross agricultural product, mln rbl.	Tax collection to the budget from agricultur e, mln rbl

Since agriculture is a strategically important economic sector, the Russian government has suggested measures of its full internal support. Despite an approved policy of import substitution, it is not always possible to cover the need of agricultural producers in production means as well agricultural goods' consumption at the national level. Practically each country is an importer of some type of food, machines, fertilizers, etc., thanks to population growth and the need of high-tech agricultural production. Consequently, a full reproduction cycle in one state is hardly possible. Since investment in digital infrastructure is mostly private, we can suppose that this tendency is of a strategic nature – a small number of companies can boast competitive advantages of innovations as the key strategic growth factor.

Discussion and Results

The need of theoretical and methodological development of agricultural reproduction is conditioned by the following.

First, an important trend of agriculture development is rising exports, which in future can threaten internal consumption. Low households' income means they are not ready to a price rise for food and agricultural raw materials for its production. Falling state support coupled with damping prices translate into the impossibility of full cost recovery, which means disruptions of reproduction processes. This dilemma requires close and comprehensive strategic assessment.

Second, our research demonstrates the importance of profitable operations of agricultural companies as a nucleus of reproductive relations system. The impossibility of endless balancing of financial results without the loss of quality of agrarian relations and productive potential requires close attention to the problem of state support. Lower state support strengthens objective and subjective contradictions and conflicts in agricultural production.

Third, support of agricultural companies has a multiplying effect both on the agricultural goods production and on the investment process. Higher investment in agriculture, in its turn, leads to expected growth of tax collection to the budgets of different levels.

Fourth, positioning of agriculture as the basis of food security restricts possibilities of the sector in receiving and boosting revenue, cultivates interest to exports of produced goods, which should be accounted for when developing strategic aims, goals and parameters.
The analysis of experts' assessments of Russian agricultural reproduction helped us formulate some recommendations for the development of this system in Russia aiming at solving the current problems.

1. The size of agricultural profit predetermines the possibility of break-even operations, self-sufficiency and self-financing, recovery of capital, productive forces and specific production potential of the sector;
2. At the moment the possibility of revenue growth on the back of production intensification and productivity and yields growth is practically exhausted, which drives us to the conclusion that maintaining profits is connected with tough cost cutting;
3. The possibility of agricultural companies' cost recovery is dwindling constantly, while falling state support exacerbates the negative influence of the factors. Between 2000 and 2018, the total number of agricultural organizations shrank by more than 80%, partially on the back of growth in the number of companies. Each fourth agricultural company is loss-making. In 2000, the highest profit was seen in plant-growing, currently the highest financial result is demonstrated by cattle-breeding. In the last three years, the agriculture products price index on the local market is below 100 % year-on-year, while annual price growth for consumed products ranges from 0.5 to 7.5% and more.
4. People employed in agriculture are most vulnerable as the agricultural processes become more efficient – at the moment employment does not exceed 3 people per 1,000 ha of agricultural land, between 2 and 8% of people are released annually. The absence of alternative employment in rural areas means disruption of reproduction processes of rural and adjacent areas.
This means that revenue is the key financial resource in the process of reproduction. If it is sufficient, contradictions of reproduction of agricultural processes are softened:

a) the employees have good salaries, which helps diminish the unfairness of invested labour and public appraisal of the results;
b) the owners receive expected dividends without hurting financing of the company and participants of reproductive relations;
c) the company participates in social programs and in the development of the territory, where it operates, pays stable taxes without the use of aggressive schemes of their optimization.
